INTRODUCTION: WOPN is a frequent sequel of acute necrotizing pancreatitis. The best approach for drainage of these collections is still controversial. We present our retrospective data comparing the two endoscopic methods for drainage of WOPN.
AIMS & METHODS: Outcomes of patients undergoing EUS guided transmural drainage (EUTMD) using a newly designed fully covered large-bore wide-flare metal stent (Nagi stent) (Gr I) were compared to the outcomes of patients who underwent placement of multiple plastic stents (Gr II). The pre-op CECT confirmed suitability of endoscopic drainage based on location, wall thickness & contents. Visual quantification of necrosis (>50% solid debris) by EUS excluded 8 patients (3 in Gr I and 5 in Gr. II). The procedure in both groups is done by standard technique by a single endoscopist. The difference between the two groups was tract dilatation (6 mm in Gr I vs. 18 mm in Gr II). Placement of NCT and subsequent necrosectomy was done whenever necessary. Follow-up imaging was done at 72 hrs and thereafter at 2, 4, & 6 weeks. The outcomes were compared in terms of clinical success, need for surgery, complications, hospital stay and mortality.
RESULTS: N: 21(Gr. I), 61(Gr. II). The two groups were comparable in terms of demographics, etiology of pancreatitis, cyst location, size and amount of debris. Placement of NCT, need of necrosectomy and no of sessions required were also not different between the two groups. Clinical success defined as resolution of symptoms was seen in 100% of Gr. I patients vs. 73% in Gr. II ($p=0.048$). None of the patients in Gr I required subsequent surgery vs 20/61 (32.7%) in Gr. II ($p=0.025$). Complications: 15% in Gr. I vs 37% in Gr. II ($p=0.016$)
Mean hospital stay was 4 days (1-33) in Gr. I vs 8 (4-65) in Gr II ($p=0.012$). Mortality was none in Gr. I vs. 6.5% (4/61) in Gr. II ($p=0.22$)
CONCLUSION: The Nagi stent™ is effective and safe for EUTMD of WOPN. It permits rapid clinical resolution with 100% technical and clinical success rates. It offers distinct advantage over plastic stents although further prospective studies are warranted.

INTRODUCTION: Complete esophageal obstruction leads to definitive fasting. The rendez-vous endoscopic approach had already been described for complex stenoses as an alternative to surgery that has high morbid-mortality.
AIMS & METHODS: This is a case series report about six patients referred for complete esophageal disruption classified in two groups: 1/ Long disruption (> 5cm), one after caustic ingestion and two due to an esophageal stripping during SEMS removal. Two had an associated loss of the SES; 2/ Short disruption (< 5cm), consecutive to radiation therapy for a neck neoplasia. They had been fasting for 3 to 18 months. All the procedures were performed according the anterograde retrograde approach, under anesthesia and with CO2 insufflation and X-rays guidance.
RESULTS: There were 3 men and women between 25 and 71 years old. All the reconstructions have been successful in one to three endoscopic sessions, using the non hydrophilic tip of a guide wire passed through a straight catheter in 5 cases and a EUS needle in only one case. In 2 cases, a neo-SES had to be created, by transillumination ($n=1$) or head and neck surgery ($n=1$). In order to guide the reconstruction, SEMS was used in one case, NGT in one case, and both were used in one patient. The first dilation was performed with a CRE balloon (12-15mm). All the patients could eat mixed after 2 POD. There was no intra-operative or post-operative complication. Then, the patients underwent 3 to 18 dilations sessions during 1.5 to 15 months; two are still undergoing dilations and all eat normally.
CONCLUSION: Endoscopic rendez-vous for esophageal reconstruction is safe and effective in case of esophageal disruption even with loss of SES, avoiding surgery.

INTRODUCTION: To reduce the risk of complications related to ESD using conventional knives, we developed the Clutch Cutter (CC), which can grasp and incise the targeted tissue using electrosurgical current.
AIMS & METHODS: From June 2007 to March 2014, 325 consecutive patients (228 men, 97 women; mean age 74 years, range 35-95) with a diagnosis of intramucosal or superficial submucosal gastric cancer without lymph node involvement, that had been confirmed by preliminary endoscopy, EUS, and endoscopic biopsies, were enrolled into this prospective study. The CC was used for all steps of ESD (marking, circumferential marginal incision, submucosal dissection, and hemostatic treatment). The therapeutic efficacy and safety were assessed.
RESULTS: The mean size of the early gastric cancers and resected specimens was 17.3 mm and 46.7 mm, respectively. The mean operating time was 97.2 minutes. The rate of en-bloc resection was 99.7% (324/325), and en-bloc resection with tumor-free lateral/basal margins (R0 resection) was 95.1% (309/325), respectively. The R0 resection rates according to tumor size and location were 97.4% (229/235) in less than 20 mm, 88.9% (80/90) in larger than 20 mm; 96.9% (127/131) in lower portion, 91.9% (91/99) in middle portion, and 94.7% (91/95) in upper portion. The mean operating time according to tumor size and location was 93.4 min in less than 20 mm, 140 min in larger than 20 mm; 73.9 min in lower portion, 108.8 min in middle portion, and 117.2 min in upper portion. Perforation during ESD occurred in one case (0.3%), which was managed with conservative medical treatment after endoscopic closure of the perforation. Post ESD bleeding occurred in 11 cases (3.4%), which were successfully treated by endoscopic hemostatic treatment.
CONCLUSION: ESD using CC is a safe and technically efficient method for resecting early gastric cancers.

INTRODUCTION: The peroral endoscopic myotomy (POEM) is a promising method for the treatment of the esophageal achalasia. But the precise technique can be refined. We developed a combined technique of water jet system for tunnelling and hook knife section for myotomy and we evaluated its results in a prospective study.
AIMS & METHODS: The patients presented with an achalasia without any prior instrumental treatment. The submucosal tunnel was created 12 cm over the cardia and 3 cm below, and then the endoscopic myotomy was performed using the Olympus Hook Knife by a single operator with CO2 insufflation, beginning 8 cms over the cardia and finishing 2 cms below. The clinical evaluation was realized before and then after the procedure at 1, 3, 6 and 12 months (score of Eckardt, score of quality of life GIQLI). A high-resolution manometry was realized before POEM and 3 months later to classify the achalasia (classification of Chicago) and to measure basal pressure and pressure of relaxation integrated (PRI) of the lower esophageal sphincter. Then an esophageal pHmetry of 24 hours was performed at 3 months to diagnose GERD. The

data are expressed in median (extremes) and compared before and later myotomie by paired t-test.
RESULTS: 21 patients (13 men, average age 61 years) were included. 18 procedures were complete, 1 was not realized because of a large esophageal diverticulum, 2 were interrupted (1 sub-mucosal fibrosis preventing the realization of the tunnel and 1 mucosal injury of the tunnel in the cardia). 2 other mucosal injuries occurred but did not prevent to continue the procedure after mucosal closure by clips. Dual Knife ® (n = 7) or the water jet Nestis Enki 2 ® (n = 11) were used for the tunnel. No mucosal injuries were observed with the water-jet system. Hook Knife ® was used for all myotomies. The average time of procedure was 94.2 min with a clear learning curve (135-35 min). A pneumoperitoneum was exsufflated with a needle during the procedure in 13 cases without any visible perforation. CT scan at day 1 showed a pneumomediastinum (n = 14/18), a pneumoperitoneum (n = 14/18) and/or a peumothorax (n = 3/18). No sepsis was observed. Feeding was always possible with liquids at day 1. All patients noted a clinical improvement. At 3 months, the basal pressure of the SIO was decreased for all patients (8 mmHg (0-15) against 23 mmHg (7-48) initially, $p < 0.01$) as well as the PRI (8 mmHg (0-16) against 23 mmHg (9-28), $p < 0.01$). pH metry showed a pathological GERD (esophageal pH 4 during more than 5% of time in 3 cases.

		Inclusion	1 month	3 months	6 months	1 year
n	21	17	14	10	3	
Eckardt	6 (3-11)	1 (0-3)*	1 (0-3)*	0 (1-4)*	0 (0-0)*	
GIQLI	82 (50-114)	115 (66-135)*	115 (82-140)*	131 (94-143)*	140 (130-142)¥	

CONCLUSION: Water-jet injection allows rapid and safe tunneling of the submucosa and myotomy with hook knife is very precise. Safety and effectiveness of mytomy is reinforced using these technical refinements.

INTRODUCTION: High-magnification endoscopy with narrow-band imaging (HME-NBI) has been used for diagnosis of gastric pathology because of its high accuracy. Nevertheless, the application of these advanced techniques in clinical practice is difficult due to the presence of various histological changes of gastric mucosa with different modifications of microvascular and microsurface patterns. Newly developed computer-aided decision support systems are designed to detect and/or classify abnormalities and thus assist a medical expert in improving the accuracy of medical diagnosis. However, there is lack of data for computer-aided devices for classification of gastric lesions with HME-NBI.
AIMS & METHODS: The aim of this study was to evaluate the effectiveness of computer-aided classifier of endoscopic magnification images of gastric lesions. We analyzed our database contains 78 endoscopy NBI magnification images of gastric lesions (Olympus Exera GIF Q160Z, Lucera GIF Q260Z). All images were classified into three classes: oval (13 images), tubular (31 images), and destroyed with vessel network (34 images). Initially we divided images of every class into two sets — training set and test set. Then we selected uniformly distributed random points with fixed density (one random point for every 300 pixels) at every picture, which were analyzed by extracting topological features for building the classifier. Training set images were used for classifier training with Adaboost algorithm and testing set images of each group were utilized for testing with previously trained classifier. We repeated the procedure described above for the estimation of classifier quality.
RESULTS: From 78 database images there were 50 images (66.6%) with the success rate of correct classification exceeding 80%. In 14 images (17.9%) all points (100%) were recognized correctly. The mean percentage of points with the correct classification was 79%.
CONCLUSION: Topological features were successfully used for description of endoscopic magnification images. The combination of topological features analyzed with Adaboost algorithm allowed for creating and effective training of computer-aided classifier of endoscopic magnification images of gastric lesions.

INTRODUCTION: Endoscopic mapping of the entire stomach with advanced techniques has been recommended as an important step of surveillance of premalignant gastric conditions/lesions [1]. Although current imaging technologies, such as narrow-band imaging (NBI) and high-magnification endoscopy, allow enhanced visualization of gastric mucosa, their application is still limited due to low contrast and brightness of endoscopic view and complexity of usage. Newly developed NBI system with dual focus (DF) magnification might be a promising tool to overcome this challenge.
AIMS & METHODS: The aim of this study was to evaluate diagnostic accuracy of new NBI-DF system in detection, characterization of gastric lesions in patients with extensive atrophy and/or intestinal metaplasia. A total of 43 patients (mean age 51.3 years, SD = 12.1) were initially examined by conventional white light endoscopy (WLE) followed by NBI overview. Afterwards chromoendoscopy (CE) with indigocarmine was performed as the ''gold standard'' for detection of lesions. Any suspicious areas detected by NBI or CE were subsequently further assessed with NBI with DF (Olympus Exera III GIF H190) and characterized accordingly. Biopsies were taken from all lesions for histological assessment.
RESULTS: From 93 detected gastric lesions there were 75 non-neoplastic (chronic gastritis, intestinal metaplasia), 3 low-grade dysplasia, and 15 high-grade dysplasia/early gastric cancer. All lesions (100%) detected by CE were found with NBI observation. Endoscopic histology prediction was successful in 88 cases (94.6%) Endoscopic misdiagnosis was found in 5 cases (5.4%): overestimation in 3 cases, underestimation in 2 cases; sensitivity, specificity, positive predictive value and negative predictive value were 80%, 97.4%, 85.7% and 96.2% respectively for early gastric cancer/high-grade dysplasia.
CONCLUSION: Observation of gastric mucosa with a novel NBI system was at least as effective as CE with indigocarmine in detection of suspicious gastric lesions in patients with precancerous conditions and lesions of the stomach. Dual focus magnification provides sufficient assessment of microvascular and microsurface patterns in order to differentiate gastric lesions. Further randomized controlled studies are needed to be performed for clarifying the role of novel endoscopic system in diagnosis of gastric pathology.

P0007 DEVELOPMENT OF A PROTOTYPE OF VIDEO SYNCHRONISATION FOR RELOCALISATION OF BIOPSY SITES DURING ENDOSCOPIC EVALUATION OF BARRETT'S OESOPHAGUS: PRELIMINARY EXPERIMENTAL AND CLINICAL STUDY

S. Adrien[1,*], V. Anant[1], H. Jerome[1], N. Stephane[2], S. Luc[2], D. Michel[1]
[1]*CHU Strasbourg,* [2]*IRCAD, Strasbourg, France*
Contact E-mail Address: *adrien.sportes@free.fr*

INTRODUCTION: The prevalence of Barrett's oesophagus (BE) is 5 to 6% in the general population, with a progression from dysplasia to adenocarcinoma 0.6 to 0.7 patient-years. Hence, endoscopic surveillance is justified to detect early lesions accessible to endoscopic treatment. However, the relocalisation of lesions detected by biopsies may be difficult during follow-up endoscopies. The purpose of this study was to evaluate the prototype of a magnetic probe for accurate location of the position of the endoscope, allowing the relocalisation of this position in a subsequent endoscopy. We report the results of a feasibility study in pigs and the use of this device in two patients with BE.
AIMS & METHODS: The system consists of an electromagnetic (EM) field transmitter and an EM probe constituting the electromagnetic tracking system (EMS) (NDI, Aurora). The EM probe is inserted through the operating channel of a double channel gastroscope. The EM field generator is positioned on the patient's chest wall. The system also includes new software developed at IHU/IRCAD, which performs simultaneous recording of the video from the endoscope alongwith its corresponding position, as measured by the EMS. During a second endoscopy, this software allows automatic synchronisation of the recorded video to provide relocalisation of the endoscope in front of previous biopsy sites in the oesophagus.
The system was tested in 5 anesthetised pigs. During the first endoscopy, ten markings were performed by argon plasma electrocoagulation (ERBE Tübingen, Germany) in the distal oesophagus. The position of each marking was recorded by the system. A second operator to then performed a blind endoscopy on the same pigs and was asked to follow the system implicitly as a guide to relocate the markings.
In 2 patients with BE, the system was then tested to facilitate relocalisation of the biopsy sites.
RESULTS: Ten markings were made in the distal oesophagus of 5. After withdrawal of the endoscope the second operator found 48 of the 50 markings (96%)

using the guidance provided by the system. The positioning of the endoscope provided by the EMS system was within a 2mm range from the initial positionning. In the evaluation of BE patients, the system relocalised the biospy sites within a range of 3mm.
CONCLUSION: This preliminary study shows the feasibility of the EMS prototype to relocalise the endoscope in the oesophagus within an acceptable range. The clinical usefulness of this system should be evaluated further during the follow-up of patients with BE.

P0008 THE UTILITY OF ROUTINE CHROMOENDOSCOPY FOR DETECTION OF DYSPLASTIC LESIONS DURING SURVEILLANCE COLONOSCOPY IN PATIENTS WITH COLONIC INFLAMMATORY BOWEL DISEASE. DOES RESEARCH TRANSLATE TO CLINICAL PRACTICE?

U. Javaid[1], R. Thethi[1], P. Luthra[1], **N. Mohammed**[2,*], J. Hamlin[1], B. Rembacken[1], V. Subramanian[2]

INTRODUCTION: Dysplasia in colonic inflammatory bowel disease (IBD) is often multifocal and flat. Chromoendoscopy (CE) has been shown in prospective studies to improve dysplasia detection rates by improving the ability to detect subtle mucosal changes. (1) The utility of CE in dysplasia detection in patients with IBD during routine clinical practice has not been reported so far. We aimed to compare the yield of dysplastic lesions detected by CE with standard white light endoscopy (WLE).
AIMS & METHODS: Retrospective cohort study of patients with long standing (>7 years) colonic IBD undergoing surveillance colonoscopy at Leeds Teaching Hospital NHS Trust between January 2012 to December 2013. Details of diagnosis, duration of disease and outcomes of the colonoscopy were collected from the endoscopy database, electronic patient records and patient notes.
RESULTS: There were 120 colonoscopies in the CE group and 220 colonoscopies in the WLE group. The groups were well matched for all demographic variables. 27 dysplastic lesions were detected in 20 patients in the CE group and 9 dysplastic lesions were detected in 6 patients in the WLE group. All the lesions were detected on targeted biopsy and harboured low grade dysplasia. The adjusted prevalence ratio (on a per patient basis) for detecting any dysplastic lesion was 4.6 (95% CI 1.6-13.7) in favour of CE.
CONCLUSION: CE colonoscopy improves detection of dysplastic lesions during surveillance colonoscopy of patients with colonic IBD even in routine clinical practice, confirming data from prospective trials. CE should be the standard of care for all IBD surveillance procedures as advocated by both BSG and ECCO guidelines.

P0009 INVOLVEMENT OF B-CELLS IN HEPATIC INFLAMMATION DURING NONALCOHOLIC STEATO-HEPATITIS (NASH)

A. Jindal[1,*], S. Sutti[1], I. Locatelli[1], M. Vacchiano[1], C. Bozzola[1], E. Albano[1] on behalf of Laboratory of General Pathology, Prof. Albano, Novara, Italy

INTRODUCTION: Growing evidence indicates that adaptive immunity contributes to the process leading to chronic hepatic inflammation in NASH. However, the mechanisms involved are still incompletely characterized. Recently, B-lymphocytes have emerged as players in orchestrating adipose tissue inflammation in obesity contributing to the development of insulin resistance.
AIMS & METHODS: We investigated the possible role of B-cell responses in the pathogenesis of NASH. NASH was induced by feeding four weeks C57BL/6 mice with a methionine-choline deficient (MCD) diet.
RESULTS: In mice receiving the MCD diet the development of steatohepatitis was associated with an increased hepatic infiltration by B220 (CD20) positive B-lymphocytes and by the detection of circulating IgG targeting oxidative stress-derived antigens such as malonildialdehyde- (MDA) and 4-hydroxynonenal-protein adducts. Moreover, immunohistochemistry showed the presence of IgG deposits within the hepatic inflammatory infiltrates that co-localized with MDA-derived antigens, indicating the formation of immunocomplexes. To substantiate the role of oxidative stress in triggering B-cell responses in NASH, mice were immunized with MDA-adducted bovine serum albumin (MDA-BSA) before feeding the MCD diet. In MCD-fed, but not in control mice, MDA-BSA immunization promoted liver B-cell expansion and enhanced transaminase release, lobular inflammation and the hepatic production of the pro-inflammatory cytokines TNF-α, IFN-γ, IL-12. Among immunized MCD-fed mice there were also positive correlations between the individual expression of the B-cell marker B220 and those of macrophage M1 activation markers IL-12p40 and iNOS ($r = 0.87$ and 0.71 respectively; $p < 0.02$).
This effect was likely mediated by B-cell interaction with CD4 T-cells as in the same animals B220 expression also positively correlated with that of IFN-γ ($r = 0.76$; $p < 0.03$) and of the co-stimulatory molecule CD40 ($r = 0.72$; $p < 0.05$). Furthermore, depleting $CD4^+$ T-cells in MCD-fed immunized mice by using an anti-CD4 monoclonal IgG did not affected B220 expression, but significantly lowered the hepatic mRNAs IFN-γ, iNOS and IL-12p40 and ameliorated lobular inflammation and focal necrosis.
CONCLUSION: These results indicate that B-cell responses triggered by oxidative stress can contribute to inflammation in NASH by stimulating T-cellular responses.

P0010 GENERATION OF A VECTOR CONTAINING AN SHRNA FOR THE RECEPTOR CB1 AS AN ANTIFIBROGENIC STRATEGY IN LIVER DISEASE

A. Díaz Rivera[1,*], V. Chagoya de Sánchez [2], G. Velasco Loyden [2], L. García Benavides [3], J. Armendáriz Borunda [1], A. Sandoval Rodríguez[1]

INTRODUCTION: Blockade of cannabinoid type I receptor (CB1) by pharmacological antagonist has demonstrated antifibrogenic effects in models of cirrhosis. Gene therapy with a shRNA molecule for CB1 wthinin an adenovirus has the advantage of hepatic tropism, which will reduce side effects and increase the transduction efficiency.
AIMS & METHODS: Design a shRNA that efficiently inhibit the expression of CB1, evaluate its antifibrogenic effect in an experimental model of liver cirrhosis and generate an adenoviral vector coding for the shRNA-CB1.
shRNA sequences were designed to blockade mRNA of CB1 at positions 877, 1232, 1501 (pshCB1-A, B, D). The effectiveness of the shRNA was evaluated by inhibition of the mRNA-CB1 after transfection of the plasmids in primary culture rHSC. To determine the optimum dose for transfection in primary cultures, lipofectamine 2000 and Fugene ® HD were tested using a GFP expressing plasmid (pITR-GFP). Later, we evaluated shRNA mediated-CB1 inhibition in cirrhotic rats intoxicated with CCl_4. The plasmids were administrated by hydrodynamic injection in a volume of 4 mL. Then, in animals transfected with the most potent shRNA-CB1, mRNA levels of fibrogenic molecules (TGF-β1, Col 1 and α-SMA) and percentage of fibrotic liver tissue was measured. Finally, Ad5 backbone coding for shRNACB1-1232 or shRNA-Irrelevant was generated by homologous recombination between pshRNA and the pAd / BLOCK-iT ™ DEST.
RESULTS: In vitro shRNA designed to block position 877 and 1232 significantly inhibited mRNA ($p > 0.05$) CB1 gene expression in 77% and 91%, respectively using Fugene ® HD. The sequence of shRNA-Irrelevant did not affect mRNA expression of CB1. Hydrodynamics-based transfection of shRNA-CB1 via iliac vein in the rat allows efficient and repeatable delivery to the liver. A volume of 4 mL carrying 3 mg/kg was administered in 5-7 seconds. In CCl_4 model shCB1-1232 showed major decrease in CB1 mRNA and protein ($p < 0.05$), and in consequence fibrogenic molecules TGF-β1, Col I, α-SMA also reduced (60%, 47% and 77% ($p < 0.05$); respectively). Fibrosis diminished 49% ($p < 0.05$) compared to untreated controls. Thus pshRNACB1-1232 was selected for production of adenovector. Homologous recombination between attL and attR regions between pshRNA-1232-CB1 and pAd / BLOCK-iT ™ DEST allowed the generation of Ad-shRNA1232-CB1 backbone.
CONCLUSION: shCB1-1232 demonstrates CB1 gene and protein silencing in vitro and in vivo, decreasing mRNA levels of key fibrogenic molecules and fibrosis, showing potential to be used as therapeutic strategy for liver fibrosis. Recombinant adenovirus expressing this shRNA will have the advantage of high titers production conserving efficient liver transduction, which will facilitate its therapeutic application in experimental models of liver cirrhosis or even clinical scenarios.

INTRODUCTION: The accuracy of non-invasive methods for the quantification of liver fibrosis in patients with PBC is still debated. Moreover, the Ludwig's PBC stages do not represent a measurement of quantitative fibrosis.
AIMS & METHODS: We determined the histomorphometrical measurement of fibrotic tissue and analyzed the accuracy of a number of indirect markers of liver fibrosis for the detection of different histological stages of PBC and the association between indirect serum markers and morphometric values (MV) of fibrotic tissue.
Methods: Sections of liver tissue were stained with hematoxylin/eosin and Sirius red. Only samples with a > 25 mm length and including at least 11 complete portal tracts were considered adequate for the study. Histomorphometrical measurement of fibrotic tissue was performed on sirius red stained sections of liver biopsies. Area percentage measures of fibrotic tissue were ranked into 4 groups reflecting Ludwig's staging and compared with values of the following serum markers of liver fibrosis: APRI, LOK, FORNS, FIB-4. The percentage of fibrosis was calculated with ImageJ. All results were expressed as mean ± standard deviation. The numerical comparison of continuous data was performed using the Wilcoxon signed ranks test applied to two-samples. Linear regression analysis between two variables was performed by using Pearson correlation. Statistical significance was set at a value of $p < 0.05$.

RESULTS: We enrolled 50 patients with PBC (mean age, 57±12.30 years; 43 F and 7 M; 8 AMA negative, 42 AMA positive). There were 19 (38%) patients in Ludwig's PBC stage I, 14 (28%) in stage II, 12 (24%) in stage III and 5 (10%) in stage IV. The morphometric values (Table 1) of fibrotic tissue were significantly different in the various Ludwig's stages of PBC ($p<0.05$). Only LOK score was statistically different between stage II and III ($p=0.02$). No other significant differences were found in the various Ludwig's stages of PBC for APRI, FORNS, FIB-4 and LOK scores (Table 1). A statistically significant correlation was found between MV and Forns ($R^2=0.3643$, $p=0.0004$), MV and FIB-4 ($R^2=0.3945$, $p=0.0002$), MV and LOK ($R^2=0.3367$, $p=0.0010$), MV and APRI ($R^2=0.1476$, $p=0.0361$).
Table 1.

Ludwig's stages	Morphometric values	FORNS	FIB-4	LOK	APRI
Stage I	**0.74% ± 0.65**	**3.61 ± 1.62**	**0.24 ± 0.26**	**0.20 ± 0.16**	**0.61 ± 0.76**
Stage II	**3.87% ± 1.5**	**4.55 ± 1.8**	**0.35 ± 0.39**	**0.22 ± 0.18**	**0.49 ± 0.35**
Stage III	**6.15% ± 1.68**	**5.52 ± 2.06**	**0.35 ± 0.16**	**0.38 ± 0.19**	**0.67 ± 0.44**
Stage IV	**14.06% ± 8.45**	**8.05 ± 1.76**	**1.00 ± 0.76**	**0.69 ± 0.34**	**1.24 ± 0.79**

CONCLUSION: Histomorphometric values of fibrotic tissue increase progressively in Ludwig's stages of PBC, where non-invasive markers do not, and correlate positively with indirect serum markers of liver fibrosis.

INTRODUCTION: The autonomic nervous system is the involuntary part of the peripheral nervous system and regulates the intestinal motor activity, smooth muscles and exocrine glands. Autonomic nerves that innervate the liver reach the organ via the hepatic hilum and run together with the portal vein, the hepatic artery and the bile duct. In the full clinical picture of liver cirrhosis, no parenchymal innervation can be detected. In addition, malignant liver tumors, such as hepatocellular carcinoma (HCC) and cholangiocellular carcinoma (CCC), are not innervated.
AIMS & METHODS: The aim of this work is the characterization of a possible hepatic neuroplasticity, including responsible neurotrophic factors. In the present work, a collective consisting of 103 patients (22 patients with normal liver tissue, 23 patients with liver cirrhosis, 45 patients with HCC and 13 patients with CCC) was examined for variations in nerve number and nerve size. In addition, growth factors, such as Growth-Associated Protein (GAP-43) and Nerve Growth Factor (NGF), as well as their receptors TrkA and p75NTR were investigated by immunohistochemistry and qRT-PCR in terms of their involvement in a possible hepatic neuroplasticity.
RESULTS: The multiple comparison of median nerve sizes of the examined entities showed a clearly significant difference. The largest nerves were discovered in HCC samples. However, no difference in neural density was detected. Furthermore, significant differences were observed for the high affinity NGF-receptor TrkA and the low affinity NGF-receptor p75NTR with regards to immunoreactivity and relative expression. The highest p75NTR expression was found in normal liver tissue and both, relative expression as well as immunoreactivity, decrease with increasing nerve size.
CONCLUSION: The results of the present study suggest that the observed neural changes in the liver are related to active neural remodeling processes. The NGF receptor p75NTR seems to take on a key role in this context. Since p75NTR binds all neurotrophins with low affinity, further research is warranted concerning its involvement in the plasticity of hepatic nerves.

P0013 HIGH CONCENTRATION OF FIBROTIC AND INFLAMMATORY MARKERS AMONG PATIENTS WITH SCHISTOSOMAL LIVER DISEASES

E. Sinkala[1,2], P. Kelly[3,4], **E. Sinkala**[1,2,*]
[1]*Internal Medicine, University of Zambia,* [2]*Internal Medicine, TROPGAN, Lusaka, Zambia,* [3]*Internal Medicine, Barts and London, Blizzard Institute, London, United Kingdom,* [4]*Internal Medicine, University Teaching Hospital, Lusaka, Zambia, Lusaka, Zambia*
Contact E-mail Address: *sinkalaeddie@yahoo.com*

INTRODUCTION: Worldwide the commonest cause of portal hypertension is cirrhosis, but in tropics it is schistosomiasis. Some parts of Zambia are hyperendemic with prevalence of 77%. Hepatocellular function is preserved in hepatosplenic schistosomiasis hence prognosis is better than cirrhosis. Liver biopsy can confirm fibrosis but it is invasive.
AIMS & METHODS: This is an ongoing case control study involving 70 cases and 20 controls. All cases had varices and were negative for HIV, hepatitis B and C viruses. Hyaluran was used as a marker of liver fibrosis while TNF receptor 1, sCD14, IL1 beta, IL 6 and CRP were inflammatory markers.
We set out to investigate fibrotic and inflammatory makers in hepatosplenic schistosomiasis patients at the University Teaching Hospital, Lusaka, Zambia.
RESULTS: Eighty patients were evaluated and serology for schistosomiasis was positive in 74 (93%) and negative in 6 (7%). Hyaluran levels compared with controls were higher, $p<0.001$ (median 111.6ng/ml, IQR 39.1, 240.3). Inflammatory markers were elevated: TNF receptor 1 concentrations compared with controls were higher, $p<0.001$ (median 3150.1pg/ml (IQR 1703.2, 10460.0), sCD14 values were higher than in controls $p<0.001$, median 2365.0ng/ml (IQR1744.9, 3128.6). IL 1 beta values were higher than in controls $p=0.013$, median 4.3pg/ml (IQR 0.8, 13.2) and so were IL 6 values $p=0.001$ (median 15.26pg/ml, IQR 10.15, 38.13). Spearman's rank correlation of hyaluran and TNF receptor 1 was positive ($r=0.44$, $p=0.002$) and so was hyaluran and IL6 ($r=0.251$, $p=0.045$).
CONCLUSION: Schistosomiasis is a leading cause of portal hypertension in Zambia and induces a liver fibrotic marker which could be used to assess disease severity. It seems hepatosplenic schistosomiasis also induces high levels of TNF receptor 1, sCD14, IL1 beta and IL6. These elevated markers could be due to bacterial translocation which needs to be confirmed by markers of bacterial translocation such as LPS.

INTRODUCTION: MMP-8 degrades preferentially collagen type I (collagen of higher proportion of hepatic fibrosis). We delivered MMP-8 gene in to the muscle, using an Adenovirus vector, protein is released systemically and is activated in the liver.
AIMS & METHODS: Our aim was to evaluate profibrogenic gene expression pattern and liver fibrosis prevention.
We used four groups of rats ($n=15$): control; thioacetamide (TAA), induced-fibrosis; TAA+AdGFP; TAA+AdMMP8. At the beginning of the fifth week of TAA intoxication, administration of vectors in soleum muscle was accomplished. Sub-groups of rats ($n=5$) at the end of first, second and third week after vector administration were sacrificed. Percentage of fibrosis, liver function, gene expression of MMP8, proinflammatory genes (IL1-beta, TNF-alpha), profibrogenic genes (collagen α1(I), CTGF and TGF-beta) and antifibrogenic genes (MMP1 and MMP9), were determined.
RESULTS: After 3 weeks of treatment: In the liver and serum, amount of MMP8 protein was sustained, fibrosis decreased up to 48%, proinflammatory genes expression was modified only at the end of the third week, profibrogenic gene expression decreased (Col α1(I) 4 times, TGF-beta 3 times and CTGF 2 times), antifibrogenic genes expression increased (MMP9 2.8 times and MMP1 10 times). According to Knodell score, a clearly diminution of inflammatory cells infiltration in comparison with counterpart animals treated with AdGFP, could be appreciated.
CONCLUSION: A single dose of AdMMP8 in muscle is enough in order to obtain a stable liver MMP8 protein expression and activity during 21 days. Degradation of collagen in the liver modifies pro and anti-fibrogenic gene expression allowing a restoration of hepatic architecture.

INTRODUCTION: Congenital disorders of glycosylation (CDG) are a heterogeneous group of autosomal recessive metabolic diseases with a wide spectrum of clinical symptoms. Depending on localization of the defective protein, two types are distinguished (CDG-I; endoplasmatic reticulum and CDG-II; Golgi apparatus). Liver involvement is frequent in both groups and can even be predominant for some CDG-II variants. Abnormal glycosylation is seen in liver cirrhosis, probably resulting from affected liver synthesis. We hypothesized that mass spectrometry (MS) differentiates between secondary and bonafide genetic causes in end-stage liver disease.
AIMS & METHODS: To determine the effect of a diminished liver function on glycosylation we analyzed anonymous serum samples drawn from end-stage liver disease patients prior to their liver transplantation. As a first step we used transferrin isoelectric focusing (tIEF) to detect abnormal glycosylation. Selected samples were further analyzed with transferrin whole-protein MS to obtain a comprehensive readout of the glycosylation profile.
We also obtained serum from 100 patients with a presumed CDG. Patients with a predominant liver phenotype were selected for further analysis using exome sequencing for identification of the pathogenic mutation.
RESULTS: We collected 1065 serum samples and found an abnormal tIEF pattern in 30%. All abnormalities were mild and resembled a CDG-II pattern.

MS of abnormal tIEF samples had increased fucosylation of transferrin and loss of one sialic acid.
We identified 18 patients with a phenotype resembling Wilson disease with liver fibrosis, elevated transaminases, low ceruloplasmin and liver copper accumulation. DNA is currently prioritized for exome sequencing. MS comparison of the Wilson disease-like patients and liver transplant patients showed that desialization is more abundant in Wilson disease-like patients and transferrin fucosylation is seen more often in liver transplant patients.
CONCLUSION: Whole protein MS enables differentiation between abnormal glycosylation secondary to liver failure and bonafide CDG. This can aid in the detection of CDG as a cause for liver pathology.

Contact E-mail Address: *okamotka@grape.med.tottori-u.ac.jp*

INTRODUCTION: Simple steatosis (SS) and non-alcoholic steatohepatitis (NASH) are regarded as histological subtypes of non-alcoholic fatty liver disease (NAFLD). The distinctive pathological difference between SS and NASH is that NASH induces chronic liver inflammation and fibrogenesis, which can lead to liver cirrhosis. The difference in pathogenesis between SS and NASH is still not clear. MicroRNAs (miRNAs) are endogenous, non-coding short RNAs that regulate gene expression by repressing translation or degrading target mRNAs. Accumulating evidence indicates that miRNAs play important roles in various life functions including inflammation, metabolism, and fibrosis.
AIMS & METHODS: The purpose of this study was to examine the relationship of miRNA expression profiles with SS and NASH in animal models and humans. DD Shionogi (DS), Fatty Liver Shionogi (FLS), and FLS ob/ob mice were subjected as the normal control, SS model, and NASH model, respectively. Microarray analysis was used to assess 375 miRNA expression profiles in mouse liver tissue. Normalized miRNA expression ratios over ±2log2 between FLS and FLS ob/ob were identified as candidates. Real time PCR was used to check the reproducibility of the microarrays predicting miRNAs from 4 mice in each group. The putative miRNA target genes were predicted using the web-driven software DIANA microT-CDS. DAVID 6.7 was used to perform gene ontology annotation and KEGG pathway enrichment analysis. The putative miRNA expression profiles in human serum were also examined in every 10 patients with asymptomatic gallbladder stones, SS, and NASH.
RESULTS: In microarray analysis, 18 miRNAs were identified as candidates. Among the 18 miRNAs, 6 showed good expression ratio reproducibility in real time PCR and were confirmed to express commonly between mice and humans. The expression levels of miR-200a and miR-200b increased in the order of normal control, SS, and NASH. miR-1 was downregulated in NASH. miR-376c, miR-409, and miR-411 showed potent high expression in SS, over 30-fold of DS. KEGG pathway analysis indicated that the strongly expressed miRNAs in SS (miR-376c, miR-409, and miR-411) had multiple targets in the TGF-β signaling pathway including TGFR, smad 2, 3, and 4. The analysis suggests that miR-376c, miR-409, and miR-411 may protect liver fibrosis through silencing the TGF-β signaling pathway. In human serum, hierarchical clustering analysis of the putative miRNA expression also showed clearly different expression profiles between SS and NASH.
CONCLUSION: The expression profiles of 6 miRNAs were different between SS and NASH models. Some potential target genes of the putative miRNAs were found to be involved in the TGF-β signaling pathway. Furthermore, the putative miRNA expression profiles in human serum were also clearly different between SS and NASH patients. These miRNAs have high potential as biomarkers to distinguish the fate of NAFLD patients and contribute to further research in the pathogenesis and treatment of NASH.

Contact E-mail Address: *celinski.krzysztof@gmail.com*

INTRODUCTION: The aim of the present study was to determine the effect of melatonin on liver fibrosis induced with long-term administration of thioacetamide (TAA) in an animal model. The antifibrotic effects of melatonin were assessed by determining activity indirect markers of fibrosis, i.e. aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (AP), and direct markers represented by proinflammatory cytokines such as interleukin 6 (IL-6), interleukin beta 1 (IL-beta1), tumour necrosis factor alpha (TNF-alpha, transforming growth factor beta 1 (TGF-beta1) and platelet-derived growth factor (PDGF- AB). Moreover, parameters of oxidative stress were determined, i.e. concentrations of oxidised glutathione (GSSG) and reduced glutathione (GSH), activity of paraoxonase 1 (PON-1), an enzyme of antioxidative properties. Inflammatory changes and extent of fibrosis were evaluated histologically.
AIMS & METHODS: Experiments were carried out in Wistar rats. Animals were divided into 4 groups, 8 individuals each: group I- controls receiving drinking water ad libitum for 12 weeks, group II – TAA, 300 mg/L ad libitum for 12 weeks, group III- melatonin, 10 mg/kg b.w. administered intraperitoneally (IP) daily for 4 weeks, group IV – TAA, 300 mg/L ad libitum for 12 weeks followed by melatonin, 10 mg/kg/b.w. administered IP daily for 4 weeks.
RESULTS: Results of serum determinations demonstrated significantly lower activity of AST, ALT and AP in the group receiving TAA followed by melatonin (IV) compared to the group receiving only TAA (II). Immunoenzymatic findings regarding the effect of melatonin on concentration of proinflammatory cytokines (Il-6, Il-beta1, TNF-alpha, TGF-beta 1, PDGF-AB) confirmed these data.
CONCLUSION: Biochemical examinations in liver homogenates revealed statistically significant improvement of oxidative stress parameters (concentration of GSH increases and concentration of GSSG decreases) in animals with TAA-induced liver damage receiving melatonin (IV). Moreover, the activity of PON-1 toward phenyl acetate and paraoxon was found to be increased in liver homogenates and serum in the group receiving TAA followed by melatonin (IV) compared to the TAA group (II). Microscopic evaluation disclosed inhibitory effects of melatonin on inflammatory changes and extent of liver fibrosis.

INTRODUCTION: Reactive lipid aldehydes formed during lipid oxidation such as 4-hydroxynonenal (4-HNE), are key activators of hepatic stellate cells (HSCs) to a pro-fibrogenic phenotype. γ-Ketoaldehydes (γ-KAs) are highly reactive lipid aldehydes formed during oxidation of arachidonic acid or as a by-product of the cyclo-oxygenase pathway. γ-Ketoaldehydes are ~100x more reactive than HNE, and form protein adducts and cross-links. Increased circulating concentrations of proteins cross-linked to γ-ketoaldehydes are present in patients with alcoholic liver disease.
AIMS & METHODS: The aim of this study was to investigate whether one specific γ-ketoaldehyde, namely levuglandin E_2 (LGE_2), can induce activation of HSCs. Cultured activated, serum-starved primary mouse and human HSCs were exposed to various concentrations (0.5 pM-5 μM) of levuglandin E_2 (LGE_2) for up to 48 hours. Endpoints measured included proliferation (BrdU incorporation), cytotoxicity (lactate dehydrogenase (LDH) release and tetrazolium (MTS) reduction), RNA expression (qRT-PCR), protein expression (Western Blot), and collagen secretion in conditioned medium (SirCol assay).
RESULTS: HSCs exposed to LGE_2 exhibited profound cytotoxicity at 5 μM concentration, as indicated by LDH leakage and reduced MTS. This was mediated by an induction of apoptosis, indicated by an increase in PARP cleavage, occurring as early as 8 hours after LGE_2 exposure. However, at lower, non-cytotoxic doses (ranging from 50 pM-500 nM, with a maximum effect observed at 0.5 nM), LGE_2 promoted HSC activation as indicated by increased expression of α-smooth muscle actin and vimentin, as well as increased proliferation and collagen secretion. In addition, LGE_2 exposure promoted sustained activation of signalling pathways, as indicated by the increased phosphorylation of the kinases ERK1/2 and JNK, as well as an increase in mRNA levels of chemokines such as IL-8 and MCP-1. We are currently investigating the potential protective action of administration of a γ-ketoaldehyde scavenger in an animal model of hepatic fibrosis.
CONCLUSION: γ-Ketoaldehydes represent a newly identified class of activators of HSCs *in vitro*, which are biologically active at concentrations as low as 50 pM.

P0019 NONINVASIVE SERUM FIBROSIS MARKERS IN COMPARISON WITH GRADING AND STAGING IN CHRONIC HEPATITIS

M. Abdollahi[1,*], A. Pouri[2], M. Somi[2]
[1]*Young Researchers and Elite Club, Tabriz Branch, Islamic Azad University,* [2]*Liver and Gastrointestinal Diseases Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic Of*
Contact E-mail Address: *Dr. M. R. Abdollahi@gmail.com*

INTRODUCTION: Chronic hepatitis is defined as a necroinflammatory disease of the liver continuing for at least six months. The aim of this study was to evaluate the role of noninvasive fibrosis markers by assessing the association among grading and staging and these diagnostic parameters in patients with chronic hepatitis.
AIMS & METHODS: We retrospectively studied 221 patients with chronic hepatitis between 2011 and 2013. Routine biochemical indices and serum fibrosis indexes such as aspartate aminotransferase (AST)/alanine aminotransferase (ALT) ratio (AAR), AST to platelet ratio index (APRI) and Fibrosis 4 score (FIB-4) were determined, and the histological grade and stage of the liver biopsy specimens were scored according to the Ishak scoring system. Receiver operating characteristic curve (ROC) analysis was conducted to compare diagnostic accuracies of these markers for prediction of significant fibrosis.
RESULTS: We identified 221 liver biopsies from chronic hepatitis patients with contemporaneous laboratory values for imputing AAR, APRI and FIB-4. From all, 135 males (61.1%) and 86 females (38.9%), with the mean age of 39.6±14.4 were studied. FIB-4, APRI and AAR were correlated significantly with the stage of fibrosis, with a higher correlation coefficient than other markers in the patients

with Hepatitis B ($r = 0.46$), C ($r = 0.58$) and autoimmune hepatitis ($r = 0.28$). FIB-4 (AUROC = 0.84) and APRI (AUROC = 0.78) was superior to AAR at distinguishing severe fibrosis from mild-to-moderate fibrosis and gave the highest diagnostic accuracy.
CONCLUSION: Application of these markers was good at distinguishing significant fibrosis and decreased the need for staging liver biopsy specimens among patients with chronic hepatitis.
Disclosure of Interest: None declared

P0020 REVEALING THE MOLECULAR MECHANISM OF RAT LIVER RESPONSE TO LONG-TERM OMEPRAZOLE TREATMENT WITH BIOINFORMATICS APPROACH

S. Vakal[1], E.A. Virag[2], K. Dvorshchenko[1], **L. Ostapchenko**[1,*]
[1]*ESC "Institute of Biology", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine,* [2]*University of Pecs, Pecs, Hungary*
Contact E-mail Address: *sergii.vakal@univ.kiev.ua*

INTRODUCTION: Omeprazole is a widely prescribed acid-suppressing drug available for clinical use for 25 years. Despite well-studied adverse effects of short-term omeprazole treatment, underlying mechanisms of some hepatotoxic effects of long-term injection of high omeprazole doses (e.g. development of oxidative stress and histopathologic changes [1]) are not understood. Transcriptome analysis is a powerful tool for elucidation of possible mechanisms of cellular response to different conditions on molecular level. Bioinformatics approach is suitable for processing of large datasets, prediction of possible regulatory circuits and generation of hypotheses on involved molecular mechanisms [2].
AIMS & METHODS: The purpose of the research was to find out possible molecular mechanisms of rat liver cells response to long-term injection of omeprazole.
GSE8858 dataset and GPL2454 platform description were downloaded from NCBI Genome Expression Omnibus database. Gene expression data from livers of rats treated with 30 mg/kg and 415 mg/kg for 1 and 25 days were compared in order to reveal differentially expressed genes (DEGs). DEGs were determined with GEO2R tool on the basis of t-criterion and adjusted p value. Gene ontology (GO), pathway enrichment analyses and building of protein-protein interactions (PPI) network were performed with STRING 9.1. Prediction of miRNAs and *cis*-elements for DEGs was carried out with WebGestalt toolkit. Clusters were identified by K-means analysis in ClusterONE. All networks were visualized using Cytoscape.
RESULTS: In total 79 DEGs (21 up- and 58 down-regulated) and 87 DEGs (41 up- and 46 down-regulated) were identified in samples of rat livers treated with 30 and 415 mg/kg during 25 days, respectively. At the same time 22 genes with similar pattern of expression (9 up- and 13 down-regulated) were found for both types of dosage. Among them are *Arntl*, *Cdk1a*, *Chka*, *Gpam*, *Litaf*, *Slc2a5*, *Usp2* etc. Enrichment in such GO terms was revealed: cell cycle, mitosis, nuclear division, lipid metabolism. Only genes involved in lipid metabolism were up-regulated, while others were suppressed. Genes involved in PPAR signalling pathway were found to be differentially regulated upon 25-day treatment with omeprazole. Most of DEGs (51 genes) were of cytoplasmic proteins (housekeeping genes). PPI networks were constructed for 98 proteins and 102 interactions revealed. The optimal amount of clusters was equal to 3. MiRNA-9, 17-5p, 20A, 20B, 106A, 106B, 200B, 200C, 429, 506 and 519D were found to be involved in regulation of revealed DEGs. 24 probable *cis*-elements were predicted for promotors of identified DEGs.
CONCLUSION: Thus, long-term treatment of rats with omeprazole is associated with changes in expression of housekeeping genes: down-regulation of genes involved in cell-cycle process and cellular division, up-regulation of genes involved in lipid metabolism, and changes in expression of PPAR signalling pathway genes.

INTRODUCTION: Recent reports indicate that both human and experimental NASH is characterized by an increase in hepatic monocyte infiltration and that macrophages have an important role in regulating the disease evolution. However, little is known about the functional changes occurring in liver macrophages during the progression of NASH.
AIMS & METHODS: NASH was induced in C57BL/6 mice by feeding a methionine-choline deficient (MCD) diet up to 8 weeks.
RESULTS: Mice receiving the MCD diet showed a progressive worsening of parenchymal damage and lobular inflammation, while liver fibrosis was evident only after 8 weeks of treatment. Hepatic F4/80-positive macrophages increased in parallel with the disease progression. In the early phases of NASH after 4 weeks on the MCD diet these cells prevalently expressed markers of inflammatory monocytes such as Ly6C and CD11b, but the prevalence of $Ly6C^+/CD11b^+$ cells decreased by extending the treatment up to 8 weeks. This paralleled with a lowering in the monocyte chemokines CCL1/CCL2 and their receptors CCR8/CCR2. We observed that the expression of the macrophage M1 activation markers iNOS and IL-12 also peaked at 4 weeks and declined thereafter. No appreciable changes were instead observed in the levels of M2 polarization markers arginase-1 and MGL-1. Histology revealed that the macrophages accumulating in advanced NASH (8 weeks MCD) were enlarged, vacuolized and formed small aggregates. Immunofluorencesce showed that these cells contained lipid vesicles positive for the apoptotic cell marker Annexin V suggesting that they have phagocytosed apoptotic bodies derived from dying fat-laden hepatocytes. At flow cytometry, enlarged macrophages were characterized by a weak Ly6C/CD11b expression and by a low IL-12 production. On the other hand, these cells showed an enhanced expression of the anti-inflammatory mediators IL-10 and annexin A1. The production of the pro-fibrogenic cytokine TGF-β was increased in the macrophages obtained from NASH livers, irrespective of the cell phenotype.
CONCLUSION: Altogether, these data indicate that during the progression of NASH liver macrophages down-modulate their pro-inflammatory phenotype in parallel with the phagocytosis of apoptotic hepatocytes and acquired anti-inflammatory properties.
This work has been supported by a grant from the Fondazione Cariplo (Milan).

INTRODUCTION: Nonalcoholic fatty liver disease (NAFL) morbidity rate in Asia Pacific region is close to 12–24%, while in Western countries is about 20–30%[1)]. And nonalcoholic fatty liver disease (NAFLD) can progress to nonalcoholic steatohepatitis (NASH), cirrhosis and hepatocellular carcinoma. In spite of its high prevalence, up till now there is no proven effective treatment for NAFLD[3)]. Along with the ''obesity epidemic,'' the worldwide prevalence of NAFLD is increasing rapidly and is generally assumed to be a consequence of obesity-induced insulin resistance [2)]. On the other hand, not all obese individuals are insulin resistant, nor are all insulin-resistant individuals obese [4)]. MicroRNAs (miRs) are a class of small non-coding RNAs that function to control gene expression by inducing the degradation or inhibiting the translation of mRNA through an association with its 3'-untranslated region (3'UTR). Although miRs play a key role in the pathogenesis of nonalcoholic fatty liver disease (NAFLD) and diabetes mellitus (DM), detailed mechanisms of this pathogenesis remain unclear.
AIMS & METHODS: We found that miR-27b increased in liver biopsy specimens of NAFLD patients with DM using microarray analysis, as compared with controls. The aim of this study was to investigate whether overexpression of miR-27b in liver could cause fatty liver formation and insulin resistance, and to examine the mechanism of NAFLD and DM onset in a murine model.
Five-week-old male C57BL/6J mice were randomized into 2 groups (n = 16 mice): basal diet (BD)-fed control mimic (BD-Con, n = 4), BD-fed miR-27b-mimic (BD-miR-27b, n = 4). In this study, miR-27b mimic is injected intravenously at 7mg/kg. We comfirmed the target genes of miR-27b using quantitative RT-PCR analysis. Insulin serum concentrations were measured by a local laboratory for clinical examinations. As an alternative method for assessing insulin resistance (IR), the homeostasis model assessment of IR (HOMA-IR) was calculated using the following formula: fasting insulin (mU/mL) plasma glucose (mg/dL) / 405.
RESULTS: BD-miR-27b significantly showed steatosis using oil red o staining and increased hepatic tryglyceride content, as compared with BD-Con. In the analysis of fat accumulation-related gene expression, hepatic Peroxisome proliferator-activated receptor α (PPARα) and Microsomal triglyceride transfer protein (MTTP) are significantly decreased. At the same time, BD-miR-27b showed hyperinsulinemia and insulin resistance. In the analysis of insulin resistance-related gene expression, hepatic Insulin receptor substrate 1 (IRS-1) is significantly decreased.
CONCLUSION: miR-27b controls multiple gene levels that are involved in fat accumulation and insulin resistance, resulting in the NAFL and DM pathology. These results propose a therapeutic approach for NAFL and DM by targeting miR-27b.

INTRODUCTION: Unilateral portal vein embolization (PVE) is used to increase future remnant liver volume in patients requiring extended resections. Reversible PVE is of interest when generating sufficient hypertrophy while preserving the embolized liver lobe. The concept of reversible PVE requires an absorbable embolization material.
AIMS & METHODS: The aim of this study is to modulate lysis time of a fibrin-glue based embolization material while using different concentrations of Aprotinin. Aprotinin inhibits fibrinolysis and thereby delays absorption of FG. PVE of the cranial liver lobe was performed in twenty-four rabbits, divided into 5 groups:
- Fibrin glue with Aprotinin (FG1000 KIU (Kallikrein Inactivotor Unit), n = 4)
- Fibrin glue with Aprotinin (FG700KIU, n = 5)
- Fibrin glue with Aprotinin (FG500KIU, n = 5)
- Fibrin glue with Aprotinin (FG300KIU, n = 5)
- Fibrin glue without Aprotinin (FG-Aprot, n = 5)

The rabbits were sacrificed after 7, 14 and 49 days, respectively. CT volumetry of non-embolized lobe (NELVol), liver damage parameters, liver-to-body weight ratio of NEL were evaluated.
RESULTS: Data were compared with a previous series using a permanent embolization material, i.e. polyvinyl alcohol + coils (PVAc), showing complete and permanent occlusion of the embolized portal vein branch in all rabbits after 7 days.
FG-Aprot was completely absorbed in 7 days and did not give any hypertrophy response of the NEL. At sacrifice on day 7, the embolized portal vein in all 4 of the FG+1000KIU Aprotinin group was still occluded and showed a hypertrophy response comparable to the PVAc group. The group of FG 700KIU Aprotinin survived 14 days and in two of the five rabbits, the embolized portal vein was recanalized at sacrifice. The hypertrophy response in these rabbits was not different from the PVAc group. The rabbits with FG 500KIU and 300KIU Aprotinin were sacrificed at day 49. In the group with FG 500KIU Aprotinin, 4 out of 5 showed recanalization of the cranial portal branches. In the group with FG 300KIU Aprotinin, 3 out of 5 rabbits showed recanalization. Both groups showed hypertrophy response rates not different compared to the PVAc group.
CONCLUSION: Fibrin glue with the concentrations 300KIU and 500KIU Aprotinin resulted in 70% reversible embolization with a hypertrophy response comparable to the PVAc group.

INTRODUCTION: Liver fibrosis is a progressed stage of chronic hepatic disease caused by a variety of factors, such as viral infections, alcohol, drugs and chemical toxicity. The only effective available treatment for end stage liver fibrosis is transplantation; however, due to the lack of donors, complications and transplant rejection, alternative treatment is needed. Mesenchymal stem cells (MSCs) have been reported to be a valuable cell source in cell therapy. Recently, bone marrow- or adipose tissue-derived MSCs have been reported to be effective in the treatment of liver fibrosis. In addition, several studies have shown that MSCs can be easily isolated from human amnion, and a large amount of cells can be obtained. Therefore, we examined the effects of transplantation of human amnion-derived MSCs (hAMSCs) in rats with liver fibrosis.
AIMS & METHODS: All pregnant women gave written informed consent, and amnion was obtained at Cesarean delivery. hAMSCs were isolated by collagenase treatment, and expanded with culture medium containing fetal bovine serum. Liver fibrosis was induced in 6-week-old male Sprague-Dawley rats by intraperitoneal injection of 2 ml/kg of 50% carbon tetrachloride (CCl_4) twice a week for 7 weeks. At 3 weeks, hAMSCs (1×10^6 cells) were transplanted intravenously. Rats were sacrificed at 7 weeks, and histological analyses and quantitative RT-PCR were performed.
RESULTS: Transplantation of hAMSCs significantly reduced the fibrotic area and deposition of type I collagen. In addition, hAMSC transplantation significantly decreased the number of α-SMA-positive hepatic stellite cells and and CD68-positive Kupffer cells in the liver of hAMSC-treated rats. mRNA expression of α-SMA was significantly decreased in the liver of hAMSC-treated rats, and mRNA expression of type I collagen, TGF-β and IL-1β tended to be decreased by hAMSC transplantation.
CONCLUSION: Transplantation of hAMSCs provided significant improvement in a rat model of liver fibrosis, possibly through inhibition of inflammatory reaction. hAMSC would be considered as a new cell source for the treatment of liver fibrosis.

P0025 VITAMIN D: HYPOTHESIS OF TROPHIC EFFECT ON LIVER CELLS IN AN ANIMAL MODEL OF NAFLD

V. Lembo[1,*], G. Mazzone[1], G. D'Argenio[1], M. D'Armiento[2], F. Morisco[1], N. Caporaso[1]
[1]*Department of Clinical Medicine and Surgery,* [2]*Department of Advanced Biomedical Science, University of Naples Federico II, Naples, Italy*

INTRODUCTION: Nonalcoholic fatty liver disease (NAFLD), the most common liver disease in Western countries, is pathogenetically related to a sedentary lifestyle as well as to poor quality diet characterized by an excessive energy intake including high fatty foods and high amounts of fructose, the so-called Western Diet (WD). The hallmark of NAFLD is hepatic accumulation of triglycerides. Vitamin D in addition to the effects on lipid metabolism, plays other biological functions, among which a trophic effect on human cultured cells.
AIMS & METHODS: To evaluate, in a rat model of NAFLD induced by Western Diet, the relationship between body weight, liver weight and grade of steatosis; and if these parameters are modified by vitamin D supplementation. Methods: Eighteen male Wistar rats were divided into 3 groups, each of 6 rats. The 3 groups were fed respectively with Standard Diet (SD); Western Diet (WD); WDVitD: WD supplemented with 23 IU/day/rat of vitamin D3. The experiment was conducted for 6 months. Weekly, the rats, body weight was recorded. At sacrifice, livers were excised and weighed and samples were stored at -80°C. Liver histology was examined by haematoxylin/eosin and Oil Red-O staining. Steatosis was numerically scored following semi-quantitative pathological standard.
RESULTS: During the experiment the increase of *body* weight was similar in the three groups. In the two groups fed with WD *liver* weight was significantly higher than SD group ($p<0.01$). A positive correlation between *body* weight and *liver* weight was observed in WD groups ($p<0.0001$). The *liver*/*body* weight ratio was significantly higher in WD and WDVitD groups than SD: 2.9±0.05, 2.8±0.07 and 2.0±0.04, respectively; $p<0.001$). Steatosis was present in 61% and 21% of hepatocytes in WD group and WDVitD group, respectively, and absent in SD group. No correlation was found between the grade of steatosis and liver or body weight nor between the grade of steatosis and liver/body weight ratio. Although vitamin D supplementation reduced the degree of steatosis, liver/body weight ratio in WDVitD group was similar to WD group.
CONCLUSION: In a rat model of NAFLD induced by WD the presence and extent of steatosis are independent from body weight. Interestingly and unexpectedly, in WD groups the supplementation with vitamin D reduces liver steatosis but not liver weight: this sustains the hypothesis of a trophic effect of vitamin D on liver cells.

INTRODUCTION: The last decade has seen nonalcoholic fatty liver disease (NAFLD) rise to become the most common cause of chronic liver disease in Western countries. It is known that insulin resistance and type 2 diabetes mellitus (T2DM) have an important role in the pathogenesis of obesity and NAFLD. A growing body of evidence points to a linked and potentially causative relationship between serum 25-hidrossivitamin D3 [25-(OH)D] levels and NAFLD.
AIMS & METHODS: Aim of this study was to evaluate whether daily vitamin D3 supplementation is able to modulate the liver effects and glucose homeostasis of a westernized diet, high in fat and fructose, in an animal model of NAFL without vitamin D deficiency. Methods: Eighteen male Wistar rats were divided into 3 groups, each of 6 rats. Group 1: Standard Diet (SD); Group 2: Western Diet (WD) containing 13 IU/day/rat of vitamin D3; Group 3: WD containing 23 IU/day/rat of vitamin D3 (WDVitD). The experiment was conducted for 6 months. Liver histology was examined by haematoxylin/eosin and Oil Red-O staining. Insulin resistance was determined according to the Homeostasis Model of Assessment (HOMA-IR) method. Grade of liver steatosis was evaluated according to Brunt EM et al.
RESULTS: In SD group, livers were normal and no hepatocytes contained fat; in WD group the percentage of hepatocytes with steatotic vacuoles was 61%, while in WDVitD group only 27% of hepatocytes contained fat. In WD group HOMA-IR was significantly higher than in SD (41.9±8.9 *vs* 6.17±1.3, $p<0.01$) and it was reduced by vitamin D supplementation in WDVitD group (41.9±8.9 *vs* 19.4±5.2, $p<0.05$). Interestingly SD and WDVitD rats were not diabetic (98.7±8.0 and 103.2±6.1, respectively) while all rats in WD group were diabetic (139±9.6) with glycemic values significantly higher than SD ($p<0.01$) and WDVitD ($p<0.05$).
CONCLUSION: These results suggest that a daily supplementation of vitamin D3 is able to improve insulin sensitivity and to prevent the development of diabetes and hepatic steatosis in WD rats.

INTRODUCTION: Sphingomyelin (SM) is a major component in lipid microdomains, and SM is synthesized from ceramide by the action of SM synthase (SMS). We have recently reported that mice deficient for SMS2 are resistant to high fat diet-induced obesity, fatty liver and insulin resistance (J Biol Chem 2011:286;28544). In this study, we examined the relationship between SM and ceramide molecular species and the development of NAFLD and insulin resistance in human.
AIMS & METHODS: Non-alcoholic students of our university with body mass index (BMI) $\geq$ 35 kg/m^2 at the regular physical checkup in 2013 were enrolled, and volunteer students with BMI of 20-22 kg/m^2 were set as a control group. Serum levels of SM and ceramide containing saturated (C14:0, C16:0, C18:0, C20:0, C22:0 and C24:0) and unsaturated (C16:1, C18:1, C20:1, C22:1 and C24:1) fatty acids were measured using LC/MS/MS. Serum levels of liver enzymes, lipids and insulin resistance were measured by blood examination. Abdominal ultrasound was performed to confirm the existence of fatty liver, and body composition including percent body fat (PBF) was measured by bioimpedance analysis.
RESULTS: The levels of total SM and ceramide were not altered in obese group (19-28 y.o., n = 12), compared with control group (18-27 y.o., n = 11). The concentrations of SM C18:0 and C24:0 in the obesity group were significantly higher than in the control group. Moreover, in the obese group, SM C20:0 and C22:0 tended to be higher than in the control group. In the analysis of total 23 cases, the serum levels of SM containing saturated fatty acids positively correlated with PBF, ALT, ChE, LDL-C, TG and HOMA-R. However, SM species containing unsaturated acyl chain and almost all ceramide species did not correlate with those items.
CONCLUSION: The present study demonstrated that the serum levels of SM species containing saturated fatty acids (C18:0, C20:0, C22:0 and C24:0) are correlated with liver function and insulin resistance, suggesting that distinct SM species are involved in the development of NAFLD and insulin resistance.

INTRODUCTION: Liver steatosis measurement by controlled attenuation parameter (CAP) is a non-invasive method for diagnosing steatosis, based on transient elastography. Plasma caspase-generated cytokeratin-18 fragments (CK-18) have been proposed as a non-invasive alternative for the diagnosis of NAFLD, especially NASH.
AIMS & METHODS: Aims: compare CK-18 serum levels in apparently healthy individuals with and without steatosis. **Methods:** Recruitment from a prospective epidemiological study of the general Portuguese adult population. Steatosis evaluated using CAP and ultrasound. Performance of CK-18 for diagnosing steatosis compared with US and CAP was assessed using AUROC.
RESULTS: 146 individuals studied (60% male), mean age and BMIs (body mass index) were 52.6±17.1 years and 28.2±4.9 kg/m2, respectively; 25% had a normal BMI, 46% were overweight and 29% were obese. Prevalence of steatosis on ultrasound was 52.1%.
The mean (SD), median (minimum-maximum), and 5th and 95th percentile values of CK-18 values were 73.4 (67.7), 57.6 (25-508), 25 and 220.1 U/L, respectively. Median CK-18 were elevated in patients with vs. without hepatic steatosis by ultrasound: 33.4 [IQR: 25–151] vs. 73.7 [IQR: 25–508] U/L, p < 0.0001.
CK-18 significantly correlated with steatosis (ρ = 0.40), ALT (ρ = 0.40), CAP (ρ = 0.38), triglyceride (ρ = 0.32), waist circumference (ρ = 0.30), HDL (ρ = -0.28), AST (ρ = 0.27), LDL (ρ = 0.26), total cholesterol (ρ = 0.21) and the number of metabolic syndrome criteria (ρ = 0.29), but not with LSM or BMI.
The CK-18 AUROC to predict steatosis using ultrasound and CAP (cut-offs of 243 dB/m) were 0.78 (95% CI = 0.71–0.86) and 0.74 (95% CI = 0.65–0.82), respectively.
CONCLUSION: In the absence of steatosis, CK-18 serum levels were below 151, with a very large range. It showed a good discriminating capacity for diagnosing steatosis.

P0029 PREVALENCE OF HEPATIC STEATOSIS IN THE GENERAL PORTUGUESE POPULATION: USING FATTY LIVER INDEX (FLI) AND ULTRASOUND

S. Carvalhana[1,2], J. Leitão[3], C. Alves[4], M. Bourbon[4], A. Carvalho[3], **H. Cortez-Pinto**[1,2,*]
[1]*Gastroenterology, Hospital de Santa Maria, CHLN,* [2]*Unidade de Nutrição e Metabolismo, FML, IMM, Lisbon,* [3]*Internal Medicine, CHUC, Coimbra,* [4]*INSA, Lisbon, Portugal*

INTRODUCTION: The fatty liver index (FLI) derived from an Italian population includes serum triglycerides, serum gamma-glutamyltransferase, body mass index (BMI) and waist circumference. It has been used as a noninvasive measure of hepatic steatosis (HS), but has not been widely validated and not examined in the Portuguese population.
AIMS & METHODS: Estimate the prevalence of HS in the Portuguese adult population by fatty liver index (FLI) and correlate with the ultrasound findings; validate FLI for prediction of fatty liver in the Portuguese population.
Methods: Recruitment from a prospective epidemiological study of the general Portuguese adult population. Steatosis evaluated using ultrasound (US) and FLI. Performance of FLI for diagnosing steatosis compared with US was assessed using AUROC.
RESULTS: We studied 950 subjects, 50.5% men. The mean age, waist circumference and BMIs were 50.5±18.4 years, 94.4±12.7 cm and 26.9±4.7 kg/m2, respectively; 43% were overweight and 22% were obese. The median of FLI was 38.1. Ultrasound was performed in 411 subjects, showing fatty liver in 35%. Using the FLI, 27.6% of subjects had HS (FLI > 60), 41.8% had no HS (FLI < 30) and 30.6% were not classifiable (FLI 30-60). However, these cut-offs proposed by Bedogni appears to be inappropriate as 11.5% of subjects with FLI <30 exhibited HS on ultrasound and 13.4% of subjects with FLI > 60 showed no steatosis. For the FLI, the area under the ROC curve was 0.88 for the diagnosis of HS.
There was a significant correlation (p < 0.01) between the FLI and the following variables: weight (ρ = 0.80), waist circumference (ρ = 0.74), presence of steatosis (ρ = 0.65), triglycerides (ρ = 0.58), BMI (ρ = 0.51), ALT (ρ = 0.43), GGT (ρ = 0.39), HDL (ρ = -0.36), age (ρ = 0.33), female sex (ρ = -0.33), insulin (ρ = 0.29), AST (ρ = 0.28), LDL (ρ = 0.24) and total cholesterol (ρ = 0.22). No correlation was found with physical activity.
CONCLUSION: FLI could accurately identify hepatic steatosis in the general Portuguese population. The calculation of FLI may be useful to suggest the possibility of the presence of steatosis and indicate the need for an abdominal ultrasound.

P0030 "NORMAL" CONTROLLED ATTENUATION PARAMETER (CAP) VALUES: A POPULATION-BASED STUDY OF HEALTHY SUBJECTS

S. Carvalhana[1,2], J. Leitão[3], C. Alves[4], M. Bourbon[4], **H. Cortez-Pinto**[1,2,*]
[1]*Gastroenterology, Hospital de Santa Maria, CHLN,* [2]*Unidade de Nutrição e Metabolismo, FML, IMM, Lisbon,* [3]*Internal Medicina, CHUC, Coimbra,* [4]*INSA, Lisbon, Portugal*
Contact E-mail Address: *sofiacarvalhana@msn.com*

INTRODUCTION: Liver steatosis measurement by controlled attenuation parameter (CAP) is a non-invasive method for diagnosing steatosis, based on transient elastography. The normal range of controlled CAP values needs to be explored in clinical and anthropometrically diverse healthy subjects. A recent study has shown an association of CAP with BMI and the number of metabolic syndrome criteria.
AIMS & METHODS: Aim: define the normal range of CAP values in healthy subjects and evaluate the associated factors.
Methods: Recruitment from a prospective epidemiological study of the general Portuguese adult population. CAP was performed using Fibroscan in 134 healthy subjects, without fatty liver on ultrasonography or positivity serology for HBsAg, anti-HBc and anti-HCV, and normal aminotransferase levels.
RESULTS: From 134 consecutive individuals studied (66 males), 4 were excluded due to failure/unreliable liver stiffness measurements (LSM). The mean age and BMIs (body mass index) were 46.9±18.0 years and 24.9±3.5 kg/m2, respectively; 50% had a normal BMI, 43% were overweight and 7% were obese. The mean (SD), median (minimum-maximum), and 5th and 95th percentile values of CAP values were 202.29 (48.4), 205.5 (100.0-297.0), 108.2 and 276.3 dB/m, respectively. Men had a higher mean CAP value than women (mean±SD: 213.1±47.1 dB/m versus 191.8±47.8 dB/m, respectively; p = 0.012).
CAP significantly correlated with gender (ρ = 0.22), age (ρ = 0.22), waist circumference (ρ = 0.33), BMI (ρ = 0.22), alcohol consumption (ρ = 0.25), systolic blood pressure (ρ = 0.27), ALT (ρ = 0.27), fasting glucose (ρ = 0.24) and the number of metabolic syndrome criteria.
After allowance for potential confounders, CAP was not independently associated with BMI or other risk factors for nonalcoholic fatty liver disease.
CONCLUSION: CAP values vary between 108.2 and 276.3 dB/m in healthy subjects and is not associated with BMI or the number of metabolic syndrome criteria.

INTRODUCTION: Several trials have demonstrated that somatostatin analogues decrease liver volume in mixed populations of patients with autosomal dominant polycystic kidney disease (ADPKD) and isolated polycystic liver disease. Chronic renal dysfunction in ADPKD may affect treatment efficacy of lanreotide and possibly enhances risk for adverse events.
AIMS & METHODS: The aim of this open-label clinical trial (RESOLVE trial) was to assess efficacy of 6 months lanreotide treatment 120 mg subcutaneously every 4 weeks in ADPKD patients with symptomatic polycystic liver disease. We excluded patients with an estimated glomerular filtration rate (eGFR) < 30 ml/min/1.73m^2. Primary outcome was change in liver volume, secondary outcomes were changes in kidney volume, eGFR, symptom relief and health-related quality of life (Euro-Qol5D). We used the Wilcoxon signed-rank test or paired two-sided t-test to analyze within-group differences.
RESULTS: We included 43 ADPKD patients with polycystic liver disease (84% female, median age 50 years, mean eGFR 63 ml/min/1.73m^2). Median liver volume decreased from 4,859 ml to 4.595 ml (-3.1%;$p<0.001$), and median kidney volume decreased from 1.023 ml to 1.012 ml (-1.7%;$p=0.006$). eGFR declined 3.5% after the first injection and remained stable up to study end. Lanreotide significantly relieved postprandial fullness, shortness of breath and abdominal distension, but had no effect on any of the EuroQol-5D dimensions. Three participants had a suspected episode of hepatic or renal cyst infection during the study.
CONCLUSION: Lanreotide reduced polycystic liver and kidney volumes and decreases symptoms in ADPKD patients. Moreover, eGFR decreased acutely after starting lanreotide, but stabilized thereafter.

P0032 THE EFFECTS OF POLY-UNSATURATED FATTY ACIDS (PUFAS) IN A RODENT NUTRITIONAL MODEL OF NON-ALCOHOLIC STEATOHEPATITIS (NASH)

V. Smid[1,2,*], K. Dvorak[1], B. Stankova[2], A. Zak[1], L. Vitek[1,2], R. Bruha[1]
[1]*4th Department of Internal Medicine, General University Hospital and 1st Faculty of Medicine,* [2]*Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic*

INTRODUCTION: NAFLD and subsequent NASH are probably the most common chronic liver diseases in western countries and have a high risk of development of liver cirrhosis associated with high morbidity and mortality.
AIMS & METHODS: The aim of the study was to determine effects of administration of PUFAs in the MCD dietary model of NASH and to assess the potential anti-inflammatory role of PUFAs in the pathogenesis of NASH.
For 6 weeks were male mice fed either with MCD or with chow. There were 4 groups of animals. Both experimental and control groups received from the beginning either PUFAs or saline. Detailed liver histology, serum biochemistry, total lipid and fatty acids compound, adiponectin and leptin levels were determined. Expressions of mRNA of key pro- and anti-inflammatory cytokines were measured.
RESULTS: Feeding with MCD resulted in histopathological changes of NAFLD/NASH and these changes were ameliorated in PUFAs-group (MP). Administration of PUFAs led to significant decreases of total animal and liver weight in MP. PUFAs also decreased cholesterol levels ($P<0.001$), ALT ($P<0.01$) and AST levels ($P<0.01$). MP developed significantly less pro-inflammatory cytokine profile, had lower leptin ($P<0.01$) and higher adiponectin levels ($P<0.01$) than controls. Administration of PUFA led also to lower serum concentrations of saturated and monounsaturated FA and to higher serum concentrations of polyunsaturated FA in MP. Total lipid content of liver was significantly lower in MP.
CONCLUSION: We conclude that PUFAs may play a causal role in the pathophysiology of NASH. In summary, PUFAs have favorable effects on histopathological changes, serum markers of liver damage, fatty acid compound and show anti-inflammatory properties. We expect that PUFAs may represent a promising way in prevention and treatment of this increasingly common disorder.

P0033 DYSBIOSIS SIGNATURE OF FECAL MICROBIOTA IN HUMANS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

W. Jiang[1], N. Wu[2], X. Wang[1], Y. Zhang[1], Y. Chi[2], Y. Hu[1], X. Qiu[1], **J. Li**[1], **Y. Liu**[1,*]

INTRODUCTION: Non-alcoholic fatty liver disease (NAFLD) is characterized by a broad spectrum of hepatic pathology that is closely linked to obesity and ranges from simple steatosis (SS), to non-alcoholic steatohepatitis (NASH) and even cirrhosis. NAFLD is recently believed to be under the influence of the gut microbiota, which may have toxic effects on the human host after intestinal absorption and delivery to the liver via the portal vein.
AIMS & METHODS: We explored the composition of gut bacterial communities of NAFLD and healthy subjects using 16S ribosomal RNA Illumina next-generation sequencing.
RESULTS: Partial least-squares discriminant analysis (PLS-DA) indicated that most of the microbiota samples were clustered by disease status. Differences were abundant at phylum, family, and genus levels between NAFLD and healthy subjects. *Lentisphaerae* at phylum level was significant higher in NAFLD microbiota. Among those taxa with greater than 0.1% average representation in all samples, five genera including *Alistipes* and *Prevotella* were the genus types exhibiting significant higher level in healthy microbiota, while genera *Escherichia*, *Anaerobacter, Lactobacillus* and *Streptococcus* were increased in NAFLD microbiota. In addition, lymphocyte profiles ($CD4^+$T cell and $CD8^+$T cell) and proinflammatory cytokines (TNF-α, IL-6 and IFN-γ) in gut biopsies of patients and healthy controls was analyzed to monitor the inflammation caused by dysbiosis microbiota. The levels of $CD4^+$ T cells and $CD8^+$ T cells were lower in NAFLD patients compared with healthy subjects, and the proinflammation cytokine TNF-α, IL-6 and IFN-γ showed high level in NAFLD patients. What was more, irregular arrangements of microvilli and widening of the tight junction were observed in gut mucosa of the NAFLD patients by transmission electron microscope.
CONCLUSION: The increased abundance of dysregulated bacteria in NAFLD microbiota, decreased numbers of $CD4^+$T cells and $CD8^+$T cells, and increased levels of TNF-α, IL-6 and IFN-γ in gut mucosa of NAFLD patients suggest a role for gut microbiota in the gut inflammation and the dysregulated gut immunity, which promote pathogenesis of NAFLD. We postulate that the distinct composition of the gut microbiome among NAFLD and healthy controls could offer a target for intervention or a marker for disease.

P0034 ASCITIC FLUID LACTOFERRIN FOR DIAGNOSIS OF SPONTANEOUS BACTERIAL PERITONITIS

A.A. Ghweil[1,*]
[1]*TROPICAL MEDICINE AND GASTROENTEROLOGY, QenaFACULTY OF MEDICINE EGYPT, Qena, Egypt*
Contact E-mail Address: *alimena1@yahoo.com*

INTRODUCTION: The diagnosis of spontaneous bacterial peritonitis (SBP) is based on a manual count of ascitic fluid polymorphonuclear cells (PMNs). This procedure is operator-dependent and lysis of PMNs during transport to the laboratory may lead to false-negative results. Furthermore, ascitic fluid culture is insensitive and leads to delays in diagnosis. The aim of this study was to assess the utility of ascitic fluid lactoferrin (AFLAC) for the diagnosis of SBP and to identify a cut-off level that can be used for future development of a rapid bedside test.
AIMS & METHODS: Sixty ascites samples from cirrhotic patients were examined for PMN count, bedside culture, and lactoferrin concentration. AFLAC concentrations were determined using a polyclonal antibody-based enzyme-linked immunosorbent assay. An ascitic fluid PMN count of 250 cells/mL or greater with or without a positive culture was used for diagnosis of SBP.
RESULTS: Fifteen (25%) samples fulfilled diagnostic criteria for SBP. Samples with SBP had a significantly higher lactoferrin concentration (median, 3200 ng/mL; compared with non-SBP samples (median, 39 ng/mL $P < .001$). The sensitivity and specificity of the assay for diagnosis of SBP were 95.5% and 97%, respectively. The area under the receiver operating characteristic curve was 0.98.
Conclusions: AFLAC can serve as a sensitive and specific test for diagnosis
CONCLUSION: AFLAC can serve as a sensitive and specific test for diagnosis of SBP. Qualitative bedside assays for the measurement of AFLAC can be developed easily and may serve as a rapid and reliable screening tool for SBP in patients with cirrhosis.

P0035 MODULAR COMPUTER-AIDED DIAGNOSIS AND PREDICTION SYSTEM FOR EARLY HEPATOCELLULAR CARCINOMA IN CIRRHOTIC PATIENTS

C.T. Streba[1,*], C.C. Vere[1], L. Sandulescu[1], A. Saftoiu[1], **L. Streba**[1], D. I. Gheonea[1], I. Rogoveanu[1]

INTRODUCTION: Hepatocellular carcinoma (HCC) is one of the most complex treatable malignancies as its management is dependent on the stage of the underlying condition – liver cirrhosis. An early diagnosis assures best curative chances, as liver resection or transplantation have good survival rates in the general population. Computer aided diagnostic and prognosis (CADP) models are currently being developed for a number of malignancies to help clinicians manage cases based on individual needs of the patients rather than general statistics.
AIMS & METHODS: Our aim was to develop a CADP based on our previous work involving artificial neural networks (ANN) [1] for successfully diagnosing early HCC cases and better prognosticate their evolution, based on a set of criteria in accordance with current guidelines.
Ethical clearance was obtained from the local board and 107 consecutive patients with previously diagnosed liver cirrhosis signed informed consents for entering the study, between January 2009 and February 2010. Clinical and demographic parameters (age, sex, body mass index, waist circumference, type of viral

infection, alcohol consumption, smoking, clinical ascites, jaundice), laboratory data (AST, ALT, GGT, alkaline phosphate, bilirubin, triglycerides, thrombocyte count, prothrombin time, alpha fetoprotein), ultrasound data (portal vein thrombosis, size and number of possible tumors), elastography data (strain ratio, complexity, kurtosis, skewness, contrast, entropy, inverse difference moment, angular second moment, correlation) and stiffness value (FibroScan) were collected and imputed in the CADP. For patients with clear liver tumors contrast-enhanced ultrasound was performed and time-intensity curve parameters were calculated and fed to the ANN system: peak enhancement, time to peak, rise time, fall time, mean transit time, area under the curve. We have followed the 4-year incidence of HCC patients in tumor-free cases and assessed the evolution when any formation, either regeneration nodule or early HCC was found.

RESULTS: We found liver tumors in 21 patients; 12 were regeneration nodules [median number of tumors per patient: 2 (min: 1, max: 5), median size 1.1 cm (min: 0.4, max: 1.6)] and 9 were early HCC [median number of tumors per patient: 1 (min: 1, max: 2), median size 1.8 cm (min: 0.7, max: 2.4)]. The CADP system correctly diagnosed HCC in all 9 cases and in 8/12 regeneration nodules based on clinical, laboratory and imaging data. A total of 28 patients also developed HCC in the four-year follow-up period; the system correctly predicted high possibility for HCC occurrence in 26 of these patients (92.85%), while giving high estimates for HCC in another 16 patients that remained cancer-free until now.

CONCLUSION: We could successfully predict the rate of malignancy in cirrhotic patients by using a novel CADP system. We believe that such tools may become worthy aids to clinical management of patients with various types of digestive pathologies.

Contact E-mail Address: *desousac@ualberta.ca*

INTRODUCTION: Cirrhotic patients with Model for End-stage Liver Disease (MELD) score ≥40 have high risk of death without liver transplant (LT). This study aimed to evaluate these patients' outcomes after transplant.

AIMS & METHODS: The retrospective cohort included 519 adult cirrhotic patients who underwent LT at one Canadian center between 2002 and 2012. Primary exposure was severity of end-stage liver disease measured by MELD score at transplant (≥40 vs. <40). Primary outcome was duration of first intensive care unit (ICU) stay after LT. Secondary outcomes were duration of first hospital stay after LT, rate of ICU readmission, re-transplant rate, and survival rates.

RESULTS: On the day of LT, 5% (28/519) of patients had a MELD score ≥40. These patients had longer first ICU stay after LT (14 vs. 2 days; $p < 0.001$). MELD score ≥40 at transplant was independently associated with first ICU stay after transplant ≥10 days (OR, 3.21). These patients had longer first hospital stay after LT (45 vs. 18 days; $p < 0.001$); however, there was no significant difference in the rate of ICU readmission (18% vs. 22%; $p = 0.58$) or re-transplant rate (4% vs. 4%; $p = 1.00$). Cumulative survival at 1 month, 3 months, 1 year, 3 years, and 5 years was 98%, 96%, 90%, 79%, and 72%, respectively. There was no significant difference in cumulative survival stratified by MELD score ≥40 vs. <40 at transplant ($p = 0.59$).

CONCLUSION: Cirrhotic patients with MELD score ≥40 at transplant utilize greater postoperative health resources; however, derive similar long-term survival benefit with LT.

INTRODUCTION: There is a quest for biomarker discovery in liver disease especially to detect cirrhosis at an early stage. Current methods are invasive, more often requiring a liver biopsy to confirm the diagnosis. For patients with Non-alcohol related Steatohepatitis (NASH), the use of fibroscan whilst generally helpful, is unable to confirm the presence of fibrosis particularly in the presence of fat within the liver which is inevitable in most cases with NASH.

The gut microbiome is altered in several gastrointestinal disorders, resulting in altered gut fermentation patterns, which we (and others) have been able to recognise by analysis of volatile organic compounds (VOC) in urine, breath and faeces[1]. The altered structure of the small intestinal mucosa and increased gut permeability (noted in liver disease), we hypothesised, would also change the microbiome, hence recognisable by its unique "fermentome" pattern, making NASH distinguishable from controls.

AIMS & METHODS: To determine if NASH results in an altered VOC pattern in the urine, detectable by ion mobility spectrometry (FAIMS), and distinguishable from cirrhotics vs non-cirrhotics.

33 patients were recruited; 8 with NASH cirrhosis; (confirmed histologically), 8 with non-cirrhotic NASH; 5 with NAFLD (non-alcohol fatty liver disease) and 12 controls (normal synthetic liver function). Urine was collected and 10 ml aliquots were stored frozen in universal containers. For assay, the containers were first heated to 40 ± 0.1°C. The headspace (the air above the sample) was then pumped from the containers and analysed by Field Asymmetric Ion Mobility Spectrometry (FAIMS). Linear discriminant analysis (LDA) was used for initial statistical evaluation, with a re-classification using a "leave one out" for calculating sensitivity and specificity.

RESULTS: LDA showed that FAIMS is able to distinguish the VOC pattern in these different groups of liver disease. The control group was significantly different to all of the other groups with a sensitivity of 100%. Of the disease groups, NASH and NASH with cirrhosis had sensitivity of 83% and 77% respectively with specificity of 80%. NAFLD however had sensitivity of 50% but specificity of 80%.

CONCLUSION: This pilot study suggests the IMS (FAIMS – technology) offers a novel non-invasive approach to separate not only NASH from controls but also those with established cirrhosis using urine. It offers the potential for early non-invasive tracking of NASH and its complications.

P0039 ELASTOGRAPHY PLUS PLATELET COUNT RATHER THAN ENDOSCOPY TO SCREEN FOR LARGE OESOPHAGEAL VARICES

N. Ding[1,*]

[1]*Gastroenterology, St Vincent's Hospital, Melbourne, Australia*

Contact E-mail Address: *dingnik@gmail.com*

INTRODUCTION: Endoscopic screening for gastro-oesophageal varices (GOV) is currently recommended for all cirrhotic patients. Noninvasive methods for liver fibrosis assessment are identifying increasing numbers of patients with "cirrhosis-range" liver stiffness measurements (LSM), increasing the number of referrals for screening endoscopy. The identification of simple non-invasive markers for the presence/absence of large gastroesophageal varices (GOV) would be clinically useful. We evaluated the performance of liver stiffness measurement (LSM) ± platelet count to identify the presence of large GOV in patients with Child Pugh (CP) A cirrhosis.

AIMS & METHODS: Data were collected retrospectively. The presence of cirrhosis was defined by LSM > 13.6 kPa using elastography. We performed a database search for patients with LSM > 13.6 kPa who underwent screening gastroscopy (2010 – 2013). Only patients with compensated liver disease were included. Large GOV were defined by diameter > 5mm or the presence of high risk stigmata. We assessed the accuracy of LSM, platelet count (Pl) or the combination of these factors to identify patients with large GOV. A training set of 71 patients was used, and results were validated using a second cohort of 201 patients from two independent centres.

RESULTS: The combination of LSM and Pl was more accurate for identifying CSPH than either marker alone (training cohort AUROC: 0.87 [0.77-0.94] vs. 0.78 [0.66 – 0.87] and 0.77 [0.66-0.86] for LSM or Pl alone). The optimal risk score was 0.11 (Sens = 0.88, Spec = 0.77, PPV = 0.33, NPV = 0.98, accuracy = 78%). Results in the validation cohort confirmed the discriminatory power of this model (AUROC: 0.76 [0.68-0.83]). We then tested clinically relevant cut-offs to improve the negative predictive value (NPV) for large GOV. The NPV for the combination of LSM < 25 kPa and Pl ≥ 100 and was 100% in both the training cohort and validation cohort. 82 (42%) of patients overall met this criteria.

CONCLUSION: The combination of LSM < 25 kPa and Pl ≥ 100 can be used to identify patients with compensated cirrhosis who do not have large GOV. These patients do not benefit from endoscopic screening, but could be followed with annual LSM and full blood count.

INTRODUCTION: Hepatic encephalopathy (HE) is a chronic complication of cirrhosis. In recurrent, overt, episodic HE, which is the most common subcategory, its seriousness is due to the chronic debilitating effects of the recurrent episodes.
AIMS & METHODS: The aim of this study was to characterise the impact of the number of prior HE episodes on the risk of future HE episodes. A post-hoc analysis was carried out using data from 322 patients with a history of HE from a phase 3, open-label study evaluating the long-term safety and tolerability of rifaximin-α 550mg BID. All eligible patients had a Conn score of 0–2 at enrolment, and had either successfully participated in a previous HE study with rifaximin-α (RFHE3001), or they were new patients enrolled with $\geq$1 verifiable episode of HE within the preceding 12 months.
RESULTS: 319 of 322 patients (647 observations) aged $\geq$18 years had all the information required for analysis. Median duration of follow-up was 17 months (IQR 8.9–25.4). Stratifying patient observations by number of prior HE episodes and using the Kaplan Meier method the probability of being event free at year one was 0.644 (95% CI; 0.543-0.763), 0.615 (0.541-0.700), 0.396 (0.303-0.518) and 0.302 (0.246-0.371) and the probability at year two was 0.579 (0.469-0.713), 0.539 (0.455-0.638), 0.292 (0.1999-0.428) and 0.218 (0.163-0.290) for 'one', 'two', 'three' and 'four or more' prior HE episodes, respectively. Plotting the Kaplan Meier curves of time to next HE episode, stratified by the number of prior HE episodes, a clear association between decreased time to next HE episode and increased number of prior episodes was seen. Using log-rank tests, there was no significant difference between the survival curves of one prior and two prior HE episodes ($\chi^2 = 0$ on 1 degree of freedom (d.f.), $p = 0.899$), however there were significant differences between survival curves of one prior or two prior episodes and greater numbers of prior episodes ($\chi^2 = 72$ on 3 d.f., $p < 0.001$).
CONCLUSION: This study supports the current understanding of the natural history of end-stage encephalopathy; as the number of prior HE episodes increased, the risk of subsequent HE episodes increased.

Contact E-mail Address: *philipp.schwabl@meduniwien.ac.at*

INTRODUCTION: Transient elastography (TE) is a non-invasive, easily repeatable tool to assess liver fibrosis and portal hypertension (HVPG). Recently, new quality criteria for TE measurements have been proposed (Boursier et al. Hepatology 2013): very reliable: IQR/M $<$0.1; reliable: IQR 0.1–0.3, or IQR/M $>$0.3 if TE $<$7.1 kPa; poor reliable: IQR/M $>$0.3 if TE $>$7.1 kPa.
AIMS & METHODS: We evaluated the diagnostic power and accuracy of TE measurements according to these new quality criteria (accurate = very reliable + reliable) for non-invasive assessment of liver fibrosis (liver biopsy) and portal hypertension. Therefore we retrospectively identified patients undergoing TE, HVPG measurement and liver biopsy within 3 months at our tertiary care center.
RESULTS: Among 278 patients (48.7±13.1 years, 74.7% male, 75.7% viral etiology, 57% F3/F4), traditional TE quality criteria identified 71.6% reliable measurements, while new criteria yielded in 83.2% accurate LS measurements (23.1% very reliable, 60.1% reliable). Reliable TE values according to traditional or new criteria were all significantly and similarly strong correlated with fibrosis stage ($R = 0.648$ vs. $R = 0.636$) and HVPG ($R = 0.836$ vs. $R = 0.846$). The accuracy for diagnosing liver cirrhosis (F4, cut-off: 14.5 kPa) was 76.5% and 75.0% for traditional and new TE criteria, respectively. The positive (PPV) and negative (NPV) values for new criteria at the 14.5 kPa cut-off were 83% and 70%. For predicting HVPG $\geq$10mmHg (cut-off: 16.1 kPa), the accuracies were 88.9% and 89.8% using traditional or new criteria, respectively. Both criteria resulted in AUCs for diagnosis of HVPG $\geq$10mmHg of over 0.95 with a PPV and NPV of 76% and 97%, respectively.
CONCLUSION: Applying new quality criteria for TE measurements significantly increases the number of valid TE measurements without affecting accuracy of TE for diagnosis of liver cirrhosis and portal hypertension.

P0042 EVALUATION OF A NOVEL, PORTABLE, PROBE-BASED TRANSNASAL ENDOSCOPE: SUPERIOR PATIENT PREFERENCE AND ACCEPTABLE DIAGNOSTIC ACCURACY FOR OESOPHAGEAL VARICES COMPARED TO CONVENTIONAL ENDOSCOPY

S.S. Sami[1,*], E. Wilkes[1], M. James[1], R. Mansilla-Vivar[2], J. Fernández-Sordo'[1], J. White[1], A. Khanna[1], M. Coletta[1], S. Samuel[1], G. Aithal[1], K. Ragunath[1], I. N. Guha[1]
[1]*Digestive Diseases NIHR Biomedical Research Unit, University of Nottingham, UK, Nottingham, United Kingdom,* [2]*Department of Gastroenterology, Pontifical Catholic University of Chile, Santiago, Chile*

INTRODUCTION: Conventional oesophagogastroduodenoscopy (C-OGD) remains the gold standard test to screen for oesophageal varices (OV) in patients with liver cirrhosis. However, it has many limitations in terms of costs, accessibility and tolerability. Hence, there is a need for less invasive and simple techniques to replace C-OGD in this setting.
AIMS & METHODS: We aimed to compare the accuracy and acceptability of a portable, disposable, office-based, unsedated transnasal video endoscope (EG Scan™ II) with C-OGD for the detection of OV.
This was a prospective diagnostic study. Consecutive adult patients with confirmed liver cirrhosis, scheduled for screening or surveillance of OV, were invited to participate in this study. We excluded patients with recurrent epistaxis (more than once a week); nasal obstruction; disease of the nasal cavity; history of variceal bleeding or band ligation therapy in the past 12 weeks. All subjects underwent two procedures on the same day (EG Scan followed by C-OGD), performed by two different operators blinded to the findings of the other test. Patients completed validated tolerability (10-point visual analogue scale (VAS)) and adverse events questionnaires on day 0 and day 14.
The primary outcome measure was diagnostic accuracy of EG scan (performed by one operator) against C-OGD (reference standard). In addition, interobserver agreement of the EG scan was calculated using the kappa (k) statistic, by nine blinded endoscopists, evaluating video recordings of 47 EG Scan procedures.
RESULTS: 50 patients were recruited to the study (mean age 59 years +/-11, 70% males). The majority (78%) had compensated cirrhosis. 45 patients (90%) completed both procedures (3 failed EG Scan (6%) and 2 failed C-OGD (4%), $p = 0.882$). OV prevalence was 48.9%.
Sensitivity, specificity and area under the receiver operating characteristic curve (AUROC) of the EG Scan for the diagnosis of any varices were 0.82 (95% confidence interval (CI) 0.60-0.95), 0.78 (95%CI 0.56-0.93), and 0.80 (95%CI 0.68-0.92), respectively. Corresponding values for the diagnosis of medium/large varices were 0.92 (95%CI 0.62-1.0), 0.97 (95%CI 0.84-1.0), and 0.94 (95%CI 0.86-1.0), respectively. Interobserver agreement was modest for the diagnosis of any size OV ($K = 0.45$, 95%CI 0.40-0.49) and medium/large OV ($K = 0.47$, 95%CI 0.42-0.52).
Patients reported better experience (mean VAS+/-standard deviation (SD)) and higher preference (percentage) with EG Scan compared to C-OGD at day 0 (7.8+/-2.2 vs. 6.8+/-3.0, $p = 0.058$; 76.5% vs. 23.5%, $p < 0.001$, respectively) and day 14 (7.0+/-2.3 vs. 5.5+/-3.2, $p = 0.0013$; 77.8% vs. 22.2%, $p < 0.001$, respectively). There was no association between procedure preference and sedation use for C-OGD (day 0: odds ratio (OR) 0.16, 95%CI 0.02-1.49, $p = 0.106$; day 14: OR 0.24, 95%CI 0.02-2.56, $p = 0.238$). 4 patients (8.5%) experienced minor self-limiting epistaxis. No serious adverse events occurred.
CONCLUSION: EG Scan was accurate for the diagnosis of any varices and clinically significant OV. Interobserver agreement was modest. More importantly, patients' experience and preference remained significantly higher for EG Scan 14 days after procedures independent of sedation use.

Contact E-mail Address: *earth-peace@yuhs.ac*

INTRODUCTION: Periodic endoscopic screening for esophageal varices (EVs) and prophylactic treatment for high-risk EVs ((HEVs); (1) medium/large EVs and (2) small EVs with red sign or decompensated cirrhosis) are currently recommended for all cirrhotic patients. Recently, two new liver stiffness measurement (LSM)-based statistical equation models (PH risk score and Varices risk score) were introduced as a noninvasive, simple, accurate models for identifying presence of EVs and clinically significant portal hypertension [1].
AIMS & METHODS: We aimed to validate predictive value of the two models for detection of HEVs comparing with LSM alone or LSM-spleen diameter to platelet ratio score (LSPS) [2]. We tried to suggest a cutoff of the two models, as well.
Between November 2004 and October 2011, we recruited 675 B-viral cirrhosis patients. All underwent laboratory workups, endoscopy, LSM, and ultrasonography. LSM was measured by transient elastography; endoscopy was used as the standard for detection of EVs. PH risk score, Varices risk score and LSPS were calculated in all cases as follows: PH risk score = -5.953 + 0.188 x LSM + 1.583 x sex (1: male; 0: female) + 26.705 x spleen diameter/platelet count ratio,

Varices risk score = -4.364 + 0.538 x spleen diameter – 0.049 x platelet count – 0.044 x LSM + 0.001 x (LSM x platelet count).
RESULTS: Among all the patients, 239 (35.4%) patients had EVs and 172 (25.5%) had HEVs. The area under the receiver-operating characteristic curve (AUROC) of PH risk score was 0.951 (95% CI 0.934-0.968) and LSPS was 0.950 (95% CI 0.931-0.970), showing superiority of diagnostic accuracy over other factors: Varices risk score (0.907, 95% CI 0.876-0.939, $p<0.001$), LSM alone (0.873, 95% CI 0.842-0.904, $p<0.001$). At PH risk score < 4.0, 94.6% negative predictive value (NPV) was provided (481 patients), whereas 94.3% positive predictive value (PPV) was achieved (70 patients) at PH risk score > 10.0. In the same way, at Varices risk score < -2.5, 95.6% NPV was provided (413 patients), whereas 91.7% PPV was achieved (72 patients) at Varices risk score > 1.3. Overall, the likelihood of HEVs was correctly diagnosed in 551 patients (81.6%) and 485 patients (71.9%), respectively.
CONCLUSION: The PH risk score is a reliable, noninvasive predictive model for detection of HEVs. Furthermore, the LSPS is considered as more simply applicable model having similar predictive value. Patients with PH risk score < 4.0 may avoid endoscopy safely, whereas those with > 10.0 should be considered for appropriate prophylactic treatments.

INTRODUCTION: Nonalcoholic fatty liver disease (NAFLD) is an important cause of chronic and progressive liver injury in many countries[1)]. NAFLD includes a wide spectrum of liver diseases that range from simple steatosis, which is generally a nonprogressive condition, to nonalcoholic steatohepatitis (NASH), which can progress to liver cirrhosis and hepatocellular carcinoma (HCC), despite the absence of significant alcohol consumption. If NAFLD patients have liver cirrhosis, they need to be kept under surveillance for early detection of hepatocellular carcinoma and gastroesophageal varices. Liver biopsy is the gold standard for diagnosis and staging of fibrosis in patients with NAFLD[2)]. However, ad the number of NAFLD patients has reached 80–100 million in the United States and about 10 million NAFLD patients are estimated in Japan, it is virtually impossible to enforce in all patients.
AIMS & METHODS: To develop a mass screening system for general physicians, which can be used for predicting liver cirrhosis in NAFLD patients, using routine laboratory parameters.
A total of 1048 patients with liver-biopsy-confirmed NAFLD were enrolled from nine hepatology centers in Japan (stage 0, 216; stage 1, 334; stage 2, 270; stage 3, 190; stage 4, 38). Statistical analysis was conducted using SPSS version 12.0. Continuous variables were expressed as mean ± SD.
RESULTS: Platelet counts, serum albumin levels, and aspartate aminotransferase/alanine aminotransferase (AST/ALT) ratio were selected as independent variables associated with cirrhosis in NAFLD patients by multiple logistic regression analysis. The optimal cutoff value of platelet count, serum albumin, and AST/ALT ratio was set at $<15.3\ 10^4/\mu l$ (sensitivity; 81.6% specificity; 88.6%), <4.0 g/dl (sensitivity; 84.2% specificity; 84.6%), and >0.9 (sensitivity; 78.9%, specificity; 82.0%), respectively, by the receiver operating characteristic curve. These three variables were combined in an unweighted sum (platelet count = 1 point, serum albumin = 1 point, AST/ALT ratio = 1 point) to form an easily calculated composite score for predicting cirrhosis in NAFLD patients, called the PLALA (platelet, albumin, AST/ALT ratio) score. The diagnosis of PLALA ≥2 had sufficient accuracy for detecting liver cirrhosis in NAFLD patients (86.8% sensitivity, 90.8% specificity, 99.4% negative predictive value, 26.1% positive predictive value).
CONCLUSION: The PLALA score may be an ideal scoring system for detecting cirrhosis in NAFLD patients with sufficient accuracy and simplicity to be considered for clinical use.

P0045 CARVEDILOL VERSUS NON-SPECIFIC BETABLOCKERS AND MORTALITY IN ALCOHOLIC CIRRHOSIS. A NATIONWIDE RETROSPECTIVE STUDY

U.C. Bang[1,*], T. Benfield[2], L. Hyldstrup[3], J.-E. B. Jensen[3], F. Bendtsen[1]
[1]*Gastrounit,* [2]*Infectious Diseases,* [3]*Endocrinology, Hvidovre Hospital, Hvidovre, Denmark*
Contact E-mail Address: *ulrichbangbang@gmail.com*

INTRODUCTION: Carvedilol may have a greater effect on portal and systemic hypertension than propranolol although reports are conflicting [1, 2]. The impact of carvedilol versus non-specific betablockers (NSBB) on mortality on patients with cirrhosis remains to be evaluated.
AIMS & METHODS: We wanted to compare the impact on mortality of carvedilol versus NSBB in patients with cirrhosis. We identified patients with alcoholic cirrhosis from the Danish National Patient Register during the period 1995 through 2010. We used the anatomical therapeutic chemical (ATC) classification to identify the user of NSBB (C07AA) or carvedilol (C07AG02). We defined risk time as the time from the first prescription of either carvedilol or NSBB until death or end of follow-up (December 31, 2010). We adjusted for gender, age, heart disease, variceal bleeding, socioeconomic status, Charlson score, and use of diuretics. We used univariate and multivariate Cox proportional hazard models to assess the HR. Persons with missing data were excluded from the analyses (0.03%). All analyses were done using SAS 9.3 (SAS Institute Inc., Cary, NC, USA).
RESULTS: We identified 83 and 2.060 patients, who were treated with carvedilol and NSBB, respectively. Three patients had received both carvedilol and NSBB and were excluded. Patients from the carvedilol group were mainly classified with uncomplicated cirrhosis without a history of laparocentesis (96%). Hence, we only included patients with uncomplicated cirrhosis in our mortality analysis (80 versus 1.857 patients). Significantly fewer patients in the carvedilol group died during follow-up compared with the NSBB group (20.5% vs. 46.5%, Chi-square $p<0.0001$). We found the un-adjusted HR for carvedilol vs. NSBB to be 0.45 (95% CI 0.3-0.7) and the HR adjusted for covariates was 0.46 (95% CI 0.3-0.7). The prevalences of variceal bleeding (11% vs. 40%) or heart disease (70% vs. 14%) prior to cohort entry were un-evenly distributed between users of carvedilol and NSBB. We did a sub-analysis where we matched patients on the presence of heart disease and variceal prior to cohort entry. In this sub-analysis we compared 80 patients using carvedilol with 240 patients (1:3 ratio) using NSBB and found an adjusted HR of 0.38 (95% CI 0.2-0.7).
CONCLUSION: The use of carvedilol compared with NSBB in patients with cirrhosis was associated with lower mortality in this retrospective study.

P0046 RESULTS OF THE UK MULTI-REGIONAL AUDIT OF BLOOD COMPONENT USE IN CIRRHOSIS

V. Jairath[1,*], M. Desborough[2], B. Hockley[2], M. Sekhar[3], S. Stanworth[2], A. Burroughs[3]
[1]*Nuffield Department of Medicine, University of Oxford,* [2]*NHS Blood and Transplant, Oxford,* [3]*Royal Free Hospital, London, United Kingdom*

INTRODUCTION: Cirrhosis is a complex acquired disorder of coagulation with a recent paradigm shift in understanding to consider cirrhosis as a pro-thrombotic disorder. It is a frequent indication for transfusion of blood components, both for prophylaxis and for treatment of bleeding, although indications and patterns of blood use are poorly characterised.
AIMS & METHODS: All NHS trusts with representation on the British Society of Gastroenterology membership list were invited to take part in a national audit. Data were collected prospectively on consecutive admissions with a confirmed diagnosis of liver cirrhosis over a 4 week period, with follow up to discharge/death/day 28. Specific information was requested on use of blood components, including indication, type of component and laboratory indices prior to transfusion. Standards were defined against guidelines on the use of red blood cells (RBCs), fresh frozen plasma (FFP), platelets and cryoprecipitate.
RESULTS: Data on 1313 consecutive patients with cirrhosis (mean age 58 years, 65% male) were collected from 85 hospitals. The predominant aetiology was alcohol (70%; 921/1313); 74% of admissions were for features of decompensation; and 21% (275/1313) cases had a positive septic screen. 30% (391/1313) of all admissions were transfused a blood component; in 61% (238/391) this was for treatment of bleeding and in 39% (153/391) for prophylaxis. In patients transfused for bleeding (81%, 192/238 for gastrointestinal bleeding), 92% (220/238) received RBCs, 32% (77/238) FFP, 14% (34/238) platelets and 4% (10/238) cryoprecipitate; in patients with bleeding who received RBCs, the Hb threshold was >8g/dL prior to RBC transfusion in 31% (69/220) cases. For prophylaxis the majority (61%, 94/153) received transfusion in the absence of a planned procedure. In patients transfused for prophylaxis prior to a procedure (59/153): 19% (3/16) received FFP at an INR ≤1.5 for high risk procedures and 33% (6/18) received FFP at an INR≤2 for low risk procedures; 36% (9/25) received platelet transfusion at a platelet count>50 prior to a procedure. The most frequent procedures resulting in prophylactic transfusion were paracentesis (18/59), surgery (15/59) and endoscopy (10/59). In-hospital venous thromboembolism was documented in 2% (29/1313) cases. Case fatality during follow up was 10% overall (128/1313) with decompensated cirrhosis (41%; 52/128) as the most frequent cause of death.
CONCLUSION: Patients with cirrhosis are frequently transfused during hospitalisation. This audit highlights areas where greater scrutiny of blood component use is required, particularly in the group transfused for prophylaxis of bleeding. Further work is needed to improve patterns of blood use in cirrhosis to ensure patients are not exposed to unnecessary transfusion and its attendant harms.

P0047 SVR12 OF 99% ACHIEVED WITH A RIBAVIRIN-FREE REGIMEN OF ABT-450/R/OMBITASVIR AND DASABUVIR IN HCV GENOTYPE 1B-INFECTED PATIENTS

A. Maieron[1,*], M. Puoti[2], J. V. Enejosa[3], P. Andreone[4], Z. Ben Ari[5], G. Norkrans[6], M. Romero-Gomez[7], W. Xie[3], D.E. Cohen[3], T. Podsadecki[3]
[1]*Elisabeth Hospital, Linz, Austria,* [2]*A. O. Ospedale Niguarda Ca Granda, Milan, Italy,* [3]*AbbVie Inc., North Chicago, United States,* [4]*University of Bologna, Bologna, Italy,* [5]*The Chaim Sheba Medical Center, Tel Hashomer, Israel,* [6]*Sahlgrenska University Hospital, Göteborg, Sweden,* [7]*Hospital Universitario Nuestra Senora De Valme, Seville, Spain*

INTRODUCTION: ABT-450 is an HCV NS3/4A protease inhibitor (identified by AbbVie and Enanta) dosed with ritonavir (r). Ombitasvir (formerly ABT-267) is an NS5A inhibitor, and dasabuvir (formerly ABT-333) is a non-nucleoside NS5B RNA polymerase inhibitor. We report the sustained virologic response 12 weeks post-treatment (SVR12) achieved in HCV genotype 1b-infected patients after treatment with these 3 direct-acting antivirals (3D regimen) with or without ribavirin (RBV).
AIMS & METHODS: Five hundred ninety-nine treatment-naïve and prior pegIFN/RBV-experienced HCV genotype 1b-infected patients without cirrhosis were enrolled and received study drugs in the PEARL-II and PEARL-III randomized phase 3 studies. Patients were randomized 1:1 to co-formulated ABT-450/r/ombitasvir (150 mg/100 mg/25 mg once daily) and dasabuvir (250 mg twice daily) with or without weight-based RBV (1000 – 1200 mg daily).
RESULTS: The combined SVR12 rate from PEARL-II and PEARL-III was 99.3% in 301 patients who received 3D regimen without RBV vs. 98.7% in 298 patients who received 3D + RBV. Two patients (0.7%) receiving 3D without RBV did not achieve SVR12, both due to missing week 12 post-treatment follow-up. Four 3D + RBV patients did not achieve SVR12: 1 (0.3%) due to virologic breakthrough, 1 (0.3%) due to missing SVR12 data, and 2 (0.7%) due to study drug discontinuation for adverse events. SVR12 rates did not differ between 3D and 3D + RBV by baseline factors including IL28B genotype, sex, age, race, ethnicity, BMI, fibrosis stage, and HCV RNA viral load. No patients receiving 3D and 0.7% of patients receiving 3D + RBV discontinued due to adverse events.

SVR12 by baseline factors, n/N (%)	3D	3D + RBV
Overall	299/301 (99.3)	294/298 (98.7)
Treatment-naïve	208/210 (99.0)	209/210 (99.5)
PegIFN/RBV Treatment-experienced	91/91 (100)	85/88 (96.6)
IL28B non-CC genotype	249/250 (99.6)	240/244 (98.4)
Female	160/160 (100)	147/149 (98.7)
Age ≥65	34/34 (100)	29/29 (100)
Black race	16/16 (100)	13/13 (100)
BMI ≥ 30 kg/m^2	62/64 (96.9)	44/45 (97.8)
Fibrosis stage, F3	31/33 (93.9)	33/34 (97.1)

CONCLUSION: Irrespective of previous pegIFN/RBV treatment response and other baseline factors, HCV genotype 1b-infected patients achieved high SVR rates after 12 weeks of 3D without RBV. Overall, only 1 (3D + RBV) of 599 (0.2%) patients experienced virologic breakthrough and none experienced relapse. Both regimens were well tolerated. ABT-450/r/ombitasvir and dasabuvir without RBV achieves optimal treatment efficacy in HCV genotype 1b-infected patients without cirrhosis.

INTRODUCTION: ABT-450 is an HCV NS3/4A protease inhibitor identified by AbbVie and Enanta, dosed with ritonavir(r); ombitasvir(ABT-267) is an NS5A inhibitor; dasabuvir(ABT-333) is an NS5B RNA polymerase inhibitor. The phase 3 PEARL trials examined the efficacy and safety of all-oral, interferon-free, 12-week regimens of ABT-450/r/ombitasvir+dasabuvir(3D) with or without ribavirin(RBV) in HCV genotype(GT) 1a- and 1b-infected patients(pts). We report pt adherence to the regimens in these trials.
AIMS & METHODS: Pts were randomized to co-formulated ABT-450/r/ombitasvir(150mg/100mg/25mg QD)+dasabuvir(250mg BID) with either weight-based RBV or placebo (PBO)/no RBV. Adherence was calculated by pill counts as the percentage of capsules/tablets taken relative to the total capsules/tablets expected to be taken.
RESULTS: In each trial, mean pt adherence to every study drug was >98.5%(Table). Adherence was comparable in those who received 3D with RBV, 3D with PBO, or 3D alone. SVR12 rates were 96.6-100% in treatment-experienced and treatment-naïve HCV GT1b-infected pts receiving 3D+/-RBV. SVR12 rates were 97.0% and 90.2%, respectively, in treatment-naïve GT1a-infected pts receiving 3D+RBV or 3D+PBO. Only 1 GT1b-infected pt had virologic failure. Pts with virologic failure had adherence rates comparable to the overall rates, but the majority was GT1a-infected and did not receive RBV. Five pts had adherence rates <80% for one or more study drugs, none of whom had virologic failure. Among 401 pts receiving 3D with RBV and 509 pts receiving 3D without RBV, 2(0.5%) and 2(0.4%), respectively, discontinued study drug due to adverse events.

	PEARL-II Treatment-experienced* GT1b		PEARL-III Treatment-naïve GT1b		PEARL-IV Treatment-naïve GT1a	
	3D+RBV	3D	3D+RBV	3D+PBO	3D+RBV	3D+PBO
Adherence, Mean % (SD)						
ABT-450/r/ ombitasvir	99.7 (2.3) n = 87	100.0 (2.6) n = 92	99.8 (1.2) n = 205	100.0 (1.1) n = 205	99.7 (1.9) n = 98	99.7 (3.3) n = 190
dasabuvir	99.0(3.2) n = 90	99.2 (1.6) n = 94	99.8 (1.2) n = 205	99.9 (1.1) n = 205	99.2 (2.0) n = 98	99.1 (3.6) n = 190
RBV	99.1 (6.5) n = 87	NA	99.6 (2.1) n = 205	99.6 (2.6) n = 203	98.6 (3.2) n = 90	98.7 (3.6) n = 181
SVR12, % (n/N)	96.6 (85/88)	100 (91/91)	99.5 (209/210)	99.0 (207/209)	97.0 (97/100)	90.2 (185/205)

Adherence data for each capsule/tablet not available for all pts.
In PEARL-II, 7 randomized patients were excluded from the intent-to-treat efficacy population because they received non-coformulated ABT-450/r/ombitasvir (N = 6) or could not be genotyped (N = 1).
CONCLUSION: Participants in these phase 3 trials had excellent adherence (>98.5%) to doses of ABT-450/r/ombitasvir, dasabuvir, and RBV. Low adherence rates, while infrequent, were not associated with virologic failure.

P0049 ASSOCIATION BETWEEN TLR-3 GENE POLYMORPHISM RS3775291 AND PROGRESSION OF HEPATITIS C VIRUS INFECTION

F.-Z. Fakhir[1,2,*], M. LKHIDER[1]
[1]*Faculté des Sciences, Chouaib Doukkali University, El Jadida,* [2]*Viral Hepatitis Laboratory, Institut Pasteur du Maroc, Casablanca, Morocco*
Contact E-mail Address: *fatimazohra.fakhir@gmail.com*

INTRODUCTION: Hepatitis C virus (HCV) is a major global health problem with about 210 million people infected worldwide, and constitutes the most important cause of chronic liver disease. HCV is an enveloped positive-strand RNA virus belonging to the genus *Hepacivirus* of the family Flaviviridae. During the viral replication cycle, double-stranded RNA (dsRNA), produced as an intermediate, is sensed by several pattern recognition receptors (PRRs) of the innate immune system including Toll-like receptors (TLR). TLRs constitute a family of receptors playing a key role in innate and adaptive immune response, among them TLR3,-7 and -8, which are expressed on endosomal membrane, and have been suggested to play an important role in antiviral immune responses based on their recognition of dsRNA and single-stranded RNA (ssRNA). Single nucleotide polymorphisms (SNPs) may shift balance between pro- and anti-inflammatory cytokines, contributing to successful resistance to infection or leading to chronic inflammation and cancer. The aim of this study was to investigate the association between the TLR-3, -7 and -8 polymorphism and the outcome of HCV infection.
AIMS & METHODS: 517 patients were enrolled in the study and genotyped for the TLR3, -7 and -8 SNPs. Logistic regression was used to assess the association between the polymorphisms and the outcome of the infection.
RESULTS: A significant association between TLR-3 SNP at rs3775291 and risk of advanced liver disease was identified. The rs3775291-A/A genotype was more common in subjects with advanced liver disease than subjects with mild chronic

hepatitis C (OR = 3.81; 95% CI, 2.16-6.72; p = 0.000004) and this difference was higher with healthy controls (OR = 5.34; 95% CI, 2.70-10.58; p = 0.000002).
CONCLUSION: Our findings indicate that a TLR-3 SNP rs3775291 is associated with progression of HCV infection to cirrhosis and hepatocellular carcinoma.

INTRODUCTION: Ribavirin (RBV) is known to cause haemolytic anaemia that can lead to hyperbilirubinaemia. In addition, the NS3/NS4A protease inhibitor ABT-450 can increase unconjugated bilirubin levels due to transporter inhibition. We report the rate of hyperbilirubinaemia in HCV genotype 1-infected patients treated with ABT-450/r/ombitasvir (formerly ABT-267) and dasabuvir (formerly ABT-333) (3D regimen) with or without RBV.
AIMS & METHODS: Data from 910 patients randomized in 3 phase 3 trials (PEARL-II, PEARL-III, and PEARL-IV), which examined the contribution of RBV to the safety and efficacy of the 3D regimen, were used to evaluate the incidence and severity of clinical events related to bilirubin (hyperbilirubinaemia, jaundice) during 12 weeks of treatment. Total, direct, and indirect bilirubin were assessed at baseline and every 1-2 weeks per protocol.
RESULTS: Total bilirubin elevations of >3X ULN occurred in 23/401 (5.7%) 3D+RBV patients and in 2/509 (0.4%) patients receiving the RBV-free 3D regimen. The majority of patients in each group (>90%) had normal total bilirubin levels at the end of treatment. Mean total bilirubin levels were significantly higher at each treatment visit in the RBV-containing treatment groups. Mean total bilirubin peaked at week 1 in both treatment groups (predominantly indirect), and declined to baseline by week 2 in the RBV-free group. Events of hyperbilirubinaemia and jaundice were mostly mild, occurred within the first 2 weeks of treatment and did not result in study drug discontinuation. One patient underwent RBV dose modification and one interrupted study drug due to hyperbilirubinaemia; both patients achieved sustained virologic response 12 weeks post-treatment. Two patients receiving 3D+RBV experienced ALT ≥3X ULN and total bilirubin ≥2X ULN, however, the timing and predominance of indirect bilirubin were not consistent with drug induced liver injury. No serious adverse events related to hyperbilirubinaemia were reported.

Bilirubin-related events, n (%)	3D+RBV (N = 401)	3D (N = 509)
Any bilirubin-related event	21 (5.2)	4 (0.8)
Hyperbilirubinaemia	13 (3.2)	3 (0.6)
Jaundice	11 (2.7)	1 (0.2)
Total bilirubin >3X ULN	23 (5.7)	2 (0.4)

CONCLUSION: Low rates of hyperbilirubinaemia were observed with both 3D regiments but was less frequent in the RBV-free 3D regimens, suggesting that increases in bilirubin associated with ABT-450-containing regimens are enhanced by RBV-induced haemolysis. Bilrubin-related adverse events were infrequent with both regimens and did not affect treatment response.

INTRODUCTION: ABT-450 is a potent hepatitis C virus (HCV) protease inhibitor (dosed with ritonavir 100mg, ABT-450/r) identified by AbbVie and Enanta; ombitasvir (ABT-267) is an NS5A inhibitor and dasabuvir (ABT-333) is a non-nucleoside polymerase inhibitor. In phase 3 trials of this 3 direct-acting antiviral (3D) regimen with ribavirin (RBV) in non-cirrhotic HCV genotype 1-infected patients, 96.3% of treatment-naïve patients (SAPPHIRE-I trial) and 96.2% of pegINF/RBV-experienced patients (SAPPHIRE-II trial) achieved SVR12 (HCV RNA <25 IU/mL at post-treatment week 12).
AIMS & METHODS: Patients in the SAPPHIRE-I and -II trials were randomized to receive the 3D regimen of co-formulated ABT-450/r/ombitasvir (150mg/100mg/25mg QD) and dasabuvir (250mg BID) with weight-based RBV (1000 or 1200 mg daily divided BID), or placebo, for 12 weeks. Data from the two trials were pooled, and SVR_{12} rates were calculated overall and according to race, ethnicity, and region.
RESULTS: 770 patients assigned to the 3D+RBV regimen received ≥1 dose of study drug. The overall SVR12 rate in the combined studies was 96.2%; high SVR rates were achieved regardless of race, ethnicity, or region (Table). Tolerability was similar across populations. Most adverse events were mild or moderate; the 3 most common adverse events were headache (34.3%), fatigue (34.2%) and nausea (22.3%). Few patients discontinued due to adverse events (6/770, 0.8%).

		3D+RBV % with SVR12 (n/N)
Overall	SAPPHIRE-I and SAPPHIRE-II	96.2 (741/770)
Race	Black	96.0 (48/50)
	Non-black	96.3 (693/720)
Ethnicity	Hispanic/Latino	93.9 (46/49)
	Non-Hispanic/Latino	96.4 (695/721)
Region	Australia/New Zealand	95.5 (42/44)
	Europe	95.8 (346/361)
	North America	96.7 (353/365)

CONCLUSION: High pooled SVR12 rates were achieved in non-cirrhotic HCV GT1 treatment-naïve and pegINF/RBV-experienced patients in the SAPPHIRE-I and SAPPHIRE-II trials, regardless of the baseline demographics assessed in this analysis.

O. U. Seconda Università degli Studi di Napoli, Naples, Italy,* [7]*Szpital Rejonowy, Oddział Obeserwacyjno-Zakaźny, Racibórz, Poland,* [8]*Trial Management Associates; LLC, Wilmington, United States,* [9]*Uludag University, Bursa, Turkey*

INTRODUCTION: ABT-450 is an HCV NS3/4A protease inhibitor dosed with ritonavir (r) 100mg, identified by AbbVie and Enanta. Ombitasvir (formerly ABT-267) is an NS5A inhibitor, and dasabuvir (formerly ABT-333) is an NS5B RNA polymerase inhibitor. The phase 3 trials PEARL II, PEARL III, and PEARL IV examined the efficacy and safety of 12 week regimens of ABT-450/r/ombitasvir + dasabuvir (3D) with or without ribavirin (RBV) in non-cirrhotic patients with HCV genotype (GT) 1a and 1b infection. Safety outcomes in patients receiving RBV-containing and RBV-free regimens in these trials are reported.
AIMS & METHODS: GT1b-infected treatment-experienced patients (PEARL II), GT1b-infected treatment-naive patients (PEARL III), and GT1a-infected treatment-naive patients (PEARL IV) were randomized to co-formulated ABT-450/r/ombitasvir (150mg/100mg/25mg QD) + dasabuvir (250mg BID) with weight-based RBV or placebo/no RBV. Adverse event (AE) assessment and clinical laboratory testing occurred at study visits during treatment and follow-up and included all randomized patients who received at least one dose of study drug.
RESULTS: In PEARL II, PEARL III, and PEARL IV, respectively, 186, 419, and 305 patients were randomized and received at least one dose of study drug. In total across the 3 trials, 401 patients received 3D+RBVand 509 received 3D. Treatment-emergent AEs and laboratory values of note are in the Table. In both the 3D+RBV and 3D groups, the majority of AEs were mild. AEs occurring in >20% of patients in both the 3D+RBV and 3D groups were fatigue (29.9% and 26.5%) and headache (24.4% and 25.3%). 8.5% of patients receiving 3D+RBV had an AE leading to RBV dose modification; all of these patients achieved SVR12. The rate of discontinuation due to AEs was 0.5% or less among patients treated with 3D+RBV or 3D.

	3D+RBV N = 401	3D N = 509
Any AE, n (%)	332 (82.8)	383 (75.2)
Any AE leading to study drug discontinuation, n (%)	2 (0.5)	2 (0.4)
Any serious AE, n (%)	9 (2.2)	7 (1.4)
Any AE leading to RBV/placebo dose modification, n (%)	34 (8.5)	1* (0.2)
RBV/placebo dose modification due to decrease in hemoglobin, n (%)	25 (6.2)	0
Hemoglobin (g/dL), n (%)	209 (52.1)/ 23 (5.7)/2 (0.5)	34 (6.7)/0/0
Total bilirubin >3X ULN, n (%)	23 (5.7)	2 (0.4)
ALT >5X ULN, n (%)	3 (0.7)	1 (0.2)

CONCLUSION: In the PEARL II, PEARL III, and PEARL IV trials, ABT-450/r/ombitasvir + dasabuvir was well tolerated either with or without RBV. Comparable low rates of discontinuation were observed in patients receiving the RBV-containing and RBV-free regimens. Clinically significant hemoglobin reductions and bilirubin elevations were infrequent and not treatment-limiting.

P0053 ALBENDAZOLE CAN ENHANCE THE RESOLUTION OF EOSINOPHILIC LIVER ABSCESS ASSOCIATED WITH TOXOCARIASIS

E.-Y. Jang[1,*], M.S. Choi[1], W. Sohn[1], G.-Y. Gwak[1], K.C. Koh[1], S.W. Paik[1], Y.-H. Paik[1], B.C. Yoo[1]

Contact E-mail Address: *hand1@dreamwiz.com*

INTRODUCTION: Visceral larva migrans, which is caused by *Toxocara canis* and *Toxocara cati*, has emerged as a significant cause of eosinophilic liver abscess (ELA). It is sometimes difficult to differentiate ELA associated with toxocariasis (ELA-T) from metastasis or primary liver malignancy. However, the role of albendazole treatment remains uncertain in this condition. We aimed to evaluate whether albendazole can enhance the radiologic resolution of ELA-T.
AIMS & METHODS: We retrospectively reviewed the medical records of the patients diagnosed with ELA-T at our institution between January 2008 and December 2011. ELA-T was diagnosed based on the imaging findings on computed tomography or magnetic resonance imaging and the presence of positive serum IgG antibody for *Toxocara canis*. Among a total of 163 patients, 32 patients received albendazole (albendazole group) and 131 did not (control group). Baseline characteristics and fate of liver nodules were compared between the two groups.
RESULTS: Baseline characteristics (age, sex, number and maximal size of lesions, eosinophil count) were similar between the two groups. Median duration for achieving radiologic resolution in the albendazole group was significantly shorter than in control group (207 days [range 186-228] vs. 302 days [range 224-380], $p = 0.023$). Cox regression analysis of the cumulative rates of radiologic resolution showed that hazard ratio for albendazole treatment was 1.99 (95% confidence interval: 1.22-3.23).
CONCLUSION: Radiologic resolution of ELA-T can be accelerated with albendazole treatment. Hence, inconvenience associated with long-term follow-up and unnecessary worries among the patients can be eliminated with albendazole treatment.

P0054 ABERRANT EXPRESSION OF KERATIN 7 IN HEPATOCYTES AS A PREDICTIVE MARKER OF RAPID PROGRESSION TO HEPATIC FAILURE IN ASYMPTOMATIC PRIMARY BILIARY CIRRHOSIS

H. Seki[1,*], F. Ikeda[1], S. Nanba[1], K. Yamamoto[1]

Contact E-mail Address: *jhare25@yahoo.co.jp*

INTRODUCTION: Routine testing for antimitochondrial antibodies has increased the identification of patients with asymptomatic primary biliary cirrhosis (PBC). A predictive marker of the rapid progression to hepatic failure is desired for patients with asymptomatic PBC.
AIMS & METHODS: We performed a systematic cohort analysis of 101 patients diagnosed as having asymptomatic PBC and the rapid progression to liver failure, by focusing on cholestasis. Cholestasis was assessed by aberrant keratin (CK) 7 expressions in the patients' hepatocytes.
RESULTS: Intralobular expressions of CK-7 were found in nine of the 101 patients (9%). The grades of CK-7 expression was significantly associated with the levels of alanine aminotransferase, alkaline phosphatase, and total bilirubin ($p = 0.0060$, 0.020, and 0.0015, respectively), but not with bile duct loss or cholestasis in orcein staining. The stepwise logistic regression analysis revealed that high grades of CK-7 expression in hepatocytes had positive correlations with high levels of total bilirubin ($p = 0.0020$). During the follow-up period, eight patients developed jaundice, and the mean period until the development of jaundice was 5.2 years. The proportional hazards models for the risk of developing jaundice identified only high grades of aberrant CK-7 expression in hepatocytes as significant risk factor (hazards ratio 8.7, $p = 0.019$).
CONCLUSION: Aberrant CK-7 expression in hepatocytes can be used as an additional marker to predict the rapid progression to liver failure in patients with asymptomatic PBC at the time of diagnosis.

P0055 THE VALUE OF 2D SHEAR WAVE ELASTOGRAPHY (2D-SWE) IN THE EVALUATION OF ESOPHAGEAL VARICES IN PATIENTS WITH LIVER CIRRHOSIS

O. Gradinaru Tascau[1], **A.S. Popescu**[1,*], I. Sporea[1], R. Sirli[1], **M. Popescu**[1], S. Bota[1], M. Danila[1], R. Sirli[1], I. Ratiu[1], on behalf of Flavia Moțiu, Athena Plaian
[1]*Department of Gastroenterology and Hepatology Timisoara, Emergency County Hospital of Timisoara, Timisoara, Romania*
Contact E-mail Address: *bluonmyown@yahoo.com*

INTRODUCTION: 2D-SWE is a new elastographic technique for the evaluation of chronic liver disease.
AIMS & METHODS: To evaluate the feasibility of 2D-SWE in cirrhotic patients with esophageal varices and the performance of 2D-SWE for predicting the presence of esophageal varices.
The study group included 71 subjects diagnosed with cirrhosis by clinical, biological, ultrasound and/or endoscopic criteria. All subjects underwent 2D-SWE with an AixplorerTM ultrasound system (SuperSonic Imagine S. A., Aix-en-Provence, France). In each patient we aimed to perform three liver stiffness measurements, with the patient in supine position and then a mean value was calculated and expressed in kiloPascals (kPa).
RESULTS: The study included 71 subjects, 65.2% men and 34.8% women with a median age of 60.5 years (ranging between 22-82 years). The etiology of liver cirrhosis was: HCV-22.2%, HBV- 12.5%, HCV and HBV-2.7%, ethanol-13.8% and other etiologies-47.2%. Esophageal varices were present in 39.4% of cases and significant esophageal varices (grade II and III) in 22.5% of cases. 2D-SWE had similar feasibility in patients with and without esophageal varices: 85.7% vs. 88.3%, ($p = 0.90$). The mean 2D-SWE values (kPa) were not statistically different in patients with and without esophageal varices: 30±13.5 vs. 24.8±12.7, ($p = 0.1$). The mean 2D-SWE values (kPa) were also not statistically different in patients with significant esophageal varices (grade II and III) vs. those without or grade I esophageal varices: 32.4±13.4 vs. 25.3±14 kPa, ($p = 0.1$).

CONCLUSION: 2D-SWE is a feasible method in patients with cirrhosis and esophageal varices but seems unable to predict the presence of esophageal varices. Further studies, in a larger number of patients, are still needed.

P0056 IMPLEMENTING A VIRTUAL PALPATION MODEL COMBINING SPIRAL CT AND ELASTOGRAPHY DATA INTO MEDICAL TRAINING – A PILOT STUDY

C.T. Streba[1,*], I.A. Gheonea[2], L. Sandulescu[1], S. Adrian[1], D. I. Gheonea[1]
[1]*Gastroenterology,* [2]*Radiology, UMF CRAIOVA, Craiova, Romania*
Contact E-mail Address: *costinstreba@gmail.com*

INTRODUCTION: There are inherent problems in providing training to novices in any safety critical task. In particular, teaching medical clinicians to perform procedures poses challenges and possible risk to patients. A palpation procedure involves the examination of a patient through direct contact. That means that palpation is traditionally restricted to organs in direct contact with the outer layers of the body.
AIMS & METHODS: Our aim was to implement a previously described virtual reality model for palpation of liver tumors based on combined spiral CT and real-time elastography (RT-E) data in a haptic simulator used by medical students in a pilot study. After clearing all ethical concerns with the local committees and obtaining written consent, we acquired spiral CT and full RT-E imaging data stored in DICOM format from 15 patients with primary liver cancers scheduled for surgery. By using previously described methods [1] we created a three-dimensional model of the liver and the tumor using the CT data and integrated elasticity information by superimposing the RT-E data on the stiffness of each tumor. We thus obtained 15 distinct virtual models containing segmented color-map data superimposed on a high-fidelity representation of the tumors. These computerized models were later integrated in a virtual reality system which projected a three-dimensional image of the tumor to the operator and allowed physical interaction through haptic devices attached to the students' body. We tested the system on a pilot group of 60 medical students in the fifth year of training. Students were presented with the experimental design and were asked to perform a series of tasks involving spatial manipulation and virtual palpation of the virtual model. They were also presented with data on the real tumor (size, shape, location). After completion, a standardized questionnaire was given to each student and results were quantified using descriptive statistics and inter-group analysis.
RESULTS: All students considered the model to be accurate in both size and shape with the actual image of the tumor (60/60, 100%). The general impression was that it increased knowledge on tumoral pathology of the liver and students agreed that it provided useful insights otherwise unobtainable through standard teaching techniques. The main issue with the physical haptic system were related with the optical system for virtual reality, which the students found hard to wear and interact. The tactile feedback device was however well accepted by the test group.
CONCLUSION: We successfully tested a haptic medical simulator in a pilot study involving medical students with already acquired clinical knowledge. The general consensus was that the haptic simulator is useful for increasing knowledge on liver tumors and provide additional data otherwise unobtainable through traditional methods.

P0057 COMPARISON OF THE ACCURACY OF SHEAR WAVE ELASTOGRAPHY AND ACOUSTIC RADIATION FORCE IMPULSE IN DETERMINING LIVER FIBROSIS AMONG PATIENTS WITH CHRONIC LIVER DISEASE

J.-A. **V. Bisnar**[1,*], J. Gopez-Cervantes[1], J. Bocobo[1], I.H. Cua[1]
[1]*Institute of Digestive and Liver Disease, St. Luke's Medical Center, Quezon City, Philippines*
Contact E-mail Address: *joannebisnar@gmail.com*

INTRODUCTION: The prognosis of chronic liver diseases (CLD) depends on the extent of liver fibrosis. Liver fibrosis is the excessive accumulation of extracellular matrix proteins including collagen that occurs in most types of chronic liver diseases.
AIMS & METHODS: The study aims to compare the accuracy of Shear Wave Elastography (SWE) and Acoustic Radiation Force Impulse (ARFI) in determining liver fibrosis among patients with chronic liver disease.
Cross-sectional study conducted between March-July 2012. SWE, ARFI and ultrasound-guided liver biopsy were performed on 120 patients. Liver fibrosis using Knodell's histologic activity index and AUROC were determined for F0-F1 vs. F2-F4, F0-F2 vs. F3-F4, and F0-F3 vs. F4. SPSS 16.0, OpenEpi 2.3.1, and Stata 11.0 software were utilized in the statistical analysis.
RESULTS: AUROCs were 0.858 (ARFI) and 0.893 (SWE), 0.944 (ARFI) and 0.95 (SWE), and 0.919 (ARFI) and 0.965 (SWE), between F0-F1 vs. F2-F4, F0-F2 vs. F3-F4, and F0-F3 vs. F4, respectively. ARFI has a sensitivity and specificity of 87.5% (64-96.5) and 84.6% (76.5-90.3), 95.8% (79.8-99.3) and 78.1% (68.9-85.2), 91.3% (79.7 – 96.6) and 43.2% (32.6-54.6) for F4 vs. F0-F3, F3-F4 vs. F0-F2, and F2-F4 vs. F0-F1. SWE has a sensitivity and specificity of 100% (80.6-100) and 83.7% (75.4-89.5), 95.8% (79.7-99.3) and 85.4% (77-91.1), and 78.3% (64.4-87.7) and 86.5% (76.9-92.5).
CONCLUSION: SWE is more accurate in assessing liver cirrhosis. Both sensitivity and specificity of ARFI and SWE increased with the severity of liver fibrosis. SWE is more sensitive between F4 vs. F0-F3 and more specific between F3-F4 vs. F0-F2 and F2-F4 vs. F0-F1. ARFI is more specific between F4 vs. F0-F3 and more sensitive between F2-F4 vs. F0-F1. Differences in estimates between SWE and ARFI were statistically significant between F0-F1 and F2-F4. Thus, both SWE and ARFI can be used as non-invasive tools in detecting liver fibrosis.

P0058 NON-INVASIVE ASSESSMENT OF PORTAL HYPERTENSION USING ELASTOGRAPHY OF SPLEEN

K. Dvorak[1,*], V. Smid[1], R. Sroubkova[1], A. Novotny[1], J. Mengerova[1], J. Petrtyl[1], R. Bruha[1]
[1]*4TH DEPARTMENT OF MEDICINE, GENERAL UNIVERSITY HOSPITAL AND 1ST MEDICAL FACULTY CHARLES UNIVERSITY IN PRAGUE, Prague 2, Czech Republic*
Contact E-mail Address: *k2dvorak@gmail.com*

INTRODUCTION: The degree of portal hypertension is one of crucial prognostic factors in patients with liver cirrhosis. Standard method used for the assessment is measurement of hepatic venous pressure gradient (HVPG) during liver vein catheterisation. Being an invasive procedure this approach is not common, has complications and moreover it does not enable monitoring of changes in the long term. Recently non-invasive approaches have been increasingly employed in evaluation of liver fibrosis; one such method is elastography.
AIMS & METHODS: The aim of our study was to evaluate the possibility of assessment of portal hypertension with elastography of the spleen in patients with various etiology of liver cirrhosis. Elastography of liver and spleen was assessed using ARFI (Acoustic Radiation Force Impulse) measurement with ultrasound system Siemens Acuson S2000 and then HVPG was measured in all patients. A total of 20 patients was examined (13 men, 7 women), average age 59±10.9, with different etiology of liver cirrhosis (10 ethylic, 4 viral hepatitis, 6 other). Diagnosis of cirrhosis was confirmed by liver biopsy or with presence of portal hypertension. There was a control group of 20 healthy individuals without signs of liver disease.
RESULTS: Clinically significant portal hypertension was diagnosed in 15 from 20 examined patients. The HVPG values were (mmHg; median, IQ range) 15 (3-26), ARFI of liver (m/s; median, IQ range) 2.96 (1.31-3.54), ARFI of spleen 3.13 (1.99-3.74). The value of ARFI of spleen significantly correlated with the degree of portal hypertension ($p = 0.038$), the ARFI of liver did not ($p = 0.251$).
CONCLUSION: Spleen elastography which is simple, reproducible and easy to repeat, could enable assessing portal hypertension in cirrhotic patients noninvasively.

P0059 OUR PRELIMINARY EXPERIENCE WITH ELASTOPQ® SHEAR WAVE ELASTOGRAPHY TECHNIQUE AND DOPPLER INDICES IN THE NON-INVASIVE ASSESSEMENT OF LIVER FIBROSIS

M. Garcovich[1,*], M.A. Zocco[1], L. Riccardi[1], M.E. Ainora[1], E.B. Annicchiarico[1], D. Roccarina[1], G. Caracciolo[1], A. Grieco[1], G.L. Rapaccini[1], M. Siciliano[1], M. Pompili[1], A. Gasbarrini[1]
[1]*Internal Medicine, Catholic University of Sacred Heart, Rome, Italy*

INTRODUCTION: Real-time shear wave elastography (RTE) is a novel non-invasive technique that assesses liver fibrosis by measuring liver stiffness (in kPa). The purpose of this study was to determine the efficacy and the feasibility for the assessment of hepatic fibrosis as compared with the histological grade in patients undergoing liver biopsy (LB).
AIMS & METHODS: Consecutive patients scheduled for LB were studied by using the iU22 Philips ultrasound system with ElastPQ technique. In addition, Doppler indices at various sites, hepatic vein and portal venous blood velocity and flows were evaluated. The correlations between these quantitative parameters and the Metavir score were analyzed using Spearman correlation and ROC curve analyses were performed to calculate AUC for $F > 2$, $F > 3$, and $F = 4$.
RESULTS: We enrolled 60 patients (39/21 males/females) who underwent LB for viral or non-viral chronic hepatitis (HCV – 58%; NASH – 30%). Liver stiffness measurements performed on the right lobe were reliable in almost all cases, while 15% of left lobe measurements were not obtainable/unreliable. Median kPa values were 4.43(range 2.98–4.82) and 3.92(2.51-6.73) for F0-F1, 7.65(4.28-12.9) and 8.21(5.43-12.3) for F2-F3, 15.12(9.9-29.16) and 18.54(9.31-31.34) for F4 in the right and left lobe, respectively. AUCs calculated for the right lobe were 0.90(0.84–0.92;95%CI) for $F > 2$, 0.84(0.73–0.88;95%CI) for $F > 3$ and 0.92(0.90–0.96;95%CI) for $F = 4$. Adding Doppler indices to liver stiffness increased no further the diagnostic accuracy of RTE.

CONCLUSION: RTE with ElastPQ appears to be a useful tool for non-invasive evaluation of fibrosis in patients with viral and non-viral chronic hepatitis, although these findings need to be confirmed in larger studies.

INTRODUCTION: Methotrexate (MTX) is among most commonly used immunosupressive agents but requires careful monitoring due to risks of hepatotoxicity. The amino-terminal of type III pro-collagen peptide (serum P3NP) is used as a surrogate of collagen turnover. Its measurement has been proposed as a marker for ongoing hepatic fibrogenesis. Liver stiffness measurement (LSM) is a simple non-invasive method for assessment of liver fibrosis (LF). Currently, only liver biopsy for assessment of liver fibrosis in long-term (>24weeks) MTX-treated patients is used. Our aim was to evaluate the presence of liver fibrosis by transient elastography (TE) in patients treated with MTX in a long-term clinical practice.
AIMS & METHODS: We consecutively enrolled 34 patients with rheumatoid arthritis or psoriasis taking MTX between 2011 and 2012. We only included patients with normal liver function and no history of underlying chronic liver disease. All patients had P3NP measurements close to TE. Liver stiffness was evaluated by TE (single operator). Cut-off of LSM to predict liver fibrosis was 7.1 KPa.
RESULTS: The study population consists of 34 patients (12 males, 35%) at mean age of 65.2 years (range 34-77, SD 11.04). Seven patients (20%) had psoriasis, 23 (68%) had RA and the remaining were with SLE. Mean MTX cumulative dose was 5320 (SD 3682) mg, and mean treatment duration was 427 weeks (range 104-670). Mean hepatic stiffness was 7.4 KPa (SD 4.46) and mean level of P3NP was 6.7 mcg/l (SD 2.25). In six patients abdominal ultrasound was suggestive of fatty liver disease and they were excluded from further analysis. The remaining 28 patients had mean LSM of 7.4 KPa (SD 4.74), which correlated significantly with serum P3NP (Pearson $r=0.46$, $p<0.02$). Ten patients had LSM > 7.2 KPa, suggestive of significant fibrosis. Patients' age, steroids, treatment duration or cumulative doses of MTX were not associated with LF.
CONCLUSION: In our series, 33% of long-term MTX treated patients developed liver fibrosis, as assessed by LSM. Transient elastography may be potentially useful in evaluation and follow-up of liver fibrosis in long-term MTX-treated patients. Further work is required to evaluate the diagnostic yield of TE as a predictor of liver fibrosis in these patients.

Contact E-mail Address: *roxanasirli@gmail.com*

INTRODUCTION: Liver stiffness measurement (LSM) using Transient Elastography (TE) for liver fibrosis assessment is difficult to perform in obese and overweight patients by standard M probe, thus the XL probe was developed.
AIMS & METHODS: The aim of our paper was to compare the LS values obtained by the XL probe vs. M probe in daily clinical practice.
Our study included 88 difficult to evaluate patients (mean BMI 29.6±3.4 kg/m^2) with chronic hepatopathies, in which paired measurements were made with the M (3.5MHz) and XL (2.5 MHz) probes in the same session. In each patient 10 valid LSM were acquired with each probe, a median was calculated, expressed in kiloPascals (kPa). Unreliable TE measurements were considered: fewer than 10 valid shots; with a success rate (SR)<60% and/or interquartile range interval (IQR)≥30%. We used published cut-offs for M probe (7.6kPa) to divide p with no significant fibrosis (F<2 Metavir) from those with significant fibrosis (F≥2), and those with no cirrhosis (F<4) vs. cirrhosis (F4) (15kPa)*.
RESULTS: XL LS values strongly and significantly correlated with those obtained by M probe (Spearman $r=0.782$, $p<0.0001$), but were significantly lower [median 6.3 kPa (range 3.1–52.3) vs. 7.2 kPa (range 3.7–57.3), Wilcoxon paired t test $p<0.001$)]. XL LS values were also lower in the F<2 group (47 patients): median 5.1 kPa (range 3.1–12.7) vs. 5.9 kPa (range 3.7–7.4), Wilcoxon paired t test $p=0.0006$); in the F2-F3 group (23 patients): median 7.3 kPa (range 5.1–16.3) vs.10.5 kPa (range 7.7–14.1), Wilcoxon paired t test $p=0.0154$); and in the cirrhotic group (18 patients): median 18.2 kPa (range 13.3–52.3) vs. 21.3 kPa (range 15.9–57.3), Wilcoxon paired t test $p<0.0001$.
CONCLUSION: LSM by XL probe are significantly correlated, but lower, than those obtained by M probe in patients with no significant fibrosis (F<2), in patients with moderate and severe fibrosis (F2,F3) and in patients with cirrhosis (F4).

INTRODUCTION: Recently, spleen stiffness (SS) assessed by various elastographic methods was evaluated for predicting liver fibrosis. Recently (Leung-Radiology, 2013) good results were published for predicting liver cirrhosis byusing SS by 2D-SWE.
AIMS & METHODS: Our aim was to validate this cut-off in an independent cohort, considering liver stiffness (LS) by Transient Elastography (TE) as the reference method.
We analyzed 89 patients with chronic liver disease. In each of the patients, in the same session LS was evaluated by TE (FibroScan, Echosens, Paris, France) and SS by 2D-SWE (Aixplorer, SuperSonic Imagine S. A., Aix-en-Provence, France). TE reliability criteria defined as: median of 10 valid LS measurements with a SR≥60% and IQR<30%. 2D-SWE results were recorded as median value of 3 valid SS measurements. For predicting the presence if liver cirrhosis, we used the LS cut-off proposed in the most recently published meta-analysis (Tsochatzis-J Hepatol 2011): 14.5 kPa. For SS the following cut-off was analyzed (Leung-Radiology2013): 22 kPa.
RESULTS: Reliable LS measurements by TE were obtained in 71 (79.7%) patients and valid SS measurements by 2D-SWE in 63/71 (88.7%) patients, who were included in the final analysis. According to the pre-specified cut-off values for LS and SS, the performance of SS assessed by 2D-SWE for predicting the presence of liver cirrhosis was: 58.3% sensitivity, 82.3% specificity, 43.7% positive predictive value (PPV), 89.3% negative predictive value (NPV) and 77.7% accuracy.
CONCLUSION: In our patient cohort, SS by 2D-SWE was a good method for excluding liver cirrhosis, with a very good NPV (89.3%), but less useful for predicting cirrhosis, with a rather poor PPV(only 43.7%).

P0063 COMPARISON BETWEEN 2D-REAL TIME SHEAR WAVE-ELASTOGRAPHY (2D-SWE) AND SIMPLE SEROLOGICAL SCORES FOR LIVER FIBROSIS ASSESSMENT FOR CLINICAL ROUTINE, CONSIDERING TRANSIENT ELASTOGRAPHY (TE) AS REFERENCE METHOD

S. Bota[1,*], R. Paternostro[1], A. Etschmaier[1], R. Schwarzer[1], P. Salzl[1], M. Mandorfer[1], T. Purevsambuu[1], M. Ferlitsch[1], C. Kienbacher[1], T. Reiberger[1], M. Trauner[1], M. Peck-Radosavljevic[1], A. Ferlitsch[1]
[1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*

INTRODUCTION: 2D-Shear Wave elastography (2D-SWE) is a new method for non-invasive assessment of liver fibrosis.
AIMS & METHODS: Our aim was to assess the performance of 2D-SWE and simple serological scores for liver fibrosis assessment, considering TE as reference method.
Our study included 127 consecutive patients with chronic liver disease undergoing both TE (FibroScan, Echosens, Paris, France) and 2D-SWE (Aixplorer, SuperSonic Imagine S. A., Aix-en-Provence, France). Biochemical parameters were recorded to calculate the noninvasive fibrosis scores. TE reliability criteria defined as: median of 10 valid LS measurements with a SR≥60% and IQR<30%. 2D-SWE results were recorded as median value of 3 valid LS measurements. TE cut-offs to stage liver fibrosis were used according to a recent meta-analysis (Tsochatzis-J Hepatol 2011): F1: 6kPa, F2: 7.2kPa, F3: 9.6kPa and F4: 14.5kPa.
RESULTS: Reliable LS measurements by TE and 2D-SWE were obtained in 74.8% and 98.4% of patients ($p<0.0001$), respectively. The following noninvasive fibrosis scores were correlated in univariate analysis with fibrosis estimated by TE: 2D-SWE ($r=0.699$; $p<0.0001$), Forns ($r=0.534$; $p<0.0001$), King's ($r=0.512$; $p<0.0001$), APRI ($r=0.373$, $p=0.001$) Fibrosis Index score ($r=0.363$; $p=0.0008$) and Lok score ($r=0.316$, $p=0.006$), while FIB-4 ($r=0.195$; $p=0.09$) was not correlated. In multivariate analysis only LS by SWE was significantly correlated with fibrosis estimated by means of TE ($p<0.0001$).
The best LS cut-off by 2D-SWE for predicting different stages of liver fibrosis, considering TE as the ''reference method'', are presented in the table.
Table to abstract P0063

Fibrosis	SWE Cut-off (kPa)	AUC	Se (%)	Sp (%)	PPV (%)	NPV (%)	Accuracy (%)
F≥2	> 8.03	0.832	77.1	76.1	77.1	76.1	76.5
F≥3	> 9.2	0.919	88.2	85	76.9	92.7	86.1
F=4	> 13.1	0.915	76.2	94.5	80	93.2	90.4

CONCLUSION: 2D-SWE results in a higher rate of successful liver stiffness measurements than TE and is superior to simple serological scores for non-invasive liver fibrosis assessment.

INTRODUCTION: Currently only liver biopsy can accurately establish the diagnosis and severity of hepatic steatosis. Few studies to date have addressed the feasibility of the Controlled Attenuation Parameter (CAP) measured by transient elastography for measuring hepatic fat content. However, the effects of hepatic fibrosis and disease etiology on the accuracy of CAP values for grading the severity of liver steatosis are still unclear.
AIMS & METHODS: The aims of this study were (1) to determine whether CAP values can discriminate grades of steatosis in a sample of consecutive patients with a spectrum of liver disease etiology and steatosis severity, and (2) to evaluate the effect of hepatic fibrosis and disease etiology on the quantification of steatosis by CAP measurements. The study involved 50 sequential patients (64% males; mean age, 47.4 years; range, 19-70 years) who had undergone a percutaneous liver biopsy and CAP measurements. The causes of liver disease were nonalcoholic fatty liver disease (n = 20), chronic viral hepatitis (n = 23), autoimmune hepatitis (n = 3), and others (n = 4). A pathologist scored the specimens in a four-graded scale as follows: $<5\%$ steatosis = S0, 5-33% = S1, 33-66% = S2, and $>66\%$ = S3. All liver biopsy specimens were at least 20 mm long and/or contained more than 11 complete portal tracts.
RESULTS: The pathology results showed that 16 (32%) patients had S0, 12 (24%) had S1, 9 (18%) had S2, and 13 (26%) had S3. Overall a close relationship was observed between the CAP values and histology steatosis scores ($r = 0.709$, $P < 0.001$). There was a stepwise increase in CAP with increasing stages of hepatic steatosis: S0, 222 dB/m; S1, 250 dB/m; S2, 270 dB/m; and S3, 318 dB/m. Regression analysis, that included a number of potential confounders, was performed to determine the influence of hepatic fibrosis and disease etiology on the relationship between CAP values and the histological assessment of steatosis. However, neither liver fibrosis ($p = 0.58$) nor disease etiology ($p = 0.96$) were found to have an interaction between CAP and the stage of steatosis.
CONCLUSION: Liver fibrosis or disease etiology does not impact on the accuracy of CAP for the assessment of steatosis. The results of this study strengthen the role of CAP measured by transient elastography as a non-invasive alternative to liver biopsy for the evaluation of liver fat content in subjects with liver disease. Given its accuracy and lack of confounding by fibrosis and disease etiology, CAP assessment is an attractive method to evaluate the presence and severity of steatosis in clinical practice and may also be a useful tool to monitor change in steatosis in subjects undergoing an intervention.

P0065 FOCAL LIVER LESIONS CLASSIFICATION BY ARTIFICIAL NEURAL NETWORKS AND SUPPORT VECTOR MACHINES EMPLOYING DYNAMIC IMAGING DATA

C.T. Streba[1,*], C.C. Vere[1], L. Sandulescu[1], A. Saftoiu[1], D. I. Gheonea[1], **L. Streba**[1], **I. Rogoveanu**[1]
[1]*Gastroenterology, UMF CRAIOVA, Craiova, Romania*
Contact E-mail Address: *costinstreba@gmail.com*

INTRODUCTION: Early diagnostic of liver malignancies is essential for therapy efficiency; differentiating hepatocellular carcinoma (HCC) from intrahepatic cholangyocarcinoma, liver metastases or benign lesions is therefore essential even in early phases. Successful classification of liver lesions by computerized methods is currently possible and artificial neural networks emerged as optimal tools for independent diagnostic.
AIMS & METHODS: Our aim was to test the validity of two separate decision making systems – an artificial neural network (ANN) and a support vector machine (SVM) in classifying focal liver lesions (FLLs) by using dynamic imaging data.
Expanding on our previous work involving ANN use in interpreting imaging data for HCC [1], we now proposed a comparative approach between two different machine learning systems, one based on ANNs and contrast-enhanced ultrasound (CEUS) quantitative data and one employing a SVM and spiral computed tomography (CT). After obtaining ethical clearance and signing individual consent forms, we prospectively included 191 patients who underwent both spiral CT and CEUS as part of their clinical work-up at the University County Hospital of Craiova between January 2009 – September 2013. Final diagnosis was based on post-treatment evaluation, follow-up and pathology, when available. Imaging data from CEUS was obtained through time-intensity curve (TIC) analysis and the main parameters (time to peak, rise time, fall time, mean transit time, area under the curve) were fed to an ANN. Spiral CT data was obtained through manually segmenting the tumor and a tumor-free parenchyma portion in distinctive images and obtaining Gray Level Co-occurrence Matrix – GLCM parameters (entropy, correlation and contrast) by using the free ImageJ software and a dedicated plug-in. These parameters were then fed to a SVM.
RESULTS: We included 54 cases of HCC, 9 intrahepatic cholangiocarcinomas, 71 liver metastases (41 hypervascular), 38 liver hemangiomas and 19 focal fatty changes. The SVM classified lesions into malignant or benign, obtaining 141 correct classifications (malignant: 113/134, benign: 28/57). Overall, the ANN in correlation with TIC-derived parameters proved to be a superior combination to SVM and GLCM.
CONCLUSION: ANNs are superior to SVMs when employed in medical classification problems. Established quantitative parameters improve the diagnostic accuracy. The differences shown here were not given by the quality of the two investigations, showing rather the adequacy of the chosen parameters and the diagnostic yields of the computer methods employed.

Contact E-mail Address: *iamann81@gmail.com*

INTRODUCTION: Aging of general population and advances in diagnostic imaging have led to more frequent detection of small hepatocellular carcinoma (HCC) in elderly adults. However, long-term outcome and its predictive factors after treatment of small HCC in these patients have not been established.
AIMS & METHODS: Between 2006 and 2009, 897 patients who had Eastern Cooperative Oncology Group (ECOG) score 0-1 and Child-Pugh class A liver function were diagnosed with single small HCC (size≤3 cm) at Samsung Medical Center. They were divided into elderly group (age≥65 years, n = 186) and young group (age<65 years, n = 711). We compared baseline characteristics, initial treatment modality, and treatment outcomes between the two groups.
RESULTS: At baseline, male patients were less common, and HCV infections and alcoholic liver disease were more common in elderly group. Elderly group underwent surgical resections less frequently but TACE more frequently compared to young group (21.5% vs. 38.8% for surgery and 26.9% vs. 12.9% for TACE, $p<0.001$). One-, 3-, and 5-year overall survival (OS) rates (OSR) of elderly group were lower than those of young group (96.7%, 81.4%, and 60.5% vs. 97.3%, 87.9%, and 82.4%, respectively, $p<0.001$).
One-, 3-, and 5-year OS rates were after surgery, RFA, and TACE were 94.9%, 89.7%, and 86.6% vs. 97.9%, 79.6%, and 56.7% vs. 96.0%, 80.0%, and 50.6%, respectively in elderly group ($p = 0.014$); 98.2%, 91.8%, and 89.5% vs. 98.2%, 87.6%, and 80.3% vs. 92.3%, 79.0% and 70.5%, respectively in young group ($p<0.001$). Although OS rates after surgery and TACE were comparable between the two groups, elderly group showed lower 1-, 3-, and 5-year OS rates than young group after RFA. In addition, 1-, 3-, and 5-year recurrence-free survival (RFS) rates of elderly subgroup were lower than those of young group (63.2%, 30.5%, and 23.0% vs. 75.7%, 48.0%, and 36.6%, respectively, $p<0.001$).
One-, 3-, and 5-year RFS rates after surgery, RFA, and TACE were 74.4%, 61.5%, and 52.5% vs. 70.2%, 23.5% and 13.8% vs. 40.8%, 18.4%, and 16.3%, respectively in elderly group ($p<0.001$); 81.4%, 63.5%, and 51.5% vs. 75.1%, 41.4%, and 29.9% vs. 59.2%, 23.6%, and 11.7%, respectively in young group ($p<0.001$). RFS rates after surgery and TACE were comparable between the two groups, whereas elderly group showed lower 1-, 3-, and 5-year RFS rates than young group after RFA. Multivariate analysis showed that sex and initial treatment modality were the significant predictive factor for OS and RFS.
CONCLUSION: Although long-term outcomes after treatment of single small HCC in elderly group were lower than those in young group, adoption of curative treatment modality was an independent predictive factor for the better outcomes irrespective of age. Therefore, in elderly patients with well-preserved liver function and good performance status, curative treatment including surgery should be more positively considered for single small HCC.

INTRODUCTION: It has been recently suggested that sorafenib should be initiated as early as possible in patients with hepatocellular carcinoma (HCC) who failed transarterial chemoembolization (TACE); however, the correlation

between the efficacy of sorafenib and the number of prior TACE procedures has not been documented. We analyze here the correlation between the efficacy of sorafenib and the number of prior TACE procedures in HCC patients included in the Nation-wide Italian database ITA. LI. CA.
AIMS & METHODS: The ITA. LI. CA. database contains data of 5136 HCC patients treated at 18 Italian Centers. All patients treated with sorafenib were included in this analysis. The following endpoints were considered: overall survival (OS), time to progression (TTP) and disease control rate (DCR). These endpoints were compared in patients with no TACE, one and ≥2 prior TACE procedures.
RESULTS: In total, 321 patients had received sorafenib (271 males; age 65±11 years; 225 in BCLC-C stage). Of these, 201 received no TACE (187 were in BCLC-C stage), 60 one TACE and 60 ≥2 TACE procedures. Median OS was significantly longer in patients who received one single TACE procedure, with respect to those with no or ≥2 TACE procedure(s) (19 months with one TACE versus 11 months with no TACE and 12 months for ≥2 TACE; $p<0.05$). No differences among groups were observed in TTP (one TACE: 4 months; no TACE: 4 months; ≥2 TACE: 5 months; p = not significant), but patients with only one TACE prior to sorafenib treatment had an improved DCR (one TACE: 34%; no TACE: 24%; ≥2 TACE: 28%; $p<0.05$).
CONCLUSION: Although with all the limitations of any observational study, this analysis, conducted in a large field-practice database, suggests that HCC patients who start sorafenib after one single TACE procedure present improved OS and DC with respect to those who received TACE ≥2 TACE procedures.

P0068 CORRELATION BETWEEN LDH LEVELS AND RESPONSE TO SORAFENIB IN HCC PATIENTS

R. Sacco[1,*], A. Romano[1], V. Mismas[1], M. Bertini[1], M. Bertoni[1], G. Federici[1], G. Parisi[1], A. Scaramuzzino[1], S. Metrangolo[1], E. Tumino[1], G. Bresci[1] on behalf of ITA.LiCA Group

Contact E-mail Address: *r.sacco@ao-pisa.toscana.it*

INTRODUCTION: Lactate dehydrogenase (LDH) is a predictor of clinical outcome in hepatocellular carcinoma (HCC) patients. However, the predictive role of LDH on the clinical outcomes of sorafenib treatment has been poorly documented. The correlation between LDH levels and clinical outcomes in HCC patients treated with sorafenib included in the Nation-wide Italian database ITA. LI. CA is investigated here.
AIMS & METHODS: The ITA. LI. CA. database contains data of 5136 HCC patients treated at 18 Italian Centers. All patients treated with sorafenib treatment and with available LDH values were considered. A ROC analysis was performed to find a suitable threshold for baseline LDH levels. Overall Survival (OS) and time to progression (TTP) were compared in patients with LDH above and below the identified threshold. Study endpoints were also evaluated according to different patterns of LDH levels during treatment.
RESULTS: Baseline LDH levels were available for 97 patients (85 males, 61 in BCLC-C stage); data on LDH levels during sorafenib were reported for 10 patients. Mean baseline LDH concentration was 324±141 U/L. The most accurate cut-off value for LDH concentration was 297 U/L. Both study endpoints were equal in patients with LDH values ≥297 U/L (n = 47) and in those with lower LDH concentrations (n = 52) (OS: 12.0 months in each population; TTP: 4.0 months in each group). During treatment, LDH values decreased in three patients (mean difference = -219 U/L). Patients with decreased LDH concentrations have a prolonged OS versus those with unmodified/increased values ($p = 0.0083$; all patients with decreasing LDH are alive, median OS for patients with increasing LDH was 8.0 months). Median TTP was 19.0 months in patients with decreasing LDH and 3.0 months in those with increasing values ($p = 0.008$).
CONCLUSION: The clinical benefits of sorafenib do not seem influenced by baseline LDH. However, a decreased LDH concentration during sorafenib might be associated with improved clinical outcomes.

P0070 SAFETY AND EFFICACY OF SORAFENIB IN ELDERLY PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA

S. Nakashita[1,*], T. Otsuka[1], Y. Eguchi[2], S. Kawazoe[3], K. Yanagita[4], K. Ario[5], K. Kitahara[6], S. Iwane[7], H. Kato[8], T. Mizuta[1] on behalf of the Saga Liver Cancer Study Group
[1]*Internal Medicine,* [2]*Liver Disease Control and Assistance Task Force, Saga University Hospital,* [3]*Hepato-Biliary and Pancreatology, Saga-Ken Medical Centre Koseikan, Saga,* [4]*Internal Medicine, Saiseikai Karatsu Hospital, Karatsu,* [5]*Internal Medicine, NHO Ureshino Medical Center, Ureshino,* [6]*Surgery, Saga University Hospital, Saga,* [7]*Internal Medicine, Karatsu Red Cross Hospital, Karatsu,* [8]*Internal Medicine, NHO Saga Hospital, Saga, Japan*

INTRODUCTION: The average age of patients with hepatitis and hepatocellular carcinoma (HCC) in Japan is increasing. Sorafenib is approved for the treatment of advanced HCC; however, its safety and efficacy for elderly patients is not established by published studies. Therefore, we aimed to evaluate the safety and efficacy of sorafenib for elderly patients (≥80 years of age) included in the Saga Liver Cancer Study Group.
AIMS & METHODS: We conducted a retrospective study between July 2008 and August 2013 that included 134 patients with advanced HCC who received sorafenib in Saga, Japan until disease progression or treatment intolerance. We divided the patients into two groups comprising 36 patients 80 years of age or greater (≥80 group) and 98 patients less than 80 years of age (<80 group). We compared antitumour effect [objective response rate (ORR), disease control rate (DCR), time to tumour progression (TTP)], overall survival (OS), and adverse events (AEs) of the two groups.
RESULTS: Baseline characteristics were not significantly different between the two groups. The median ORRs were 6.9% and 8.3%, and the median DCRs were 37.9% and 46.4% in the ≥80 and <80 groups, respectively. These values were not significantly different between the two groups ($p = 0.81$, $p = 0.43$). The median TTPs were 2.9 months for both groups, and the median OSs were 14.7 and 9.2 months for the ≥80 and <80 groups, respectively, which were not significantly different. The frequencies of AEs were 97.2% and 96.6% in the ≥80 and <80 groups. The frequencies of grade 3 AEs between the ≥80 and <80 groups were significantly different (69.4% and 49.0% respectively, $p = 0.036$).
CONCLUSION: Sorafenib treatment is equally effective for elderly and non elderly patients with advanced HCC. However, the high frequency of AEs in elderly patients is problematic and requires close attention.
Disclosure of Interest: None declared

P0071 HEPATOCELLULAR CARCINOMA INCIDENCE IN CHRONIC HEPATITIS C PATIENTS ACCORDING TO SUSTAINED VIROLOGIC RESPONSE (SVR) AND FLUCTUATION OF ALFA FETO-PROTEIN LEVELS DURING ANTIVIRAL TREATMENT

T. Purevsambuu[1,*], S. Bota[1], H. Florian[1], H. Hofer[1], P. Ferenci[1], W. Sieghart[1], M. Peck-Radosavljevic[1]
[1]*Gastroenterology and Hepatology, Internal Medicine III, Medical University of Vienna, Vienna, Austria*
Contact E-mail Address: *tuulaigirl@yahoo.com*

INTRODUCTION: Chronic hepatitis C (CHC) is an important risk factor for progression of liver disease to advanced fibrosis and hepatocellular carcinoma (HCC) and the published studies showed that the kinetics of alfa feto-protein (AFP) levels in cirrhotic patients are more valuable than single AFP values for predicting the HCC.
AIMS & METHODS: Our aim was to assess the HCC incidence in relation to antiviral treatment response and fluctuation of AFP levels during antiviral treatment in a large number of patients from a single institution. We retrospectively collected data of HCV patients, who were diagnosed and treated between 1989-2011. We analyzed the HCC incidence according to AFP fluctuation (baseline vs. end of treatment-EOT) in the entire Cohort of patients and in SVR and non-SVR patients.
RESULTS: We identified 2627 patients diagnosed with chronic hepatitis C. We excluded 975 patients because they did not receive antiviral therapy, 5 because they were diagnosed simultaneously with HCV/HCC and 321 patients due to lack

Table to abstract P0071
Table 1. HCC incidence in different groups, according to AFP levels at baseline and EOT (P0071 table)

Cohort	Group A: n=50 (3.8%) AFP > 10/ AFP > 10 (ng/ml,baseline/EOT)		Group B: n=81 (6.1%) AFP > 10 /AFP < 10 (ng/ml, baseline/EOT)		Group C: n=1167 (88%) AFP < 10 /AFP < 10 (ng/ml,baseline/EOT)		Group D: n=28 (2.1%) AFP < 10/AFP > 10 (ng/ml,baseline/EOT)		P value
All	24%		9.8%		1.8%		17.8%		A vs. B: p=0.004 Avs.C:p < 0.0001 A vs. D: p=0.72 B vs.C: p < 0.0001 B vs. D: p=0.42 C vs.D: p < 0.0001
SVR	30.7%	p=0.77	7.1%	p=0.83	0.5%	p < 0.0001	12.5%	p=0.93	A vs. B: p=0.12 A vs.C: p < 0.0001 A vs. D: p=0.67 B vs. C: p=0.003 B vs. D: p=0.81 C vs. D: p=0.04
Non-SVR	21.6%		11.3%		4.7%		20%		A vs. B: p=0.30 A vs.C: p=0.0002 A vs. D: p=0.84 B vs. C: p=0.10 B vs. D: p=0.56 C vs. D: p=0.01

of AFP values at baseline and EOT. We included in the final analysis 1326 patients. The median follow-up time was 10 years (0.2-25 years). The overall HCC incidence was 3.5% and the median time between HCV and HCC diagnosis was 7 years (0.5-15 years). According to baseline fibrosis stage, HCC incidence was: 0.9% in F(0-2) patients, 1.8% in F3 and 10.1% in F4 patients.
The HCC incidence was significantly higher in non-SVR as compared with SVR patients: 7.4% vs. 1.2%, $p < 0.0001$.
AFP values > 10 ng/ml at baseline, EOT and the increase of AFP values during the antiviral treatment are associated with high HCC incidence in both SVR and non-SVR patients (Table 1). The decrease of AFP values during the antiviral treatment is associated with reduced HCC incidence, comparative to the cases with high AFP at baseline and EOT. AFP levels < 10 ng/ml in both baseline and EOT are protective against HCC development exclusively in the SVR group.
CONCLUSION: The fluctuation of AFP levels during antiviral treatment plays an important role on HCC development. The patients with AFP > 10 ng/ml at both baseline and EOT had the highest risk to HCC, however they achieved SVR. Hence, an intensified HCC surveillance should be performed in these patients.

P0072 INFLUENCE OF HBV REACTIVATION ON THE RECURRENCE OF HEPATITIS B-RELATED HEPATOCELLULAR CARCINOMA AFTER CURATIVE RESECTION IN PATIENTS WITH LOW VIRAL LOAD

W. Sohn[1,*], Y.-H. Paik[1], J.Y. Cho[1], G.-Y. Gwak[1], M.S. Choi[1], J.H. Lee[1], K.C. Koh[1], S.W. Paik[1], B.C. Yoo[1]

Contact E-mail Address: *hand1@dreamwiz.com*

INTRODUCTION: It is unclear whether the reactivation of hepatitis B virus (HBV) influences the prognosis of hepatocellular carcinoma (HCC) after resection in patients with chronic hepatitis B. The aim of this study was to identify the effect of HBV reactivation on the recurrence of hepatitis B-related HCC after curative resection in patients with low viral load (HBV DNA <2.000 IU/mL).
AIMS & METHODS: We retrospectively analyzed a total of 130 patients who underwent curative resection for HBV-related early-stage HCC (single nodule; <5 cm / two or three nodules; <3 cm) with preoperative HBV DNA level <2.000 IU/mL and serial check-up on HBV DNA. The predictive factors including HBV reactivation for the recurrence of HBV-related HCC after curative resection were investigated. HBV reactivation was defined as the reemergence or an increase of more than 10-fold in serum HBV DNA as compared with the level before resection.
RESULTS: Fifty-three patients (41%) had HBV reactivation after resection among 130 patients. HBV reactivation was observed in 22 of 53 patients with undetectable baseline HBV DNA and in 31 of 77 patients with detectable HBV DNA. Cumulative recurrence rates after resection at 1, 2, and 3 years were 17.0%, 23.3%, and 31.4%, respectively. The multivariable analysis demonstrated that the risk factors for the recurrence were the presence of microvascular invasion (hazard ratio (HR) 2.62, $p = 0.003$), multi-nodularity (HR 4.61, $p = 0.005$), HBV reactivation after resection (HR 2.03, $p = 0.032$), and HBeAg positivity (HR 2.06, $p = 0.044$).
CONCLUSION: HBV reactivation after curative resection was associated with the recurrence of HBV-related HCC in patients with low viral load. This study suggests that aggressive viral suppression by anti-viral therapy can help to reduce the recurrence of HCC after resection in chronic hepatitis B with low viral load.

INTRODUCTION: Cancer cell prolidase enzyme activity has been reported to be important for tumor invasiveness and metastasis. As far as we know, plasma prolidase activity (PPA) has not been studied in patients with hepatocellular carcinoma (hcc).
AIMS & METHODS: We aim to assess the correlation between the PPA and AFP levels in patients with hepatocellular carcinoma. A total of 51 patients with cytopathological diagnosis of HCC in the setting of cirrhosis, 31 patients with cirrhosis without HCC and 33 cases as healthy volunteers were enrolled in this study. There were no significant differences with respect to gender and age of the study cohort with the healthy group. The patients with HCC were divided into groups according to tumor size, number and presence of vascular invasion. Barcelona-Clinic Liver Cancer (BCLC) criteria was used for staging of patients with hcc. PPA was measured spectrophotometrically. AFP level was measured with immunoassay method.
RESULTS: PPA was significantly higher in cases with HCC than cases with cirrhosis without HCC and, healthy controls (1182 U/L versus 932 U/l and 880 U/l, respectively). Patients with cirrhosis had PPA similar to those of healthy controls ($p > 0.05$). PPAs differed significantly in the group of tumor diameters less than 3 cm (n:13), compared to the group of tumor diameters between 3-5 cm (n:9) and more than 5 cm (n: 29) (($p = 0.003$) According to the tumor number, a significant difference has been seen in the group which has more than two tumors compared to the group which has one ($p = 0.001$) and two tumors ($p = 0.027$). PPA also differed in patients with regard to BCLC staging classification ($p = 0.003$). However, prolidase levels showed no statistically significant difference with presence of macrovascular invasion in patients with HCC ($p = 0.898$). There was a significant positive correlation between PPA and serum AFP values ($r = 0.731$; $p < 0.001$)
CONCLUSION: To our knowledge, this is the first study reporting increased PPA in patients with HCC, and it was found to be significantly associated with size, number and BCLC stage of the tumor. This was not seen in patients with cirrhosis without HCC. Furthermore, PPA significantly associated with serum AFP levels. However, further studies should be done to clarify clinical significance and pathophysiological role of augmented prolidase activity in cases with HCC.

INTRODUCTION: Up to 33 percent of patients with symptomatic cholelithiasis report persisting abdominal pain after cholecystectomy, suggesting alternative causes for these symptoms. Esophagogastroduodenoscopy (EGD) may serve as a tool to identify additional symptomatic abdominal disorders beforehand, in order to avoid unnecessary gallbladder surgery. There is controversy whether routine EGD prior to cholecystectomy is appropriate.
AIMS & METHODS: We performed a systematic review and meta-analysis to assess the value of EGD prior to cholecystectomy. A systematic literature search was conducted in Pubmed, Embase, Web of Science, ClinicalTrials.gov, and the Cochrane library. All studies were included that reported the proportion of patients who were referred for cholecystectomy, but in whom surgery could be avoided after treatment of abnormalities detected with EGD. Pooled estimates were calculated using a random effects model.
RESULTS: Twelve eligible studies were included with a total of 6.317 patients with cholelithiasis receiving EGD. The pooled estimate of abnormalities detected with EGD was 36.3% (95% CI, 28.0-45.0). Treatment of these findings avoided cholecystectomy in 11.0% (95% CI, 3.9-21.1) of patients. In a total of 3.8% (95% CI, 1.4-7.6) of patients referred for cholecystectomy who underwent prior EGD, gallbladder surgery was avoided.
CONCLUSION: Our study indicated that the value of prior EGD in preventing gallbladder surgery is limited. EGD should only be considered selectively in patients with cholelithiasis referred for cholecystectomy.

INTRODUCTION: Serum total bile acid (tBA) concentrations are prognostic and predictive markers for hepatic disorders. Due to the lack of data on normal value ranges of tBA in children and adolescents we aimed to determine such ranges as well as the composition of BA in this age group.
AIMS & METHODS: tBA concentration was measured in 194 healthy children and adolescents (0 - 19 years). Unconjugated and taurine or glycin conjugated BA were measured by using high performance liquid chromatography tandem mass spectrometry (HPLC MS/MS). Patients were classified in five groups according to their age: 0-5 months (n = 17), 6-24 months (n = 13), 3-5 years (n = 22), 6-11 years (n = 44), and >11 years (n = 98), respectively.
RESULTS: tBA values found in children were significantly higher compared to reference ranges in adults (0.28 – 6.50 µmol/l). Serum tBA increased constantly after delivery (0-5 months: 3.85 – 6.32 µmol/l) and reached a peak at the age of 6-24 months (6.61 – 9.43 µmol/l). Henceforward tBA decreased continuously (3-5 years: 4.27 – 6.43 µmol/l, 6-11 years: 3.61 – 5.14 µmol/l and >11 years: 3.10 – 4.12 µmol/l). In neonates levels of taurine conjugated BA were elevated; however, after 6 months glycine conjugated clearly predominated.
CONCLUSION: This study shows that serum tBA levels vary substantially in the first years of life indicating age-dependent reference ranges for tBA and the BA profile; the causes of the variations need further clarification.

P0076 EUS-GUIDED DRAINAGE WITH A LUMEN APPOSING METAL STENT IS FEASIBLE FOR THE TREATMENT FOR ACUTE CHOLECYSTITIS IN HIGH RISK PATIENTS

D. Walter[1,*], A.Y. Teoh[2], T. Itoi[3], M. Pérez-Miranda[4], A. Larghi[5], A. Sanchez-Yague[6], P.D. Siersema[1], F.P. Vleggaar[1]

INTRODUCTION: Percutaneous gallbladder drainage is the treatment of choice in high-risk surgical patients with acute cholecystitis. However, it is associated with discomfort and risk of inadvertent drain removal which may lead to bile leakage and recurrent cholecystitis. Recently, EUS-guided drainage has been introduced as an alternative treatment option.
AIMS & METHODS: Our aim was to determine the feasibility and safety of EUS-guided gallbladder drainage with a lumen apposing metal stent (AXIOS) in patients with acute cholecystitis at high risk for surgery. We performed a prospective, multicenter study. Stent removal was scheduled after 3 months and patients were followed until 9 months after removal. Study endpoints included safety, recurrent symptomatic cholecystitis, clinical and technical success.
RESULTS: Between June 2012 and Feb 2014, 30 patients were included (11 men (37%), mean age 85±7 years). Median time between onset of symptoms and stent placement was 2 days (range 1-28 days). The majority of patients (87%) presented with calculous cholecystitis. In 11 patients (37%) a transgastric approach and in 19 patients (63%) a transduodenal approach was used. Stent placement was technically successful in all patients (100%), but in 4 patients (13%) a second stent was placed due to problems with stent deployment. Clinical success was achieved in all but one patient (97%) after a median of 3 days (IQR 3-5 days). In one patient with ongoing fever for 14 days, endoscopic irrigation was successfully performed through the stent to drain large amounts of pus from the gallbladder. Stent removal was successfully performed in 12 patients (40%) after a median of 91 days (range 15-133), of which one was evaluated as being difficult due to tissue overgrowth (125 days). In 18 patients (60%) no stent removal was performed, including 2 patients (2%) with significant tissue overgrowth (105 and 150 days), 5 patients (17%) with follow-up <3 months, 5 unrelated deaths <3 months (17%), 4 patients (13%) with a poor clinical condition, 1 patient (3%) with a polypoid lesion in the gallbladder and 1 patient (3%) with lingering stones. Causes of death included urosepsis (n=1), pneumonia (n=1), myocardial infarction (n=1) and progression of pancreatic adenocarcinoma (n=2). Major complications were reported in 4 patients (13%). One patient presented with melena due to mucosal gangrene of the gallbladder for which endoscopic irrigation of the gallbladder was performed. One patient developed fever due to food contents in the gallbladder for which stent removal was performed. This patient also developed acute biliary pancreatitis 21 days later. Two patients developed symptoms of cholestasis due to common bile duct stones for which ERCP was performed. During a mean follow-up of 212 days (95% CI 149-274) none of the patients developed recurrent cholecystitis.
CONCLUSION: EUS-guided gallbladder drainage with a lumen apposing stent was found to be feasible in high-risk surgical patients with a high clinical success rate. Difficulties with stent deployment was seen in approximately 15% of patients. The overall number of major complications was low, but tissue overgrowth may complicate stent removal.

P0077 THE EFFECT OF PERIAMPULLARY DIVERTICULUM ON THE CLINICAL PRESENTATION OF CHOLEDOCHOLITHIASIS AND OUTCOME AFTER ERCP

F. Benjaminov[1,*], A. Stein[1], V. Bieber[1], T. Naftali[1], F.M. Konikoff[1]
[1]*Gastroenterology and Hepatology, Meir medical center, Kfar Saba, Israel*
Contact E-mail Address: *fabianabenjaminov@gmail.com*

INTRODUCTION: Periampullary diverticulum (PAD) is an incidental finding in up to 20% of ERCPs. Its incidence increases with age. PAD is associated with CBD stones and is considered a risk factor for obstructive jaundice, cholangitis and pancreatitis even in the nascence of CBD stones. However, the impact of PAD on the presentation and consequences in patients with CBD stones is unclear.
AIMS & METHODS: The aim of our study was to investigate the effect of PAD on the clinical presentation and course of patients with suspectedcholedocholithiasis.
All ERCPs performed in our unit from 1/2010 to 7/2013 were reviewed. Studies performed for documented or suspected choledocholithiasis were included in the study. Patients were divided into two groups. Group I- patients without PAD and group II- with PAD. The following data were recorded: Age, gender, comorbidities, indication for ERCP, previous imaging studies, liver function tests, presence of gallbladder, prior sphincterotomy, CBD diameter,ERCP success and complications, as well as the presence, size and type of PAD.
RESULTS: Three hundred and two patients met the inclusion criteria. Mean age was 66.4 ± 20.5y (range 19-98), 173 (57.3%) women. Altogether, 86 patients (28.4%) had PAD. Ninety-nine percent of ERCPs were successful. Two hundred and fifty-three patients (83.8%) had CBD stones on ERCP. Significant complications (pancreatitis, perforation, death) were recorded in 14 patients (6.5,3, respectively) (4.6%). Patients with PAD were older (73.4±16.2y Vs 63.6±21.4y) and predominantly male (53.5% Vs 38.4%), $p<0.01$. Patients with PAD presented more often with cholangitis compared to those without PAD (58.1% Vs 34.6%, $p< 0.001$). There were no differences between the two groups regarding imaging findings, laboratory tests, presence of gallbladder, comorbidities, procedural success, prior ERCP, inadvertent pancreatic duct cannulation, presence of CBD stones, number and size of CBD stones, procedure related complications and their severity, or number of ERCPs for stone clearance.
CONCLUSION: PAD is a risk factor for infectious complications ofcholedocholithiasis. However, the presence of PAD does not predispose patients to misinterpretation of imaging studies, procedural difficulty, failure or complications of ERCP.

INTRODUCTION: The gallstone is still a most prevalent medical issues in the pancreatobiliary system. Laparoscopic cholecystectomy is a treatment of choice; however, oral litholysis with bile acids has been an attractive alternative therapeutic option for asymptomatic or mild symptomatic subgroups. Ursodeoxycholic acid (UDCA) and chenodeoxycholic acid (CDCA) or both had been investigated for their effectiveness on stone dissolution. Recently, the prevalence of gallstones has increased due to the wide availability of sonographic examination and dietary habit modification. We conducted a prospective, multicenter, phase IV clinical study to evaluate the efficacy of magnesium trihydrate of UDCA and CDCA for gallstone dissolution at present.
AIMS & METHODS: The objects of this study are to evaluate the effects of CNU® on GB stone dissolution and to assess the improvement of stone associated symptoms and to find out predictive factors for gallstone dissolution.
In total 10 medical centers in Korea participated in the investigation from Jan 2011 to June 2013. Inclusion criteria were; GB stone (diameter <15mm) in sonography, GB EF ≥ 50% in DICIDA biliary scan, radiolucent on Plain X-ray and asymptomatic or mild symptomatic patients. Exclusion criteria were: age under 18 years, complicated GB stones, patients with severe co-morbidity, abnormal LFT (ALT >2x N). The treatment consisted of 1 tablet (114mg of UDCA and 114mg of CDCA) at morning and 2 tables at bedtime. Patients were followed up at 1Mo, 3Mo and 6Mo for LFT, symptom score and ultrasonography (6Mo)
RESULTS: Total 236 cases were enrolled and 196 cases (Male 87, Female 109, mean age 54.8+12.8)) were finished the study and were analyzed. Complete dissolution was achieved in 13.3% after 6 months administration of CNU. Partial dissolution (defined as reduction in volume more than 25%) was 32.1%. Overall response rate was 45.4%. Stone size and BMI are factors for predicting gallstone dissolution. Gallbladder ejection fraction is not a predictive factor for dissolution. CNU treatment showed significant symptomatic improvements regardless of stone dissolution.

CONCLUSION: Magnesium trihydrate of UDCA and CDCA (CNU) is a well tolerated and effective agent for gallstone dissolution. However, a substantial portion of gallstones are still ineffectively treated with CNU. This group may have pigment stones rather than cholesterol stones. Further study is needed to evaluate effect of longer Tx duration and recurrent rate after cessation of Tx. Development of methods for predicting chemical composition of gallstones is warrant for selecting good candidates for medical dissolution Tx.

P0079 SIZE OF RECURRENT SYMPTOMATIC COMMON BILE DUCT STONES AND FACTORS RELATED TO RECURRENCE

J.H. Chang[1,*], M. Park[1], C.W. Kim[1], S.W. Han[1]
[1]*Internal Medicine, The Catholic University of Korea, Bucheon, Korea, Republic Of*

INTRODUCTION: Common bile duct (CBD) stones can be treated successfully by endoscopic stone extraction. Unfortunately, 4% to 24% of patients have recurrent CBD stones after the initial extraction of CBD stones. Some patients even have multiple recurrences. Unfortunately, little information is available on the size and recurrence interval of recurrent symptomatic CBD stones or on ways to prevent recurrence.
AIMS & METHODS: Between January 2007 and December 2011, 481 consecutive patients undergoing endoscopic extraction of CBD stones at a single institute were enrolled. We selected 34 patients with recurrent symptomatic CBD stones and 63 patients who were followed up more than five years without recurrence. We evaluated the role of endoscopic papillary large-balloon dilation (EPLBD) ($\geq$ 10 mm) in preventing the recurrence of CBD stones while identifying risk factors related to recurrence. Furthermore, the characteristics of symptomatic recurrent CBD stones and the interval of recurrence were investigated in patients with the first, second, and third recurrences of CBD stones.
RESULTS: The sizes of the CBD stones increased during the recurrences: 10.1 $\pm$ 5.2 mm, 13.5 $\pm$ 7.3 mm, and 16.8 $\pm$ 7.8 mm at the initial presentation, the first recurrence, and the second recurrence, respectively ($P = 0.016$). Among CBD stone recurrences, 50% occurred within 2.3 years, and 80% occurred within 5.3 years. The recurrence group had a smaller proportion of patients under 50 years of age, larger CBD diameters, fewer histories of more than 10 mm EPLBD, and more type I periampullary diverticula, compared with the non-recurrence group ($P < 0.05$). Multivariate analysis revealed that EPLBD more than 10 mm and smaller CBD diameter were independently related to less recurrence of CBD stones ($P = 0.001$ and 0.012, respectively).
Table. Multivariate analysis of the factors related to the recurrence of common bile duct stones

Factors	OR (95% CI)	P value
Endoscopic papillary large-balloon dilation ($\geq$ 10 mm)	0.161 (0.055 – 0.473)	0.001
CBD diameter	1.126 (1.027 – 1.235)	0.012
Type I periampullary diverticulum	3.322 (0.608 – 18.17)	0.166
Age ($<$ 50)	0.314 (0.073 – 1.360)	0.122

CONCLUSION: The sizes of CBD stones increased during recurrences. EPLBD more than 10 mm and smaller CBD diameter were related to less recurrence of CBD stones.

P0080 A COMPARATIVE STUDY BETWEEN PTGBD AND ETGD AS A BRIDGE TO SURGERY IN PATIENTS WITH ACUTE CHOLECYSTITIS AND A SUSPICION OF CBD STONE

J.H. Kim[1,*], M.J. Yang[1], B.M. Yoo[1]
[1]*Gastroenterology, Ajou Unversity School of Medicine, Suwon, Korea, Republic Of*

INTRODUCTION: To compare the technical feasibility, clinical and surgical outcomes between a single-step approach of endoscopic removal of CBD stones with endoscopic transpapillary gallbladder drainage (ETGD group) and a two-step approach of endoscopic removal of CBD stones and percutaneous transhepatic gallbladder drainage (PTGBD group) as a bridge treatment before cholecystectomy, in patients with acute cholecystitis and a high suspicion of common bile duct (CBD) stones.
AIMS & METHODS: From March 2006 to May 2013, a total of 79 patients were enrolled in this study retrospectively. The PTGBD group (n = 39) was compared with the ETGD group (n = 40, ENGBD: 22, ERGBD: 18) in terms of technical and clinical success rates, adverse events, and surgical outcomes of surgery time and rate of conversion to open surgery in the non-inferiority analysis.
RESULTS: PTGBD and ETGD groups had similar outcomes in terms of technical success rate (97.4% 38/39 vs 92.5% 37/40; 95% 1-sided confidence interval (CI) lower limit, -14.6%; $p = 0.028$ for noninferior margin of 15%) and clinical success rate (94.7% 36/38 vs 91.9% 34/37; 95% 1-sided CI lower limit, -12.9%; $p = 0.045$ for noninferior margin of 15%). The two groups did not differ significantly in the rates of adverse events (5.1% 2/39 vs 7.5% 3/40; $p = 1.000$), surgery time (59.3 vs 55.7 min; $p = 0.361$), rates of conversion to open cholecystectomy (5.2% 2/38 vs 0% 0/37; $p = 0.135$). There was no significant differences in the technical, clinical, and surgical outcomes between ENGBD and ERGBD groups respectively.
CONCLUSION: In patients with acute cholecystitis and a high suspicion of CBD stones, the single-step approach through ERCP and simultaneous ETGD could be an effective alternative treatment modality to the two-step approach through PTGBD followed by ERCP.

P0081 VISCERAL ABDOMINAL FAT MEASURED BY CT SCAN IS ASSOCIATED WITH AN INCREASED RISK OF SYMPTOMATIC GALLSTONE DISEASE

K. Sekine[1,*], N. Nagata[1], K. Watanabe[1], S. Mikami[1], Y. Nozaki[1], T. Sakurai[1], C. Yokoi[1], Y. Kojima[1], M. Kobayakawa[1], J. Akiyama[1], M. Yanase[1]
[1]*National Center for Global Health and Medicine, Tokyo, Japan*
Contact E-mail Address: *hawaiiantuberider@gmail.com*

INTRODUCTION: Previous studies have shown that obesity measured as BMI is a causal risk of gallstone disease. Visceral fat promotes systemic inflammation by secreting adipokines and inflammatory cytokines.
AIMS & METHODS: This study aims to investigate whether visceral fat measured by computed tomography (CT) is a risk factor for symptomatic gallstone disease (cholangitis or cholecystitis). A total of 582 participants (451 without gallstone and 131 symptomatic gallstone disease) who underwent CT and abdominal ultrasonography were analyzed. The associations between body mass index (BMI), visceral adipose tissue (VAT) area, subcutaneous adipose tissue (SAT) area, and symptomatic gallstone disease were estimated using odds ratios (ORs) and 95% confidence intervals (CIs) adjusted for age, sex, dyslipidemia, and diabetes mellitus.
RESULTS: In multivariate analysis, symptomatic gallstone disease was significantly associated with VAT area and SAT area (P for trend <0.001, and 0.045, respectively), but not BMI (P for trend 0.40). When the obesity indices were considered simultaneously, symptomatic gallstone disease remained significantly associated with VAT area for both categorical data and trend (P for trend 0.003), but not BMI (P for trend 0.536). The adjusted ORs for the highest quartile of the VAT area in gallstone disease were 3.2, compared with the lowest quartile.
CONCLUSION: Abdominal visceral tissue measured by CT, rather than BMI, is a better predictor for risk of symptomatic gallstone disease.

P0082 POSITIVE PREDICTIVE VALUE OF ENDOSCOPIC ULTRASOUND (EUS) FOR THE DETECTION OF INTRALUMINAL FILLING DEFECTS IN THE COMMON BILE DUCT (CBD) IN A LARGE NON-ACADEMIC TEACHING HOSPITAL

L.Van Driel[1,*], R. Quispel[1], B. Veldt[1], M. Bruno[2]
[1]*Reinier de graaf hospital, Delft,* [2]*Erasmus medical centre, Rotterdam, Netherlands*
Contact E-mail Address: *L.vandriel@rdgg.nl*

INTRODUCTION: In small academic studies, endoscopic ultrasound has been shown a reliable and safe method to assess the presence of common bile duct stones.
AIMS & METHODS: The aim of this study was to calculate the positive predictive value (PPV) for the presence of CBD stones with EUS. For this we retrospectively included all patients in whom CBD stones were detected with EUS and who subsequently underwent endoscopic retrograde cholangiography (ERC). This study was performed in a large non-academic teaching hospital in The Netherlands between November 2006 and January 2011. PPV was calculated by dividing the number of true positives by the total number.
RESULTS: EUS detected CBD stones in 99 patients who subsequently underwent ERC. The median time-interval between EUS and ERC was 5 days (interquartile range 1-15 days). The PPV for the total group was only 56% (57/99). However, the PPV depended on the time-interval between EUS and ERC, being: 80% (8/10) within 24 hours, 63% (32/51) within 1-6 days, and 47% (18/38) after one week. Moreover, the PPV differed substantially depending on the type and number of intraluminal filling defects in the CBD, namely sludge (10/21, PPV 48%), or one stone (29/51, PPV 58%), or more than one stone (18/24, PPV 75%), or more than one stone with acoustic shadow (8/10, PPV 80%).
CONCLUSION: EUS performed in a large non-academic teaching hospital has a lower PPV for detection of CBD stones than overall reported in literature. This seems to be explained at least in part by the large variation in time-intervals between EUS and ERC indicating that ERCP should promptly follow a positive EUS and may be delayed a few days after the onset of symptoms to allow for spontaneous stone passage. Sludge in the CBD as finding on EUS has the lowest PPV when compared with stones with or without an acoustic shadow.

P0083 WHICH IS A BETTER PROCEDURE: SINGLE SESSION VERSUS MULTIPLE SESSIONS OF ERCP FOR COMMON BILE DUCT STONES WITH OR WITHOUT ACUTE CHOLANGITIS?

R. Maeshima[1,*], M. Asano[1], H. Kobashi[1], H. Himei[1], S. Inoo[1], M. Omori[1], S. Ando[1], E. Yoshimura[1], M. Shigetoshi[1], J. Toshimori[1], M. Inoue[1], M. Yokoyama[1]
[1]*Gastroenterology and hepatology, Japanese Red Cross Okayama Hospital, Okayama city, Japan*

INTRODUCTION: Tokyo guidelines (TG13) for management of acute cholangitis (AC) and acute cholecystitis were revised and published in 2013. TG13 recommend the elective, early or urgent biliary drainage using endoscopic retrograde cholangiopancreatography (ERCP), followed by treatment of etiology such as common bile duct (CBD) stones after the resolution of AC. However,

the usefulness of completion of endoscopic clearance of CBD stones with biliary drainage in a single session, remains unclear.
AIMS & METHODS: The aim of this study is to clarify which of these, a single session or multiple sessions of ERCP, is better for the patients with CBD stones with and without AC. This is a retrospective study. Between August 2012 and March 2014, a total of 411 ERCPs were performed in 252 patients with biliary and pancreatic diseases in our hospital. The patients with CBD stones with or without AC treated with ERCP-related procedure were eligible for the study. The patients with recurrent disease were excluded. Finally 116 consecutive patients (56 males and 60 females) were included in the study. They were divided into two groups; Group A for the patients in a single session of ERCP, and Group B for those in multiple sessions of ERCP. Groups A and B were compared with each other for the clinical outcomes, namely total duration of hospitalization (DH) and frequency of adverse events. The grade of AC, Grade I (mild), Grade II (moderate) and Grade III (severe), were also taken into account. Wilcoxon/Kruskal-Wallis test and Kaplan-Meier analysis were used as statistics. This study was approved by the local committee of ethics.
RESULTS: Group A and Group B was consisted of 84 and 32 patients, respectively. Mean age was 72.4 in Group A and 78.8 in Group B. The sphincterotomy and the maneuver using retrieval basket or balloon were performed more frequently in Group A ($p < 0.001$). In total, 74 patients were complicated with AC; grade I in 44, grade II in 17 and grade III in 13, and 42 patients were without AC. In Group A, grade I in 35, grade II in 10 and Grade III in 5, and without AC in 34 patients, respectively. In Group B, grade I in 9, grade II in 7 and grade III in 8, and without AC in 8 patients, respectively. The mean DH was 12.7 days in total. It was significantly shorter in Group A (9.9 days), as compared with Group B (20.1 days) ($p < 0.001$). In total, DH was incrementally longer according to the degree of AC grade ($p < 0.0001$); it was significantly longer (32.0 days) in grade III, as compared with Grade I (11.3 days), grade II (15.6 days) and without AC (7.0 days). In the patients with AC grade III, DH was significantly shorter in Group A (18.0 days) as compared with Group B (40.75 days) ($p = 0.0437$). Also in the patients without AC, DH was significantly shorter in Group A (6.4 days) as compared with Group B (9.9 days) ($p = 0.033$). As for adverse events, post ERCP pancreatitis was occurred in 4 patients in Group A and in 1 patient in Group B, and there was no significant difference between both groups ($p = 0.69$).
CONCLUSION: A single session of ERCP for completion of clearance of CBD stones with biliary drainage is superior to multiple sessions of ERCP, especially for the patients complicated with AC grade III and those without AC.

INTRODUCTION: The main component in the pathogenesis of acute pancreatitis is the transition from local to the system inflammation that causes the severity of disease. Changes of microcirculation and endothelial dysfunction are an important step from mild to severe disease.
AIMS & METHODS: The study involved 53 acute pancreatitis patients (28 - severe, 25 - mild). We measured interleukin-6, interleukin-18, ICAM-1 and E-selectin in the blood plasma. Flow in the visceral arteries was assessed with the help of the Doppler sonography.
RESULTS: A significant increase of both pro-inflammatory cytokines and adhesion molecules was determined only in severe acute pancreatitis. We determined that the level of IL-6 significantly correlated with the appearance of liver dysfunction. There was a significant correlation between the concentration of IL-18, ICAM-1, E-selectin and the appearance of multiple organ dysfunction syndrome. There was a significant direct correlation concentrations of IL-6 with peak systolic velocity in the superior mesenteric artery ($R = 0.502941$, $p = 0.047063$), with an index of resistance in common hepatic ($R = 0.532845$, $p = 0.033574$), splenic ($R = 0.511125$, $p = 0.043028$) and superior mesenteric ($R = 0.563200$, $p = 0.023107$) arteries. The level of IL-18 was significantly correlated with peak systolic velocity in the common hepatic artery ($R = 0.589102$, $p = 0.016342$), splenic artery ($R = 0.547865$, $p = 0.028022$) and superior mesenteric artery ($R = 0.504783$, $p = 0.046131$), as well as the resistance index in the common hepatic artery ($R = 0.524375$, $p = 0.037051$) and superior mesenteric artery ($R = 0.573230$, $p = 0.020271$). The level of ICAM-1 was significantly correlated with changes in blood flow in the visceral vessels, in particular, peak systolic velocity in the common hepatic artery ($R = 0.802061$, $p = 0.000186$), splenic ($R = 0.764581$, $p = 0.000,562$) and the superior mesenteric artery ($R = 0.768212$, $p = 0.000509$), as well as the resistance index ($R = 0.527422$, $p = 0.035770$; $R = 0.608824$, $p = 0.012315$; $R = 0.736152$, $p = 0.001148$, respectively) in them. The level of soluble E-selectin may also affect splanchnic flow in patients with acute pancreatitis, defined as a significant direct correlation between the concentration dependence of E-selectin and peak systolic velocity of blood flow in the common hepatic ($R = 0.838249$, $p = 0.000095$) and splenic ($R = 0.689902$, $p = 0.004424$) arteries and resistance index in the common hepatic ($R = 0.710321$, $p = 0.003002$) and superior mesenteric ($R = 0.759862$, $p = 0.001012$) arteries.
CONCLUSION: It was determined that the levels of proinflammatory cytokines and adhesion molecules increase in the blood of acute pancreatitis patients. Their level correlates with the organ dysfunction and disturbances in splanchnic blood flow.

INTRODUCTION: It is unclear whether there is consensus regarding the timing of intervention in patients with infected necrotizing pancreatitis (INP).
AIMS & METHODS: We evaluated the current expert opinion regarding timing of intervention in INP. An anonymous digital survey was sent to 118 expert pancreatologists (surgeons, gastroenterologists, radiologists) from all continents. The survey consisted of 18 questions and 10 clinical cases including CECT images of varying disease stages. Diagnostic and therapeutic options included fine needle aspiration (FNA), antibiotics, (percutaneous or endoscopic) catheter drainage and necrosectomy.
RESULTS: Response rate was 74% ($N = 87$). The step-up approach, initial catheter drainage if needed followed by necrosectomy, was accepted by most experts (87%). Consensus was lacking regarding the use of FNA to diagnose INP: 0% used FNA routinely, 40% only in case of clinical suspicion, 45% rarely and 15% never. After definitively diagnosing INP, 55% would postpone an intervention and await the effect of antibiotics, whereas 45% would immediately perform an intervention. Walled-off necrosis was not considered a technical prerequisite for percutaneous catheter drainage by 88% of experts whereas 66% considered it essential for endoscopic transluminal drainage. More experts would intervene in case of proven INP (gas in the (peri)pancreatic necrotic collection on CECT) vs. clinical signs of INP: i.e. day 7: 34% vs 2%, day 14: 57% vs 25%, day 30: 89% vs 72%.
CONCLUSION: Although the step-up approach is well accepted as routine management strategy of INP, consensus regarding the timing of initiating this approach is lacking. Proof of infection and disease duration influence the timing of intervention. This study highlights the need for a randomized trial on timing of intervention in INP.

P0086 PREDICTION OF POST-ERCP PANCREATITIS BY 4-HOUR POST-ERCP SERUM AMYLASE AND LIPASE LEVEL

J.H. Kim[1,*], M.J. Yang[1]
[1]*Gastroenterology, Ajou Unversity School of Medicine, Suwon, Korea, Republic Of*

INTRODUCTION: Acute pancreatitis is the most common and serious complication of endoscopic retrograde cholangiopancreatography (ERCP). Early prediction of possible post-ERCP pancreatitis (PEP) could allow for an earlier safe discharge of a patient on the same day after ERCP.
AIMS & METHODS: The aim of this study was to investigate a predictive cut-off value of 4-hour post-ERCP serum amylase and lipase levels for the PEP. In patients who underwent ERCP procedures and had tests for serum amylase and lipase levels of 4-hour post-ERCP and the next morning at Ajou Medical Center from January 2012 to August 2013, patient demographics, the procedure reasons, performance of pancreatograms, serum amylase and lipase levels were retrospectively evaluated.
RESULTS: PEP occurred in 16 (3.1%) after 516 ERCP procedures. Its severity was mild in 4 (25%), moderate in 9 (56.3%), and severe in 3 (18.8%). The mean 4-hour amylase level was significantly higher in patients with PEP, compared with those without PEP (965 U/L vs. 158 U/L, $p = 0.001$). There were no statistically significant differences in age, gender, and the procedure reasons between both groups. The sensitivity, specificity and negative predictive value (NPV) of a 4-hour post-ERCP amylase level with a cut-off value of 2.5 times of its normal upper limit (290 U/L) was 75.0%, 88.0% and 99.1%, respectively. The sensitivity, specificity and negative predictive value (NPV) of a 4-hour post-ERCP lipase level with a cut-off value of 8 times of its normal upper limit (480 U/L) was 75.0%, 91.3% and 99.1%, respectively. The patient group undergoing pancreatogram revealed high incidence of post-ERCP pancreatitis, but no significant difference in the 4-hour post-ERCP serum amylase and lipase level, compared to its counterpart group.
CONCLUSION: The 4-hour post-ERCP serum amylase level and lipase level with cut-off value of 2.5 times and 8 times of their normal upper limit have so far proven to be useful predictive values for an earlier safe discharge of a patient on the same day after ERCP.
Disclosure of Interest: None declared

P0088 PREDICTING SUCCESS OF CATHETER DRAINAGE IN INFECTED NECROTIZING PANCREATITIS

R.A. Hollemans[1,*], T.L. Bollen[2], S.van Bruschot[3], U. Ahmed Ali[4], O.J. Bakker[4], H.van Goor[5], M.A. Boermeester[6], H.G. Gooszen[7], M.G. H. Besselink[6], H.C. van Santvoort[4] on behalf of Dutch Pancreatitis Study Group

INTRODUCTION: Catheter drainage as the first treatment step of infected necrotizing pancreatitis is successful in at least 30% of patients. It is currently not possible to predict which patients will also need necrosectomy. We evaluated predictive factors for success of catheter drainage in infected necrotizing pancreatitis.
AIMS & METHODS: We performed a post-hoc analysis of 130 prospectively included patients who underwent primary catheter drainage for (suspected) infected necrotizing pancreatitis. Using logistic regression we evaluated the association between success of catheter drainage (i.e. survival without necrosectomy) and 22 factors regarding demographics, disease severity (e.g. CRP, APACHE-II score and organ failure), morphologic characteristics on CT (e.g. percentage and distribution of necrosis and CTSI) and drainage criteria (e.g. timing of drainage and type of drain).
RESULTS: Drainage was performed percutaneously in 113 patients and endoscopically in 17 patients. Infection was confirmed in 116 patients (89%). Catheter drainage was successful in 45 patients (35%). In multivariable regression, the following variables were associated with success of drainage: female gender (odds ratio[OR] 4.84; 95% > confidence interval[CI] 1.89-12.4; $p = 0.001$), absence of multi-organ failure (OR 6.19; 95% > CI 1.50-25.53; $p = 0.012$), percentage of pancreatic necrosis (< 30%/30-50%/ > 50%: OR 2.29; 95% > CI 1.21-4.36; $p = 0.011$), primarily left-sided pancreatic necrosis (OR 13.35; 95% > CI 1-174; $p = 0.048$) and homogeneity of the collection (OR 5.23; 95% > CI 1.60-17.05; $p = 0.006$). A prognostic nomogram including these factors yielded probability of success ranging from 99% (all factors present) to 1% (none of the factors present).
CONCLUSION: Female gender, absence of multi-organ failure, low percentage of necrosis, left-sided pancreatic necrosis and a homogeneity of the collection are independent predictors for success of catheter drainage in infected necrotizing pancreatitis. The constructed nomogram can easily predict success in clinical practice.

P0089 FUNGAL INFECTION IN PATIENTS WITH WALLED-OFF PANCREATIC NECROSIS IS ASSOCIATED WITH A POOR PROGNOSIS

S. Roug[1,2,*], M. Werge[1], S. Novovic[1], P.N. Schmidt [1], E. Feldager[1], B. Søndergaard[1], J.D. Knudsen[3]

INTRODUCTION: Patients with necrotizing pancreatitis and infected necrosis have a worse prognosis than patients with sterile necroses. While there is clear evidence that bacterial infection in pancreatic necrosis increases mortality and morbidity, studies on the influence of fungal infections have been conflicting.
AIMS & METHODS: To evaluate the impact of fungal infections in patients with walled-off pancreatic necrosis (WON) treated by endoscopic, transmural drainage and necrosectomy (ETDN). In addition, to evaluate the effect of antifungal treatment.
We retrospectively retrieved medical charts of 123 patients who underwent ETDN for WON in our department between November 2005 and December 2013.
RESULTS: Fifty-seven out of the 123 patients (46%) had fungus in their necrosis. The median time from the symptom debut to the first fungal finding was 61 days (range 8-195). In 20 patients (35%) the first fungal finding was at the index endoscopy, in 24 patients (42%) it was at the second endoscopy, and in 9 patients (16%) at the third endoscopy. The prevailing fungal finding at both the index and secondary endoscopy was Candida albicans (55% and 56%, respectively).
Ten of the 57 patients (18%) with fungal infection died during admission, and 18 (32%) developed organ failure. The mortality in patients infected with bacterial infection, only, was 6.5% ($p = 0.046$). Concomitant fungemia was found in 6 patients. Three patients with concomitant fungemia died, as opposed to seven with fungi in the necrosis, only (50% vs. 14%, respectively $p = 0.027$).
Thirty-nine of the 57 patients (70%) were treated with antifungals. There was no significant difference in mortality or occurrence of organ failure between this group and the group that was not treated with antifungals.
Culturing from the necrosis was repeated in 35 out of 57 patients (61%), of which 17 patients were positive for fungus. The same fungal species on both the first and the second culture was found in 15 out of the 17 patients (88%) despite adequate antifungal treatment based on the susceptibility pattern.
CONCLUSION: Fungal infection in WON, especially with concomitant fungemia, is associated with a poor prognosis. Whether the outcome may be explained by the fungal infection per se or it is merely a consequence of a prolonged disease course is, however, at present unknown. Only about one-third of all cases with fungal infection in necrosis were found at the index endoscopy, which is why continuous culturing should be mandatory throughout the disease course

INTRODUCTION: Early in the course of acute pancreatitis (AP) management revolves primarily around supportive care and fluid resuscitation remains the cornerstone. Inflammatory cytokines play a crucial role in extravascular fluid sequestration. Recent evidence shows the superiority of Ringer lactacte (RL) over normal saline (NS) as the fluid of resuscitation patients with AP.
AIMS & METHODS: To study the effect of two different types of resuscitation fluids viz. normal saline (NS) and Ringers lactate (RL) on inflammatory markers IL-6 and IL-10 and on the clinical course and outcome of patients with acute pancreatitis (AP).
Consecutive adult patients with AP who presented within 5 days of onset of symptoms between July 2012 and June 2013 were randomized to receive NS or RL. The patients were classified as having mild, moderate or severe AP and managed in a high dependency unit as per a uniform protocol. Intravenous fluid was infused initially as 20ml/kg bolus till a base line CVP of 8 cm of water and a urine output of > 0.5ml/kg/hr. was established. Further fluids were infused to maintain urine output as mentioned above. Serum samples were obtained at admission days 0, 3 and 7. IL-6 and IL-10 were estimated on the cryo-preserved serum samples using a Diaclone ELISA kit. Patients were monitored for the development of organ failure, sepsis, local complications, duration of hospital stay and final outcome till 28 days of admission. Data was recorded using Microsoft excel and analyzed using SPSS software v17.0.
RESULTS: 50 patients of AP with a mean age of 45.82±16.46 years (56% males) were included. NS and RL groups included 25 patients each who were well matched for age and sex. There was no significant difference in the severity of AP between the 2 groups ($p = 0.77$). IL-6 levels on day 0, day 3 and day 7 were significantly elevated in patients with severe AP (SAP) compared to those without severe disease [183.66±43.92, 178.20±36.28, 143.85±47.21 pg/ml vs 145.90±60.93, 119.99±58.86, 86.44±38.50 pg/ml ($p < 0.05$)] and remained persistently elevated at the end of first week in SAP group. No such correlation was seen with IL-10 level ($p > 0.05$). The cumulative fluid infused over first 7 days of admission was not statistically significant between the 2 groups (13.56±4.93 liters vs. 13.99±4.58 liters, $p > 0.05$). There was no statistically significant difference in the serum IL-6 levels noted between the NS and RL groups but among patients with severe disease ($n = 29$), those who received RL had significantly lower serum IL-6 levels at the end of first week than those in RL group; $p = 0.043$. Patients receiving NS had significantly longer duration of hospitalisation (22±12.45 days versus 14±7.17 days; ($p = 0.015$), higher incidence of infective complication ($p = 0.037$) and a higher need for intervention ($p = 0.050$). Patients receiving RL were found to show a greater magnitude of reduction in their organ failure score on day 3 and 7 in comparison to those receiving NS ($p = 0.012$ and 0.001).
CONCLUSION: There was no significant reduction in cytokine levels among patients resuscitated with RL or NS. However, patients receiving RL had an early organ failure resolution, fewer infections and shorter hospital stay, making RL the preferred fluid for resuscitation.

INTRODUCTION: Pancreatic ductal adenocarcinoma (PDAC) represents one of the deadliest malignancies with an overall life expectancy of six months despite current therapies. NF-kB signalling has been shown to be critical for this profound cell-autonomous resistance against chemotherapeutic drugs and death-receptor induced apoptosis, but little is known about the role of the c-Rel subunit in solid cancer and PDAC apoptosis control.
AIMS & METHODS: In the present study, by analysis of genome-wide patterns of NF-kB dependent gene expression we investigated the role of c-Rel in apoptosis resistance of PDAC.
RESULTS: TRAIL resistant Panc1 and Patu8988 cells exhibited a strong TRAIL inducible NF-kB activity, whereas TRAIL sensitive MiaPaca2 cells displayed only a small increase in NF-kB binding activity. Transfection with siRNA against c-Rel sensitized the TRAIL resistant cells in a comparable fashion to siRNA targeting the p65/RelA subunit. Gel shift analysis revealed that c-Rel is part of the TRAIL inducible NF-kB complex in PDAC. Array analysis identified NFATc2 as a c-Rel target gene amongst the 12 strongest TRAIL inducible genes in apoptosis resistant Panc1 cells. By database search and chromatin immunoprecipitation we were able to funcionally characterize one regulatory element for c-Rel in the NFATc2 promoter. In line, siRNA targeting c-Rel strongly reduced TRAIL induced NFATc2 activity in TRAIL resistant PDAC cells. Furthermore, siRNA targeting NFATc2 sensitized these PDAC cells against TRAIL induced apoptosis. Finally, TRAIL induced expression of COX-2 was diminished

through siRNA targeting c-Rel or NFATc2 and pharmacological inhibition of COX-2 with celecoxib enhanced TRAIL apoptosis.
CONCLUSION: In conclusion, we were able to delineate a novel c-Rel, NFATc2 and COX-2 dependent anti-apoptotic signalling pathway in PDAC with broad clinical implications for pharmaceutical intervention strategies.

INTRODUCTION: The pathogenesis of pancreatic ductal adenocarcinoma involves the multi-stage development of molecular aberrations affecting signaling pathways that regulate cancer growth and progression. Tissue microarray analysis of pancreatic tumors allows simultaneous assessment of genetic disorders, which can lead to identification of biomarkers of poor prognosis.
AIMS & METHODS: To characterize the gene expression of pancreatic adenocarcinoma compared to normal tissue from the same patient. We investigated sixteen samples of T3 pancreatic adenocarcinoma obtained intraoperatively and compared them to normal pancreatic tissue from the same patients. RNA was extracted and assessed qualitatively and quantitatively, followed by amplification of cDNA using reverse transcriptase, cRNA synthesis, and hybridization of microarray slides. For each sample 1000 ng of total RNA was available. The overexpressed and underexpressed genes were classified by their known function in the cell. We selected genes over- or underexpressed three times compared to normal adjacent tissue some described previously in pancreatic pathology, and used RT-PCR for validation.
RESULTS: On microarray tissue analysis 41 genes were overexpressed and 402 were underexpressed in the pancreatic adenocarcinoma samples. There were selected genes involved in transcription process as ZNF 428, MIXL1, SEPT 1, genes involved in intracellular signaling as FLJ21865, AGRP and genes involved in transmembranar and intracellular transport as CCDC88, UTP14A,VPS11, LLRC21,CHRM3, Marveld3. Validation by qRT-PCR confirmed the involvement of AGRP and MIXL1 gene in pancreatic adenocarcinoma tissue.
CONCLUSION: Microarray tissue analysis of pancreatic adenocarcinoma showed more underexpressed than overexpressed genes. After validation, the overexpressed gene AGRP was shown to be one possible factor responsible for anorexia and perineural invasion. The possible role in pancreatic cancer of MIXL1, known to play a role in cellular proliferation and differentiation, should be further clarified.

INTRODUCTION: Cholecystokinin-B (CCK-B) receptor is often overexpressed in pancreatic ductal adenocarcionoma (PDAC); stimulation of the receptor promotes tumor growth. An intronic mutation (c.811+37C>A) in the *CCKBR* gene causes retention of intron-4, resulting in a new spliceform, which was previously shown to correlate with higher PDAC risk and a more aggressive phenotype.
AIMS & METHODS: Our aim was to test the effect of the c.811+37C>A mutation on PDAC risk and prognosis in a Hungarian population. 122 subjects with PDAC (cases) and 106 subjects with no pancreatic disease (controls) were recruited from the Hungarian National Pancreas Registry. Genomic DNA was isolated from peripheral blood. Intron-4 of the CCKBR gene, including exon-intron boundaries, was amplified and sequenced.
RESULTS: We found the c.811+37C>A intronic mutation in 35 heterozygous and 5 homozygous cases and in 32 heterozygous and 3 homozygous controls (allele frequency 18.4% and 17.9% respectively). One case subject carried a p. R319Q and one control subject a p. R319W missense mutation. Survival analysis showed no significant difference in median survival between wild type cases and carriers for the mutation (8.7 months and 6.9 months respectively)
CONCLUSION: In our cohort, the c.811+37C>A intronic mutation was not associated with increased risk for PDAC. Also, the mutation was not associated with shorter survival, indicating that this genetic variant is not a clinically relevant prognostic factor. Supported by TÁMOP and OTKA.

INTRODUCTION: Pancreatic cancer (PCa) is characterized by prominent intrapancreatic neuropathy and neuropathic pain. Up to now, the impact of glia cells on the development of the pancreatic neuropathy has not yet been investigated.
AIMS & METHODS: We studied whether there is an activation of peripheral glia cells (Schwann cells, SC) in PCa and what signalling pathways might be responsible for intrapancreatic glial activation. SC were cultured under hypoxia, in pancreatic cancer cell (PCC) supernatants or co-coltured with PCC and T-lymphocytes and investigated via immunoblotting, MTT viability assay, Multiplex-Luminex-ELISA® and cell area measurement. Nerves in PCa and normal pancreas (NP) were analysed for their immunoreactivity for glial fibrillary acidic protein (GFAP), hypoxia inducible factor 1 alpha (HIF-1α) and carboanhydrase IX (CA-IX). The SC distribution and frequency in conditional PCa knock-out mice was assessed after in-vivo blockade of the IL-6 signalling pathway.
RESULTS: Hypoxia leads to upregulation of the intermediate filaments GFAP, Nestin and Vimentin and pro-inflammatory cytokines in SC. The nerves in PCa were immunoreactive for HIF-1α and CA-IX, and the extent of neuro-immunoreactivity for HIF-1α and CA-IX correlated to the intraneural GFAP amount. PCC supernatants led to upregulation of GFAP and Nestin in SC, cellular hypertrophy (stellation) and higher proliferation rate. The serverity of pancreatic neuritis correlated with the intraneural GFAP amount. The blockade of IL-6, but not of IL-1β in PCC supernatants abolished the upregulation of GFAP and Nestin. GFAP/SOX10 double positive SC were found around pancreatic intraepithelial neoplasia (PanIN) of Ptf1a-Cre;$Kras^{G12D}$, but not around PanINs of Ptf1a-Cre;$Kras^{G12D}$;$IL6^{-/-}$ mice. The blockade of IL-6 *trans*signalling in Ptf1a-Cre;$Kras^{G12D}$;$sgp130^{tg}$ mice had no influence on the SC distribution around PanINs.
CONCLUSION: SC in PCa show typical features of reative gliosis, which is induced via the classical IL-6 signalling.

INTRODUCTION: The diagnostic efficiency of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) cytology varies largely depending on the processing methods of specimens.
AIMS & METHODS: The present study aimed to evaluate the diagnostic efficiency of cell block (CB) with methods of immunostaining, smear cytology (SC) and liquid-based cytology (LBC) without on-site cytopathologist in patients with pancreatic lesions. 72 patients with pancreatic lesions were prospectively enrolled in this study. After EUS-FNA, specimens were determined by SC, LBC and CB with immunostaining, respectively. Diagnostic efficiency of SC was compared with that of LBC and CB. The final diagnosis was confirmed by surgically resected specimens, diagnostic imaging and clinical follow-up.
RESULTS: 60 malignant and 12 benign pancreatic lesions were determined. The diagnostic sensitivity, negative predictive value and accuracy (90.0%, 66.7% and 91.7%) of CB with immunostaining were significantly higher than those of SC (70.0%, 30.0% and 75.0%, $P < 0.05$), LBC (73.3%, 31.6% and 77.8%, $P < 0.05$). The combination of CB and SC, or CB and LBC did not significantly increase the efficiency compared to CB with immunostaining alone ($P > 0.05$). Table: Diagnostic efficiency of SC, LBC and CB methods in pancreatic lesions

	SC	LBC	CB	SC+CB	LBC+CB
Sensitivity,% (n)	70.0 (42/60)	73.3 (44/60)	90.0 (54/60)*	91.7 (55/60)	93.3 (56/60)
Spcificity, % (n)	100 (12/12)	100 (12/12)	100 (12/12)	100 (12/12)	100 (12/12)
PPV, % (n)	100 (42/42)	100 (44/44)	100 (54/54)	100 (55/55)	100 (56/56)
NPV, % (n)	30.0 (12/40)	31.6 (12/38)	66.7 (66/72)*	70.6 (12/17)	75.0 (12/16)
Accuracy, % (n)	75.0 (54/72)	77.8 (56/72)	91.7 (66/72)*	93.1 (67/72)	94.4 (68/72)

CONCLUSION: The CB with immunostaining technique presents a higher diagnostic efficiency than both of SC and LBC without on-site cytopathologist in patients with pancreatic lesions who had undergone EUS-FNA.

Contact E-mail Address: *mdsophie@gmail.com*

INTRODUCTION: Pancreatic ductal adenocarcinoma (PDAC) shows dismal prognosis due to early metastasis, frequent recurrence and chemo-resistance. However, there is no effective treatment to overcome these problems. GV1001 is a telomerase-based cancer vaccine made of a 16-mer TERT peptide and human telomerase reverse transcriptase (hTERT), the rate-limiting subunit of the telomerase complex, is therefore an attractive target for cancer vaccination.
AIMS & METHODS: AIMS: The aim of this study was to evaluate the combination benefit of telomerase peptide vaccination, GV1001 combined with Gemcitabine in PDAC.
METHODS: Human PDAC cell lines (Panc-1 and AsPC-1) and PDAC stem cells (CD133+) were used in in vitro experiments. Also, a PDAC xenograft mice model was established using PDAC cell lines (Panc-1 and AsPC-1) and PDAC stem cells (CD133+). Treatment groups were divided as follows; control, Gemcitabine alone, GV 1001 alone and Gemcitabine and GV 1001 combination. The changes of weight and tumor size were evaluated in regular intervals before and after the treatment. The inflammatory cytokines (IL-6, TNF-α, INF-γ), leptin and ghrelin were measured from the serum of xenograft PDAC mice model.
RESULTS: ***In vitro experiments:*** GV1001 alone did not affect the proliferation of PDAC cells.
Almost 100% of the population of each PDAC cell line was positive for Epithelial Specific Antigen (ESA, Epithelial Cellular Adhesion Molecule). The positive results in PDAC cells ranged from as few as 0.5% to as many as 3% for ESA+CD133+ cells.
In vivo experiments: Mean tumor volume and size were decreased in treatment of Gemcitabine only group and Gemcitabine with GV 1001 group, and there were no significant differences between the two groups. However, Gemcitabine only or Gemcitabine with GV 1001 treatment groups had significantly small tumor size and volume compared to control group ($P < 0.001$). Interestingly, there was significant difference in mean body weight between the groups with Gemcitabine only vs. Gemcitabine with GV 1001 combination groups. Mice of Gemcitabine with GV 1001 treatment group did not have significant weight loss compared to Gemcitabine only group although they have decreased tumor size and volume. There was no mortality of mice until the end of the treatment.
CONCLUSION: GV1001 showed beneficial effects combined with Gemcitabine in the PDAC xenograft mice model, preventing emaciation and increasing anti-inflammatory effects. Moreover, GV 1001 combined with Gemcitabine treatment showed significant loss of fibrosis in tumor tissue. Therefore, further investigation of GV1001's effect may give us useful insights to understand the biology of PDAC progression and the synergistic effects of anti-cancer drug delivery in PDAC treatment.

INTRODUCTION: Previous reports describe that Prdx1 is an antioxidant enzyme that participates in the regulation of hydrogen peroxide-mediated signal transduction, and is also implicated in the immune response, cell proliferation, differentiation, and apoptosis. Prdx1 interacts with apoptosis signal-regulating kinase 1 (ASK1), a member of the mitogen-activated protein kinase kinase kinase (MAPKKK) family that activates both MKK4/MKK7-JNK and MKK3/MKK6-p38 MAPK signaling cascades, via the thioredoxin-binding domain of ASK1; the redox-sensitive catalytic activity of Prdx1 is required for the interaction with ASK1.
AIMS & METHODS: Pancreatic ductal adenocarcinoma (PDAC) is among the deadliest cancers because PDAC cells are highly invasive, they easily invade surrounding tissues, and they metastasize at an early stage. Since the role of Prdx1 in migration and invasion of cancer cells, including pancreatic cancer cells, has not been reported, the aim of this study was to investigate the role of Prdx1 in invasiveness of pancreatic cancer cells. This study describes new and unique findings regarding the molecule Prdx1.
RESULTS: Prdx1 plays a role in promoting cell motility and invasion by regulating the activity of p38 MAPK, a member of the MAPK family protein. Prdx1 interacts with active forms of p38 MAPK, and complexes of Prdx1 and phosphorylated p38 MAPK localize at the leading edges of migrating PDAC cells. Suppression of Prdx1 decreases active p38 MAPK and inhibits cell motility and invasion. Treatment of PDAC cells with a p38 MAPK inhibitor decreases invasiveness. The peroxidase activity of Prdx1 was likely not associated with cell motility and invasion in PDAC. Thus, Prdx1-dependent promotion of cell motility and invasion is likely associated with increased active p38 MAPK. Suppression of Prdx1 inhibits membrane ruffling and protrusions and decreases peripheral actin structures in membrane protrusions. The p38 MAPK inhibitor also inhibits the formation of membrane protrusions via inhibition of accumulation of Prdx1 in cell protrusions.
CONCLUSION: Prdx1 regulates actin-cytoskeleton rearrangements at membrane protrusions through modulation of the activity of p38 MAPK, which in turn promotes pancreatic cancer cell motility and invasion. Inhibition of binding of Prdx1 with active p38 MAPK may be effective for targeted molecular therapy, because any such therapy would inhibit the formation of cell protrusions and consequently limit cell motility and invasion of pancreatic cancer cells.

P0098 TIME-RESTRICTED ACTIVATION OF PROTEIN KINASE D2 DIRECTS VASCULOGENESIS DURING MOUSE EMBRYONIC STEM CELL DIFFERENTIATION

M. Müller[1,*], J. Schröer[1], N. Azoitei[1], F. Genze[2], A. Illing[1], T. Seufferlein[1], S. Liebau[3], A. Kleger[1]
[1]*Department of Gastroenterology,* [2]*Department of Urology, Universitätsklinikum Ulm, Ulm,* [3]*Institute of Anatomy, Universität Tübingen, Tübingen, Germany*

INTRODUCTION: The protein kinase D (PKD) isoenzymes PKD1, -2, and -3, are prominent downstream targets of PKCs and phospholipase D in various biological systems. Recent data from our laboratory identified PKD isoforms as novel, essential mediators of tumour cell-endothelial cell communication but also as regulators of tumour cell motility and metastasis formation. The role of PKD isoforms during vascular development remains elusive.
AIMS & METHODS: In the current study, we aimed to dissect the contribution of PKDs to vasculogenesis and angiogenesis in early embryonic development using mouse embryonic stem (ES) cells as bona fide tool.
RESULTS: First, we identified Protein Kinase D2 as the predominant isoform in undifferentiated ES cells leading us to particularly focus on this isoform. Time-restricted PKD2 activation using an inducible knock-in allele in differentiating mouse ES cells prevented cardiac mesoderm but activated a vascular differentiation program as shown by gene and protein regulation. Interestingly, the proliferative capacity is strongly diminished as a consequence of forced PKD2 expression. Finally, we aimed to underpin our findings in two independent *in vivo* models: First, embryoid bodies were transplanted on the chorioallantois membrane (CAM) of fertilised chicken eggs, a widely used model to study pro- and anti-angiogenesis. In line, with our *in vitro* data pronounced vessel formation was evident in the tumour-like structures arising at day 4 of the CAM assay. Second, we used the teratoma assay and induced PKD2 in immunodeficient mice during teratoma formation. While there was no difference in teratoma weight or size, a strong increase of CD31 expression as an indicator of vasculogenesis was observed in teratoma lysates.
CONCLUSION: Our data obtained in murine ES cells demonstrate that PKD2 contributes to the regulation of angiogenesis during early development and ascribes a vascular fate in two independent embryonic tumorgenesis models.

INTRODUCTION: Although 5-fluorouracil (5-FU)-based combination chemotherapy (e.g. FOLFIRINOX) has demonstrated effectiveness against pancreatic cancer, novel therapeutic strategies must be developed to enhance increase the therapeutic window of these cytotoxic agents. Genistein is a soy-derived isoflavone with pleiotropic biologic effects that can enhance the antitumor effect of chemotherapeutic agents.[1-3]
AIMS & METHODS: To understand how genistein potentiates the antitumor effects of chemotherapeutic agents, we examined apoptosis and autophagy in the MIA PaCa-2 human pancreatic cancer cell line and subcutaneous pancreatic tumor xenograft model. Apoptosis was evaluated using DNA fragmentation assay and Western blot of poly (ADP ribose) polymerase and caspase-3. Meanwhile, autophagy was evaluated using Western blot of microtubule-associated protein light chain 3 (LC3)-I/II and fluorescent microscopy observation of green fluorescent protein-LC3B puncta and acidic vesicular organelle formation. In animal study, induction of apoptosis and autophagy was assessed by TUNEL assay and immunohistochemistry staining of LC3B, respectively.
RESULTS: We observed that genistein enhanced 5-FU-induced apoptosis by down-regulating B-cell lymphoma 2 (bcl-2). Moreover, genistein enhanced 5-FU-induced autophagy and triggered autophagic cell death by decreasing bcl-2 while inducing beclin-1. In vivo treatment studies demonstrated that the combination of 5-FU and genistein significantly decreased final tumor volume comparing to genistein alone or 5-FU alone by inducing apoptosis as well as autophagy.
CONCLUSION: Genistein can potentiate the antitumor effect of 5-FU by inducing apoptotic cell death as well as autophagic cell death. These results demonstrate the potential of genistein as an adjuvant therapeutic agent to enhance the antitumor effects of current first-line cytotoxic agents against pancreatic cancer.

INTRODUCTION: Pancreatic stellate cells (PSC) emerged in recent years as the main actor for the generation of pancreatic fibrosis in pancreatic cancer (PCa). Subsequent to their activation, PSC start to proliferate, migrate, and produce several extracellular matrix (ECM) components as well as cytokines. In this context, neural invasion and pancreatic neuroplasticity is most prominent in the desmoplastic areas.
AIMS & METHODS: The present study aims at elucidating the characterisation of the interactions of nerves, carcinoma cells and PSC and the potential impact of PSC during the generation of neuropathic alterations in PCa.
PSC were isolated from Wistar rats and cultivated under hypoxia, stimulated with TGFβ or left untreated as controls. After cell lysis, the expression of neurotrophic factors and their receptors (GFRα) was determined by Immunoblotting and by qRT-PCR. For neuroplasticity assays, dorsal root ganglia (DRG) were isolated from newborn Wistar rats and treated with supernatants of quiescent and activated PSC. Changes in neurite length, axonal branching, perikaryonal diameter and glial density were determined.
RESULTS: PSC produce neurotrophic factors as well as their receptors and alter the expression pattern of neurturin and artemin after activation towards their active forms, whereas the GFRα expression remains unchanged. After treatment of PSC with hypoxia or TGFβ, PSC are activated. Cell culture supernatants of activated PSC lead to an increased neurite and glial density in isolated DRG.
CONCLUSION: Activated PSC alter their expression pattern of neurotrophic factors, influence neuroplasticity of isolated DRG and therefore may play a seminal role in the generation of pancreatic neuropathy and pain in PCa.

INTRODUCTION: The last decade has focused attention on the central role of platelets interacting with tumor cells and the immune system in promoting tumor progression and distant spread through release of growth factors, such as transforming growth factor beta (TGF-β), vascular endothelial growth factor A (VEGF-A) and plasminogen activator inhibitor-1 (PAI-1), into the tumor microenvironment. We focused on the potential metastasis-promoting role of extravasated platelet aggregation (EPA) in pancreatic cancer and stroma.
AIMS & METHODS: Resected pancreatic cancer specimens from 40 patients were used in this study. To examine the expression and localization of platelet aggregation in the epithelial-mesenchymal transition (EMT) region in cancer and stroma, CD42b, Snail1 and E-cadherin were assessed using immunohistochemistry. We determined the correlation of these expressed proteins with clinical features and overall survival.
RESULTS: CD42b expression was detected at the invasive front of the tumor, which was in 73% of the EMT portion, but not in the region of tubular formation. Increased Snail1 and loss of E-cadherin expression were noted in 85% and 75% of the EMT portion, respectively. There was a significant correlation between CD42b and Snail1 expression ($p = 0.02$) and CD42b and loss of E-cadherin expression ($p = 0.008$). No prognostic impact of CD42b, Snail1 or loss of E-cadherin expression on overall survival was identified using Kaplan–Meier survival analysis.
CONCLUSION: We demonstrate that EPA is associated with the first step in the formation of the EMT. These data suggest a potential role for antiplatelet agents to suppress EMT and metastasis by changing the tumor microenvironment.

INTRODUCTION: Remodelled extracellular matrix (ECM) has been implicated in the resistance of cancer cells to chemotherapy. Stromal-cell-derived proteases, e.g. cathepsins, are involved in tumorigenesis and tissue invasion but their role in regulating pancreatic stellate cells (PSCs) and thus ECM formation is unknown. We studied whether cathepsin B and D, lysosomal proteases both highly expressed in pancreatic cancer, contribute to fibrogenesis by activating PSCs.
AIMS & METHODS: Cathepsin B and D activity was measured in serum of PDAC patients. PSCs were isolated by Nycodenz-gradient from mouse pancreas for immunoblotting and immunofluorescence staining. TGFβ1 was measured using ELISA and LC/MS-mass-spectroscopy.
RESULTS: Serum cathepsin D activity was increased and correlated with poor survival of patients with PDAC. Expression of cathepsin B and D was negligible in quiescent PSCs but increased in parallel with PSC trans-differentiation to myofibroblasts. Silencing or inhibition (Pepstatin, CA074Me) of cathepsin B and D decreased phenotypic markers of PSC activation. Moreover, latent TGFβ1 was cleaved to TGFβ1 leading to an increase in the PSC fibrogenic potential in a time-dependent manner. Cathepsin D activated cathepsin B and both acted directly on latent TGFb1. TGFb1 increased proliferation, invasion and extracellular matrix remodedelling of PSCs.
CONCLUSION: We show that Cathepsin D activity correlates with poor survival in PDAC patients. Cathepsin B and D expression increases during PSC activation *in vitro* and both modulate ECM-formation via proteolytic cleavage of latent TGFβ1. Via PSC activation cathepsins B and D regulate fibrogenesis and stroma development in pancreatic cancer and therefore represent a promising treatment target.

INTRODUCTION: To investigate the signaling pathways involved inKAI1-reduced vascular endothelial growth factor C (VEGF-C) down-regulation and lymphatic metastasis in MIA PaCa-2 pancreatic cancer cells.
AIMS & METHODS: MIA PaCa-2 pancreatic cancer cells were transfected with KAI1 by liposomes. The expression level of VEGF-C was assessed by Western blot. Levels of vascular endothelial growth factor (VEGF)-C secreted by cells measured by enzyme-linked immunosorbent assay (ELISA). Src and STAT3 phosphorylation was detected by Western blot. Signaling transduction inhibitors, PP2 and AG490, were used to block Src and STAT3 signaling pathways, respectively.
RESULTS: KAI1 overexpression decreased VEGF-C expression and inhibited Src and STAT3 phosphorylation. PP2 pretreatment efficiently reversed the upregulation of Src and STAT3 phosphorylation and VEGF-C expression. AG490 pretreatment efficiently reversed the upregulation of STAT3 phosphorylation and VEGF-C expression, but not the upregulation in Src phosphorylation.
CONCLUSION: This study identified that Src/STAT3 signaling pathways were involved in KAI1-reduced VEGF-C down-regulation and suggested their important roles in lymphatic metastasis in pancreatic cancer.

INTRODUCTION: Single-nucleotide polymorphisms (SNPs) of TP53 gene (codon 72, rs1042522) and mouse double minute 2 (MDM2) promoter (SNP309, rs2279744), have been associated with increased risk of various human cancers. However, few studies have analyzed these polymorphisms in pancreatic cancer.
AIMS & METHODS: We investigated TP53 codon 72 and MDM2 SNP 309 polymorphisms in 32 patients with pancreatic ductal carcinoma (PDAC) and 21 patients with controls (non-neoplastic pancreatic epithelium attached to resected specimens without pancreatic disease), using paraffin-embedded tissue sections.

RESULTS: The frequencies of TP53 codon72 arginine (Arg)/Arg, Arg/proline (Pro), and Pro/Pro were 6, 28, and 66% in PDAC and 29, 52, and 19% in controls, respectively. The ratio of Pro/Pro genotype to Arg/Arg genotype was significantly higher in PDAC than controls [p = 0.004, adjusted odds ratio (OR) = 15.75; 95% confidence interval (CI) 2.30-107.9]. On the other hand, those of MDM2 SNP309 TT, TG, and GG genotypes were 22, 44, and 34% in PDAC and 38, 33, and 29% controls, respectively. There were no significant differences among them.
CONCLUSION: This is the first study to evaluated the significance of TP 53 codon 72 and MDM2 SNP 309 polymorphism using paraffin-embedded pancreas tissue. The proportion of Pro/Pro genotype was significantly higher in PDAC, while the proportion did not differ in MDM2. This finding indicates that TP53 codon 72 polymorphism is likely to be correlated with increased risk for pancreatic cancer.

INTRODUCTION: Pancreatic cancer is a rapidly invasive, metastatic tumor, which is resistant to standard therapies, thus only 10–15% of patients are candidates for potentially curative surgery. None of the currently available chemotherapeutic agents have an objective response rate of over 10%. Recent studies show that RNA binding proteins regulate post transcriptional gene expression and play a critical role in RNA stability andtranslation, thus they potentially could become an important group of new therapeutic targets.
AIMS & METHODS: We examined the association of this postranscriptional regulation pathway (CUGBP2 and HuR) and the expression of COX-2 and HO-1, which are known to be associated with inhibition of apoptosis, increased tumor invasiveness and resistance to oxidative stress and/orchemotherapy, and promotion of angiogenesis. Western blot analysis, immunohiostochemistry and quantitative RT-PCR were employed to show the expression of mRNA and protein in normal pancreas (from organ donors), cancer tissue (surgical specimens).
RESULTS: RT-PCR analysis showed 10.3 and 14 fold lower HuR and CUGBP2 mRNA levels in pancreatic cancer compared to normal tissue ($p < 0.05$), COX-2 levels were 1.5 times higher and HO-1 expression on average was upregualted 6-fold in the pancreatic cancer samples, compared to the normal pancreatic tissue ($p < 0.05$). Western blot analysis showed very low levels of HuR and CUGBP2 in pancreatic cancer compared with the normal tissue ($p < 0.05$). Expression of COX-2 protein levels was 2-fold higher in pancreatic cancer. Western blot analysisrevealed 3.5 times higher ($p < 0.017$) expression of HO-1 in pancreatic cancer.
CONCLUSION: The decreased or altered activity of CUGBP2 and HuR could be associated with high chemoresistance and early dissemination of pancreatic cancer through the HO-1 and COX-2 mediated cytoprotective and carcinogenesis pathways. These results mandate further functional studies and evaluation of postranscriptional regulation as a new potential therapeutic target.

INTRODUCTION: Preoperative differentiation between malignant and benign pancreatic tumors can be difficult. Consequently, some 5-14% of patients undergoing pancreatoduodenectomy for suspected malignancy are ultimately diagnosed with benign disease.
AIMS & METHODS: We aimed to determine the diagnostic value of a pancreatic mass on computed tomography (CT) in patients with presumed pancreatic cancer and the additional value of reassessment by expert-radiologists.
We performed a multicenter retrospective cohort study in 1629 consecutive patients undergoing pancreatoduodenectomy for suspected malignancy (2003-2010). All patients with unexpected benign disease at postoperative pathological diagnosis were included in a 1:3 ratio with random patients with (pre)malignant disease. The preoperative CT scan was reassessed by two expert-radiologists separately and subsequently (after defining a mass as *'a measurable space occupying soft tissue density, except for an enlarged papilla or focal steatosis'*) in consensus.
RESULTS: 86 patients with benign and 258 patients with (pre)malignant disease were included. A mass was reported in the original CT report in 66% of patients versus 48% and 50% on reassessment by the two expert-radiologists, respectively. Interobserver agreement among expert-radiologists was moderate (kappa = 0.47, 95%CI 0.38-0.56); they disagreed on the presence of mass in 29% of patients. The incidence of mass decreased to 44% after consensus reading ($P < 0.001$ vs. original report). 167/212 (79%) masses identified in the original report proved to be malignant after pancreatoduodenectomy versus 139/150 (93%) masses identified by expert-radiologists in consensus ($P < 0.001$). The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of masses identified in the original CT report were 68%, 42%, 79%, 7%, and 67%, respectively. For masses identified by expert-radiologists in consensus these were 54%, 87%, 98%, 12%, and 56%, respectively.
CONCLUSION: In patients with presumed pancreatic cancer, the diagnostic value of a pancreatic mass on CT is high, whereas the absence of a mass cannot rule out malignancy. Expert-radiologists less frequently identified a pancreatic mass as compared to the original CT-report, with doubled specificity for malignancy.

INTRODUCTION: Farnesoid X Receptor (FXR) belongs to the group of nuclear receptors (NRs). As a transcription factor, it binds to DNA either as a monomer or as an heterodimer with Retinoid X Receptor (RXR). FXR affects several metabolic pathways, including development of atherosclerosis, intestinal bacterial growth and liver regeneration. Additionally, FXR is involved in the pathogenesis of cholestatic diseases, non-alcoholic fatty liver disease, inflammatory bowel disease and cancer. Although many studies have investigated FXR expression in various cancer types, a few data exist, so far, on the clinical significance of this receptor in pancreatic cancer.
AIMS & METHODS: The expression levels of FXR and its heterodimeric partners RXR-α, -β and -γ were assessed immunohistochemically on histopathological samples obtained from pancreatic adenocarcinoma patients, and associated with various clinicopathological parameters, tumor proliferative capacity (Ki-67 labeling index), and patients' survival.
RESULTS: Moderate/strong FXR expression was noted in 27 (49.1%) out of 55 pancreatic adenocarcinoma cases, being at borderline level associated with earlier histopathological stage ($p = 0.054$). Moderate/strong FXR/RXR-α expression was significantly correlated with low tumour histopathological grade of differentiation ($p = 0.017$). Moderate/strong FXR/RXR-β and FXR/RXR-γ expression was significantly correlated with smaller tumor size ($p = 0.037$, $p = 0.005$, respectively) and earlier histopathological stage ($p = 0.017$, $p = 0.004$, respectively), while moderate/strong FXR/RXR-γ expresssion was also significantly correlated with the absence of lymph node metastases ($p = 0.018$). Furthermore, patients presenting moderate/strong FXR expression showed significantly longer survival times compared to those with negative/weak (log-rank test, $p = 0.013$). In multivariate analysis, FXR expression and histopathological stage were identified as independent prognostic factors for patients' survival (Cox-regression analysis, $p = 0.044$ and $p < 0.001$). Patients presenting moderate/strong FXR/RXR-β or FXR/RXR-γ expression showed significantly longer survival times compared to those with negative/weak (log-rank test, $p = 0.021$, $p < 0.001$, respectively).
CONCLUSION: FXR, FXR/RXR-α, FXR/RXR-β and FXR/RXR-γ expression levels in pancreatic cancer are associated with important histopathological parameters and better patients' outcome.
Disclosure of Interest: None declared

P0108 CLINICAL SIGNIFICANCE OF PREGNANE X RECEPTOR (PXR) AND RETINOID X RECEPTORS (RXRS) EXPRESSION IN HUMAN PANCREATIC ADENOCARCINOMA: AN IMMUNOHISTOCHEMICAL STUDY

I. Koutsounas[1,*], K. Giaginis[2], A. Zizi[3], G. Kouraklis[4], E. Patsouris[1], S. Theocharis[1]

INTRODUCTION: Pregnane X Receptor (PXR) is a member of the nuclear receptor (NR) superfamily, expressed mainly in the liver and intestine, exerting its transcriptional regulation by binding to DNA response elements as an heterodimer with Retinoid X Receptor (RXR). PXR is involved in the homeostasis of numerous endobiotics, as well as in inflammatory bowel disease, bone homeostasis, liver steatosis and antifibrogenesis. Additionally, PXR has a multifactorial impact on cancer, either by directly affecting cell proliferation and apoptosis or by inducing chemotherapy resistance. Even though many studies have investigated PXR implication in various types of cancer, data on the clinical significance of this receptor in pancreatic cancer are still very limited.
AIMS & METHODS: The expression levels of PXR and its heterodimeric partners RXR-α, -β and -γ were assessed immunohistochemically on histopathological samples obtained from pancreatic adenocarcinoma patients, and associated with various clinicopathological parameters, tumor proliferative capacity (Ki-67 labeling index), and patients' survival.
RESULTS: Moderate/strong PXR expression was noted in 24 (43.6%) out of 55 pancreatic adenocarcinoma cases, being positively correlated with tumour histopathological grade of differentiation ($p = 0.023$). Moderate/strong PXR/RXR-β and PXR/RXR-γ expression was significantly correlated with smaller tumor size ($p = 0.005$, $p = 0.012$, respectively) and earlier histopathological stage ($p = 0.003$, $p = 0.014$, respectively). Additionally, pancreatic adenocarcinoma patients presenting moderate/strong PXR/RXR-β or PXR/RXR-γ expression showed longer survival times compared to those with negative/weak, at non significant levels though (log-rank test, $p = 0.278$, $p = 0.053$, respectively).
CONCLUSION: In our study, PXR and PXR/RXRs expression was for the first time examined in human pancreatic cancer cases, being correlated with favourable histopathological parameters and associated with longer patients' survival.

INTRODUCTION: Urokinase-Type Plasminogen Activator (uPA) is a serine proteinase, which transforms inactive plasminogen to the active plasmin. UPA is involved in cancer progression, growth and metastasis through degradation of extracellular matrix (ECM), growth factors FGF, IGF, VEGF release and cellular migration activation. UPA overexpression was confirmed in many human cancers including pancreatic cancer and was connected to the poor survival. UPA expression was found in the vessels of tumor stroma, which suggests that it can be detected in serum.
AIMS & METHODS: The aim of this study was to evaluate the uPA serum concentration in patients with pancreatic cancer (PC) and chronic pancreatitis (CP) in order to determinate it's possible diagnostic and prognostic value.
The study group included 90 patients: 40 with pancreatic cancer, 30 with chronic pancreatitis and 20 healthy individuals (control group). Serum level of uPA was analyzed using an enzyme-linked immunosorbent assay (ELISA). Pancreatic cancers were classified according to the TNM classification. Criteria for resectability included: absence of distant metastases, lack of evidence of tumor involvement of major arteries, and (if there is venous invasion) a suitable segment of portal vein (above) and superior mesenteric vein (below) the site of venous involvement to allow for venous reconstruction.
RESULTS: We revealed threefold increase in uPA serum level in patients with pancreatic cancer (3.23ng/ml) and twofold increase in patients with chronic pancreatitis (2.18ng/ml), with was significant higher than in control group (1.01ng/ml) ($p < 0.05$ PC vs CP; PC vs control; CP vs control). We observed significantly higher level of uPA in patients with pancreatic cancer and CA19-9 > 500 IU/l compared to patients with CA19-9 <500 IU/l – 3.98 ng/ml vs 2.8 ng/ml ($p < 0.03$). We noticed lower level of uPA in patients with resectable pancreatic cancer: 2.28 ng/ml vs 3.4 ng/ml in patients with unresectable pancreatic cancer but difference was not significant ($p = 0.14$). In addition there was no correlation between uPA level and pancreatic cancer stage. We found the significant correlation between high serum uPA concentration and shorter survival ($p < 0.05$); mean survival in patients with uPA > 2 was 181 days ±155.11 and in patients with uPA < 2 ng/ml- 335 days ±313.75 ($p = 0.04$).
CONCLUSION: The results suggest the possible use of serum uPA in pancreatic cancer diagnosis and differentiation from chronic pancreatitis. Significant correlation between serum uPA concentration and decreased survival, may indicate on the role of uPA as a prognostic marker in pancreatic cancer.

P0110 PARTIAL COVERED BILIARY METALLIC STENT WITH/WITHOUT DUODENUM METAL STENT AND NEOADJUVANT CHEMORADIATION THERAPY PROVIDES SYMPTOMATIC BORDERLINE RESECTABLE PANCREATIC HEAD CANCER WITH A CHANCE FOR R0 SURGERY

Y. Sekino[1], K. Kubota[1], K. Hosono[1], A. Nakajima[1], Y. Fujita[1,*]
[1]*Gastroenterology, Yokohama City University, Yokohama, Japan*
Contact E-mail Address: *kubotak@yokohama-cu.ac.jp*

INTRODUCTION: Neoadjuvant chemradiationtherapy (NACRT) may lead to successful margin-negative resection (R0) in pts with borderline resectable pancreatic head cancer (BRPHC). NACRT using a covered metallic biliary stent has been attempted in pts with BRPHC, however, the efficacy of this therapy with/without metallic duodenal stent (MDS) and the influence of using partially covered metallic stent (PCMS) for its delivery in the treatment of BRPHC has not been evaluated.
AIMS & METHODS: To evaluate the efficacy of and complications associated with the use of PCMS with/without MDS during NACRT and the surgical period.
We reviewed the outcomes of consecutive pts with BRPHC had histopathologically proven pancreatic adenocarcinoma, who presented with symptomatic biliary obstruction, and divided the patients chronologically, in terms of the period of stent placement into two groups: group A; plastic stent (PS) deployment plus NACRT between August 2009 and October 2010; group B; prospectively PCMS deployment with/without MDS plus NACRT between November 2010 and December 2013. The pts were categorized as having borderline resectable cancer based on the NCCN clinical practice guideline established in 2013. Data on the pts demographics, complications, non re-intervention rate (NRR), surgical time, operative blood loss, length of hospital stay, complications after resection, the rate of R0 and prognosis were studied. Safe R0 surgery was defined as R0 surgery without the need for re-intervention or postoperative complications.
RESULTS: There were a total of 57 pts with LAPHC (group A and B: 29 and 28 pts, respectively). The median time from stent placement to surgery in the overall subject population were 130.5 Days in group A and 130.7 days in group B. MDS was deployed in one pts with group A and three pts with group B. NPR for the 1st 30 days in group A (PS) and B (PCMS) were 48% and 96%, respectively. NPR for the 2nd 30 days in group A and B were 23% and 92%, respectively. NPR for the 3rd 30 days in group A and B were 15% and 92%, respectively. Regarding NPR, PCMS is superior to group using PS ($p < 0.05$). No severe complications including gastrointestinal bleeding after irradiation were noted in any pts. There were no significant differences between groups regarding surgical time, operative blood loss, length of hospital stay. The rates of achievement of R0 surgery in groups A and B were 68.9% (20/29) and 89.3% (25/28), respectively. The PCMS and MDS did not interfere with the conduct of the NACRT and pancreaticoduodenectomy in any patients. The rates of achievement of safe R0 surgery in groups A and B were 10.3% (3/29) and 70.4% (20/28), respectively ($p < 0.05$). Multivariate analysis showed that odds ratio for safe R0 surgery was 18.426 ($p < 0.0001$) for PCMS placement.
CONCLUSION: Insertion of PCMS should be considered for the relief of biliary and/or duodenum obstruction in pts with BRPHC scheduled to receive NACRT, in view of the minimize need for re-intervention for recurrent biliary obstruction, and a potentially high rate of achievement of safe R0 surgery, as compared to the results obtained with PS deployment.

P0111 BRANCH DUCT INTRADUCTAL PAPILLARY NEOPLASMS WITH CYSTS LARGER THAN 3 CM WITHOUT HIGH-RISK STIGMATA: SHOULD WE RESECT THESE NEOPLASMS OR NOT?

K.T. Lee[1,*], **M.J. Lee**[1], **Y.J. Lee**[1], **J.K. Lee**[1], **K.H. Lee**[1]
[1]*Department of Medicine, Samsung Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: In 2012, revised international consensus guidelines were published, and they suggested a more conservative approach for the management of BD-IPMN with cysts larger than 3 cm without other ''high-risk stigmata''. But, several recent studies have challenged the safety of this guideline. The aim of this study is to compare the prognosis in patients who underwent surgical resection because of the cyst size and the prognosis in patients who chose close observation.
AIMS & METHODS: We retrospectively reviewed the data of 48 BD-IPMN patients with a cyst size ≥ 3cm, without any other suspicious features, between March 1995 and October 2013. We divided the patients into 2 groups (21 patients underwent surgery, and 27 patients chose close observation), and compared the patients' characteristics and prognosis.
RESULTS: The patients in the observation group were older than the patients in the surgery group and they had severe co-morbidities (≥2 ACE-27 co-morbidity score (moderate)). None of the patients developed new ''worrisome features'' or ''high-risk stigmata'' during the follow-up period, and the causes of death were not related to IPMN. Among the 21 patients who underwent resection; 4 patients (19%) were diagnosed with invasive carcinoma, and 1 patient (4.8%) was diagnosed with intestinal type of invasive carcinoma. No surgery-related death and major postoperative complications were noted.
CONCLUSION: While making a decision regarding the management of BD-IPMN with a cyst size ≥ 3cm in the absence of high-risk stigmata, we should consider the risk of surgery in patients, but we should not hesitate to perform resection in surgically fit patients especially in high-volume centers with experienced surgeons.

INTRODUCTION: For the detection of pancreatic cancer in early stage, it is important to identify high-risk individuals and follow up those patients periodically. We have started an early detection system for pancreatic cancer since 1998, and revealed that individual with either pancreatic cyst (>5mm) or dilated main pancreatic duct (>2.5mm) is high-risk for pancreatic cancer. Follow up of high-risk individuals (HRIs) with imaging tests, such as trans abdominal ultrasound which is specialized to pancreato-billiary area (pancreatic US: pUS), endoscopic ultrasound (EUS) and computed tomography (CT) or magnetic resonance imaging (MRI), can lead to the detection and treatment within asymptomatic patients, however usefulness of the optimal imaging approach is not known.
AIMS & METHODS: Between June 2007 and January 2014, 535 asymptomatic HRIs were examined periodically at single center, using pUS (every 3 or 6 month) and CT or MRI (once a year). EUS was performed when any changes such as hypoechoic mass, new nodule or rapid change in cyst size were detected by pUS. ERCP was recommended for cytology when the size of cyst become bigger than 3cm or main pancreatic duct was dilated bigger than 3mm or a newly narrowed part appeared, or the size of cyst or main pancreatic duct changed rapidly. EUS-FNA was performed when an invasive nodule or hypoechoic mass was detected. Contrast harmonic pUS/EUS was also performed if necessary.
RESULTS: Sixteen patients with pancreatic cancer have been confirmed as malignancy during follow up (2.99% incidence rate), 8 males and 8 females (mean age = 69.1 yrs). Eight patients had an intraductal papillary mucinous neoplasms (IPMNs) with an associated carcinoma (2: invasive, 6: non-invasive), six had an invasive ductal adenocarcinoma, and two had ductal carcinoma in situ (PanIN3). Mean total follow up period until the detection of cancer was 34.8 months (range 6.6 - 64 mo). Fourteen patients were asymptomatic. The number of patients with cancer stage of 0, IA, IIA, IIB, III, was 7, 4, 2, 1 and 2, respectively. Ten cases were brought to further examination by the findings detected by pUS, two with symptoms such as abdominal pain, one with tumor marker elevation, one with MRI finding, one with CT finding and one with EUS finding which was found by chance during further examination for another lesion. All invasive pancreatic cancers (smaller than 10mm) were detected only by either pUS or EUS but not by CT nor MRI. Invasive cancer showed hypo-vascularity in pUS/ CE-EUS. Three cases were comfirmed as malignant by EUS-FNA and twelve cases by ERCP. Thirteen cases had surgical resection and three cases had chemotherapy.
CONCLUSION: Periodical examination of asymptomatic HRIs frequently detects small pancreatic cancer with early stage. EUS and pUS could detect invasive pancreatic cancer in early stage better than CT or MRI and are thought to be important modalities in surveillance.

P0113 THE INFLUENCE OF NEURAL INVASION ON SURVIVAL AND TUMOR RECURRENCE IN PATIENTS WITH PANCREATIC DUCTAL ADENOCARCINOMA – A SYSTEMATIC REVIEW AND META-ANALYSES

S. Schorn[1,*], I.E. Demir[1], B. Haller[2], H. Friess[1], G.O. Ceyhan[1] on behalf of Pancreatic Neuropathy and Pain
[1]*Department of Surgery,* [2]*Institute of Statistics and Epidemiology, Klinikum Rechts der Isar der TU München, München, Germany*

INTRODUCTION: The aim of this study is to assess the true impact of perineural invasion/Pn on survival and tumor recurrence in pancreatic ductal adenocarcinoma/PDAC.
Pn is a histopathological hallmark of PDAC, which affects overall survival/OS and tumor recurrence. Until now, recent studies could demonstrate that Pn influences disease-free-survival-time/DFS and progression-free-survival-time/PFS. However, at this time point, there is still no consensus on the real impact of Pn in PDAC.
AIMS & METHODS: Pubmed, Cochrane library, Ovid and Google Scholar were scanned for the terms "pancreatic ductal adenocarcinoma", "pancreatic cancer", "survival", "tumor recurrence" and "perineural invasion". Using the *P*referred *R*eporting *I*tems for *S*ystematic review and *M*eta-*A*nalysis/PRISMA guidelines, a systematic review/SR and meta-analyses was performed. All articles meeting the predefined criteria were critically analyzed on relevance and meta-analyses were performed by pooling univariate and multivariate hazard ratios/HR.
RESULTS: 23 studies for the influence of Pn on tumor recurrence and a total of 101 studies analyzing the influence of Pn on survival were identified by the SR. The performed analyses revealed the prognostic influence of Pn on PDAC patients. The pooled HR of the univariate (1.86; CI 1.67-2.08; $p < 0.00001$) and multivariate analyses (1.50; CI 1.36-1.65; $p < 0.00001$) showed a strong negative impact of Pn on OS in PDAC. Interestingly, Pn was also closely linked to decreased DFS (HR: 2.23, CI 1.13-4.41; $p < 0.05$) and PFS (HR: 2.82; CI 1.97-4.04; $p < 0.00001$) in the pooled multivariate analyses.
CONCLUSION: This is the first systematic review and meta-analyses focusing on the prognostic impact of Pn on OS, DFS and PFS in PDAC. Here we could demonstrate that Pn is an independent prognostic factor among PDAC patients, which decreases OS, PFS and DFS. Therefore, Pn should receive increased attention for improved patient stratification and be considered much more intensively in the development of novel therapeutic algorithms in PDAC.

INTRODUCTION: Obesity was described as a risk factor of pancreatic cancer in combination with metabolic abnormalities. The respective roles of intravisceral and subcutaneous fat are unknown and the prevalence of precancerous lesions in obese patients was never evaluated.
AIMS & METHODS: To characterize the frequency and severity of pancreatic intraepithelial neoplasia (PanIN) in patients with fatty pancreas, to correlate pathological findings with metabolic abnormalities, tobacco intake and type of fat. Consecutive pancreatic specimens of patients operated on for benign neuroendocrine tumors were analyzed. The pancreatic parenchyma was analyzed at least 2 cm apart from the tumor. Fatty infiltration and fibrosis of the parenchyma in intra- and extralobular locations were assessed. Dysplastic lesions were described according to the PanIN classification. General characteristics of the patients were collected, including body mass index (BMI), diabetes and tobacco intake. Liver steatosis was assessed by CT scan (mean of 3 regions of interest, threshold >58UH). The subcutaneous and intravisceral fat (% of the total area) was estimated on CTscan by the ImageJ software (1.47, NIH, USA).
RESULTS: 110 patients (males: 57%) were included (median surface of pancreatic specimen: 7.5 cm2). Median age at surgery was 53.8 [17-85] years. Arterial hypertension, diabetes, tobacco intake were found in 19, 9 and 23%, respectively. Median BMI was 24 [16-37], (BMI < 25: 45%, 25-< 30: 24%, > 30: 11%). Overall, PanIN lesions were found in 65% of the patients, Type 1, 2 and 3 PanIN were observed in 62, 38 and 1% of the cases, respectively. Fibrosis and fatty pancreas (intra- and extralobular locations) were found in 1% and 24% and in 30% and 51%, respectively. Liver steatosis was observed in 27%. A correlation was observed between the presence of PanIN lesions on one hand and fatty pancreas [extra- (0.01) and intralobular (< 0.0001)], intralobular fibrosis (0.003), high BMI ($p = 0.02$), liver steatosis ($p = 0.03$) and subcutaneous ($p = 0.02$) and intravisceral fat ($p = 0.02$) on the other. Presence of PanIN was not influenced by tobacco intake or diabetes. The number of PanIN lesions was correlated with the severity of liver steatosis ($r = -0.25$, $p = 0.02$), the percentage of intravisceral fat ($r = 0.22$, $p = 0.04$) but not with the percentage of subcutaneous fat ($r = 0.14$, $p = 0.22$) or patient age at surgery.
CONCLUSION: Obesity -and especially android obesity with increased intravisceral fat- is a risk factor for precancerous lesions of the pancreas. These results suggest that fatty infiltration *per se* plays a specific role in pancreatic oncogenesis.

INTRODUCTION: Prognosis after surgical resection of pancreatic ductal adenocarcinoma remains poor because of the high incidence of recurrence. Some studies have described the sites of metastasis after resection of pancreatic ductal adenocarcinoma, but little is known about the relationship between clinicopathological features of the primary carcinoma and site of recurrence. Both normal and malignant epithelial cells of a variety of organs contain mucous substances that are rich in very high molecular weight glycoproteins called mucins, which contain many serine- and threonine-linked carbohydrate chains. However, few studies examine the relationship between mucin phenotype of primary pancreatic ductal adenocarcinoma and the site of metastasis.
AIMS & METHODS: The current study focused on clinicopathological features, including mucin phenotype, in primary pancreatic ductal adenocarcinoma and their relationship to sites of metastasis after surgical resection. A total of 323 patients underwent pancreatic resection in our hospital from 1982 to 2003. Seventy-four patients died from a known cause. Patients with intraductal papillary mucinous neoplasm were excluded. The follow-up period was 61 to 288 months. Clinical data were obtained from patients' charts, and pathological factors were assessed according to the WHO classification. A control group comprised 13 patients who had survived more than 10 years after surgery for carcinoma of the pancreas (10 group). Sections were stained with hematoxylin and eosin and high iron diamine blue stain for detection of sulfomucin and sialomucin. The staining pattern was classified into three groups: pure sialomucin type (Si type), pure sulfomucin type (Su type), and mixed type. With regard to immunohistochemical staining for MUC1, MUC2, MUC5AC and MUC6, staining of more than 10% of the carcinoma was defined as positive. Neurovascular invasion was deemed to be present if involvement of more than five sites on a typical section was seen.
RESULTS: Of the 74 patients with an obvious cause of death, 45 died of peritonitis carcinomatosa following local recurrence (P group), 25 died of liver metastasis (L group), 2 died of lung metastasis, and 2 died of bone metastasis. We compared the clinicopathologic features between the L group, P group, and 10 group. Clinicopathologic features of each group are as follow: L group: frequent

Si type of carcinoma (vs. P group, $p < 0.0001$; vs. 10 group, $p = 0.0002$), high rate of venous invasion (vs. P group, $p < 0.0001$; vs. 10 group, $p < 0.0001$), and shorter prognosis (3–34 months, vs. P group, $p = 0.0257$). P group: advanced pT factor (vs. 10 group, $p = 0.0015$) and high rate of R1 status (vs. L group, $p = 0.0370$; vs. 10 group, $p = 0.0243$). 10 group: lower grade of pT factor (vs. L group, $p = 0.0086$; vs. 10 group, $p = 0.0015$) and lower stage (vs. P group, $p = 0.0037$).
CONCLUSION: We might be able to predict the occurrence of liver metastasis by preoperative histochemical mucin staining of carcinoma cells that were classified as Si type preoperatively using EUS-FNA or biopsy.

INTRODUCTION: Previous reports demonstrated endoscopic ultrasound-guided fine-needle aspiration biopsy (EUS-FNA) for gastrointestinal submucosal lesion (SML) is feasible and safe with high diagnostic yield. On the other hand, since it is difficult to perform EUS-FNA for small SML especially less than 15mm, almost small SMLs are observed without EUS-FNA. However, because SMLs include malignant lesions even though a tumor is small, it is desirable to perform EUS-FNA when possible.
AIMS & METHODS: The aim of this study is to evaluate feasibility and safety of EUS-FNA using forward-viewing echoendoscope attached with a cap device to the tip of scope for the small SML. Eight patients who had small SML less than 15mm I upper GI were enrolled in this study. EUS-FNA was done using forward-viewing EUS scope (XGIF-UCT160J-AL5; Olympus, Tokyo, Japan) and needle devices (22G, 25G), with rapid on-site evaluation. To fix the SML at the needling, a cap device was attached to the tip of scope. We evaluated the rate of sampling, accuracy, and complication.
RESULTS: Mean diameter of SMLs was 10.6 mm±2.94mm (mean±SD, range 8-15mm). The puncture could be done in all 8 cases, and mean number of FNA passes was 4.6±1.59 (mean±SD, range 3-7). The adequate materials were obtained in 6 (87.5%) for cytology, in 4 (50%) for histological examination with immunostaining. In 1 (12.5%) patient, adequate sample for both cytology and histology was not obtained. As final diagnosis, 6 patients were gastrointestinal stromal tumor (2 in definition, 3 in suspicion), 2 patients were leiomyoma. No complication was noted.
CONCLUSION: Although the rate of definitive diagnosis was 50%, EUS-FNA using forward-viewing echoendoscope attached with a cap device for small SML was feasible and safe.

P0117 ENDOSCOPIC CHARACTERISTICS OF EARLY GASTRIC CANCERS MIXED WITH WELL AND POORLY DIFFERENTIATED ADENOCARCINOMA

A. Takahashi[1,*], T. Oyama[1]
[1]*Endoscopy, Saku Central Hospital Advanced Care Center, Nagano, Japan*
Contact E-mail Address: *aurevoireurope@yahoo.co.jp*

INTRODUCTION: The risk of lymph node metastasis of superficial gastric cancer depends on histological type, invasion depth and the size. Sometimes, well differentiated gastric adenocarcinoma has poorly differentiated component partially. And, the incidence of lymph node metastasis is higher than that of the well differentiated type. Therefore, endoscopic diagnosis of histological type is important. However, the endoscopic characteristics of such a histologically mixed gastric adenocarcinoma are unknown.
AIMS & METHODS: The aim of this study is to investigate the endoscopic characteristics of early gastric cancers partially with poorly differentiated type. One hundred eighty-two gastric adenocarcinomas from 172 patients treated by ESD from January to December 2012 were enrolled in this study. All of the examination was performed by Olympus H260Z with Lucera. And, narrow band imaging (NBI) magnified observation was performed after white light imaging (WLI) observation. Magnified endoscopic findings were divided into surface and vascular pattern. Surface pattern was divided into villous, pit and unclear. The gross type was classified into 0-I, 0-IIa, 0-IIb and 0-IIc type, and the number was 9, 67, 7, and 99, respectively. The histology was classified into well and poorly differentiated type. When the cancer had only well differentiated type, it was classified as pure well differentiated type. And, when the well differentiated adenocarcinoma had a poorly differentiated component, it was classified as mixed type. And when the cancer was composed of only poorly differentiated adenocarcinoma, it was classified as pure poorly differentiated type.
RESULTS: 1. The numbers of pure well differentiated type, mixed type and pure poorly differentiated type were 157, 23 and 2, respectively.
2. 0-I type: Seven of 9 lesions were pure well differentiated type, and two of 9 lesions were mixed type. The size of these two lesions was more than 20mm.
3. 0-IIa type: Sixty three and 4 of 67 lesions were well differentiated and mixed type, respectively. The incidence of mixed type has relationship with the size. When the lesions were divided three groups depends on the size such as 1-9, 10-19, 20-29, 30mm or bigger, the incidence of mixed type was 0% (0/15), 8% (2/24) and 0% (0/15), 15% (2/13), respectively.
4. 0-IIb type: All of seven lesions were pure well differentiated type.
5. 0-IIc type: 80, 17 and 2 of 99 lesions was pure well, mixed and pure poorly differentiated type, respectively. And when the size was subclassified into four groups 2-9, 10-19, 20-29, 30mm or bigger, 0% (0/30), 25% (12/48), 27% (4/15) and 50% (3/6) were mixed type.
6. The surface pattern of well differentiated adenocarcinoma observed by magnified endoscopy showed irregular villous or pit pattern. However, the surface pattern of mixed type was unclear in some cases. However, sometimes the surface was covered by thick mucus, and magnified endoscopic observation was impossible.
CONCLUSION: The incidence of mixed type depends on the size and macroscopic type of the superficial gastric cancer. Magnified endoscopy was sometimes useful to detect mixed type from the surface pattern.

P0118 SUBMUCOSAL FIBROSIS AFFECTS THE OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR GASTRIC NEOPLASMS

A. Shimozato[1,*], N. Ogasawara[1], Y. Kondo[1], Y. Ito[1], H. Noda[1], K. Yanamoto[1], M. Sasaki[1], K. Kasugai[1]
[1]*Gastroenterology, Aichi Medical University, Nagakute City Aichi, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is an effective treatment for gastric neoplasms. However, because of its technical difficulty, it takes longer, and there is a greater risk of complications such as bleeding and perforation. The success of ESD depends on the technical proficiency of the endoscopist and the condition of the gastric tumor. Even for a skilled endoscopist, however, submucosal fibrosis can be an obstacle to success of ESD. Submucosal fibrosis, which usually results from inflammation or tumor invasion, makes it harder to lift the tumor tissue from the muscle layer. This in turn lengthens the procedure time, creates risk of complications such as perforations, and reduces the success rate of complete en bloc resection. Despite its importance, there has been little investigation of the relationship between the degree of submucosal fibrosis and outcomes of ESD in early gastric tumors. Accordingly, the aims of this study were 1), to examine the association between endoscopic and pathologic findings and submucosal fibrosis in gastric neoplasms; 2), to examine the association between degree of submucosal fibrosis and outcomes of ESD.
AIMS & METHODS: Two hundred forty six patients with gastric neoplasms (52 cases of adenomas and 194 cases of early gastric cancers) were treated by ESD from November 2008 to September 2013. Endoscopically, the degree of submucosal fibrosis was classified as follows, based on the findings obtained after a solution including indigo carmine was injected under the submucosal layer: F0, no fibrosis, which appeared as a blue transparent layer; F1, mild fibrosis, which appeared as a white web-like structure in the blue submucosal layer; and F2, severe fibrosis, which appeared as a white muscle-like structure without a blue transparent layer.
RESULTS: The presence of endoscopic submucosal fibrosis was not significantly related to tumor size, ulceration, histological findings, submucosal invasion, and en bloc resection rates in univariate analysis. However, posterior walls of the stomach harbored higher frequency of submucosal fibrosis compared with anterior wall regardless of upper, middle or lower portion of the stomach ($p < 0.05$). The procedure time according to the degree of endoscopic submucosal fibrosis were as follows (mean ±SD): F0, 82.1±42.1 minutes; F1, 146.6±81.6 minutes, and F2, 171.4±106.7 minutes, showing significant difference between groups ($p < 0.01$). The severity of endoscopic submucosal fibrosis was associated with abundant immediate bleeding which required hemostasis using hemoclips during ESD procedure ($p < 0.05$). However, delayed bleeding was not significantly related to the degree of submucosal fibrosis.
CONCLUSION: Submucosal fibrosis of gastric neoplasms is closely related to tumor location, procedure time, and severe bleeding during ESD. Moreover, the more advanced the endoscopic submucosal fibrosis, the longer the time required for ESD and the higher the frequency of immediate bleeding. Further development of endoscopic devices and peripheral equipments are needed for safe and complete resection of lesions with severe fibrosis.

P0119 NEW ENDOSCOPIC TECHNIQUE FOR SECONDARY PLACEMENT OF VOICE PROSTHESIS

A.M. Seraphim[1,*], A. Pelosof[1], L. Kowalski[2], J. Vartanian[2], C.Z. Sztokfisz[1]
[1]*endoscopy,* [2]*head and neck surgery, AC Camargo Cancer Center, Sao Paulo, Brazil*
Contact E-mail Address: *alvaroseraphim@yahoo.com.br*

INTRODUCTION: The functional speech rehabilitation in laryngectomized patients after total laringectomy remains as one of the most challenging matters for head and neck surgeons and speech therapists.
The use of voice prostheses has been considered the gold standard in voice rehabilitation for the last 25 years. Insertion can be performed either as a primary procedure during laryngectomy or as a secondary procedure with rigid esophagoscope or trocar. In some patients these procedure became technically impossible due to some post treatment cervical abnormalities such as necks reduced hyperextension (post surgery or radiotherapy) anastomotic reduced diameter (post surgery), trismus and other impairments situations.
AIMS & METHODS: Objective: To present an endoscopic technique for secondary placement of Provox prosthesis using the flexible endoscope, a plastic

pliable overtube (to keep the virtual esophageal lumen open so the traqueoesophageal puncture could be performed safely, avoiding unexpected lesions on the posterior esophageal wall), a 14 gauge intravenous catheter to perfomed the puncture, and a flexible guidewire. Furthermore, using the flexible endoscope instead of the rigid esophagoscope we can avoid some of the major complications of the classical technique i.e.: mediastinitis, cervical cellulitis, fracture of cervical vertebra, and esophageal perforation
Methods: 7 patients referred to voice rehabilitation with Provox II vocal prosthesis in a secondary placement, in which the classic technique could not be performed, underwent a new surgical technique, performed with a flexible endoscope, a plastic pliable overtube, a 14 gauge intravenous catheter and a flexible guidewire,
RESULTS: The procedure was successfully performed in all seven patients. There were no complications related to the surgical technique.
CONCLUSION: In patients where the classic technique for secondary insertion of the Provox prosthesis is technically impossible, this new technique could be a good alternative

P0120 ARE OUTCOMES FOLLOWING ENDOSCOPY FOR EMERGENCY UPPER GI BLEEDING WORSE AT NIGHT AND WEEKENDS?

A. Rehman[1,*], P. Mundre[1], B. Rembacken[1]
[1]*Leeds teaching hospital Leeds, Leeds, United Kingdom*
Contact E-mail Address: *bjorn.rembacken@leedsth.nhs.uk*

INTRODUCTION: Patients admitted out of hours or at weekends may have an excess mortality due to the fact that they undergo emergency endoscopy by junior staff. We retrospectively looked at the predictors of mortality in patients undergoing emergency endoscopy for severe bleeding in Leeds.
AIMS & METHODS: The survival of patients with the most significant upper GI bleeding lesions who underwent emergency endoscopy in Leeds between end of April 2008 and middle of June 2012 were selected for retrospective analysis using data from our endoscopy reporting system and hospital records.
RESULTS: A total of 509 significant emergency gastroscopies were carried out with the finding of 197 duodenal ulcers, 105 gastric ulcers, 161 oesophageal varices, 26 gastric varices, 12 Dieulafoy's and 9 other bleeding lesions (bleeding biopsy site, bleeding EMR site, gastric lymphoma, 3 PHG, 3 angioectasia).
After 22% of procedures (114/509), the patient died within 30 days. As expected, patients who died had a significantly higher Rockall score (7.6 vs. 6.0 $p < 0.0001$), a higher ASA level (3.5 vs. 2.7 $p < 0.001$) and a lower systolic BP at the time of the examination (94.8 vs 103 $p = 0.025$). Patients who died following endoscopy for bleeding ulcers were significantly older than those who survived (77.7 vs. 67.5 yrs, $p = 0.006$). There was no significant difference in mortality with the type of bleeding lesion, Hb (8.0 vs. 7.8) or heart rate (100 vs. 102 bpm) at the time of the endoscopy between those who survived and those who died. Patients who died, were transfused significantly more blood than those who survived (5.9 units vs 3.8). Of the patients who suffered a re-bleed, 52 patients died and only 62 survived. A total of 28 patients required emergency angiography and embolisation of a bleeding vessel. This small group had suffered a significantly greater blood loss (21 had suffered a re-bleed) and had an average Hb of only 6.9 in spite of having received an average of 12.9 units of blood. In spite of this, 22 patients survived following embolisation.
Undergoing an emergency gastroscopy at night or during the weekend or a bank holiday was not associated with an increased risk of death ($p = 0.50$, $p = 0.32$ respectively). Whether the examination was carried out by a SpR or a Consultant made no difference to the survival of the patient ($p = 0.40$).
CONCLUSION: Our study had the statistical power to detect all the recognised risk factors for death following admission with an acute upper GI bleed including advancing age, increasing comorbidity, hypotension, re-bleeding and transfusion requirement. We found no evidence that undergoing an emergency endoscopy at night or during the weekend or a bank holiday had any adverse effect on outcomes. Similarly, the level of seniority of the endoscopist did not affect outcomes.
Disclosure of Interest: None declared

P0121 LONG-TERM OUTCOMES OF PATIENTS WITH MALIGNANT DYSPHAGIA THAT HAVE UNDERGONE STENTING

A. Gaglia[1,*], H. Smart[2], P. O'Toole[1], N. Haslam[1], S. Sarkar[1]
[1]*Gastroenterology,* [2]*Royal Liverpool University Hospital, Liverpool, United Kingdom*
Contact E-mail Address: *gagliam2000@hotmail.com*

INTRODUCTION: Oesophageal stenting with fully covered self-expanding metal stents (SEMS) has transformed the care of patients with malignant dysphagia. SEMS are easily removable and have fewer reported long-term complications of tumour ingrowth although possibly more migration. However, predictive factors for favourable outcomes are yet to be fully defined for those with malignant dysphagia.
AIMS & METHODS: The aim of this retrospective study was to evaluate the complications, the re-intervention rate and the survival after insertion of fully covered SEMS for malignant dysphagia and to identify any predictive factors for outcomes other than tumour stage. All SEMS procedure data were retrieved from Royal Liverpool University Hospital patient database retrospectively in a 2-year inclusion period and analysed regarding SEMS characteristics, procedural events, re-interventions and survival on a standard proforma.
RESULTS: A total of 96 fully covered SEMS were inserted in 74 patients (47 males) with a median age of 73 (range 36-89) years. Technical success was 99% (95/96), with no complications of perforation or bleeding. Minor ($n = 6$) complications included chest pain, vomiting & severe GORD. The 30-day mortality was 12% but was not directly related to the SEMS insertion. The 7-day readmission rate following SEMS placement was 5% as result of symptoms caused by SEMS including pain & vomiting. The median survival was 125 (range 4-910) days. 26 (35%) of the patients needed re-intervention due to recurrence of dysphagia due SEMS migration or tumour overgrowth. The SEMS migration rate was 18% ($n = 14/96$) occurring after a median of 120 (range 10-365) days. 87% of the migrated SEMS were from tumours of the lower oesophagus and GOJ. Tumour overgrowth occurred in 16% ($n = 15/96$) at a median of 120 (range 28-210) days. In 19/26 (73%) cases palliation was successfully achieved with re-intervention; further SEMS placement in 17 & APC in 2. Interestingly, the patients with recurrence of dysphagia had significantly ($p \leq 00.5$) prolonged survival (median 156 (range 30-790) days) compared to patients who did not need any intervention (median 125 (range 4-910) days).
CONCLUSION: Fully covered SEMS are safe and offer extremely effective palliation of malignant dysphagia for up to 3-4 months. Re-intervention beyond this point is for recurrence of dysphagia due to SEMS migration and/or tumour overgrowth that may be due to increased patient survival. The majority of patients can be re-palliated successfully with further endotherapy.

P0122 HIGH DIAGNOSTIC YIELD OF EUS-ASSISTED SINGLE INCISION-NEEDLE KNIFE (SINK) BIOPSY FOR HISTOLOGICAL ANALYSIS OF UPPER GASTROINTESTINAL STROMAL TUMORS

C.de la Serna- Higuera[1,1,*], P. Diez- Redondo[1], F. Santos[1], I. Peñas[1], P. Gil[1], H. Nuñez[1], M. Pérez-Miranda[1]
[1]*Gastroenterology, Rio Hortega Hospital, Valladolid, Spain*
Contact E-mail Address: *csernah@hotmail.com*

INTRODUCTION: Gastrointestinal stromal tumors (GIST) are the most frequent type of mesenchymal neoplasms of the upper gastrointestinal tract and may be malignant regardless their echopattern or size, therefore, histologic and immunohistochemical (IH) analysis are crucial for diagnostic and pronostic purposes. EUS- guided FNA provides a low diagnostic yield, specially for smaller GIST. EUS - assisted SINK biopsy is an alternative method with promising preliminary results.
AIMS & METHODS: We aimed to evaluate the diagnostic yield of SINK samples for IH analysis and mitotic index (MI)assessement.
Retrospective evaluation of a prospectively-mantained database, including all patients with upper gastrointestinal subepithelial tumors (SETs) who underwent EUS-assisted SINK biopsy since April 2010 to March 2014. All patients underwent previous radial/linear EUS for size measurement and morphological characterization; then a needle-knife was used in blended current at 30W to 60W settings and a 6 to 12 mm linear incision was made along the highest convexity zone of the lesion. Then, 3 to 5 biopsy samples were obtained from the exposed tissue with a standard biopsy forceps and included in formalin. When histologic analysis revealed features of mesenchymal origin (spindle cells), specific IH markers for GISTs (cKit- CD 117, CD 34) and mitotic count per 50 high- power fields (HPF) to assess malignant potential were performed.
RESULTS: 72 patients (M/F: 38/34) were included (mean age 63.66, range 22-89). There were 27 mesenchymal lesions (27/72: 37.5%); GIST 23, leiomioma 4. Median size: 3.53 mm (1.34-5.90). IH analyses for SINK samples was positive in 25/ 27 GISTs (92.59%) and MI determination was feasible in 21/ 27 (77.77%). 16/21 showed < 5 mitoses per 50 HPF and were categorized as 'very low risk' according to the NIH classification-all these lesions with diameters under 30 mm. There were no procedure-related complications.
CONCLUSION: EUS-assisted SINK-biopsy of upper GISTs appears to be an easy and safe technique and provides sufficient tissue samples for IH diagnosis and assessment of malignancy by means of an accurate MI calculation.

INTRODUCTION: Functional dyspepsia (FD) is a highly prevalent gastrointestinal disorder characterized by symptoms originating from the gastroduodenal region in the absence of underlying organic disease as defined by Roma III criteria. Upper endoscopy (UE) associated to digital chromoendoscopy (DC), magnification (M) and high definition (HD) had shown excellent results for

the diagnosis of Barret esophagus (BE) and esophagitis. However, not all patients are investigated with this kind of technology, where UE results are considered as absence of organic lesions, thus diagnosed as FD.
AIMS & METHODS: Based on the hypothesis that HD UE associated to DC and M can detect more mucosal details than standard UE, we evaluate the effectiveness of i-Scan^{TM} (HD UE+DC+M) in patients with functional dyspepsia for the identification of organic esophageal lesions. After approval by the ethics committee and signing of an informed consent, a prospective study was performed in consecutive patients undergoing for UE from Nov 2012 to June 2013. Inclusion criteria: Criteria of FD in accordance to ROMA III criteria, normal standard UE in the last 3 months previous to the inclusion in this study. Exclusion criteria: age <18, pregnancy, history of: gastritis, GERD, gastrointestinal cancer, H pylori infection, pancreatic disease, choledocolitiasis, alcohol or smoke abuse, use of medications (IBP, NSAIDs, Antibiotics). HD UE+DC and M was performed using the EPK-i processors with i-Scan^{TM} from Pentax. Under sedation patients underwent HD UE, analyzing all the mucosa aspects using initially white light (WL), with especial regard in the Z-line at the level of the cardia. Then DC was performed using i-Scan. Any alteration in the mucosa pattern (color, pitt or vascular pattern) was analyzed and then classified as inflammation or BE using Los Angeles and Prague classifications respectively. Finally acetic acid was performed and a target biopsy was done as the gold standard method to confirm i-Scan findings.
RESULTS: 491 patients were included. 48% were men with a mean age of 47 (ranges: 18-87). 151/491 patients (30.7%) had an organic esophageal lesion detected at i-Scan. 45/151 patients were detected initially by HD-UE-WL. Biopsy confirm the esophageal lesions in 125 cases. i-Scan detect 94 cases of short BE (C<1,M<1), 25 cases of esophagitis (Grade A), and 6 cases where considered to have a mixed disease (BE and esophagitis). The accuracy to predict BE for i-Scan was 95% and 100% for esophagitis.
CONCLUSION: HD UE+M+DC (i-Scan^{TM}) could detect an important number of organic esophageal lesions as BE and esophagitis in patients initially overdiagnosed as a functional disease.

P0124 COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARIS PROPRIA

C.B. Ryu[1,*], M.S. LEE[2], J.Y. BAE[3], J.Y. SONG[4]
[1]*Department of Internal Medicine, Soon Chun Hyang University School of Medicine,* [2]*Department of Internal Medicine, SOON CHUN HYAN UNIVERSITY SCHOOL OF MEDICINE, BUCHEON,* [3]*SEOUL MEDICAL CENTER, SEOUL,* [4]*SUWON MEDICAL CENTER, SUWON, Korea, Republic Of*

INTRODUCTION: Endoscopic resection for gastric subepithelial tumors (SETs) originated from the muscularis propria (GSET-PM) has offered less invasive alternatives to surgical resection. The aims of this study were to compare endoscopic subtumoral dissection (ESD) with surgical resection for the removal of GSET-PM.
AIMS & METHODS: This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5cm and showed an endoluminal growth pattern according to endoscopic ultrasound (EUS) finding.
RESULTS: ESD group were more likely to have upper portion (10/17, 58.8%) and surgery group were more likely to have mid portion (41/76, 53.8%) (p=0.039). ESD group had smaller median tumor size (25.6 mm vs 35.9 mm, p=0.037) and higher endoluminal ratio (58.5±9.1% vs 45.8±15.4%, p=0.002). ESD group mostly had Yamada type III (10/17, 58.8%) and the surgery group were mostly Yamada type I (52/76, 68.4%) (p<0.001). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, p<0.001). In ESD group, 3 performed surgical resection after ESD (1 incomplete resection and 2 uncontrolled bleeding) and 1 showed perforation which was completely resected with endoscopic closure. In the surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group (p=0.006), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between the two groups.
CONCLUSION: ESD can be a good option for the resection of endoluminal GSET-PM and could replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been widely performed for the treatment of early gastric cancer (EGC).
AIMS & METHODS: The aim of this study is to confirm the effectiveness of ESD in submucosal invasive gastric cancers (SM-GC), with a special focus on patients who underwent non-curative resection.
Data for 1,246 patients who underwent ESD for treatment of EGC at six medical centers in Daegu-Gyeongbuk, Korea, between February 2003 and May 2010 were collected. After retrospective analysis of ESD databases, 118 patients were enrolled in the study. The corresponding EGC lesions were classified into three groups based on the results of pathological examination: 1) gastric cancers with submucosal invasion less than 500μm (SM1-GC) that met the expanded criteria (EC) (SM1 EC group, n=42); 2) SM1-GC that did not meet the EC (SM1 non-EC group, n=38); and 3) gastric cancers with submucosal invasion greater than 500μm (SM2-GC group, n=38).
RESULTS: The en bloc resection rate (SM1 EC group/SM1 non-EC group/SM2-GC group: 85.7%/94.7%/97.4%, respectively) and complete resection rate (SM1 EC group/SM1 non-EC group/SM2-GC group: 81.0%/81.6%/71.1%, respectively) did not differ significantly among the three groups. However, the curative resection rate was significantly better in the SM1 EC group (69.0%) compared to that in SM1 non-EC and SM2-GC groups (0% in both cases). Out of a total of 118 patients, 89 (75.4%) underwent non-curative resection. Cancer recurrence was observed in 9 patients (9/89, 10.1%) during the median follow-up period of 40 months (range: 3-99). We analyzed the overall survival and disease-free survival in non-curative patients that underwent or did not undergo additional surgery. The overall survival and disease-free survival did not differ significantly between patients that were treated with additional surgical resection and those that were simply followed up after ESD.
CONCLUSION: Non-curative resection in SM-GC does not always lead to cancer recurrence. Thus, if additional surgery cannot be performed because of the patient's unsuitable condition (due to age, underlying disease, etc.) or refusal, a close follow-up with endoscopy can be considered as an alternative for carefully selected patients. Moreover, as the ESD technology continues to evolve, it might be possible to expand the criteria for curative ESD in patients with SM-GC.

P0126 PROSPECTIVE LONG-TERM OBSERVATION TRIAL OF ARGON PLASMA COAGULATION (APC) FOR SHORT-SEGMENT BARRETT'S ESOPHAGUS IN AN OUTPATIENT SETTING

D. Schädlich[1,*]
[1]*Universität Erlangen-Nürnberg, Erlangen, Germany*
Contact E-mail Address: *e-mail@daniela-hascher.de*

INTRODUCTION: Barrett's esophagus (BE) is the only known precursor lesion to esophageal adenocarcinoma of the distal esophagus. There are various endoscopic treatments to ablate BE to generate a neo-squamous epithelium such as radiofrequency ablation (RFA), cryotherapy and argon plasma coagulation (APC). However, there is limited data available for APC in an outpatient setting.
AIMS & METHODS: Prospective long-term observation trial of Argon Plasma Coagulation in an outpatient setting.
Patients of a gastroenterology practice were considered for entry into this trial. At the initial endoscopy a chromoendoscopy was undertaken and biopsies were taken (bioptic mapping). Then the patients were treated with a high frequency pulsed APC (16 boosts/sec) in order to ablate BE completely. One session was necessary for tongue-shaped and complete covering epithelium, more than two sessions for distal circular BE. Follow-ups were scheduled after six weeks, six months, one and two years.
RESULTS: 73 patients (17% women, median age: 71 years, range: 34 -82 years) were enroled but only 70 patients were finally included in this trial. Other than rare minor retrosternal pain after large ablations there were no other treatment-associated complications. Of all patients treated with APC-ablation 87.5% showed a stable complete eradication with regenerated neo-squamous epithelium in the follow up. During the 2-year follow up 4.3% showed a macroscopic and histological recurrence. However, the clinical role of residual or recurrent BE in form of so called "Buried glands" (10%) is still uncertain and worth discussing.
CONCLUSION: In this trial it was shown the first time that APC was a safe and efficient endoscopic treatment to ablate short-segment non-dysplastic BE especially in an outpatient setting.

INTRODUCTION: Patients suffering from neurogenic dysphagia often get caught in the trap: they find themselves somewhere in the space between different specialists. This dilemma might be due to a lack of pathophysiological knowledge of the complex swallowing process from the oral cavity to the stomach and an inability to directly visualize the esophageal phase of deglutition.

AIMS & METHODS: In a multidisciplinary setting, 31 consecutive patients with suspected neurogenic dysphagia were evaluated by transnasal access applying an ultrathin video endoscope with an outer diameter of 3.8 mm (BF-3C160, Olympus Europe). Patients were examined in sitting position while ingesting water and food of different consistencies. Diagnostic was completed by videofluoroscopy and high-resolution manometry. The study was approved by the local Ethics Committee.
RESULTS: Functional endoscopy was successfully performed in all patients. We were able to show that functional endoscopy is a feasible and safe method; no adverse events were noted. Endoscopic findings correlated well with the clinical signs of the patients and the other diagnostic modalities. A variety of disorders was documented by functional endoscopy and recorded as video files: Incomplete and delayed closure of the upper esophageal sphincter (in retroflex view), clearance disturbance of tubular esophagus, esophageal hyperperistalsis and hypomotility. The most common findings in the oral and pharyngeal phase were bolus leakage, delayed swallowing reflex, vallecular residues, and, aspiration during food intake.
CONCLUSION: By interdisciplinary cooperation with additional assessment of the esophageal phase of deglutition using the innovative method of functional endoscopy, the diagnostic of neurogenic disorders including dysphagia may be tremendously improved leading to a better clinical understanding of complex dysfunctional patterns. To our best knowledge, this is the first study to show that a retroflex view of the ultrathin video endoscope within the esophagus may be safely performed. This diagnostic comprehensive approach should be helpful to apply focused prophylactic and therapeutic actions.

P0128 REPEATED BOLUS INJECTION VERSUS SLOWLY CONTINUOUS INFUSION OF PROTON PUMP INHIBITOR FOR THE MANAGEMENT OF BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION

D.K. Kang[1,*], **D.H. Kang**[1], H.W. Kim[1], C.W. Choi[1], S.B. Park[1], S.J. Kim[1], Y.S. Shin[1], Y.Y. Choi[1], H.K. Lim[1], S.K. Oh[1], H.S. Nam[1]
[1]*Division of Gastroenterology, Department of Internal Medicine, School of Medicine Pusan National University, Pusan National University Yangsan Hospital, Yangsan-si, Korea, Republic Of*
Contact E-mail Address: *shadam@naver.com*

INTRODUCTION: Elevated intra-gastric pH is important in management of bleeding and healing the artificial ulcer after endoscopic submucosal dissection. The Proton Pump Inhibitor (PPI) has powerful acid suppression. At present, the standard treatment of choice for the prevention of gastric ulcer bleeding is continuous infusion of PPI after intravenous bolus loading.
AIMS & METHODS: Our aim is to compare the effects of repeated bolus injection and slowly continuous infusion of PPI for the management of delayed bleeding after gastric ESD.
From March 2012 to Feb 2013, 273 patients with gastric superficial epithelial neoplasm were enrolled. The group was divided into two. One is the repeated bolus group, the other one the slowly continuous-infusion group. All patients are undergod ESD. In slowly infusion group After initial pantoprazole 80mg bolus loading for 30 min before ESD, 8mg/hr continuous infusion for 72 hours is done after initial 80mg bolus loading for continous infusion group. For repeated bolus group (n = 136), pantoprazole 40mg bolus is injected q 12 hours for 72 hours. After 72 hours, Oral pantoprazole 40 mg daily for 4 to 8 weeks. Follow-up endoscopy is performed 2 days and 4 weeks after ESD. (In case of incomplete ulcer healing, 8 week endoscopy and pantoprazole 8 wk medication was done.)
RESULTS: No difference on clinical characteristics were seen between two treatment groups. Bleeding events occurred in 8.4% (23/273) of all patients. In follow up endoscopic findings, high risk of stigma was found in 15.8% (43/273) of all patients. No difference in bleeing event was seen between repeated bolus group and slowly continous infusion group. Submucosal invasive, gross type of lesion and coronary disease were significant risk factors for rebleeding events rather than the method of PPI administration.
CONCLUSION: The method of PPI administration was not significantly different to predict post ESD delayed bleeding. Submucosal invasive, gross type of lesion and coronary disease were more important to predict post ESD delayed bleeding.
Disclosure of Interest: None declared

P0129 A NOVEL STRATEGY IN THE ENDOSCOPIC TREATMENT OF REFRACTORY UPPER GI-BLEEDING IN ANTICOAGULATED PATIENTS WITH THE OVER-THE-SCOPE-CLIP (OTSC) – ARE WE ENTERING TO A NEW ARA IN THE TREATMENT OF UPPER GI-BLEEDING?

E. Wedi[1,*], A. Sportes[2], T.M. Reißig[2], J. Hochberger[1]
[1]*Departement of Gastroenterology and Interventional Endoscopy,* [2]*University Hospital Strasbourg, Strasbourg, France*
Contact E-mail Address: *edris1@web.de*

INTRODUCTION: The OTSC (OVESCO, Germany) is a novel endoscopic device successfully applied for severe GI bleedings, perforations, fistulas and experimental NOTES procedures.
We performed a retrospective analysis of all OTSC applications for acute gastrointestinal bleeding from February 2009 to March 2014 using our endoscopy database and individual patient records.
AIMS & METHODS: Over a 5 year period 55 patients [median 73 y (29-97) 17 w, 38 m, ASA 2-4] with acute severe upper gastrointestinal bleeding (hemoglobin < 7 g/dl at admission for acute bleeding or as emergency endoscopy for hospitalized patients) using 56 OTSCs (n = 54 T-type 12/6 17.5 mm OD; n = 2 T-type 14/6 21 mm OD).
RESULTS: In 48/55 cases (87.2%) acute bleeding was related to peptic ulcer disease, in 2 cases due to bleeding from a malignant ulcer (1x gastric AC, 1x gastric lymphoma), 2 cases due to recurrent bleeding after polypectomy and clip in the stomach. In 1 case a heavily bleeding Mallory Weiss tear and in 1 case a bleeding ulcer at a gastro-jejunal anastomosis was treated. One patient bled heavily from a deep muscle laceration after balloon dilatation for achalasia. 18/55 (32.7%) were treated due to a failure of a previous hemostasis methods (standard hemoclips, injection or radiologic embolization).
Of the 55 patients 44 (80%) were on pre-existing anticoagulation, 9/55 (16.4%) took warfarin, 24/55 (43.6%) aspirin, 10/55 (18.2%) heparin/enoxaparin and 1 (1.8%) was anti-coagulated with a combination of aspirin plus clopidogrel.
In 46/55 of all cases, primary treatment with the OTSC was successful (83.6%), in all the cases without re-bleeding events. In 7/55 (12.7%) surgical treatment was necessary due to insufficient hemostasis. However, 4 of those 7 patients died during the hospital stay. 2 multi-morbid patients not fit for surgery passed away.
CONCLUSION: The OTSC system is a promising new tool for the management of acute severe GI-bleeding. Especially patients with pre-existing anticoagulation and multi-morbidity seem to profit from this system.

P0130 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION FOR GASTRIC NEOPLASMS IN THE PYLORUS

E.J. Gong[1,*], D.H. Kim[1], H.-Y. Jung[1], H. Lim[2], K.-S. Choi[1], J.Y. Ahn[1], J.H. Lee[1], K.D. Choi[1], H.J. Song[1], G.H. Lee[1], J.-H. Kim[1]
[1]*Gastroenterology, University of Ulsan College of Medicine, Asan Medical Center, Seoul,* [2]*Gastroenterology, Hallym University Sacred Heart Hospital, Anyang, Korea, Republic Of*

INTRODUCTION: Endoscopic resection (ER) for gastric neoplasms in the pylorus is a technically difficult procedure.
AIMS & METHODS: We investigated clinical outcomes to determine the feasibility and effectiveness of ER for gastric neoplasm in the pylorus. Subjects who underwent ER for gastric neoplasm in the pylorus at Asan Medical Center between January 1997 and February 2012 were eligible. The clinical features of patients and tumors, histopathologic characteristics, adverse events, results from ER, and survival were investigated.
RESULTS: A total of 227 subjects underwent ER for 228 gastric neoplasms in the pylorus. Median age was 62 years (interquartile range [IQR]: 53-68 years), and the male to female ratio was 2.2:1. Median tumor size was 14 mm (IQR: 10-22 mm), and median procedure time was 23 minutes (IQR: 15-33 minutes). En bloc resection was achieved for 193 lesions (84.6%), including complete resection (CR) of 195 lesions (85.5%), and curative resection (CuR) of 167 lesions (73.2%). Rates of CR and CuR were significantly lower for pyloric and postpyloric lesions than for prepyloric lesions ($p = 0.002$ and $p = 0.006$). Adverse events occurred in 19 patients, including delayed bleeding in 12 (5.3%) and stricture in 7 (3.1%). During a median follow-up period of 79.0 months, local tumor recurrence was detected in 2.6%. The 5-year overall and disease-specific survival rates in the 83 patients with gastric cancer were 81.5% and 96.9%, respectively.
CONCLUSION: ER appears to be a feasible and effective method for the treatment of gastric neoplasms in the pylorus, on the basis of these favorable clinical outcomes.

P0131 THE ROLE OF NONCONTRAST COMPUTED TOMOGRAPHY (CT) PRIOR TO THE ENDOSCOPIC INTERVENTION FOR THE SUSPICIOUS ESOPHAGEAL FISH BONE (FB)

E.K. Choi[1,*], S.U. Jeong[1], H.U. Kim[1], S.-J. Boo[1], S.-Y. Na[1], H.J. Song[1], **Y.-K. Cho**[1], **B.-C. Song**[1]
[1]*Internal Medicine, Jeju National University Hospital, Jeju-Do, Korea, Republic Of*
Contact E-mail Address: *suhmok@gmail.com*

INTRODUCTION: Accidental foreign body ingestion is not uncommon among patients of all ages. The immediate risk to the patient ranges from negligible to life threatening. In Asian countries, fish bones (FB) are the most prevalent esophageal foreign bodies and they are usually ingested accidentally together with food. The FBs have sharp polygonal or pin-like pointed structure and they can perforate or tear the esophageal wall. Therefore, endoscopic intervention should be performed if FB is impacted in the esophagus. However, it is difficult to diagnose esophageal FB with symptom, sign or plain radiography in most cases. Computed tomography (CT) has been proven to be accurate and noninvasive technique for evaluating the structures of esophagus. There are few reports or practical guidelines for using CT scan for the diagnosis of esophageal FB till now.
AIMS & METHODS: The aim of this study was to evaluate the usefulness of CT scan for the diagnosis of esophageal FB. Between March 2009 and March 2014, consecutive patients with suspected esophageal FB at Jeju National University Hospital were identified. Among those, patients with normal plain radiography were included, and medical records were abstracted for CT scan and endoscopy with outcomes. In some patients, noncontrast neck CT scan was performed prior to endoscopic intervention. We evaluated the outcome in two groups (pre-endoscopic CT or No CT).
RESULTS: During the study period, 134 patients (M:F = 55:79) who were strongly suspected of FB ingestion with normal plain radiography were enrolled. The mean age was 54.5±15.6. Of those 134 patients, 91 (68%) underwent CT

scan, and 43 (32%) underwent endoscopic intervention without CT scan. Among 91 patients with pre-endoscopic CT scan, 57 patients had positive CT findings of FB. The subsequent endoscopic procedure showed FB in 56 (98%), and FB was removed in all patients successfully. Among 34 patients who had negative finding of FB on the CT scan, 20 patients underwent endoscopy because of patients' request. However, FB was found in only 2 (10%) patients at the inlet of esophagus. In these two patients, artifacts which were made by dental prosthesis interfered with detecting FB on the CT scan. Among 43 patients without pre-endoscopic CT scan, 31 patients (72%) had esophageal FB in endoscopic examination. The sensitivity, specificity, positive predictive value, and negative predictive value of CT scan for the detection of FB was 98.2%, 90.1%, 96.5%, and 94.7%, respectively.
CONCLUSION: Pre-endoscopic CT scan is accurate and noninvasive diagnostic modality for the detection of ingested esophageal FB. Moreover, CT scan prior to endoscopic procedure is very useful to avoid unnecessary endoscopic procedure. Further studies are needed about the advantages of pre-endoscopic CT scan for the evaluation of pre-endoscopic complication and for the planning of endoscopic removal method.

P0132 ENDOSCOPIC THERAPY IN UPPER GI BLEEDING: ARE WE FOLLOWING THE GUIDELINES?

G. Goodchild[1,*], S. Subramaniam[1], K. Besherdas[1]
[1]*Gastroenterology, Barnet and Chase Farm NHS Trust, London, United Kingdom*

INTRODUCTION: Acute upper gastrointestinal bleeding (UGIB) is a common medical emergency that carries a 10% inpatient mortality. Acute peptic ulcer disease is the most common aetiology followed by variceal bleeding. Mortality has not significantly improved over the last 50 years, highlighting the need to follow best practice guidelines in order to improve outcomes.
Upper GI endoscopy allows us to diagnose and treat the cause of UGIB as well as to help prevent re-bleeding. The 2012 NICE guidance on the management of non-variceal UGIB states that adrenaline as monotherapy should be avoided. It suggests that only mechanical therapy (e.g clips) be used as monotherapy and that adrenaline should always be used as dual therapy with either clips or thermal coagulation (APC).
The aim of our study was to audit our practice and compliance with NICE guidance in delivering appropriate endoscopic therapy for non variceal UGIB and to ascertain the rate of re-bleeding.
AIMS & METHODS: A retrospective analysis of all patients who underwent upper GI endoscopy for melaena or haematemesis as a primary symptom over an eight year period (2006-2013) was performed within a large district general North London NHS trust. Data was obtained from the Unisoft Endoscopy reporting software. The therapies used at endoscopy for UGIB were scrutinized.
RESULTS: 3759 patients were referred for upper GI endoscopy with melaena or haematemesis. 594 patients received endoscopic therapy (102 for variceal bleeds and 492 for non-variceal bleeds).
Table 1: Therapies in non-variceal upper GI bleeding:

Therapy	Number of patients (%)
Adrenaline monotherapy	172 (34.9%)
Adrenaline + Endoclip*	117 (23.8%)
APC monotherapy	94 (19.1%)
Adrenaline + APC*	53 (10.8%)
Endoclip monotherapy*	32 (6.5%)
Adrenaline + APC + endoclip*	18 (3.7%)
Endoclip + APC	6 (1.2%)
Total	**492**

A total of 26 patients (5.3%) diagnosed with non-variceal upper GI bleeding experienced re-bleeding (defined as the re-appearance of melaena/haematemesis with repeat endoscopy within 7 days). Of these patients 14 (53.8%) had received optimal (NICE recommended) therapy whilst 12 (46.2%) had received sub-optimal therapy (7 had adrenaline monotherapy and 5 had APC monotherapy). There was no associated increase in mortality compared to the national average.
CONCLUSION: This study demonstrates poor adherance to current NICE guidance on dual therapy in non variceal UGIB as only 45% of patients received optimal intervention. Endoscopic monotherapy for acute UGIB– either with adrenaline (35%) or APC (19%), though no longer recommended was still evident within our trust. The type of therapy given did not influence the risk of re-bleeding in our population and our overall mortality rates fell within expected levels.

INTRODUCTION: Obesity is at epidemic proportions and rising[1]. Bariatric surgical procedures have demonstrated better durable weight loss than diet and exercise. However risk may limit adoption of these procedures[2]. Endoscopic procedures like the Primary Obesity Surgery Endolumenal (POSE), may offer less risk and satisfactory results, however, limited safety and outcome data is available[3].
AIMS & METHODS: The objective of the study was to describe the POSE procedure, perioperative care, one year safety and weight loss outcomes for a single center.
Methods: 162 patients undergoing the POSE procedure between July 2011 and April 2013 were followed for one year. Overall patient status and weight data was collected at baseline and at 1 year (n = 130). Outcomes included adverse events, change in total body weight (TBWL), percentage of TBWL (%TBWL) and percentage of excess weight loss (%EWL).
RESULTS: Patients tolerated the procedure well with no serious short or long term adverse events. All but one patient was discharged within 24 hours of procedure. Mean age was 43.7±11.0 years and baseline BMI was 38.0 ± 4.9 kg/m^2. Initial body weight (106.7± 18.0 kg) was significantly reduced at 1 year: mean TBWL was 16.0±10.2 kg and mean % TBWL was 14.4±8.2%. At 1 year of follow up %EWL was 43.4±25.6%
CONCLUSION: The POSE method can be considered an effective, safe and well tolerated for the treatment of patients with obesity, at least at 1 year of follow-up.

INTRODUCTION: Recently, a new over-the-scope clip (OTSC) (Ovesco Endoscopy, Tuebingen, Germany) system has been developed and used for the primary non-surgical closure of GI tract perforations and fistulas.
AIMS & METHODS: The aims of this study were to investigate the therapeutic yield of endoscopic management by the OTSC system. We performed a multicenter prospective study. In total six experts (five centers) performed OTSC procedure.
RESULTS: This study involved in total 17 patients (median age 55 years (range 32-77 years), 12 men) with GI leaks from anastomotic dehiscence, fistulas, and esophageal perforation due to Boerhaave's syndrome: Three gastrojejunostomy site, three esophagojejunostomy site, three esophagogastrostomy site, two Boerhaave' syndrome, two gastrobronchial fistula, one gastrocolonic fistula, one endoscopic full thickness resection site closure, one jejuno-jejunal fistula, one colonopseudocyst fistula. The diameter of leaks ranged between 5 and 20 mm. Mean procedure time was 18.3 min. Technically, all procedures were succssful. Complete sealing of leaks was achieved by using OTSC alone in 14 of 17 patients. For one OTSC fail patient, closure was completed by placing one additional covered stent. Two fistula cases required surgical repair.
CONCLUSION: The OTSC system is very useful in the management of GI leaks especially in case of anastomotic leakage after bowel surgery.

INTRODUCTION: Thermal ablation for Barrett's esophagus has widely been established in gastrointestinal endoscopy during the last decade. The mainly used methods of radiofrequency ablation (RFA) and argon-plasma coagulation

(APC) carry a relevant risk of stricture formation of up to 5-15%. Newer ablation techniques that are able to overcome this disadvantage would therefore be desirable.
AIMS & METHODS: The aim of the present study was to compare the depth of tissue injury of the new method of Hybrid-APC versus standard APC within a randomized study in a porcine esophagus model. Using a total of 8 explanted pig esophagi, 48 esophageal areas were ablated either by standard or Hybrid-APC (APC with prior submucosal fluid injection) using power settings of 50 and 70W. The depth of tissue injury to the esophageal wall was analysed macroscopically and histopathologically.
RESULTS: Using 50 W, mean coagulation depth was 937±469μm during standard APC, and 477±271μm during Hybrid-APC ($p = 0.064$). Using 70 W, coagulation depth was 1096±320μm (standard APC) and 468±136 μm (Hybrid-APC; $p = 0.003$). During all settings, damage to the muscularis mucosae was observed. Using standard APC, damage to the submucosal layer was observed in 4/6 (50 W) and 6/6 cases (70 W). During Hybrid-APC, coagulation of the submucosal layer occurred in 2/6 (50 W) and 1/6 cases (70 W). The proper muscle layer was only damaged during conventional APC (50W: 1/6; 70W: 3/6).
CONCLUSION: Hybrid-APC reduces coagulation depth by half in comparison with standard APC, with no thermal injury to the proper muscle layer. It may therefore lead to a lower rate of stricture formation during clinical application.

INTRODUCTION: Although the macroscopic characteristics of submucosal tumors (SMTs), such as gastrointestinal stromal tumors (GISTs), have been characterized, the assessment of SMTs by their endoscopic visualized features (EVF; which are observed by endoscopic imaging under direct view) remains unevaluated.
AIMS & METHODS: The aim of the present study was to investigate the potential of endoscopic diagnostics for SMTs using EVF. The EVF of 26 gastric SMT cases, in which the final pathological diagnosis was obtained by bloc biopsy using the submucosal endoscopy with mucosal flap method, were retrospectively reviewed. Each type of SMT was classified according to the following five EVF: Color, clarity, shape, tumor coating and solidity. Additionally, the EVF of 13 low-risk GISTs and 13 benign submucosal tumors (BSTs) were comparatively evaluated for the five abovementioned EVF.
RESULTS: Similar trends were identified between the low-risk GISTs, granular cell tumors and the schwannoma with regard to EVF. While these tumors exhibited cloudy EVF, leiomyomas tended to exhibit clear EVF. Among SMTs of the heterotopic pancreas type, the EVF demonstrated particularly small nodules of the pancreatic tissue itself. Although the sample size included in the present study is small, a classification system for gastric SMTs was proposed according to the EVF. When compared with the BST group, the GIST group demonstrated a significantly higher frequency of tumors that exhibited a combination of three EVF (white, cloudy and rigid) that are consistent with all gastric GISTs ($P < 0.05$).
CONCLUSION: Gastric SMTs may be classified based on the EVF, which indicates that the EVF possess potential diagnostic value for the differentiation of GISTs from BSTs.

P0137 MIXED HISTOLOGICAL-TYPE (INTESTINAL AND DIFFUSE TYPE) EARLY GASTRIC CANCER PATIENTS TENDED TO BE NON-CURATIVE RESECTION BY ENDOSCOPIC SUB-MUCOSAL DISSECTION

H. Osumi[1,*], J. Fujisaki[1], M. Igarashi[1]
[1]*Department of Gastroenterology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*
Contact E-mail Address: *hiroki.osumi@jfcr.or.jp*

INTRODUCTION: It is well known that the histological types of gastric cancer are intestinal and diffuse type (by Lauren[1]). Intestinal type mucosal gastric cancer will be cured by ESD. However, Diffuse type gastric cancers have lymph node metastasis and even intramucosal cancer. Intestinal type was divided into well (tub1) differentiated adenocarcinoma and moderately (tub2) differentiated adenocarcinoma according to their structure abnormality by Japanese Classification of Gastric carcinoma (JCGC). Intestinal type is equal to differentiated adenocarcinoma and Diffuse type is equal to undifferentiated adenocarcinoma by JCGC. Mixed-histological type (Intestinal and Diffuse) early gastric cancer sometimes yields different results in pre-endoscopic submucosal dissection (ESD) biopsy diagnosis and post-operative ESD diagnosis. This complicates the diagnosis of the cancer region using narrow band imaging (NBI).
AIMS & METHODS: The purpose of this study is to evaluate the clinical characteristics and tendencies of mixed-histologic-type early gastric cancer, and bring up points of consideration of pre-operative ESD diagnosis. 1259 patients who were diagnosed with predominantly differentiated early gastric cancer (M: 1026 cases, SM: 233 cases) and who were treated with ESD between 2005 and 2012 without previously being treated at the Cancer Institute Hospital were retrospectively studied. The histological type of the cancer tissue, the criteria used to determine the stump, and the degree of SM invasion were determined based on the Japanese Classification of Gastric Carcinoma (JCGC). The Chi-square test and logistic regression analysis were used as univariate and multivariate analysis respectively to statistically compare the test groups.
RESULTS: Mixed-histologic-type early gastric cancer was defined as showing 10% or more undifferentiated adenocarcinoma in the post-operative ESD diagnosis. 94.6% of well (tub1) differentiated adenocarcinoma diagnosed by biopsy accorded with final ESD specimens pathology. However, 68.2% of moderately (tub2) differentiated adenocarcinoma diagnosed by biopsy accorded with ESD specimens. Mixed-histologic-type adenocarcinoma tended to be bigger in size and had a higher positive rate of sub-mucosal invasion than pure differentiated adenocarcinoma. (Size: 23.2 mm (±13.2) vs14.7 mm (±9.8), $p < 0.05$ SM: 45% vs 26%, $p < 0.05$) The rates of lateral margin involvement (LM), Lymphatic invasion (ly) and Lymph node metastasis (LN) were significantly different between groups of pure differentiated adenocarcinoma and mixed-histologic-type adenocarcinoma.(LM: 5.4% vs 1.0%, $p = 0.003$ ly: 18% vs 3.1%, $p < 0.05$ LN: 3.6% vs 0.3%, $p = 0.003$) In the multivariate analysis, all the above factors are significantly different between groups.
CONCLUSION: If pre-operative histological diagnosis using biopsy specimens before ESD shows tub2, there is the possibility that it is mixed-histologic-type early gastric cancer. We consider it necessary in such a case to conduct a careful pre-operative diagnosis of the cancer region using NBI or a biopsy of the surrounding area, while keeping in mind the clinical characteristics of mixed-histologic-type adenocarcinoma avoiding non- curative resection by ESD.

P0138 A MORPHOLOGICAL CLASSIFICATION OF WHITE OPAQUE SUBSTANCE WITHIN GASTRIC NEOPLASIA VISUALIZED BY MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING

H. Ueyama[1,*], A. Nagahara[1], K. Matsumoto[1], Y. Nakagawa[1], K. Matsumoto[1], T. Yao[2], S. Watanabe[1]
[1]*Gastroenterology,* [2]*Human Pathology, Juntendo University School of Medicine, Bunkyo-Ku, Japan*

INTRODUCTION: White opaque substance (WOS) identified within gastric neoplasias is a unique finding visualized in magnifying endoscopy with narrow-band imaging (ME-NBI) and represents intramucosal accumulation of lipid droplets. The morphological classification of WOS within gastric neoplasia has not been investigated in detail.
AIMS & METHODS: The aim of the current study was to establish the morphological classification of WOS and investigate whether it can be used to discriminate between adenoma and early carcinoma. This study retrospectively investigated two hundred twenty-seven patients with 242 gastric neoplasias (29 adenomas and 213 early carcinomas) who underwent ME-NBI before endoscopic resection in our hospital between January 2010 and December 2013. We studied the frequency of WOS within gastric neoplasias and identified the following morphological patterns: 1) dotted pattern, scattered and distributed as dots; 2) linear pattern, shaped like a line composed of aggregated dots; 3) reticular pattern, shaped like a honeycomb composed of connected lines; 4) speckled pattern, mottled and composed of aggregated dots; and 5) diffuse pattern, diffusely distributed by dense WOS in the intervening part. We also investigated the irregularity of WOS within adenomas and early carcinomas. We defined irregular WOS as disorganized and asymmetrical distribution of WOS in all patterns.
RESULTS: WOS was more frequently observed in adenomas (13/29: 44.8%) than in early carcinomas (62/213: 29.1%). WOS within adenomas showed a symmetrical distribution with a regular reticular pattern because the intervening part has no severe structural abnormalities. The WOS within carcinomas showed an asymmetrical distribution with an irregularly dotted or speckled pattern because the intervening part has severe structural abnormalities.

	Adenoma (13)	Carcinoma (62)	*P value*
Dotted pattern	2 (15.4%)	30 (48.4%)	<0.05
Linear pattern	5 (38.5%)	13 (21.0%)	NS
Reticular pattern	8 (61.5%)	9 (14.5%)	<0.01
Speckled pattern	4 (30.8%)	40 (64.5%)	0.053
Diffuse pattern	1 (7.69%)	8 (12.9%)	NS
Irregular WOS	3 (23.1%)	60 (96.8%)	<0.01

CONCLUSION: In gastric neoplasias containing WOS, the morphological classification of WOS is useful in discriminating between adenoma and early carcinoma.

P0139 ESTABLISHMENT OF AN ENDOSCOPIC DIAGNOSIS FOR GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE (CHIEF CELL PREDOMINANT TYPE) USING MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING

H. Ueyama[1,*], K. Matsumoto[1], A. Nagahara[1], Y. Nakagawa[1], K. Matsumoto[1], T. Yao[2], S. Watanabe[1]
[1]*Gastroenterology,* [2]*Human pathology, Juntendo University School of Medicine, Bunkyo-Ku, Japan*

INTRODUCTION: Gastric adenocarcinoma of the fundic gland (chief cell predominant type, GA-FG-CCP) has recently been proposed as a new and rare variant of gastric adenocarcinoma. We previously described the clinicopathological and endoscopic features of GA-FG-CCP using conventional endoscopy (CE) in 2010 and 2014[1-2]. If this tumor type is not recognized by a physician, it may be misdiagnosed as a submucosal tumor or fundic gland polyp or it may be overlooked. Therefore, the endoscopic diagnosis of GA-FG-CCP using magnifying endoscopy with narrow-band imaging (ME-NBI) may be useful; however, this technique has not been investigated in detail.
AIMS & METHODS: The aim of the current study was to evaluate the endoscopic features of GA-FG-CCP using ME-NBI. A total of 17 GA-FG-CCPs were evaluated retrospectively between January 2008 and December 2013. The endoscopic and clinicopathological features of the lesions were analyzed to provide information of diagnostic value.
RESULTS: A total of 17 patients [median age 66 y (57-75), 10 men, 7 women] with 17 lesions were treated as follows: 12 were treated with ESD, 3 were treated with EMR, and 2 underwent surgery. Except for 2 cases that underwent additional surgery, all of the cases underwent an endoscopic removal without further treatment. Twelve of the lesions were detected in the upper stomach, 4 in the middle stomach, and 1 in the lower stomach. Macroscopically, 9 lesions were submucosal tumors in shape, whereas 5 were depressed, 1 was flat-elevated, 1 was protruded and 1 was flat in shape. The mean tumor size was 11.8 (3-39) mm. Histopathologically, there were 5 intramucosal cancers and 12 submucosal invasive cancers. The mean depth of the submucosal invasion was 337.5 (50-1200) μm. Lymph node metastasis was observed in one case (25%, 1/4). The most common features of the 17 lesions with CE were 1)submucosal tumor shape in 10(58.8%) cases, 2) whitish color in 12(70.6%) cases, 3)dilated vessels with branching architecture in 9(52.9%) cases and 4)background mucosa without atrophic change in 15 (88.2%) cases. The endoscopic findings for a GA-FG-CCP using ME-NBI did not meet the criteria for carcinoma. However, we detected the four most frequently occurring features using ME-NBI to be 1)an indistinct line of demarcation between the lesion and the surrounding mucosa 8/8(100%), 2)a dilatation of the crypt opening 7/8(87.5%), 3)a dilatation of the intervening part between the crypts 5/8(62.5%) and 4)the presence of microvessels without distinct irregularities 7/8(87.5%).
CONCLUSION: GA-FG-CCP has distinct endoscopic characteristics, especially in terms of its shape, color, vessels and background mucosa using CE and in its demarcation lines, the shape of the crypt opening, the shape of the intervening part between the crypts and the microvessels observed with ME-NBI. Further investigations should include collecting cases using CE and ME-NBI based on these endoscopic features.

P0140 DIAGNOSTIC AND THERAPEUTIC EFFICACY OF ENDOSCOPIC ENUCLEATION FOR SMALL GASTRIC MUSCULARIS PROPRIA LAYER TUMOR

H. Kim[1,*], B. Bang[1], K. Kwon[1], Y. Shin[1]
[1]*Internal Medicine, Inha University Hospital, Incheon, Korea, Republic Of*

INTRODUCTION: Gastric subepithelial tumors originated from muscularis propria (MP) are partly benign tumors, but some gastric stromal tumors have malignant potential, especially gastrointestinal stromal tumors (GISTs). PM tumors are usually treated by surgical intervention and endoscopic treatment remains controversial. The aim of this study was to retrospectively evaluate the utility of endoscopic enucleation for diagnosis and treatment of MP tumors.
AIMS & METHODS: From January 2010 to June 2013, forty patients with gastric MP tumor ($\leq$ 20 mm) underwent endoscopic enucleation. Before endoscopic resection, all patients performed endoscopic ultrasound to determine the layer of origin and the accurate size. Small PM tumor ($<$12 mm) was resected by using band ligation method and PM tumor (range 12-20 mm size) was enucleated by endoscopic submucosal resection (ESD) technique using various endo-knifes. Tumor characteristics, tumor size, procedure technique, complete resection rate and recurrence were analyzed.
RESULTS: A total 40 patients (16 men, 24 women; mean age 50.3 years) were eligible for inclusion in this study. The histologic diagnosis was leiomyoma (n = 24), GIST (n = 15) and schwanoma (n = 1). Band ligation method was used in 20 patients. Median procedure time was 8 min (5-26) and complete resection rate was 95% (19/20). Two patients developed perforation, which was closed by endoscopic methods with metallic clips. ESD method was used in 20 patients. The mean procedure time was 41.1 minutes (range 10 – 260) and complete resection rate was 60% (12/20). Four cases were complicated by perforation, and the perforations were closed with metal clips. The mean follow-up time was 9.8 months (range 3-35). No recurrence was developed during follow-up period.
CONCLUSION: Endoscopic enucleation appears to be effective method for the histologic diagnosis and removal of small MP layer tumors ($<$2cm). Although there is a risk of perforation which has become manageable endoscopically.

P0141 COMPARISON OF DEXMEDETOMIDINE VERSUS MIDAZOLAM FOR PROCEDURAL SEDATION DURING ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC TUMOR

I.-K. Sung[1,*], H.S. Park[1], J.H. KIM[1], S.-Y. Lee[1], S.-P. Lee[1], C.S. Shim[1]
[1]*Konkuk university medical center, Seoul, Korea, Republic Of*
Contact E-mail Address: *inksung@kuh.ac.kr*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is nowadays commonly performed as a treatment for gastric tumor. However, the sedation with midazolam (MDZ) often did not reach a satisfactory sedation during the procedure and the drug could suppress respiration and blood pressure also.
AIMS & METHODS: To investigate the safety and efficacy of dexmedetomidine (DEX) in comparison with midazolam (MDZ) as a sedative during an endoscopic submucosal dissection (ESD) of gastric tumor.
Design: Prospective, randomized, double-blind study.
Setting: Tertiary-care institution.
Patients: Scheduled patients undergoing ESD of gastric tumor.
Main Outcome Measurements: The depth of sedation by using a MOAA/S score (Modified Observers Assessment alertness/sedation), interfering actions of patients, sedation related-adverse events, and the satisfaction degree of the doctors.
RESULTS: Eighty patients were randomly assigned to one of two treatment regimens (40 patients of each). There was no statistically significant difference between the two groups regarding age, sex, body mass index, ASA classification, and tumor characteristics. Appropriate sedation rate and the satisfaction degree of the doctors were significantly high in the DEX group. There were more movements of patient leading to an interruption of the procedure in the MDZ group than in the DEX group. There was no difference in the adverse events between the two groups.
CONCLUSION: DEX for the sedation during gastric ESD is as safe as MDZ and the sedation effect of DEX is superior to that of MDZ.
Key words: Procedural sedation; Endoscopic submucosal dissection; Sedative agents; Dexmedetomidine; Midazolam

P0142 A NEW METHOD TO PERFORM DIRECT PERCUTANEOUS ENDOSCOPIC JEJUNOSTOMY USING DOUBLE BALLOON ENTEROSCOPY AND FLUOROSCOPY

J. Velazquez[1,2,*], R. Beyer[2], K. Kabir Baig[2], K. Monkemuller[2]
[1]*ENDOSCOPY, UNIVERSIDAD NACIONAL AUTÓNOMA DE MÉXICO, MEXICO, Mexico,* [2]*ENDOSCOPY, UNIVERSITY OF ALABAMA, Birmingham, United States*
Contact E-mail Address: *jacovelazquez@gmail.com*

INTRODUCTION: Direct percutaneous endoscopic jejunostomy (DPEJ) is usually performed using traditional push enteroscopes or pediatric colonoscopes. The success rate of DPEJ in expert hands is about 68%. Herein we present a new method to perform DPEJ using DBE and fluoroscopy.
AIMS & METHODS: To report on the efficacy and safety of DBE-assisted DPEJ with simultaneous use of fluoroscopy.
The DBE was performed by using the standard push-pull-technique after the balloon enteroscope was advanced beyond the ligament of Treitz. During advancement, a site in the jejunum was sought for PEJ tube placement by transillumination and finger indentation. In addition we confirmed the site of indentation by placing a radio-opaque marker on the skin and verifying that the small bowel loop was closed to the skin. After a suitable site was identified, DPEJ placement was performed by using the Ponsky-method (pull-type-percutaneous gastrostomy tube technique and 20 Fr PEG-kit.
After placing the DPEJ we administered water soluble contrast through the tube to clearly confirm intraluminal jejunal positioning.
RESULTS: The study included 24 patients (11 females, 13 males, mean age 55 years, age range 31-79). The indications for DPEJ were feeding in 23 patients and venting for malignant small bowel obstruction in one. The technical success was 91.6%. In two patients no transillumination was possible. The mean distance of DPEJ was 74 cm (range 50 to 90 cm) past the pylorus or the anastomosis. One jejunostomy site got infected (4.1%). There were no major complications associated with the procedure.

CONCLUSION: DBE-DPEJ using fluoroscopic assistance seems an efficacious, safe and successful approach for patients requiring jejunal enteral feeding. Nevertheless, studies comparing the double balloon enteroscopy technique to the standard push enteroscopy technique are needed to establish potential advantages of this technique.

INTRODUCTION: The novel over-the-scope-clip (OTSC) allows for excellent apposition of tissue, potentially permitting closure of various types of GI defects.
AIMS & METHODS: To evaluate the usefulness and safety of OTSC for endoscopic closure of fistulas and leaks and perforations in patients with post-obesity surgery altered upper GI anatomy
Case series of all patients with post-obesity surgery altered upper GI anatomy referred for attempted endoscopic closure over a 14-months period. Data analysis included clinical characteristics, demographics, indication, and type of bariatric surgery, primary closure, recurrence, complications, and long-term follow-up clinical outcome.
RESULTS: Seven consecutive patients with fistulas and leaks associated with previous bariatric surgery, four men, three women, were included. The mean age was 50.3 years (range 29-66), mean ASA score of 3 (range 2-4). The most common surgery was gastric sleeve (n = 4), followed by gastric bypass (n = 3). Four patients had a gastropleural fistula; three patients had a gastro-peritoneo-cutaneous fistula. Endoscopic closure was achieved in 6/7 (85.7%). Whereas 4 patients had resolution of the fistula after one endoscopic session, two patients required two sessions and one patient required three sessions. On long-term follow-up there was one recurrence, which was treated with another OTSC. There were no complications associated with OTSC-applications.
CONCLUSION: This is the largest series reported so far on the utility of OTSC for closure of fistulas associated with bariatric surgery. OTSC represents an effective, easy to perform and safe endoscopic therapeutic modality for various types of fistulas. This therapy should be added to the armamentarium of therapeutic endoscopists.

P0144 IMPROVING OUTCOMES FROM UPPER GASTROINTESTINAL BLEEDING IN ENGLAND BETWEEN 2001 AND 2012

J. Rees[1,*], F. Evison[2], R. Vohra[3], N. Trudgill[1]

Contact E-mail Address: *jamesrees@doctors.org.uk*

INTRODUCTION: Upper gastrointestinal bleeding (UGIB) is a common medical emergency with significant mortality. UGIB management has changed in recent years with early therapeutic endoscopy and interventional radiology (IR) rather than surgery for uncontrollable bleeding. We have therefore examined outcomes for patients with UGIB over the last decade in England.
AIMS & METHODS: Hospital attendances in England are collated using Hospital Episode Statistics (HES). ICD-10 coding was used to identify admissions to hospital with UGIB between 2001 and 2012. Death in hospital, 30 day mortality, emergency readmission within 30 days, median time to endoscopy, need for surgery or IR and length of stay were examined.
RESULTS: 679,505 episodes were examined involving 378057 men and 301448 women. 51.9% were coded as undergoing inpatient endoscopy. The overall in-hospital mortality and 30-day mortality for UGIB was 12.2% and 16.1% respectively. Both in hospital and 30-day mortality fell over the 10 year period examined (2001-2003 14.4% and 18.1% vs. 2009-2012 10.2% and 14.3%, $p < 0.001$). There has been a large fall in age-adjusted in-hospital mortality (81.7 per 1000 (95% CI 79.1-84.3) in 2001-2002 vs. 56.5 (95% CI 56.5-58.3) in 2011-2012). Age-adjusted 30-day mortality has also fallen from 102.9 per 1000 (95% CI 99.9-105.9) in 2001-2002 to 79.9 (95% CI 77.7-82.1) in 2011-2012. In-hospital mortality for bleeding varices has fallen by 21.8% from 235.6(95% CI 207.8-265.5) per 1000 in 2001-2003 to 184.3 (95% CI 165-205) in 2009-2012 and for bleeding peptic ulcer it has fallen by 18% from 82.2 per 1,000 in 2001-2003 (95% CI 76.7-88) to 67.4 (95% CI 62.4-72.7) in 2009-2012. For patients who were not coded as undergoing endoscopy, overall in-hospital and 30-day mortality was higher (16.4% and 21% respectively) but also fell over the decade. During the same period there has been a significant fall in the number of patients undergoing surgery (2001-2003 1.84% vs. 2009-2012 0.75%, $p < 0.001$) and a rise in the proportion of patients undergoing an IR procedure (2001-2003 0.04% vs. 2009-2012 0.18% $p < 0.001$). Median time to endoscopy did not change significantly (2001-2003 1(IQR 1-3) days vs. 2009-2012 1(IQR 0-3)days) and the percentage of patients undergoing endoscopy within 48 hours of admission remained 55% over the same time period. Average length of stay fell from 5 (range 2-12) days in 2001-2003 to 4 (range 1-9) days in 2009-2012 but rates of emergency readmission within 30 days have significantly increased (2001-2003 18.2% vs. 2009-2012 27.8% $p < 0.001$).
CONCLUSION: Outcomes for patients with UGIB have improved over the past decade with significant reductions in associated mortality and age-adjusted mortality. There has been a reduction in surgery and increase in IR for UGIB.

P0145 ROUTINE CONFOCAL ENDOMICROSCOPY IN A CLINIC SPECIALIZED IN THE MANAGEMENT OF THE DIGESTIVE PATHOLOGY WITH MUCOSECTOMY, SUBMUCOSAL DISSECTION, PROSTHESIS AND PUNCTURE: RESULTS OF THE FIRST MONTHS OF USE

J.M. Canard[1,*]
[1]*Gastro Enterology, Clinique du Trocadero, Paris, France*
Contact E-mail Address: *jm.canard@hotmail.fr*

INTRODUCTION: Probe-based Confocal Laser Endomicroscopy (pCLE) is an imaging technique that allows the achievement of an extemporaneous microscopic exam of a lesion before the treatment or to control the quality of the endoscopic treatment.
The aim of the study is to appreciate the real indication of Cellvizio in routine in a clinic specialized in the management of the digestive pathology.
AIMS & METHODS: In 5 months of practice (from May 16th until November 23rd 2013) during 436 endoscopies, 51 procedures of pCLE were performed. In all cases, the pathologist exam supports the conclusions of the probe-based microscopic exam.
Among these 51 procedures, 6 are presented:
- One in the esophagus showing the utility of pCLE to find a dysplasia area on a Barrett's Esophagus before mucosectomy followed by a BARRX destruction.
- One in the colon showing the utility of pCLE to differentiate serrated polyps from hyperplasic polyps so as to realize an immediate resection.
- One in the stomach showing the utility of pCLE to find a gastric dysplasia area inside relief abnormalities and treat it by submucosa dissection.
- One in the duodenum showing the utility of pCLE to differentiate an inflammatory granuloma from an adenomatous residue which would justify an ARGON treatment and/or a mucosectomy on a duodenal scare or a right colic that could initiate major complications.
- One in the biliary duct showing the utility of pCLE for the immediate diagnosis of cholangiocarcinoma (1) allowing to choose the most appropriate prosthesis.
- One in the pancreas showing the utility of pCLE for the differential diagnosis of pancreas cysts (serous, mucinous, pseudocysts, cystic forms of neuroendocrine tumors)

RESULTS: For the first 51 procedures the repartition was: 2 cases in the esophagus (4%), 3 in the cardia (6%), 3 in the stomach (6%), 2 in the duodenum (4%), 1 in the small bowel (2%), 3 in the biliary duct (6%), 3 in the Vater papillia (6%), 1 in the pancreas and 33 in the colon (64%).
In 43 cases (84%), the pCLE diagnosis was consistent with those of the pathologist. In 6 cases (12% of cases, 1 in cardia BE, 1 in the stomach, 1 in colonic mucosectomy scares, 1 at the Vater papillia and 2 colonic polyps). pCLE over evaluated the lesion. In 2 cases (4% of cases, 2 cases with colon polyp) pCLE didn't concur with the diagnosis of the pathologist.
CONCLUSION: Optical biopsies have been useful in the management of the lesions in the whole digestive tract in 51 cases out of 436 (11.7% of cases) before E. M. R, E. S. D., installation of biliary prosthesis, pancreatic cysts treatment and to control the nature of potential residues on an E. M. R or E. S. D. scares.

INTRODUCTION: The HybridKnife water-jet system (ERBE, Tubingen, Germany) has been shown to increase dissection speed and decreased the risk of perforation during endoscopic submucosal dissection (ESD). Glycerol mixture is a viscous, long-lasting solution preferentially used by Japanese ESD experts. The combination of the HybridKnife system with a glycerol solution has not been evaluated to date.
AIMS & METHODS: A prospective non-randomised comparative study of ESD with HybridKnife injecting of either a glycerol mixture or normal saline was performed. Twenty dissections (ten per group) were performed on four anaesthetised domestic mini-pigs. Dissection speed (mm^2/min), size of the specimen (mm^2), duration (min), en bloc resection rate, and bleeding and perforation rates were prospectively recorded. An evaluation of operator comfort and perception of safety (dissection score) was performed using a visual analogue scale with 0 being the worst score and 10 the best.
RESULTS: High-pressure injection of the glycerol mixture and dissection with the HybridKnife was feasible without complications. Dissection was significantly more rapid (1.67-fold) with glycerol injection than normal saline injection (27.44 vs. 16.44 mm^2/min; $p<0.001$). The dissection score was significantly higher in the glycerol group than in the normal saline group (5.9 vs. 2.9; $p<0.001$) indicating that both operators felt more comfortable and safe performing ESD with the glycerol mixture injection. No differences were observed in the rates of en bloc resection, bleeding and perforation.
Table 1: Results

Solution	Glycerol (n = 10)	NaCl 0.9% (n = 10)	p
Mean surface (mm^2)	1495 (+/- SD 430.3)	976 (+/- SD 117.8)	0.0127
Mean time (min)	54 (+/- SD 9.43)	62.6 (+/-SD 17.08)	0.082
Mean speed (mm^2/min)	27.44 (+/- SD 5.70)	16.44 (+/- SD 3.43)	<0.001
Perforation	0%	0%	NS
Bleeding	20%	20%	NS
En bloc resection	100%	100%	NS
Dissection score	5.9 (+/- SD 0.7)	2.9 (+/- SD 0.78)	<0.001
Preliminary incision	5	4	NS

CONCLUSION: In an in-vivo pig model, high-pressure jet injection of glycerol with HybridKnife for ESD is feasible and increases the speed and safety of the procedure compared with use of normal saline.

INTRODUCTION: ESD is a beneficial procedure that allows higher rates of en bloc and *complete* resection for large precancerous lesions or superficial cancer. However, training in ESD requires numerous sessions to become efficient, and so takes time and patience especially in Western countries. A well-structured training program is essential, because the outcome of ESD is dependent of the experience of the endoscopist. European experts recommend structured training programs with animal models to overcome the initial learning curve. Afterwards, constant practicing of ESD is required to increase success and decrease the procedure time and complications. We report the sucessful experience of a standardized local training program for ESD in a french tertiary center with a starting recruitment.
AIMS & METHODS: Between March and December 2013, 31 pig gastric ESD were performed by two operators. After the 11 initial pig gastric ESD, operators began human rectal ESD and 8 rectal human ESD were performed during the same period. The 20 next animals ESD were performed in parallel in order to keep a constant exposure to ESD cases. All procedures were performed with a hybridknife type T (Erbe medical, Erlangen, Germany). Glycerol mixture and physiologic serum were used for submucosal injection. Live, 20 kg, domestic mini-pigs, fasted for 48h prior to the procedure, were used. The duration of the procedure, size of the specimen, speed of the dissection, en bloc resection rate, complete resection rate and complications rate were prospectively recorded.
RESULTS: In the pig model, the en bloc resection rate was 96.7% (29/30). The speed of dissection increased with the experience of the operator to reach a plateau (30 mm^2/min) after 10 dissections. The speed of dissection for the 15 last ESD was significantly higher than the 16 first ESD (16.6 vs 28.2 mm^2/min; $p<0.001$). The mean size of the resected specimen was 1072.8 mm^2, the mean dissection time was 47.9 min and the mean speed of dissection was 22.4 mm^2/min. Only 1 perforation occurred and 6 (19.3%) per procedure bleedings imposed the use of a coagulation forceps.
In human rectal ESD, en bloc and complete resection rate were 100%. The mean specimen size was 1909.2 mm^2, the mean procedure time was 256 min. The average speed of dissection was 8.6 mm2/min: 5.8 mm^2/min for the first 4 cases vs 10.9 mm^2/min for the last 4 cases ($p=0.03$) No perforation occurred and 2 patients presented per procedure bleeding considered as a complication. 2 patients presented post procedure bleeding at day 7 and day 17 successfully treated with hemoclips.
CONCLUSION: A local training program with a pig model allows starting human dissection with high safety and efficiency. Initial training accelerates the learning curve and the continuous practice in pig model allows maintaining constant training until the recruitment of patients becomes sufficient.

P0148 BURIED BUMPER SYNDROME - MANAGEMENT BASED ON ACCURATE STAGING

J. Cyrany[1,*], R. Repak[1], T. Douda[1], S. Rejchrt[1], M. Kopacova[1], J. Bures[1]
[1]*2nd Department of Internal Medicine - Gastroenterology, Charles University in Prague, Faculty of Medicine in Hradec Kralove; University Hospital Hradec Kralove, Hradec Kralove, Czech Republic*
Contact E-mail Address: *jiri.cyrany@fnhk.cz*

INTRODUCTION: Buried bumper syndrome (BBS) is one of the major complications of percutaneous endoscopic gastrostomy (PEG). Until now there is no universal diagnostic and therapeutic algorithm based on the degree of disc submersion.
AIMS & METHODS: to assess safe and effective algorithm for diagnosis and therapy of BBS based on easy-to-use classification of severity. Methods: retrospective analysis of an endoscopic database, composition and evaluation of BBS severity scale
RESULTS: We have identified 40 cases of BBS in 38 patients (pts.) out of 1248 procedures of PEG performed from 01.01.2002 to 31.12.2012 at our endoscopy unit. The cohort consisted of 27 men and 11 women of 22-84 years of age (mean age 64 years). The most frequent indications for gastrostomy were neoplasma (18 cases) and neurological impairment (16 cases). Duration of gastrostoma to the diagnosis of BBS varied from 2 weeks to 64 months (mean 13 month). The incidence of BBS was 3.2% and it has almost tripled between subsequent five-year intervals - from 1.8% in group A (year 2003-2007) to 5% in group B (year 2008-2012). Potential reasons for the increase we found in more frequent detection of asymptomatic BBS (0 in group A, 8 in group B, $p=0.05$), often in patients with already minimal or no use of the stoma (0 in group A, 9 in group B, $p=0.03$). New classification of the depth of disc migration was composed based on clinical examination, gastroscopy and abdominal ultrasound (Table). Endoscopic component of this classification was validated with a high inter-rater agreement ($\kappa=0.93$) and abdominal ultrasound showed favourable parameters in the localisation of the buried bumper inside the stomach (sensitivity, specificity, positive and negative predictive value were 100%, 90%, 92% and 100%, respectively). Spectrum of severity in our cohort according to this classification was: grade 1 - 6 pts., grade 2 - 5 pts., grade 3 - 15 pts., grade 4 - 0 pt., grade 5 - 13 pts., grade 6 - 1 pt. 13 patients with grade 3 were treated endoscopically by various techniques of dissection, only one case was complicated by pneumoperitoneum. From 13 patients with BBS grade 5, six underwent laparotomy - bumper was localized outside the stomach in all cases.

STAGE	gastroscopy/abdominal ultrasound (US)/clinical finding
0	normal
1	ulcer below the disc and/or partial overgrowth of the disc (less than a half of disc area covered)
2	disc components still visible (more than a half of disc area covered)
3	disc completely covered, guide wire can be introduced; US: disc localized inside the stomach
4	disc completely covered, guide wire cannot be introduced; US: disc localized inside the stomach
5	disc completely covered; US: disc localized out of the stomach
6	disc protrudes out of the skin or palpable just below the skin

CONCLUSION: Incidence of BBS in our series was 3.2% with significant rise during 11 year period. New BBS severity classification based on gastroscopy and abdominal ultrasound is easy tool for stratification of patients for surgical and endoscopic therapy. Acknowledgement: Supported by the project PRVOUK 37-08.

P0149 ENDOSCOPIC SUBMUCOSAL RESECTION FOR METACHRONOUS TUMOR IN THE REMNANT STOMACH AFTER SUBTOTAL GASTRECTOMY

J. Lee[1,*], B.-H. Min[1], **J.H. Lee**[1], J.J. Kim[1], P.-L. Rhee[1], K.-M. Kim[2]
[1]*Department of Internal Medicine,* [2]*Department of Pathology, Samsung Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Subtotal gastrectomy is one of the most common procedures to resect gastric cancer curatively. However, if the patients have a remnant stomach after the surgery, the risk of metachronous gastric tumor remains. Because early gastric cancer (EGC) patients have a good prognosis after curative surgery, the incidence of metachronous tumor in the remnant stomach is now problematic. When the metachronous gastric tumor is detected, endoscopic submucosal dissection (ESD) can be considered as an alternative treatment option than an additional operation.
AIMS & METHODS: Little information exists concerning the optimal treatment of metachronous tumor in the remnant stomach. The aim of this study was to assess the clinical outcomes and safety of ESD for this lesion. We retrospectively enrolled patients who had undergone ESD for metachronous tumor in the remnant stomach after subtotal gastrectomy from December 2007 to January 2013 at the Samsung Medical Center in Seoul, Korea. A total of 18 lesions in 12 patients with EGC and 6 patients with high grade dysplasia (HGD) were treated by ESD. The patient characteristics, endoscopic findings and histopathological features and technical outcomes of ESD were investigated.
RESULTS: A total of 18 patients had previously undergone 17 Billoth-I (94%), 1 Billoth-II (6%) gastrectomies. The median period from the previous gastrectomy to the subsequent ESD for metachronous tumor in the remnant stomach was 71months (range 13-207 months), the median tumor size was 13mm (range 4-22mm). En block resection with curative resections achieved for 16 lesions (88.9%). Adverse events showed 1 case of perforation (5.6%) and there was neither case of requiring emergent surgery nor treatment-related mortality during this study period. The patients who requiring additional surgery for curative treatment due to deep submucosal invasion were 2 (11.2%).
CONCLUSION: ESD for the metachronous tumor in a remnant stomach after subtotal gastrectomy showed a high en bloc resection rate and very low complication rate. Therefore, we suggest that ESD is an effective and safe treatment method for metachronous tumor in the remnant stomach if it is performed by highly qualified experts. It is less invasive than additional surgery. Therefore, it can give a better quality of life to the patients, and the treatment outcome is excellent, with no treatment-related mortality in this study.

P0150 EFFICACY OF REBAMIPIDE IN THE HEALING OF IATROGENIC ULCERS POST ENDOSCOPIC SUBMUCOSAL DISSECTION: A META-ANALYSIS

J.-A. **V. Bisnar**[1,*], I.H. Cua[1]
[1]*Institute of Digestive and Liver Disease, St. Luke's Medical Center, Quezon City, Philippines*
Contact E-mail Address: *joannebisnar@gmail.com*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is a treatment option for early gastric cancer (EGC). It is less invasive, however, it is associated with larger, deeper ulcers post-procedure. Combined use of mucosal protective anti-ulcer drugs such as rebamipide and proton pump inhibitors (PPI) was reported to promote ulcer healing.
AIMS & METHODS: The study aims to determine the efficacy of rebamipide in the healing of post ESD associated ulcers.
PubMed, Cochrane Database and bibliographies of retrieved articles were searched for eligible articles. Randomized controlled trials involving patients with EGC who underwent ESD and were given rebamipide monotherapy or as adjunct to PPI were included in this meta-analysis. 2 reviewers extracted the data and assessed the quality of the studies included. Review Manager 5 software was used to analyze data from the studies included. Random effects model was used for combining quantitative data.
RESULTS: 6 studies with a total population of 758 were included in the review. 356 patients were randomized to the treatment group (rebamipide alone or as an adjunct to PPI). 354 patients were randomized to the control group (PPI or H2-RA). Rebamipide monotherapy or as an adjunct to a PPI compared to placebo (PPI or H2-RA) significantly improved healing with a p value of 0.0002 (RR 1.50, 95% CI 1.21-1.87).
CONCLUSION: Rebamipide improves the healing of post ESD associated ulcers especially when administered with PPI for 4 weeks.

INTRODUCTION: Endoscopic submucosal dissection (ESD) is an advanced technique used for en-bloc curative resection of early neoplasms of the gastrointestinal tract. Main advantages are high rate of curative resection and low recurrence rate, avoiding in most cases the need of surgery.
AIMS & METHODS: Initial training on Animal Research facilities was carried out for 2 years before starting ESD in humans. Prospective analysis of ESD performed for suspected early neoplasia of GI tract. The interventions were performed mostly in the endoscopy suite, full equipped to provide general anaesthesia in selected cases (all cases on the oesophagus and stomach, as selected colorectal cases). Flush knife BT® (Fujifilm Co. Japan) was the main knife used, both in versions BT 1.5mm (oesophagus, colon and rectum) and 2.0mm (stomach); occasionally other knifes were applied, such as Hook-knife®and Dual-Knife® (Olympus Co, Japan)
RESULTS: From January 2012 to February 2014 ESD was completed in 31 patients. The mean age was 64.4 years (SD12), with a male proportion of 55%. Over 60% of the cases were performed in colorectal location (colon 12 (39%); rectum 7 (22%)); other locations were stomach (9 (29%)) and oesophagus (3 (10%)). Initial success of ESD was 93.5%, with 2 cases requiring surgery due to failure or severe complication (both colonic cases). The en-bloc resection rate was 96.5%, the average specimen size 18.1 cm2 (max. length on average 46.4mm), with a median of 114 minutes (34-256) to complete the procedure. Regarding the morphology, 16 cases were 0-IIa, 5 cases 0-Is, 3 cases 0-IIa/0-IIc, 2 cases 0-IIb, 2 cases 0-Is/IIa 1 case 0-IIa/0-IIb and 1 case 0-IIb/0-IIc. Lateral spreading tumors (LSTs) distribution was: LST granular mixed type 5 cases, LST granular homogeneous type 7 cases, and 1 case of LST non-granular type. The R0 resection rate for successful ESD was 90% (26 cases). There were 12 cases (39%) with perforation (38%), of which 10 (80%) were managed successfully with local endoscopic treatment (closure with clips). There were 2 cases of late complications (splenic rupture and mild lower gastrointestinal bleeding), with no mortality associated. We analyzed the population according to chronological inclusion and divided into 3 similar periods. The average dissection speed during the initial phase was 0.36mm/min, compared to 0.49mm/min and 0.44mm/min during the intermediate and the final phase respectively, with no statistically significant differences ($p = 0.2$) due to the small sample size.
CONCLUSION: ESD is an effective technique in the treatment of early neoplastic lesions in the digestive tract, particularly in cases of flat-depressed morphology, with a size greater than 20mm and/or the presence of submucosal fibrosis. The technical difficulty, along with the prolonged time of endoscopy and the risk of serious complications (essentially perforation) are the main constraints of ESD. However, in our own experience, high en-bloc and R0 resection rate can be achieved, along with remarkable technical progress during the learning curve and successful endoscopic management of perforation. Our results demonstrate the possibility of successful adoption of ESD in Europe after completing proper training.

P0152 ENTONOX DURING COLONOSCOPY; HOW SHOULD IT BE USED?

A. Ball[1,*], S. Din[1], M. Donnelly[1], K. Smith[1], S.A. Riley[1]
[1]*Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*
Contact E-mail Address: *alex.ball@sth.nhs.uk*

INTRODUCTION: Entonox can be used to ease the discomfort associated with colonoscopy but the optimal mode of administration is unknown. We have compared continuous and as required Entonox use during screening colonoscopy examinations.
AIMS & METHODS: Patients attending for screening colonoscopy were invited to participate. Eligible patients were randomised to using Entonox as required or continuously. Procedural and demographic details including HADS score were collected. Examinations were performed by three experienced colonoscopists. Patients rated pain on a 10 point numerical ratings scale (0 = no pain and 10 = extreme pain) every 2 minutes during colonoscopy, prior to discharge and 1-3 days following colonoscopy. The colonoscopist and specialist screening practitioner (SSP) also rated the patient's overall pain severity and the technical difficulty of colonoscopy.
Continuous and categorical data were compared using a *t* test and chi-squared test respectively. Correlations were assessed using Pearson's correlation coefficient and the agreement between observers was assessed using the intra-class correlation coefficient (ICC).
RESULTS: 157 patients were screened and 49 were excluded (34 opted for intravenous sedation, 13 declined and 2 had a cardiac pacemaker). 108 patients were randomised and 8 patients were withdrawn (7 had a cancer and 1 was unable to activate Entonox). Study participants had a mean age of 67 years and 75% were male. 46 patients were randomised to continuous and 54 to as required use.
15/54 (27.7%) patients in the as required group did not use Entonox and 7/46 (15.2%) of patients in the continuous group reverted to as required use due to side effects. The number of patients requiring additional analgesia was not significantly different between continuous use and as required use (4/46 vs 3/54, $p = 0.54$).

There was no significant difference in the overall pain scores given by patients who used Entonox continuously and as required (mean score = 2.4 vs 3.2, p = 0.08 and peak score = 4.2 vs 4.8, p = 0.26). Overall patient satisfaction was high with the continuous and as required methods (mean = 9.9 vs 9.7, p = 0.23) as was willingness to undergo a repeat examination (mean = 9.2 vs. 9.7, p = 0.09). A HADS anxiety score of ≥7 was associated with higher overall pain scores (mean score = 2.1 vs 3.6, p = 0.004 and peak scores = 3.7 vs 5.6, p = 0.003). Patient with a HADS anxiety score <7 who were allocated to continuous rather than as required use had lower pain scores (mean = 1.4 vs 2.5, p = 0.045) but there were no significant differences between strategies in the patients with a HADS score ≥7 (3.3 vs 3.8, p = 0.6) There was no significant difference in the pain ratings according to gender.

Patients overall rating of pain prior to discharge correlated highly with the mean intra-procedural pain score (r = 0.84) and peak rating of pain (r = 0.84). There was also a very high correlation between the patients overall pain rating prior to discharge and 1-3 days later (r = 0.94). There was good agreement between the patients and the SSPs (ICC = 0.79) and endoscopists (ICC = 0.76) overall pain rating.

CONCLUSION: Overall, the method of Entonox administration did not influence pain ratings. However, continuous Entonox use was more effective in patients with a low anxiety level.

INTRODUCTION: Propofol allows the best sedation in colonoscopy. There is only one Randomized Controlled Trial (RCT) comparing Non-Anaesthesiologist Administered Propofol (NAAP) with sedation by an anaesthesiologist.

AIMS & METHODS: Our goal was to compare the incidence of sedation-related adverse events (AE), colonoscopy quality, and patient satisfaction between NAAP and anaesthesiologist sedation. We performed a single blinded RCT with two parallel intervention groups (group A – NAAP; group B – anaesthesiologist sedation). In group A, a 40-60 mg propofol bolus was administered followed by 10-20 mg bolus as needed. In group B propofol was administered under the anesthesiologist indication. The primary endpoint was the incidence of AE as defined by the World SIVA International Task Force on Sedation. Secondary endpoints were propofol dose, patient satisfaction, and pain assessed by a 10-point visual analogue scale, procedure and recovery time, and colonoscopy quality indicators (cecal intubation rate, withdrawal time, adenoma detection rate). A sample size of 330 (1:1) cases was calculated for a power of 90% at a 5% level of significance, and based on the AE incidence in our preliminary experience. Patients aged 18-80 with low anaesthetic risk (ASA I-II) were included (patienťs characteristics presented in table 1). Herein we present the interim analysis of the first 100 cases. Statistical analysis was performed with SPSS version 21. Chi-square, Fischer's exact, t-tests and logistic regression were used as appropriated.

RESULTS: The incidence of AE was 34.3% on group A and 42.4% on group B (odds ratio 0.709; 95% CI 0.302-1.668; p = 0.43). There were no severe (sentinel) AE events. The following interventions were necessary: atropine administration (0% vs 6.1%); airway repositioning (14.9% vs 9.1%); increase in O2 administration (8.9% vs 6.1%); increase in fluids rate (4.5% vs 0%). Mean propofol dose: group A 222 ± 84 mg vs group B 245 ± 118mg (p = 0.276). Procedure times were 22.24 ± 13.12 and 21.39 ± 10.78 min (p = 0.75), withdrawal time was 11.97 ± 10.36 vs 11.84 ± 6.15 min (p = 0.949) and recovery time was 62 ± 44 vs 61 ± 22 min (p = 0.856) in group A and group B respectively. Patients had no pain (0) in 84.5% vs 88.5% (p = 0.946) and reported complete satisfaction with the sedation in 84.8% vs 81.2% (p = 0.58). Procedural amnesia was reported in 88 vs 93.8% (p = 0.49). All the patients were willing to repeat the colonoscopy under propofol sedation. Cecal intubation rates were 95.5% vs 93.9% (p = 1.0), adenoma detection rates were 30.4% vs 31.3% (p = 0.93).

Patient characteristics	Group A(n = 67)	Group B(n = 33)	p
Male sex, n (%)	24(35.8)	14(42.5)	n.s.
Mean age, years (sd)	57(14)	51(18)	n.s.
ASA I/II, n	6/61	7/26	n.s.
Cardiovascular disease, n (%)	10(14.9)	5(15.2)	n.s.
Smoking, n (%)	15(22.4)	5(15.2)	n.s.
Snoring history, n (%)	4(8.0)	2(6.0)	n.s.

CONCLUSION: In the interim analysis NAAP was equivalent to anaesthesiologist sedation in the rate of adverse events in a low risk population. Clinicaltrials.gov (NCT02067065).

P0154 MACROSCOPIC COLONOSCOPY FINDINGS OF COLLAGENOUS COLITIS; A THREE-CENTRE EXPERIENCE

A. Koulaouzidis[1,*], K. Sjöberg[2], L. Bartzis[1], M. MacNeill[3], A. Nemeth[2], G. Wurm Johansson[2], P. Finneron[3], A.J. Lucendo[4], E. Toth[2]
[1]Endoscopy Unit, Centre for Liver & Digestive Disorders, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom, [2]Endoscopy Unit, Department of Gastroenterology, Skane University Hospital, Malmo, Sweden, [3]Pathology Department, Western General Hospital, Edinburgh, United Kingdom, [4]Endoscopy Unit, Hospital General de Tomelloso, Tomelloso, Spain

INTRODUCTION: Microscopic colitis (MC) encompasses 2 entities, collagenous colitis (CC) and lymphocytic colitis (LC).[1] Although (by definition) a histopathological diagnosis, there are occasions when colonoscopy reveals findings such as alteration of the vascular mucosal pattern/innominate grooves, mucosal nodularity and a sequence of mucosal changes from defects/lacerations to cicatricial lesions that are thought to be characteristic of MC, and especially CC.[1,2] The aim of this study was to evaluate the frequency and type of endoscopic findings in patients diagnosed with CC in two University Hospitals.

AIMS & METHODS: Retrospective study. The database of the Pathology Department of 2 university hospitals in Edinburgh (Scotland) and Malmo (Sweden), and a district general hospital in Spain (general Hospital de Tomelloso) were searched for patients who have been diagnosed with CC between May 2008 and August 2013. Endoscopy reports & endoscopic images were retrieved and reviewed; data on lesions, sedation, bowel preparation (type and effect) and endoscopists' experience were abstracted. Categorical data are reported as mean ±SD. The Fischer's exact, the *chi-square* and the *t* (unpaired) tests were used to compare datasets. A two-tailed *P* value of <0.05 was considered statistically significant.

RESULTS: A total of 416 patients' (96M/320F; mean age: 67.1±12.1 years) case notes, who were diagnosed with CC, were collected and reviewed.

The colonoscopies had been carried out by senior medical/surgical staff (consultants or associate specialists) in 331 (79.6%). A total of 81 (19.5%) patients had a mix of findings, previously described as being suggestive of CC in endoscopy, such as mucosal erythema/oedema (mosaic pattern): **65**, colonic mucosa linear defects (lacerations, tears, ulcers/fractures, mucosal furrows): **10**, cat-scratch mucosa: **4,** and cicatricial lesions: **3**.

Although the use of polyethylene glycol (PEG) offer superior quality of bowel prep effect (as compared to other pre-colonoscopy preparations; $P<0.0001$), this was not associated with higher detection rate of (all types) macroscopic findings and/or colonic mucosal defects in specific ($P=1.0$). Furthermore, mucosal colonic defects had no association with either the experience of the colonoscopist ($P=0.812$), or the use of general anaesthesia/propofol ($P=0.53$), and/or the use spasmolytic (hyoscine butylbromide/glucagon), $P=0.568$.

CONCLUSION: A substantial minority of patients with CC (19.5%) had endoscopic findings indicative of CC. The presence of these findings is not associated with procedural factors such as endoscopist's experience, quality of bowel prep, and/or use of spasmolytic during colonoscopy.

P0155 A TAILORED SEDATION FOR COLONOSCOPY BY NON-ANESTHESIOLOGISTS: USE OF PROPOFOL TARGET CONTROLLED INFUSION FOR SAFELY ERASE PATIENTS' PAIN

A. Della Rocca[1,*], A. Scatto[2], P. Tresin[3], S. Gallo[1], E. Rosa-Rizzotto[1], L. Peraro[1], E. Guido[1], D. Caroli[1], B. Licata[3], F. De Lazzari[1]
[1]Dpt of Specialized Medicine, Gastroenterology Unit, St Anthony Hospital, [2]Anesthesiology, Azienda Ospedaliera, [3]Anesthesiology, St Anthony Hospital, Padua, Italy

INTRODUCTION: Pharmacokinetics and pharmacodinamic of both Midazolam(M) and Pethidine(P) (the most common drugs for procedural sedation) don't allow during colonoscopy to rapidly adjust dosage according to patient response and to the complexity and length of the procedure. As result patients may be too much or not enough sedated. Propofol sedation overcomes these limitations but may expose the patient to dangerous side effetcs such as hypotension and respiratory depression.

AIMS & METHODS: Demonstrate that Propofol Target Controlled Infusion (PTCI) enables properly modified infusion rate (ie total drug dose) in order to perform a zero pain colonoscopy and without affecting safety. 3 types of sedation were utilized in this trial: PTCI, M+P, Propofol titration (PT). Propofol infusion was controlled by a TCI pump set on Schnider protocol. Propofol administration and monitoring was performed by a nurse trained on recognizing adverse effects and on basic resuscitation maneuvers; an anesthesiologist was always on call. Colonoscopy started 1 min after infusion was begun. Initial Effect Site Target Concentration was 2.5 μg/ml, increments of 0.5 μg/ml/min were allowed until total pain relief. We monitored pts' $ETCO_2$, SpO_2, NIBP, ECG. At the end of the procedure pts were transferred to recovery room only when Observer's Assessment of Altertness/Sedation (OAA/S) scale was > 3 and then discharged when ALDRETE score was > 8. Satisfaction was established by Numeric Visual

Scale (NVS, pain evaluation from 1 to 10). A control group (treated with M+P) followed the same protocol.
RESULTS: 721 consecutive pts undergoing both diagnostic and operative colonoscopy were included. No exclusion critheria were stipulated. 345 pts PTCI at an average drug dosage (ADD) of 156.8±69.6 mg; 376 pts M+P at an ADD, respectively, of 4.18±1.3 mg and 47.5±5.5 mg; The 2 groups were clinically homogeneus (M = 55.4%; F = 44.6%; ASA 1-2 = 90%, ASA 3 = 10%) *Adverse events:* Hypoxemia (So2 < 90%): PTCI = 0.M+p = 8 (p < 0.05); Apnea: PTCI = 3, M+p = 26 (p < 0.001); Hypotension (SBP < 90mmHg): PTCI = 44, M+p = 36 (p = ns); Bradycardia (<40 bpm) PTCI = 5, M+p = 11 (p = ns). Apnea was treated successfully with neck extension. *Outcome and satisfaction:* mean NVS (all procedures) PTCI 0.36±1.2 vs 1.07±2.1 M+P (p < 0.001); mean NVS (only difficult proceures) PTCI 0.24±1 vs 1.97±2.8 M+P (p < 0.001); mean cecal intubation time (intubation rate was 98.4%) PTCI 6.14±3.6 min vs M+P 7.52±4.8 min (p < 0.01), mean time for the entire procedure (colonoscopy + recovery time): PTCI 38.76±15.1 min vs M+P 53.95±14.6 min (p < 0.001). PTCI total mean dosage was compared with the mean dosage of 50 colonoscopies in propofol titration, at the univariate analysis less total propofol (adjusted for BMI, Sex, Age, Endoscopist, Abdominal surgery) was administered using PTCI than the titration method: 156.85±69.63 vs 212.50±85.70 (p < 0.0001).
CONCLUSION: Propofol TCI provide a extremely flexible technique which ensures a sedation tailored to the individual patient and gives the possibility to guarantee an effective sedation for long lasting procedures without affecting recovery time. The final results are the opportunity to totally relieve pain, high performance (time length and quality of recovery) and less operator-dependent process.

P0156 HOW WELL DOES RADIOLOGY PREDICT COLITIS? CORRELATING IMAGING WITH ENDOSCOPY; A RETROSPECTIVE STUDY

A. Sinha[1], **J. Gulliver**[1,*], M. Shaw[2], R. Makins[1]
[1]*Gastroenterology,* [2]*Radiology, Gloucestershire Hospitals NHS Trust, Cheltenham, United Kingdom*
Contact E-mail Address: *ashish.sinha@glos.nhs.uk*

INTRODUCTION: A common indication for endoscopic assessment of the large intestine is to clarify an abnormal finding on either cross sectional or contrast radiological imaging. Our aim was to assess how often a positive diagnosis of colitis of any form was made following either CT scanning or barium enema. We then aimed to correlate these radiological findings with those seen at a subsequent endoscopy.
AIMS & METHODS: The endoscopy database at Gloucestershire Hospitals NHS Foundation Trust was reviewed for procedures performed between January 2008 and June 2013. Cases where endoscopy was performed for the indication of ''abnormal radiological findings'' were selected. The patients' radiology reports were reviewed and the cases where ''colitis'' or ''inflammation'' was described as possible differentials were selected. We then compared these radiological findings with those seen on endoscopy for positive correlation. The endoscopic finding of diverticular disease was taken as a positive correlation where relevant. Histology reports from the biopsies taken during the endoscopic procedures were also reviewed to confirm the endoscopic findings.
RESULTS: Between January 2008 and June 2013, 562 colonoscopies or flexible sigmoidoscopies were performed as a result of an abnormality seen on radiological imaging. In 168 (30%) a positive diagnosis of colitis was mentioned on the radiology report. Demographics showed a fairly even sex distribution with 53% of patients female, 47% male. The ages ranged from 22-98 with a mean age of 60.9 years. A total of 5 cases were excluded, with the colonoscopy failing to reach the region of interest in 4 cases.
Endoscopy confirmed mucosal inflammation in 60 of the 163 cases (37%) whereas the endoscopy was reported as normal in the remaining 103 cases (63%). In patients with positive endoscopic correlation, biopsies were taken in 34 (57%) of cases. Biopsies were not taken in cases where diverticular disease was identified and considered a positive diagnosis.
In those with histological specimens 28 of the 34 (82%) showed histology consistent with an inflammatory process. Of these the majority (57%) showed Crohn's disease. 6 specimens showed no inflammatory change on histology despite a macroscopic impression of inflammation.
Interestingly 2 biopsy series were taken despite negative endoscopic correlation, of which 1 was confirmed as lymphocytic colitis on histology. Another showed features of Crohn's on histology (this patient had known Crohn's).
CONCLUSION: 37% of the cases in our series referred for endoscopic evaluation after the finding of ''colitis'' on radiological imaging were confirmed to have colonic inflammation at endoscopy. This suggests that there is a limited correlation between radiological and endoscopic imaging when a diagnosis of colitis is being considered.
Further studies are required to determine whether a number of parameters considered together to create a scoring system would increase the likelihood of a positive pick up at endoscopy following colitis identified on radiological imaging, thereby improving diagnostic yield and reducing the number of unnecessary procedures. Interestingly, with one diagnosis of lymphocytic colitis made on samples from endoscopically normal colon, an argument could be made for taking biopsy series in all cases to exclude microscopic colitis.

P0157 SHORT MESSAGE SERVICE (SMS) IN COLONOSCOPY PREPARATION - PERICLES-I -A FEASIBILITY STUDY

B.M. Walter[1,*], P. Klare[1], B. Neu[1], R.M. Schmid[1], S.von Delius[1]
[1]*II. Medizinische Klinik und Poliklinik, Klinikum rechts der Isar, München, Germany*
Contact E-mail Address: *benjamin.walter@lrz.tum.de*

INTRODUCTION: High quality preparation is essential for colonoscopy. A sufficient colon cleaning improves adenoma detection rate and reduces rates of necessary re-colonoscopies due to invalid preparation. Several studies showed importance of patients education and correct pre-colonoscopy diet. Only few studies have evaluated feasibility of using new media such as SMS in high quality preparation. The ***PERICLES***-project (*prospective studies for improvement of colonscopy preparation by optimized visualisation*) aims to optimize patient guidance by reminding the most important steps during colonoscopy preparation.
AIMS & METHODS: Objective: To assess the feasibility of colonoscopy preparation using SMS (short message service) starting 4 days prior colonoscopy appointment and to assess sufficient colonoscopy preparation.
Design: A feasibility study Setting: Tertiary care center, university hospital.
Subjects: Patients scheduled for out-patient colonoscopy at a university hospital.
Interventions: Patients enrolled in the SMS study group get SMS information at different timepoints according to the next step of colonoscopy preparation and diet information. Data of out-patient colonoscopies with regular preparation procedure were collected as control group during time of SMS study.
RESULTS: Colonoscopy could be performed in all patients included in the study. Overall patient satification receiving SMS based information was high. Asked if the SMS reminder system was helpful to get the colonoscopy preparation done (1 not helpful to 10 very helpful) an average score of 7.8 was counted (n = 18). On the contrary asked if the SMS reminder system was inhibitory (1 not inhibitory to 10 very inhibitory) an average of 1.1 was counted (n = 19). The average total BBPS was significantly higher than in the control group (Mean±SEM 7.316 ± 0.2967 (SMS-group), Mean±SEM 6.269 ± 0.1925 (control group); good bowel preparation for colonoscopy ≥5). BBPS calculated for the different colon regions. LC = Left colon (Mean±SEM 2.500±0.1357 (SMS group) Mean±SEM 2.138±0.06530 (control group)), TC = transverse colon (Mean±SEM 2.400±0.1124 (SMS group) Mean±SEM 2.115±0.06875 (control group)), RC = right colon (Mean±SEM 2.400±0.1124 (SMS group) Mean±SEM 2.015±0.07325 (control group)) were higher than in the control group.
CONCLUSION: A SMS (short message service) system in colonoscopy preparation works is stable and effective. Quality of colonoscopy preparation was higher than in regular preparation procedure. Patients were highly satisfied by using the SMS system during colonoscopy preparation.

P0158 WHY DON'T WE RETRIEVE ALL THE ENDOSCOPIC RESECTED POLYPS?

C. Fernandes[1,*], R. Pinho[1], S. Leite[1], L. Proença[1], A. Rodrigues[1], L. Alberto[1], I. Ribeiro[1], T. Pinto-Pais[1], A. Ponte[1], J. Silva[1], J. Fraga[1], J. Carvalho[1]
[1]*Gastroenterology, C. HOSPITALAR VILA NOVA GAIA, V N Gaia, Portugal*

INTRODUCTION: Colonoscopy is able to diagnose, resect and retrieve colonic polyps. The latter is of major importance to allow an accurate histological evaluation. Factors associated with failed polyp retrieval are not yet clear.
AIMS & METHODS: To evaluate the prevalence of failed polyp retrieval; to define factors associated with polyp retrieval failure.
A single center retrospective study that considered all the resected polyps by snare in consecutive colonoscopies performed between September 2011 and December 2012. Eleven gastroenterology specialists and 3 residents were considered as endoscopists. Demographic and endoscopic data obtained through the colonoscopy report.
Statistical analysis (SPSS v.19): Chi-square, t-student.
RESULTS: 496 colonoscopies were evaluated, corresponding to 484 patients (male gender 66.1%, mean age 63.4 years [±10.2]). Considering a total of 1111 resected polyps, 52 (4.7%) were not retrieved. A deficient bowel preparation (p = 0.0006), a coloretal surgery history (p = 0.008), a higher number of resected polyps (p < 0.0001), a smaller size of resected polyps (p < 0.0001), a right-side location (p = 0.0006) and a cold snare resection versus current snare resection (p = 0.0007) were factors associated with failed polyp retrieval. Colonoscopy performed by a resident (p = 0.81), under deep sedation (p = 0.94) or with diverticulum (p = 0.44) were not related with failed polyp retrieval.
CONCLUSION: In our study the polyp retrieval failure prevalence was 4.9%. A 1) deficient bowel preparation, 2) a colorectal surgery history, 3) a greater number of resected polyps, 4) a smaller size of the resected polyps, 5) a righ-side location and 6) a cold snare resection were associated with polyp retrieval failure.

P0159 FUSE COLONOSCOPY YIELDS HIGHER DETECTION OF ADVANCED AND MULTIPLE ADENOMAS AS COMPARED TO STANDARD FORWARD VIEWING COLONOSCOPY: A POST-HOC PER PATIENT ANALYSIS FROM A RANDOMIZED COMPARATIVE TRIAL

C. Hassan[1,*], I. Gralnek[2]
[1]*ONRM Hospital, Rome, Italy,* [2]*Rambam Health Care Campus, Haifa, Israel*
Contact E-mail Address: *cesareh@hotmail.com*

INTRODUCTION: As compared with Standard Forward Viewing (SFV) colonoscopy, Full Spectrum Endoscopy (Fuse) colonoscopy has been shown to significantly increase the yield of adenomas detected (per lesion analysis) [1].

However, the accuracy of FUSE based upon a per-patient analysis has not fully been addressed.
AIMS & METHODS: We performed a post-hoc analysis of the data from a recently completed international, multicentre, randomized trial (NCT01549535) in which 197 patients underwent same-day, back-to-back tandem colonoscopy with SFV- and FUSE-colonoscopes. The per-patient detection rate of polyp/advanced adenoma was calculated for each of the two colonoscopy techniques according to polyp size and multiplicity (≥3 polyps). The relative detection rate was defined as the ratio between the number of patients classified by either SFV or FUSE colonoscopy in each lesion category and the cumulative detection with both of the colonoscopy techniques (SFVor FUSE) for the same lesion category. Statistical analysis was performed by Chi-square test.
RESULTS: We found 111, 23 and 9 patients presenting with at least one ≤5mm, 6-9mm, or ≥10mm polyp respectively, while 22 and 27 additional patients had as their most severe lesion an advanced adenoma or multiple adenomas, respectively. The relative sensitivity of SFV and FUSE for each type of lesion is shown in Table 1. In detail, the sensitivity of FUSE was statistically significantly superior to SFV for all categories except for polyps ≥10mm. As compared to SFV colonoscopy, FUSE detected an additional 9 patients with multiple adenomas, resulting in a relative per-patient sensitivity of 94%, as compared with 27% for SFV colonoscopy.
CONCLUSION: As compared to SFV colonoscopy, FUSE colonoscopy appears to be more effective in identifying patients with multiple polyps and polyps up to 9 mm in size, including 6-9mm advanced adenomas. These data appear to further demonstrate the clinical relevance of the additional adenoma detection of FUSE as previously shown at a ''per lesion'' level [1].

P0160 DISCRETE DYSPLASTIC LESIONS IN ULCERATIVE COLITIS MAY BE ADEQUATELY MANAGED ENDOSCOPICALLY: A LONG TERM FOLLOW-UP STUDY

C.H. R. Choi[1,*], A. Ignatovic-Wilson[1], A. Askari[1], J. Warusavitarne[1], M. Moorghen[1], S. Thomas-Gibson[1], B. Saunders[1], A.L. Hart[1]
[1]*Academic Institute, St. Mark's Hospital, London, United Kingdom*
Contact E-mail Address: *pacoblue@gmail.com*

INTRODUCTION: While there is evidence to support endoscopic resection of adenoma-like mass (ALM) occurring in patients with ulcerative colitis (UC), its long-term follow up data is currently limited. The aim of this study is to evaluate the long-term outcomes of patients with UC who have had an endoscopic resection of dysplasia within segment of bowel affected by colitis.
AIMS & METHODS: All patients who had their dysplastic lesions resected endoscopically between 1998 and 2008 were retrospectively identified from the endoscopic and histology databases. Patients who were immediately referred to colectomy were excluded. Medical records, endoscopy and histology reports were reviewed to determine the primary study outcome, which was defined as no further dysplasia episode, recurrence of dysplasia, or development of colorectal cancer (CRC).
RESULTS: A total of 100 patients underwent endoscopic resection for 121 discrete dysplastic lesions during the study period (table 1). The median follow-up duration from the time of dysplasia resection was 70 months (interquartile range (IQR), 53 – 89 months). The Paris classifications of the resected lesions were: Ip (60 lesions, 50.4% of 121 lesions), Is (36, 29.8%), IIa (3, 2.5%), IIb (4, 3.3%), IIa/c (1, 0.8%), and lateral spreading tumour (1, 0.8%). Remaining 16 lesions (13.2%) were described as ''appearance suspicious for dysplasia associated lesion or mass (DALM)'', where Paris classification was not recorded. Median size of the resected lesions was eight millimetres (IQR, 4 – 15 millimetres). Lesions were removed using snare polypectomy (66 lesions, 54.5% of 121 lesions), EMR (30, 24.8%), hot biopsy (21, 17.4%) or ESD (4, 3.3%) techniques. Histology showed low-grade dysplasia (LGD) in 111 (91.7% of 121 lesions) and high-grade dysplasia (HGD) in 10 lesions (8.3%). Pathologist's interpretations on the lesions were as follows: histological features favour DALM (36 of 121 lesions, 29.8%) favour sporadic adenoma (56, 46.3%), or ''distinction not possible on histological grounds alone (29, 23.9%)''. Overall, 23 patients (23% of study population) had developed recurrent episode of dysplasia in median of 41 months since the time of resection (IQR, 16 – 55 months). Seven of these patients underwent colectomy: cancer was detected in two patients (Duke's A and C), but no other patients had HGD or CRC in surgical specimen. The patient who developed Duke's C cancer did not have surveillance colonoscopy for five years prior to the cancer diagnosis. The cumulative incidence of recurrent episode of dysplasia following endoscopic resection was 3.1% in 1 year, 7.4% in 2 years, 11.9% in 3 years, 16.7% in 4 years and 22.0% in 5 years.

Table to abstract P0160

Patient demographics	
Sex (%)	
Male	66 (66%)
Female	34 (34%)
Disease extent (%)	
Extensive	87 (87%)
Left-sided	13 (13%)
Disease duration (years) (Median, interquartile range)	24 (13 – 33)
Age at the time of dysplasia diagnosis (years) (Median, interquartile range)	61 (54 – 69)

CONCLUSION: Patients with endoscopically resectable, well-circumscribed dysplastic lesions within the segment of colitis may be appropriately managed with endoscopic resection. However, close surveillance is necessary given the relatively high rate of recurrence.

INTRODUCTION: One of the most challenging aspects of managing low-grade dysplasia (LGD) in ulcerative colitis (UC) is the identification of patients who will progress to high-grade dysplasia (CRC) or colorectal cancer (CRC). The aim of this study was to identify risk factors associated with progression to HGD or CRC in UC patients diagnosed with LGD.
AIMS & METHODS: Patients with UC who were diagnosed with LGD between 1990 and 2012 were identified from the UC surveillance database of a large tertiary centre in the UK and followed up to 1st January 2013. Data on patient demographics, endoscopic and histological variables at the time of the first LGD episode were collected and correlated with progression to HGD or CRC, our primary outcome measure. Time to event analysis was performed using Cox proportional hazards methods with a Bonferroni adjusted significance level ($p = 0.0022$).
RESULTS: A total of 189 patients were evaluated during 1,100 patient-years of follow up from the date of the first LGD diagnosis (median, 53 months; interquartile range, 19 – 92 months). Overall, 38 (20.1% of study population) had progressed to HGD (16 patients) or CRC (22 patients). Table 1 shows the variables significantly associated with progression to HGD or CRC on univariate analysis. A statistically non-significant trend towards the progression to HGD or CRC was observed in those patients with history of primary sclerosing cholangitis (hazard ratio (HR), 3.54; $p = 0.018$), a shortened colon (HR, 2.75; $p = 0.024$), multiple episodes of dysplasia (HR, 2.59; $p = 0.005$), and histological active inflammation in the segment of LGD (HR, 2.20; $p = 0.025$). At the multivariate level, only non-polypoid shape (HR, 7.3; 95% confidence interval (CI), 2.4 – 21.8; $p < 0.001$), lesion size one centimeter (cm) or bigger (HR, 4.2; 95% CI, 1.3 – 13.3; $p = 0.015$) remained significant variables contributing to HGD or CRC.

Variables	Categories	Hazards ratio (HR)	95% confidence interval (CI)	P
Lesion shape	Polypoid §	1	10.0 – 58.1	<0.001
	Non-polypoid¶	24.1	1.5 – 22.6	
	Invisible‡	5.8		
Lesion size	<1cm	1	4.8 – 41.3	<0.001
	≥1cm	14.1		
Stricture	No	1	2.4 – 21.1	<0.001
	Yes	7.1		
Previous indefinite dysplasia	No	1	1.9 – 8.4	<0.001
	Yes	4.0		
Pathologist's interpretation on histological features	Adenoma more likely	1	1.4 – 109.4	<0.001
	Distinction not clear	12.2	5.1 – 273.6	
	UC associated dysplasia more likely	37.2		
Multifocal dysplasia	No	1	1.6 – 6.0	.001
	Yes	3.1		

Table 1: Results of Univariate Analysis (only significant variables are shown). §: Discrete pedunculated or sessile polyps (Paris classification type I). ¶: Flat, depressed (Paris type II), irregular, diffuse, plaque-like or lesions with poorly defined edges. ‡: LGD with no evidence of endoscopic abnormality.
CONCLUSION: Low-grade dysplastic lesions that are non-polypoid or large (≥1cm) have a high-risk of progression to HGD or CRC in patients with UC. Patients harboring these lesions require careful counseling of management options including colectomy. Conversely, small polypoid low-grade dysplastic

lesions may be appropriately managed with endoscopic resection and close surveillance.

INTRODUCTION: New endoscopic technologies improve visibility of early colorectal cancers. However, flat lesions especially in lateral spreading tumor of the non-granular type (LST-NG) are sometimes hard to detect even with such modalities. γ-glutamyl-transpeptidase (GGT) is poorly expressed in normal tissue, but overexpressed on the cell membrane of various cancer cells in vivo. The use of γ-glutamyl hydroxymethyl rhodamine green (gGlu-HMRG) has been reported to show specific and immediate fluorescence activity with overexpressed GGT in tumor. This fluorescence active probe is expected to be applied to a new modality for cancer-selective fluorescence imaging[1].
AIMS & METHODS: This pilot study aimed to evaluate ex-vivo fluorescent imaging of colorectal tumor using the GGT fluorescence activity probe. 30 endoscopically resected colorectal tumors from March 2013 to March 2014 were included in this study. 1000μl of gGlu-HMRG in a concentration of either 50μM or 500μM was sprayed on the freshly resected specimen fixed on a black board. Fluorescent images of the resected specimen were taken after spraying gGlu-HMRG every 30 seconds for 15 minutes using a dedicated imaging machine providing 550nm of blue excitation light (Discovery; INDEC Inc.). The fluorescence image 7 minutes after spraying (when fluorescence activity had almost reached equilibrium) was evaluated by 3 endoscopists. The fluorescence activity was judged positive or negative. Lesions showing partial fluorescence activity were considered positive. This pilot study assessed the proportion of lesions positive for fluorescence and correlation with their clinicopathological characteristics.
RESULTS: The clinicopathological features were; mean age was 68±7, male/female = 15 /15, mean tumor size: 39±13mm, macroscopic type: lateral spreading tumor of the granular type (LST-G)/LST-NG = 20/10, adenoma/ carcinoma in adenoma = 13/17. 20 (67%) of images after 7 minutes were positive for fluorescence activity and 10 (33%) were negative. The mean tumor size of lesions positive for fluorescence activity was 42mm and that of negative was 32mm. Of 13 adenoma, 7 (54%) lesions were positive and 6 (46%) were negative. Of 17 carcinoma in adenoma, 13 (76%) lesions showed positive and 4 (24%) were negative. 16 LST-G lesions (80%) and 4 LST-NG lesions (40%) revealed positive. 18 (75%) of 24 lesions in 50μM gGlu-HMRG and 2 (33%) of 6 lesions in 500μM revealed positive.
CONCLUSION: Topically spraying gGlu-HMRG to identify GGT activity in ex vivo colorectal tumors provides rapid and selective fluorescent imaging.

INTRODUCTION: Colorectal endoscopic submucosal dissection (ESD) has recently been used for the resection of large colorectal neoplasms that could not be completely resected by conventional endoscopic mucosal resection (EMR). The colorectal ESD technique has an advantage of high en bloc resection rates, but is not accepted as a standard procedure due to several limitations, such as relatively high perforation rate and very high technical difficulty. However, ESD was applied to the lesions such as the giant colorectal lateral spreading tumor (LST) larger than 10 cm by some expert ESD-endoscopist. Thus, we investigated the feasibility and safety of ESD of giant colorectal LST over 10 cm.
AIMS & METHODS: A total of 133 patients received colorectal ESD between March 2009 and August 2013 by a single expert ESD-endoscopist at Gangnam Severance Hospital, Seoul, Korea. Among them, 7 patients had giant colorectal LSTs larger than 10cm. The tumor features, complete resection rate, and complications of ESD of giant colorectal LST were evaluated. We compared the clinicopathologic factors of ESD between giant colorectal LSTs and others. All patients underwent regular follow-up to evaluate for any local recurrence or distant metastasis.
RESULTS: The colorectal LSTs larger than 10cm were categorized as the giant colorectal LST. The locations of the 7 giant colorectal LST lesions as follows: cecum (n = 1), sigmoid colon (n = 2), and rectum (n = 4). The average maximal diameter of the giant colorectal LST lesions was 124.3 mm (range: 110-160 mm), and the procedure time was 294.3 min (range: 146-570 min). 2 lesions were whole nodular types and 5 lesions were focal nodular lesions by the Japanese Classification of Colorectal Carcinoma. According to the World Health Organization classification system, histologic diagnosis determined that 1 lesion was low grade dysplasia, 2 lesions were high grade dysplasia, and 4 lesions were carcinoma. Profound bleeding occurred in 1 patient with whole nodular type LST, who changed to piecemeal resection and was needed transfusion during ESD. Perforations developed in 2 patients after ESD, which were managed by endoscopic clipping treatment. The duration of hospitalization in the giant colorectal LST was 5.6 day (range: 2-12 day). During a mean follow-up period of 18.5 mo (range: 5.9-27.4 mo), no local recurrence and distant metastasis occurred. The complication rate was higher in giant colorectal LST than others (42.9% vs 8.7%, $p = 0.026$). The en-bloc resection and curative resection rate of ESD for the giant colorectal LST was 85.7% and 100%, respectively, and these rates were comparable with that of ESD for LST smaller than 10 cm. (en-bloc resection rate 92.1%, and curative resection rate 92.9%)
CONCLUSION: The ESD of giant colorectal LSTs appears to be a feasible and curative treatment, even if, it endure the higher complication rate, higher technical difficulty and longer procedure time.

P0164 ANALYSIS OF THE BLEEDING AFTER THE ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) AND THE ENDOSCOPIC MUCOSAL RESECTION (EMR) OF COLORECTAL NEOPLASMS FOR THE PATIENTS TAKING ANTI-THROMBOTIC AGENTS

D. Okamoto[1,*], M. Tosa[1], D. Komazawa[1], H. Ito[1], N. Dairaku[1], T. Ikeda[1], S.-I. Ikeya[1], H. Nakayama[1], N. Hiwatashi[1], S. Takahashi[1]

Contact E-mail Address: *oka1572@gmail.com*

INTRODUCTION: Recently, EMR and ESD for the patients with many complication has been increasing. Anti-thrombotic therapy is usually provided to prevent cerebro-cardiovascular events. In 2012, the endoscopic treatment guidelines for the patients taking anti-thrombotic agents were published from Japan Gastroenterological Endoscopy Society. Thereafter, in our institution, we perform endoscopic treatment in accordance with the guidelines. Delayed bleeding is one of the major complications of EMR and ESD, but little is known about the influence of anti-thrombotic therapy.
AIMS & METHODS: In this study, we analyzed the delayed bleeding rate after colorectal EMR and ESD for the patients taking anti-thrombotic agents. This is a retrospective study for the consecutive patients treated in our center from February 2014 to January 2013. Furthermore, we divided the patients taking anti-thrombotic agents into three groups, and compared the bleeding rate and the clinical background with control group. [A]: anti-coagulant continuation group, [B]: heparin or anti-coagulant single agent replacement group, [C]:anti-coagulant discontinuation group. Statistical analysis was made by Chi-squared test (significance: $p < 0.01$).
RESULTS: We treated 328 patients with 633 colorectal neoplasms by EMR, and the delayed bleeding rate was 1.9% (12/633). Male/Female ratio was 237:91 and the mean age was 64.5 years. 63 patients (19.2%) with 129 neoplasms (20.4%) received anti-thrombotic therapy and divided into three groups, [A]:16/28, [B]:21/45, [C]:26/56 (patients/neoplasms). Patients taking the anti-coagulant agents were significantly older than control group ($P < 0.01$). The delayed bleeding rate was 1/28(3.6%) in group A, 2/45(4.4%) in group B and none (0/56) in group C. We found no significant differences about the delayed bleeding rate when we compared each group with the control group (9/504; 1.9%). On the other hand, we treated 47 patients with 47 neoplasms by ESD. Male/Female ratio was 32:15 and the average age was 68.7 years. 11 patients (23.4%) received anti-thrombotic agent and divided into three groups, [A]:4, [B]:2, [C]:5. In ESD, patients taking anti-thrombotic agents were significant older ($P < 0.01$), and the delayed bleeding was not recognized in all cases. In addition, cerebro-cardiovascular events did not occur in all cases during the clinical course of EMR and ESD.
CONCLUSION: We found no significant differences about the delayed bleeding rate between patients taking anti-thrombotic agents and control group. Although this is a single institutional study, we thought that EMR and ESD for the patients taking anti-thrombotic agents could be performed without increased risk of delayed bleeding in accordance with the guidelines.

INTRODUCTION: Sessile Serrated Adenoma may be the precursor of 30% of colorectal cancers. The colonoscopy finding and identification of this type of lesion can reduce the incidence of colorectal cancer.
The correct approach on the search of this specific type of lesion is known to be a true challenge for the colonoscopists nowadays, and the precise identification, in number and type, of these lesions is associated to the quality of the colonoscopy exam.
Not much can be found in the literature about the combined use of acetic acid, FICE and image magnification in the identification of this specific type of lesion.
AIMS & METHODS: 150 lesions in the right colon were prospectively evaluated: the lesions were larger than 10mm, had a mucus cap and their morphology suggested sessile serrated adenoma, by the analysis of these lesions, crypts pattern. The study was performed by an endoscopist with extensive experience in chromoendoscopy and magnification and a single pathologist with extensive experience in this type of lesion. The lesions were classified into three types of Pits: type II Classic (Pit II - C), Pit II Open Shape (Pit II - O), and Pit II Fat

Shape (Pit II - F). The crypts were evaluated after instillation of acetic acid, chromoscopy (FICE), and image magnification.
RESULTS: From all the 150 lesions, 122 were classified as SSA. The Pit pattern II –C was found in all of the lesions analyzed, revealing a low specificity in the association of this pattern with SSA. However, the Pit II – O pattern was found in 120 lesions, and 118 of these were classified as SSA form, showing a stronger association of this pattern and SSA than the Pit II- C pattern. When it comes to the Pit II –F, it was found in 122 lesions, and 120 of these were classified as SSA. All lesions containing the association of Pit II- O and Pit II –F pattern, were classified as SSA.
CONCLUSION: The strong correlation between the colonoscopic findings of SSA with the use of acetic acid, FICE and image magnification and histological/molecular alterations of the suspicious lesions, reveals the importance of this technique in this type of lesions' management decision and in the participation on the colorectal cancer prevention.

Contact E-mail Address: *shadam@naver.com*

INTRODUCTION: Colorectal cancer can be prevented effectively by colonoscopy, because it can detect polyps and adenoma. It can miss from 5 to 32% of polyps, and proximal colon cancers are not efficiently prevented by colonoscopy screening. Cimetropium bromide has antispasmodic activity and improves polyp detection, especially in the right side colon.
AIMS & METHODS: We studied the effect of cimetropium bromide on detection of adenoma in colonoscopy.
Patients undergoing colonoscopy for screening and diagnostic examinations were included and received 5 mg cimetropium bromide at cecal intubation in Pusan National University Yangsan Hospital during 2 months in 2013 and 2014, respectively. We studied retrospectively polyp detection rate (PDR), adenoma detection rate (ADR), advanced adenoma detection rate (AADR), and sessile serrated adenoma detection rate (SADR) in right side colon as well as in whole colorectum.
RESULTS: A total of 1025 patients were analyzed in this study. Cimetropium group consisted of 214 patients and control group consisted of 811 patients. ADR, AADR in whole colorectum were significantly higher in cimetropium group, respectively (38.2% vs 28.4% ($p=0.03$), 10.5% vs 5.3% ($p=0.026$)). Also, PDR, ADR, and AADR in right side colon were significantly higher in cimetropium group, respectively (25.6% vs 19.4% ($p=0.015$), 23.4% vs 15.6% ($p=0.023$), 7.2% vs 3.5% ($p=0.024$)). But, PDR in whole colorectum and SADR in right side colon between two groups were not different. In non-right side colon, PDR and ADR were not significantly higher in cimetropium group, respectively (31.6% vs 27.8% ($p=0.487$), 25.0% vs 21.0% ($p=0.154$)).
CONCLUSION: Cimetropium bromide can improve ADR and AADR in right side colon as well as colorectum in colonoscopy.
Disclosure of Interest: None declared

P0167 CORRELATION BETWEEN ENDOSCOPIC AND ENDOMICROSOPIC SCORES IN CROHN'S DISEASE PATIENTS IN DETECTING RELAPSE AFTER SURGERY

D. Moussata[1,2,*]
[1]*Gastroenterology, Lyon Sud Hospital, Pierre Benite,* [2]*CREATIS, CNRS, Villeurbanne, France*
Contact E-mail Address: *driffa.moussata@chu-lyon.fr*

INTRODUCTION: As clinical relapse risk is well correlated with the endoscopic appearance in operated Crohn's disease (CD) patients, it's recommended to perform an endoscopy in the year following the surgery in order to adapt treatment. In endoscopy, the relapse is based on Rutgeerts score superior to i2 defined by the presence of more than 5 ulcerations. Confocal Laser Endomicroscopy (CLE) can detect inflammation on a macroscopic healing mucosa (whereas macroscopically the mucosa appears normal). Inflammation is evaluated by CLE according to percentage of gaps reported to total villous perimeter and to Watson's score based on shedding and luminal signal.
AIMS & METHODS: Aim: To evaluate inflammation with CLE into the ileum above the anastomosis (ileocolic anastomosis) and compare with Rutgeerts score.
Patients and methods: In the year following the surgery, under sedation, an endoscopy with CLE (EC3870K Pentax, Tokyo) was performed after 3 ml fluorosceine injection. Relapse was scored endoscopically with Rutgeerts score and endomicroscopically with percentage of gaps and Watson's score, which were quantified as calprotectine in stools, urinary neopterine and C-reactive protein (CRP). We compared Harvey Bradshaw score, Watson's score, calprotectine, neopterine, CRP and histology (Gomes score) with Rutgeerts score.
RESULTS: 26 patients (12 men, mean age 36 ± 11 years (± SD)) were included prospectively. The endoscopy was performed in 9 ± 3 (range 6 to 13) months after the surgery. 9 patients relapsed with a mean Rutgeerts score 2.7 ± 0.8 after 10 ± 2.5 months and 17 patients did not relapse with a mean Rutgeerts score 0.4 ± 0.5 after 8 ± 3 months. 5, 2 and 2 patients presented a Rutgeerts score i2, i3, i4, and 10 and 7 presented a Rutgeerts score i0 and i1, respectively. The mean percentage of gaps was 11.5 ± 17 (range 0 to 55). Watson score was 1.7 ± 0.9 (range 0 to 3). The mean HB was 1 ± 1.1 (range 0 to 4). Mean Gomes score was 1.1 ± 0.9 (range 0 to 3). Mean CRP, calprotectine and neopterine were 5.4 ± 9.3 (range <2 to 44 mg/l), 811 ± 2207 (range 35 and 9200) and 553 ± 287 (range 142 and 992), respectively. The correlation was significantly positive between Rutgeerts and Watson score and percentage of gaps (Rho 0.65). The correlation was positive but not significantly with CRP, Gomes and calprotectine (Rho 0.47, 0.35 and 0.27, respectively). However, in 5/10 and 2/7 patients with i0 and i1 Rutgeerts score, respectively, CLE detected inflammation (Watson score 2).
CONCLUSION: There is a good correlation between CLE score and Rutgeerts but CLE detected inflammation in 5 patients without endoscopic relapse. The follow-up of these patients would be interesting to evaluate CLE in predicting relapse in CD patients.

P0168 ENDOSCOPIC SELF-EXPANDABLE METAL STENTS IN ACUTE MALIGNANT LARGE BOWEL OBSTRUCTION – SINGLE CENTER EXPERIENCE

E. Rodrigues-Pinto[1,*], P. Pereira[1], A. Peixoto[1], S. Lopes[1], A. Ribeiro[1], G. Macedo[1]
[1]*Gastroenterology, Centro Hospitalar São João, Porto, Portugal*
Contact E-mail Address: *edu.gil.pinto@gmail.com*

INTRODUCTION: Endoscopic self-expanding metal stents (SEMS) may be used in acute malignant large bowel obstruction (AMLBO) emerging as an alternative to surgery.
AIMS & METHODS: Characterize the population of patients with AMLBO that placed endoscopic SEMS in clinical practice. Cross-sectional study of patients with AMLBO that placed SEMS in a tertiary center in a 3 year period.
RESULTS: We placed SEMS in 47 patients, with a mean age of 71±13 years. The distal top of the tumor was located in the descending colon in 12.8%, in the sigmoid colon in 61.7% and in the rectum in 25.5%. Eighty-one percent of patients had lymph node invasion and 68.1% had metastasis. The location of the tumor did not influence the presence of lymph node involvement ($p=0.764$), metastasis ($p=0.885$) nor the extent of the stent used ($p=0.511$). Fluoroscopy was used in 57.4% of the procedures. There was need for placement of a second stent in 6.4% of patients due to migration during the opening. The rate of early complications was 11% and late complications was 4.6%. The use of fluoroscopy did not influence the occurrence of immediate complications ($p=0.385$), early complications ($p=0.950$) or late complications ($p=0.057$). Thirty-three percent of patients underwent surgery at a later time, with neo-adjuvant therapy in 17.8%. The median time of follow-up was 150 days (P25-75: 23 – 437), with a mortality rate at first year of 60.6%. The survival was significantly higher in patients submitted later to combined therapy in relation to chemotherapy, surgery or symptomatic treatment (838.5 days [± 35.0] *vs* 387.6 days [± 87.7] *vs* 354.3 days [± 80.2] days *vs* 222.3 [± 104.6 therapy], $p<0.001$).
CONCLUSION: The majority of patients with AMLBO had advanced disease. SEMS have a high success rate with a low complication rate, reducing the high morbidity and mortality associated with emergency surgery and creation of a stoma.

P0169 COLONIC CHICKEN SKIN MUCOSA IS AN INDEPENDENT ENDOSCOPIC PREDICTOR OF DISTALLY LOCATED ADVANCED COLORECTAL ADENOMA

E.J. Chung[1,*], J.Y. Lee[1], S.-J. Myung[2]
[1]*Health promotion and screening center,* [2]*Gastroenterology, Asan medical center, Seoul, Korea, Republic Of*

INTRODUCTION: Chicken skin mucosa (CSM) surrounding colorectal adenoma is described as an endoscopic finding with pale yellow-speckled mucosa and aggregations of lipid-filled macrophages in the lamina propria noted on histopathology. However, its clinical significance is unknown.
AIMS & METHODS: The aim of this study was to evaluate the prevalence, clinical characteristics of CSM, and association between colorectal carcinogenesis and CSM. This cross-sectional study was performed on 733 consecutive patients who underwent endoscopic polypectomy for colorectal adenoma after screening colonoscopy at the Asan Health Promotion Center between June 2009 and December 2011. The colonoscopic and pathological findings of colorectal adenoma including number, size, location, dysplasia, and morphology, and clinical parameters were reviewed.
RESULTS: The prevalence of CSM was 30.7% (225 of 733 patients), and most CSM-related adenomas were located in the distal colon (93.3%). Histological analysis revealed lipid-laden macrophages in the lamina propria of the mucosa. According to multivariate analyses, CSM was significantly associated with advanced pathology, including villous adenoma, high-grade dysplasia, and carcinoma *in situ* (OR 2.078, 95% CI 1.191-3.627, $p=0.010$), multiple adenomas (i.e., ≥ 2 adenomas; OR 1.692, 95% CI 1.143-2.507, $p=0.009$), and a protruding morphology (OR 1.493, 95% CI 1.027-2.170, $p=0.036$). There were no significant differences found in terms of polyp size or clinical parameters between patients with and without CSM.
CONCLUSION: CSM-related adenoma was mainly observed in the distal colon. CSM was associated with advanced pathology and multiple adenomas. CSM may be a potential marker of the carcinogenetic progression of distally located colorectal adenomas.

INTRODUCTION: Colorectal cancer (CRC) is one of the leading causes of death in different countries. Due to slow progression of GC, detection of CRC in early stage is important issue. There have been no high quality studies from the Middle East.
AIMS & METHODS: We aimed to investigate the prevalence of preneoplastic and neoplastic lesions of the colon in the average risk population.
Eligible asymptomatic, average risk adults between 2008 and 2012, aged older than 40 years old, in Firoozgar general hospital were involved. They underwent screening colonoscopy. All polypoid lesions were removed and examined by an expert gastrointestinal pathologist. The lesions were classified by size, location, numbers and pathologic findings. Size of lesion was also measured by endoscopists.
RESULTS: One thousand and eight subjects were enrolled in this study. The mean age of participants was 56.45 ± 9.59 years and 51.6% subjects were male. Overall polyp detection rate was 199/1208 (16.5%). Of them 26 subjects had non-neoplastic polyps including hyperplastic polyps, and 173/1208 (14.3%) subjects had neoplastic polyps of which, 26 (2.15%) were advanced neoplastic lesion. The prevalence of colorectal neoplasia was more common among 50-59 years old (p =); although, prevalence of adenoma was noticeable in 40-49 years old group. The advanced adenoma was also more frequent among age over 50 years old. Majority of adenomas were detected in distal colon, but a quarter of advanced adenomas were detected in proximal colon. Most colorectal adenoma was detected beyond sigmoid. The increasing age and male gender were associated with presence of adenoma.
CONCLUSION: It seems that CRC screening among average-risk population might be recommended in countries such as Iran. However, sigmioidoscopy alone would have missed many colorectal adenomas. Furthermore, the 50-59 age group could be considered as an appropriate target population for this purpose.

INTRODUCTION: Efforts to improve quality in endoscopy are ongoing and quality measures determined by examining the procedure report have been proposed as a mechanism for meeting this goal. Complete documentation is necessary for patient care and appropriate use of endoscopy. However, quality measures are very numerous and it is undetermined which are really critical for quality of cure.
AIMS & METHODS: To identify the quality measures to be included in the upper and lower GI endoscopy report of standard quality. Quality measures were extracted from the Quality Assurance Task Groups of the US Gastroenterology Societies (ASGE, AGA, ACG). Measures included in the questionnaire were divided in three categories: 1) pre-procedural with patient demographics (n. 15); 2) procedural (n. 27); 3) post-procedural (n. 9). A Rand Delphi method was used to reach the consensus. Participants were asked to label each measure using a 6 point Likert scale from 0 (not required) to 5 (absolutely required). The questionnaire was iteratively proposed to via a web-based application with a feedback of the results observed at the preceding round (median value; % of patients expressing the median value). Consensus was reached when no significant change was observed between values of the last two rounds (median, IRQ range, P value by Wilcoxon test). Measures with a score-5 were considered to characterize the standard (minimum) quality.
RESULTS: A total of 72 participants completed the 3 Delphi rounds required to reach the consensus: mean age 48; working experience (yrs) 11; n. endoscopy/week >15 in 61%; public employment 61%. A strong consensus was obtained for 33 (61%) out of 51 metrics. A score-5 was achieved for the following measures: patient name and birth date; exam indication; date and findings of the previous endoscopy for follow-up; anti PLT/coagulants use; informed consensus collection; assistants/anesthesiologist names; sedation drugs and doses; antibiotic prophylaxis use; causes of incomplete examination; stricture lumen according to the endoscope diameter; photographic documentation of landmark and findings; findings localization and biopsies; operative interventions: description of technique and completeness; definition of complete EGD retroversion manouvre; definition of complete colonoscopy: ileoscopy and retroversion in the rectum; indications after endoscopy in case of adverse events and follow-up.
CONCLUSION: The availability of a huge number of measures may be one of the causes of the poor report quality. The identification of the list of measures defining the endoscopy report of standard quality could provide endoscopists with an improvement tool and referring physicians with a report that use standard terms and provide follow-up recommendations. The identification of mandatory quality measures within their long list will ensure a fair accounting of the procedure and may encourage broader adoption of quality improvement efforts.

Contact E-mail Address: *ghassanovii@yahoo.co.uk*

INTRODUCTION: Acute intestinal obstruction occurs in up to 30% of patients with colorectal carcinoma. Historically, emergency surgical decompression was the treatment of choice. Self-expandable mesh metal stents (SEMS) have been increasingly used for malignant colonic obstruction. Several studies showed its efficacy in relieving obstruction, offering good palliation, avoiding emergency surgery and reducing the need for stoma creation.
AIMS & METHODS: A password-protected database of prospectively recorded endoscopic activity in our UK centre was analysed. Endoscopic records of patients undergoing SEMS for colonic obstruction from April 2007 to April 2014 were assessed. Data parameters included: patient demographics; site and pathology of obstruction; SEMS details; technical success of SEMS placement (correct placement of the stent across the stricture); clinical success (colonic decompression, with relief of obstructive symptoms and no significant complication); complications and the need for further intervention.
RESULTS: 107 SEMS insertion procedures were performed on 95 patients during the study period. M: F 46%:54%; median age 70 years (range 20 – 95); 50% were tertiary referrals. Causes of obstruction were primary colorectal cancer (CRC) (78%), extrinsic compression (18%) due to other malignancy mainly gynaecological; unspecified (4%). Obstruction occurred in left colon (distal to mid transverse) in 87% of cases. The majority of patients (97%) had sedation and only 3% were done under general anaesthesia. 3 stent types were used: 98% uncovered (Boston Wallflex (n = 27), Cook Evolution (n = 78)), 2% fully covered (Taewoong Medical (n = 2)). The median length of SEMS was 80mm (range 60mm – 120 mm). A single SEMS was inserted in 92% of patients, with 2 SEMS in the same session in 8 patients, and 3 SEMS in one patient. All SEMS were inserted under combined endoscopic and fluoroscopic guidance. Technical success was achieved in 98% of patients, with clinical success in 76%.

Complication	Number (%)	Post perforation management
Perforation	5/107 (5%)	4/5 (80%)-emergency laprotomy 1/5 (20%)- palliated
Obstruction due to 'flat valving'	2/107 (2%)	
stent migration	6/107 (6%)	
Stent occlusion	3/107 (3%)	

Median time to perforation from stent insertion was 4.5 days (range 1 – 15 days). Median time to death from stent insertion was 8.5 months; 6/107 (6%) died < 30 days from stent insertion, with one attributed to stent-related perforation. Stent migration noted to occur more in non-CRC extrinsic obstruction (2/19 (11%)) than primary CRC (4/88 (4.5%)).
CONCLUSION: Our data demonstrate that SEMS insertion for acute colonic obstruction is technically highly successful. However, technical success does not guarantee clinical success in all cases, and non-CRC extrinsic compression may be associated with higher rates of SEMS migration. The 5% perforation rate was similar to other reported studies, and needs to be considered in conjunction with the risks of emergency surgery in this patient group. The results of large randomised multicentre trials of SEMS vs surgery in palliating acute colonic obstruction are awaited.

Contact E-mail Address: *gheorghe.hundorfean@uk-erlangen.de*

INTRODUCTION: Confocal laser endomicroscopy (CLE) is a modern imaging technique that enables real time histology in vivo, during endoscopy, providing new insights of mucosal pathology. Monitoring histological activity to assess

MH is important in evaluating the therapy response and management of inflammatory bowel diseases (IBD). Our group has recently validated an endomicroscopic mucosal healing score (eIBD-MHs), which has to be interpreted by skilled endoscopists.
AIMS & METHODS: Our first aim was to analyze the learning curve (LC) of MH assessment by CLE in endoscopists naïve to the CLE technique. Secondly, we comparatively investigated the LC between endoscopists and residents (i.e. physicians acquainted neither to endoscopic nor to CLE techniques).
Therefore, 4 study groups were established: a.) senior endoscopists (n = 3), board certified (>2000 procedures, >2 years of experience); b.) junior endoscopists (n = 3) (significant endoscopic skills, <2 years of experience); c.) internal medicine residents (n = 4) without endoscopic experience, and d.) a skilled endomicroscopist (n = 1). Initially, all attendees received a random set of 20 CLE images from 10 IBD patients with different inflammatory activity and a table with the eIBD-MHs (9 criteria) for a spontaneous offline assessment (based only on histologic knowledge from medical school and interdisciplinary medical-histopathology meetings). Thereafter, all physicians participated in a short training session including explanation of the CLE technique, terminology, elementary CLE lesions, and assessment of IBD cases based on the eIBD-MHs before and after therapy). Subsequently, the same set of 20 CLE pictures was re-assessed (in a modified, paired succession, grouped per patient, before and after therapy). All physicians were blinded regarding patients' identity, diagnosis and disease activity. Assessment scores and duration from the pre- and post-teaching evaluation were statistically analyzed.
RESULTS: The average evaluation times before and after training for the groups a; b; c and d were: 25 vs. 12,33; 23 vs. 15; 24,5 vs. 15,25; 14 vs. 9 minutes, respectively). Overall, the evaluation time before the CLE instruction session was significantly longer ($p < 0.001$) compared to second evaluation times. No significant differences were observed between the physicians with or without endoscopic experience regarding assessment duration and quality. Interobserver agreement of the MH evaluation in the groups (compared to the assessment results of the skilled endomicroscopist) for group a; b and c were: 0.72; 0.52 and 0.75, respectively.
CONCLUSION: In conclusion, the LC for MH and inflammatory activity assessment by CLE is fast, can be easily learned and is independent of basic or advanced endoscopic skills or experience.

INTRODUCTION: Residual/locally recurrent lesions may occur after endoscopic resection: endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) or after transanal endoscopic microsurgery (TEM) for rectal lesions. ESD may be useful for resection of scar-embedded lesions, not lifted by standard injection of saline solution, but may be more technically difficult. We evaluated the feasibility and safety of ESD, as a salvage therapy for residual/locally recurrent lesions compared to primary lesions.
AIMS & METHODS: From January 2012 to March 2013 we performed 30 colonic ESD. Fifteen patients were on the first endoscopic treatment and the remaining fifteen had residual/recurrent lesions (median diameter of 21 mm) and have received at least an attempt at endoscopic resection using standard techniques including snare polypectomy, EMR or argon plasma coagulation, or TEM (5/15). The tumor size, the procedure duration, complications and early recurrence rate were compared between the two groups.
RESULTS: Procedure time was similar between groups (70±22 min vs 72±35 min). The lesions were significantly smaller (23±9 mm vs 35± 15 mm; $P < 0.05$) in the residual/ locally recurrent group, compared with primary lesions. Immediate bleeding rate was significantly higher in primary lesions group (46.6% vs 6.6%; $P < 0.05$). However, there were no cases of delayed bleeding in both groups. Intraprocedural perforations were observed only in residual/ locally recurrent group (3/15: 20%): surgery was needed in one patient, while two patients were managed using endoclips. Early recurrence, evaluated at three months, was similar between groups (20%)
CONCLUSION: Endoscopic submucosal dissection for residual/locally recurrent lesions was more difficult with higher risk of perforation due to presence of scar. However, the presence of lesions of smaller size and the low risk of intraprocedural bleeding, may recommend this procedure for scar-embedded lesions instead of surgical resection.

P0175 THE USE OF DOUBLE CHANNEL GASTROSCOPE REDUCED THE PROCEDURAL TIME IN LARGE LEFT-SIDED ENDOSCOPIC MUCOSAL RESECTIONS

V. Evangelos[1], G. Tribonias[1], A. Tavernaraki[1], A. Theodoropoulou[1], E. Vardas[1], G. Chlouverakis[2], **G. Paspatis**[1,*]
[1]*Gastroenterology, Venizeleion Hospital, Heraklion, Crete,* [2]*Department of Social Medicine, University of Crete, Heraklion, Greece*
Contact E-mail Address: *gpaspatis@gmail.com*

INTRODUCTION: Endoscopic mucosal resection (EMR) of large colorectal lesions is associated with an increased procedural time. Usually the ''inject and cut'' EMR technique is applied for large sessile or flat colorectal lesions. The use of double channel gastroscope (DCG) might reduce the procedural time in the rectosigmoid area.
AIMS & METHODS: To evaluate the effect of DCG use in the procedural time of injection-assisted EMR performed in the rectosigmoid area. To the best of our knowledge this is the only comparative study on this subject. All EMRs for sessile or flat rectosigmoid lesions larger than 2cm performed from July 2012 to September 2013 were retrospectively analyzed. The use of DCG was mainly dependent on the availability.
RESULTS: There were 55 lesions 2cm or larger in the rectosigmoid area in 55 patients, of which 26 were removed by EMR using a DCG (DC group) and 29 by using an ordinary colonoscope or gastroscope (OS group). The mean size of the removed polyps was not statistically different between the two groups (4.3cm ±1.86 & 3.9 cm ± 1.9 in DC and OS group respectively). The Paris classification was similar between the two studied groups. The mean procedural time in the DC group (24.4±18.3 min) was significantly lower compared to that of OS group (36.3±24.4 min) ($p < 0.05$). Moreover, in the subgroup of patients with polyps larger than 40mm the statistical difference in the mean procedural time between the DC group (33±21min) and OS group (58.7±20.6 min) ($p < 0.01$) was even more pronounced. Outcome parameters such as recurrence rate (12 months follow-up), post-procedural bleeding rate and hospital stay were similar between the two groups. No case of perforation was observed. Multivariate linear regression analysis revealed that the polyp size ($b = 0.92$, $p < 0.001$) and use of DCG ($b = 15.5$, $p < 0.001$) were significantly associated with the procedural time.
CONCLUSION: Our data suggest that the use of DCG for large sessile or flat rectosigmoid lesions significantly reduces the procedural time. The use of DCG seems to be more effective in larger polyps. These results should be confirmed in a prospective study.

P0176 ADENOMATOUS HISTOLOGY IN COLONIC POLYPS: INFLUENCE OF POLYP LOCATION, SIZE AND PARIS-CLASSIFICATION

H.F. Hammer[1,2], **J.L. Klein**[1,*], M. Okcu[3], K.H. Preisegger[3]

Contact E-mail Address: *heinz.hammer@medunigraz.at*

INTRODUCTION: Published data on the likelihood of a polyp being an adenoma in relation to its location in the colon, size and form are incomplete.
AIMS & METHODS: To evaluate these factors in a consecutive patient group all histologically verified colonic adenomas which were removed by one endoscopist between 01-01-2011 and 31-12-2013 were included into this analysis. Before polypectomy polyps were classified as protruded (Paris classification type I) or flat (Paris type II), their size was estimated as compared to an open biopsy forceps, and the location in the colon was noted. Polyps were grouped according to their diameter using groups of sizes published in the literature. In the study period 698 patients were colonoscoped by one of the authors (mean patient age 62 years, 392 female). Visibility was reduced by fecal residues in 43 patients (6.2%). In 12 patients (1.7%) the cecum was not reached. In 8 patients (1.1%) the polyp could not be retrieved.
RESULTS: 1877 polyps were removed and histologically assessed. In 8 patients (1.1%) the polyp could not be retrieved for histological analysis. In 7 patients (1.0%) the location of the polyp was not described. In 34 polyps (6% of polyps) the estimated diameter was not described. Carcinoma of the sigmoid colon was detected in one patient. Adenoma was detected in 565 polyps (n = 222 Paris type I lesion; n = 343 Paris type II lesion). 13% of all adenomas were located in the coecum (18 Paris I; 56 Paris II), 23% in the ascending colon (52 Paris I; 79 Paris II), 27% in the transverse colon (71 Paris I; 79 Paris II), 7% in the descending colon (19 Paris I; 22 Paris II), 22% in the sigmoid colon (43 Paris I; 80 Paris II) and 8% in the rectum (19 Paris I; 27 Paris II). The table shows the total number of adenomas in 5 groups according to lesion diameter, and the likelihood of a polyp having adenomatous histology in % of all removed polyps, again in relation to diameter and to Paris-classification of the lesion.
Table to abstract P0176

Diameter	"minute" <5 mm	"small" 6-7 mm	8-9 mm	"large" >10 mm		Total
Number of adenomas	270	189	40	10-19 mm 27	≥20 mm 5	531
Adenoma, % of all polyps	23%	39.5%	51.3%	82%	100%	—
Adenoma in Paris I	58%	61%	64%	91%		62%
Adenoma in Paris II	20%	29%	32%	75%		23%

CONCLUSION: Summary: 63% of adenomas are located oral to the left colonic flexure. 61% of adenomas are flat lesions. Both in the right and in the left colon the majority of adenomas are flat. However, in polyps of all sizes protruding lesions have a significantly higher likelihood of being adenomatous as compared to flat lesions. In flat and protruding lesions the likelihood of a polyp being adenomatous increases with polyp size, from 58% to 91% in protruding and from 20% to 75% in flat lesions. **Conclusion:** Almost two thirds of colonic adenomas are flat or are located oral to the left colonic flexure. Although only a minority of small and flat polyps are adenomatous, they comprise the majority of adenomas. The high number of lesions in the right sided colon has not been reported before and may be related to excellent colonoscopy preparation with only 6% of colonoscopies having been influenced by fecal residues. The clinical role of the right sided and the small polyps needs to be determined.

P0177 A HAND-HELD METAL DETECTOR IS AN ACCURATE, LOW COST ASSESSMENT OF FLEXIBLE SIGMOIDOSCOPY COMPLETION TO THE SPLENIC FLEXURE

H.C. Matthews[1,2,*], G. Sadler[2], R. Leicester[3]
[1]*Gastroenterology, Kingston Hospital Foundation Trust,* [2]*Gastroenterology,* [3]*Endoscopy, St George's NHS Trust, London, United Kingdom*
Contact E-mail Address: *h.matthews1@nhs.net*

INTRODUCTION: Flexible sigmoidoscopy (FS) is a validated screening test to reduce the incidence of colorectal cancer. Bowel scope screening is due to be implemented in the UK by 2016. There is variability in FS performance between operators; internal colonoscopic markings are unreliable for colonoscope position. Three dimensional (3D) magnetic imaging systems eg Scopeguide™ (Olympus, UK) represent real time instrument position but are not widely available. Hand-held metal detectors (HHMD) can easily localise metal objects within the body. We assessed use of HHMD to confirm flexible endoscopic tip placement at the splenic flexure (SF).
AIMS & METHODS: Adult subjects undergoing outpatient FS/colonoscopy were eligible and gave consent. When the operator judged examination complete to the SF, an independent observer placed the HHMD at the left 10th intercostal space, anterior-axillary line (corresponding to the internal fixation of the colon at the SF). A positive result was recorded if the HHMD beeped. Position was then assessed by Scopeguide™. If the SF could not be reached, the patient was excluded. We evaluated 3 different HHMD from different manufacturers. Patient experience was also studied. Ethical review NREC Ref no 13/LO/1065; IRAS Project ID 121224.
RESULTS: 44 subjects were recruited consecutively: mean age 64 years (range 17-74), 50% male (n = 22), mean BMI 27 kg/m^2 (range 20-41 kg/m^2). Endoscopic confirmation of position at SF showed concordance with Scopeguide™ in 95% (42/44). Subjects 1-6 were examined using BDS200 (Black & Decker) HHMD. Despite promising results on colonoscopic training models, this proved insensitive in humans and was abandoned. For subjects 7-30 (n = 24) studied with GMS120 (Bosch) HHMD, positive reading at the correct anatomical marking was recorded in 88% of examinations with Scopeguide™ validation. Of the 3 failures, 2 had a BMI of >30 kg/m^2. Use of an X-Ray screening trolley improved specificity. For subjects 31-44, n = 14, a detector with increased sensitivity and directional capabilities, GPP (Garrett Metal Detectors USA), was used on standard endoscopy trolleys. This showed concordance with 3D imaging in 100% of cases (n = 14) including 4 patients with BMI >30kg/m^2. There was one true negative versus endoscopic assessment confirmed by Scopeguide™. The technique was further validated by loss of signal on scope withdrawal. Patient questionnaires showed high acceptability.
CONCLUSION: Use of HHMD in FS has shown excellent concordance with ScopeguideTM for colonoscope localisation at SF. Specificity and sensitivity are improved by adapting the specifications of the HHMD. A HHMD is an accurate and very cheap (€100 per unit) means of assuring quality during FS and further studies may confirm its role as a useful training tool especially during future service expansion.

P0178 CONFOCAL LASER ENDOMICROSCOPY (CLE) DEMASKS SUBTLE MUCOSAL CHANGES IN PATIENTS WITH IRRITABLE BOWEL SYNDROME (IBS)

H. Neumann[1,*], G.E. Tontini[1,2], M. Vieth[3], C. Günther[1], S. Zopf[1], M.F. Neurath[1], Y. Zopf[1]
[1]*UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen, Germany,* [2]*IRCCS Policlinico San Donato, San Donato Milanese, Italy,* [3]*Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: IBS is a symptom-based diagnosis characterized by chronic abdominal pain, bloating, and alterations of the bowel habits without any organic cause. CLE allows in vivo visualization of microscopic features of the intestinal epithelium in real time during endoscopy.
AIMS & METHODS: To assess whether CLE is able to demask microscopic alterations of the small and large bowel mucosa in patients with established diagnosis of IBS.
Patients with established diagnosis of IBS according to Rome-III criteria and control patients underwent ileocolonoscopy. Fluoresceine guided CLE was performed in the terminal ileum and random optical biopsies were additionally performed in the colon and rectum. Attention was paid to presence or absence of epithelial gaps, intramucosal bacteria, crypt and vessel morphology, goblet cells and cellular infiltrate within the lamina propria. Physical biopsies were additionally taken for histopathological analysis.
RESULTS: Epithelial gap density and the microvascular pattern were increased in a subgroup (44%) of patients with IBS according to Rome-III as compared to control patients suggesting an altered intestinal permeability. No differences were observed regarding the presence of intramucosal bacteria, colonic crypt morphology, presence of goblet cells or the cellular infiltrate within the lamina propria ($P > 0.05$).
CONCLUSION: Confocal imaging revealed subtle changes of the mucosa in patients with IBS. These findings were not visible in every patient with IBS according to Rome-III criteria suggesting that some IBS patients may have an organic cause of the disease.

P0179 IN VIVO ASSESSMENT OF PORTAL HYPERTENSIVE COLOPATHY AND CLINICAL OUTCOME OF PATIENTS WITH LIVER CIRRHOSIS WITH CONFOCAL LASER ENDOMICROSCOPY (CLE)

H. Neumann[1,*], G.E. Tontini[2], C. Günther[1], M. Vieth[3], Y. Zopf[1], M.F. Neurath[1], S. Zopf[1]
[1]*UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen, Germany,* [2]*IRCCS Policlinico San Donato, San Donato Milanese, Italy,* [3]*Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: Recent data has highlighted the role of mucosal integrity for bacterial translocation in the gut which is also discussed as a major cause for development of spontaneous bacterial peritonitis (SBP) and/ or hepatic encephalopathy (HE) in patients with liver cirrhosis. CLE has emerged as a valuable tool for real time diagnosis of mucosal integrity and allows in vivo imaging of commensal bacteria in the gut.
AIMS & METHODS: To prospectively assess the value of CLE for in vivo diagnosis of portal hypertensive colopathy and its association to Child-Pugh class, Model for End Stage Liver Disease (MELD), HE and development of SBP. Patients with established diagnosis of liver cirrhosis and portal hypertension were prospectively included. Clinical, biochemical, and ultrasound criteria, including portal vein thrombosis, ascites and collateral portosystemic vessels were assessed in addition to endoscopic criteria (e.g. esophageal varices, portal gastropathy) and beta-blocker intake. Fluoresceine aided CLE was performed in every patient in the sigmoid colon, rectosigmoid junction, and rectum. Afterwards biopsies were taken, unless contraindicated, for corresponding histopathological analysis.
RESULTS: Overall, more than 14,700 CLE images were collected. Confocal imaging revealed dilation and/or ectasia of microvessels, congestion of blood flow, edema, and a non-specific increase of the cellular infiltrate within the lamina propria. These findings were directly correlated to Child-Pugh class and MELD score with patients at higher scores showing more distinct changes of the microarchitecture. Of note, disturbed mucosal integrity, as observed by CLE, was strongly correlated with occurrence of HE and SBP, even in the follow-up of the patients. The procedure was well tolerated by the patients, and no adverse events were observed.
CONCLUSION: Fluoresceine guided CLE in patients with liver cirrhosis and portal hypertensive colopathy is safe and well tolerated. In vivo imaging revealed similar microscopic changes of portal colopathy as conventional histology without the need of physical biopsies. Of note, confocal imaging corresponds to clinical outcome parameters, including development of HE and/or SPB.

P0180 HIGH-DEFINITION ENDOSCOPY WITH COMPUTED VIRTUAL CHROMOENDOSCOPY FOR PREDICTION OF FOOD ALLERGY IN REAL-TIME – A PROSPECTIVE, RANDOMIZED STUDY WITH CROSS-OVER DESIGN

H. Neumann[1,*], M. Vieth[2], G.E. Tontini[1,3], S. Zopf[1], C. Günther[1], M.F. Neurath[1], Y. Zopf[1]
[1]*UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen,* [2]*Klinikum Bayreuth, Bayreuth, Germany,* [3]*IRCCS Policlinico San Donato, San Donato Milanese, Italy*

INTRODUCTION: Food allergy is mediated via IgE and non-IgE mediated mechanisms. White-light endoscopy is not feasible to detect any specific mucosal alterations in patients with intestinal food allergy.
AIMS & METHODS: To access the value of advanced endoscopic imaging using high-definition colonoscopy with computed virtual chromoendoscopy (CVC) for prediction of mucosal changes in patients with suspected food allergy.
Patients suffering from recurrent abdominal pain and diarrhea were consecutively included. At baseline, patients underwent a standardized clinical interview in order to contain the diagnosis. Afterwards, patients underwent ileocolonoscopy with high-definition white-light endoscopy alone followed by CVC or the reverse. The mucosa of the terminal ileum, caecum and at the rectosigmoid junction was carefully inspected with or without CVC. Following the endoscopic inspection, a diagnostic lavage examination was performed at the above mentioned locations and analysed by measuring 13 different allergic markers, including TNF-alpha, IgE, and eosinophilic cationic protein. Finally, biopsies were obtained for additional histopathological analysis of the tissue.
RESULTS: 46 patients were randomized of which 39 patients (31 female, mean age 50 years; Range 21-78 years) completed the study protocol. Based on the clinical presentation, histopathological results and the lavage diagnosis 61% (24/39) of patients were diagnosed with intestinal food allergy. High-definition imaging with CVC visualized lymphoid hyperplasia, slight mucosal edema and

blurred mucosal vascular pattern. No mucosal changes were observed with high-definition endoscopy alone. CVC allowed correct diagnosis in 21 of 24 intestinal food allergy cases as compared with the criterion standards, giving a sensitivity, specificity and accuracy of 88%, 87%, and 87%, respectively. Positive and negative predictive value of CVC to predict food allergy was 91% and 81%, respectively.
CONCLUSION: High-definition endoscopy with CVC could mimic slight mucosal changes in patients with intestinal food allergy which were highly predictive for the disease. Therefore, advanced endoscopic imaging could add valid new criteria for diagnosis of intestinal food allergy.

INTRODUCTION: Underwater endoscopic mucosal resection (UEMR) without submucosal injection has recently been reported to be a useful to remove large colorectal polyps in one single institution (1). The aim of this study was to examine if UEMR is a safe and effective procedure for removing large colorectal lesions in our institution.
AIMS & METHODS: Two experienced interventional endoscopists performed all UEMR cases after observing UEMR procedures. UEMR was performed by use of a colonoscope with hood and the polyp was fully immersed in water during the entire procedure. All polyps were removed by en bloc or piecemeal resection and without submucosal injection. The size of the snare (15 or 33 mm) depended on lesion size. Patient data were collected prospectively.
RESULTS: A total of 13 consecutive patients (8 men, mean age 74 years, range 52-84) referred for polyp removal of colorectal lesions underwent UEMR. Totally 16 lesions with a mean size of 17 mm (range 7-30) were removed by UEMR. Lesions were located in the cecum (n = 8), ascending colon (n = 2), transverse colon (n = 4) and rectum (n = 2). 56% of the polyps were removed en bloc and the rest by piecemeal technique. All lesions were radically removed as judged endoscopically. Minor bleeding events occurred during three procedures which were easily managed with coagulation forceps and clips. No complications, such as perforation or delayed bleeding, occurred.
CONCLUSION: UEMR seems to be an effective and safe method for removing colorectal polyps and should be incorporated into the therapeutic arsenal of institutions managing large colorectal lesions.

P0182 A PREDICTOR OF THE DIFFICULTY OF COLORECTAL ESD FROM THE STANDPOINT OF DISSECTION SPEED

H. Chiba[1,*], D. Kurihara[1], T. Suto[1], K. Ashikari[1], N. Kawano[1], S. Seki[1], S. Tsuruta[1], A. Takahashi[1], T. Ida[1], T. Morohashi[1], T. Goto[1]

Contact E-mail Address: *h.chiba04@gmail.com*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been applied to the treatment of large colorectal tumors in Japan. However, the rate of complications is still higher than conventional endoscopic resection. For a management of complications, it is so important that we try to predict the difficulty of ESD in advance. Dissection speed during ESD will be related to the stability of the intraoperative visual field or ESD procedure itself.
AIMS & METHODS: To evaluate the difficulty of ESD from the dissection speed, we retrospective analyzed 94 patients who underwent colorectal ESD in Omori Red Cross Hospital from 2012 April to 2014 March. Because the mean dissection speed of total cases was 29.4±15.5(mm^2/min), we divided the patients into two groups: a low speed group (≦14 mm^2/min) (group A) and a control group (≧15 mm^2/min) (group B). The two groups were compared with respect to their clinical background and tumor characteristics predicted as a difficult case. In this study, for keeping uniform the quality of ESD, ESD procedure with a needle type device was done by one experienced ESD physician who under took more than 150 colorectal ESD before this study. In addition, the degree of submucosal fibrosis was classified into three types (F0–2) [(1)] (F0: no fibrosis, F1: mild fibrosis, F2: whitish submucosa or severe fibrosis). Independent and significant predictors were determined by multivariate analysis.
RESULTS: 94 lesions (male/female: 51/43) underwent ESD procedures; 14 in group A and 80 in group B. In a low speed group (group A), tumor location was C1/A2/T3/D3/S4/R1, and the mean tumor size was 25.3±9.8mm (15-50), and 5 cases had a fibrosis (F1; 2 cases and F2; 3 cases), and the rate of en bloc and curative resection was 100% and 13/14 (92.9%), and the mean operation time was 73.3min. The mean age, sex, the number of having antithrombotic agents was similar between two groups. The statistical analysis showed that severe fibrosis (F2) was predictor of a low speed (OR = 36.0; 95%CI = 2.46-527.1; p = 0.009), but tumor size (≧30mm), depressed tumor (IIc or LST-NG-PD), total fibrosis, location of tumors in the rectum or cecum, and the straddle of the fold did not have any significant differences. With respect to the postoperative course, there was also no differences in WBC, CRP, a number of having a high fever (≧38°C), using antibiotic agents, taking a painkiller, and a hospital period. Otherwise, there was one complication case in all lesions. This case (group A) had a thick fibrosis (F2) after severe radiation colitis and resulted in a delayed perforation the following day.
CONCLUSION: The size or location of tumors will not be related to dissection speed. This study showed a severe fibrosis was only a predictor, which was independent of the tumor size, of decelerating a dissection speed during colorectal ESD. In a case with severe fibrosis, an operation will take much time because of the difficulty, so an experienced physician should perform ESD. Additional cases, while considering dissection speed, will probably be a good reference for a predictor of the difficulty of colorectal ESD.

INTRODUCTION: *En bloc* resection by the procedure of endoscopic mucosal resection (EMR) for colorectal tumors over 2 cm in diameter is difficult according to previous reports. However, predictive factors of difficulty of *en bloc* resection are not indicated in colorectal EMR.
AIMS & METHODS: The aim of this study is to clarify predictive factors of an incomplete *en bloc* resection in EMR for colorectal tumors. From January 2012 to December 2013, a total of 277 patients with 370 colorectal tumors larger than 10 mm in diameter except pedunculated type tumors underwent EMR at Izumiotsu Municipal Hospital (Osaka, Japan). Age (mean): 70 years, sex: male 169 / female 108, location: right hemicolon 183 / left hemicolon (including the rectum) 187, macroscopic type: protruding type including sessile (Is) 43 / semi-pedunculated (Isp) 151 / flat-elevated type (IIa) 156 / IIa+Is 20. DRAGONEA bipolar snare (ZEON Medical Co., Tokyo, Japan) was used and selected width of snare 13 mm or 26 mm in diameter in reference to the lesion size in EMR procedures. Standard saline solution was injected into the submucosa in all cases. We retrospectively analyzed predictive factors of an incomplete *en bloc* resection on age, sex, tumor size, location, macroscopic type, and histological findings by multivariate analysis.
RESULTS: With crude-OR, location was 1.98 (95% Confidence Interval (CI), 1.12 to 3.48) and tumor size 1.11 (95% CI, 1.05 to 1.18) were associated with the incomplete *en bloc* resection. Regarding the location, the multivariate-adjusted OR of the incomplete *en bloc* resection for the right hemicolon was 1.9 (95% CI, 1.06 to 3.38) compared with the left hemicolon. Regarding the tumor size, the multivariate-adjusted OR of the incomplete en bloc resection for the highest tertile was 2.97 (95% CI, 1.53 to 5.75) compared with the lowest tertile (p for trend < 0.01, cutoff value: 16 mm).
CONCLUSION: Size (cutoff: 16 mm in diameter) and location (right hemicolon) of the colorectal tumors are indicated to be predictive factors for an incomplete *en bloc* resection by EMR. Especially, when lesion over 16 mm in diameter or located in right hemicolon is treated by EMR, the consideration of EMR-precutting technique or endoscopic submucosal dissection may be needed.

INTRODUCTION: Endoscopic submucosal dissection (ESD) for colorectal neoplasms was developed in Japan but is now spreading rapidly. The technique was started in our institute in the year 2010.
AIMS & METHODS: The aim of this study is to evaluate the results of colorectal ESD procedures for the first 4 years. The subjects are 205 consecutive lesions in 180 patients which were treated with ESD technique. The indications for ESD in our hospital are; 1. Neoplasms larger than 20mm but confined to the mucosa or invading minimally to the submucosal layer, 2. Those smaller than 20mm but unable to be lifted by injection due to fibrosis. The instruments used are PCF-Q260AZI or JI (Olympus), Short ST Hood and Flush Knife (Fujifilm) and VIO 300D (Erbe).
RESULTS: Male: female ratio was 86:94 and the average age was 68.0 (39-90) years old. The location was the cecum, ascending colon, transverse colon, descending colon, sigmoid colon and rectum in 36, 51, 48, 6, 24 and 40 of the lesions, respectively. The final pathological diagnosis was sessile serrated adenoma/polyp (SSA/P) in 18, adenoma in 63, mucosal cancer in 101, minimally invasive cancer (SM1) in 15 and deeply invasive cancer (SM2) in 7, and neuroendocrine tumor in 1. The gross appearance of the adenomas and cancers was flat or laterally spreading tumor (LST) in 174, sessile or 0-Is in 9, and depressed or 0-IIc in 3. The LSTs were subdivided into 53 lesions of homogeneous granular-type (LST-GH), 41 mixed-nodular type (LST-GM), 41 flat-elevated type (LST-NGF), and 39 pseudo-depressed type (LST-NGPD). The average size in LST-GH, LST-GM, LST-NGF, LST-NGPD, 0-Is, 0-IIc, and SSA/P was 41.1mm, 39.7mm, 30.7mm

and 25.7mm, 36.4mm, 10.3mm, and 23.9mm respectively. Invasive rates in these subtypes in order was 1.9%, 14.6%, 9.8%, 20.5%, 22.2%, 33.3%, and 0%. Post-procedure bleeding occurred in 2 cases (0.98%). Minor intra-procedure perforation was encountered in 6 cases (2.93%), but no emergency operation was required. Delayed pneumoperitoneum was witnessed in one case, but it was attributable to the ileus caused by anal stricture. If we divide the cases into 1st, 2nd, 3rd, and 4th fifty lesions, the en bloc resection rate was 78%, 88%, 98% and 98%. Local recurrence was witnessed in 3 cases (1.46%) in all of which the ESD procedure had resulted in piecemeal resection due to fibrosis, but the recurrent lesions were all small and removed endoscopically.
CONCLUSION: Submucosal dissection in the colorectum was successful with low rate of piecemeal resection and recurrence, but without serious complications.

P0185 COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) PERFORMED BY EXPERTS IN COLONOSCOPY WITH LITTLE EXPERIENCE OF GASTRIC ESD

H. Shiga[1,*], M. Kuroha[1], K. Endo[1], J. Kusaka[1], T. Tadano[1], K. Matsushita[1], Y. Kakuta[1], Y. Kinouchi[1], T. Shimosegawa[1]
[1]*TOHOKU UNIVERSITY GRADUATE SCHOOL OF MEDICINE, Sendai, Japan*

INTRODUCTION: The efficacy of colorectal endoscopic submucosal dissection (ESD) has been reported mainly from Japanese referral centers. However, it is technically difficult and is associated with a higher risk of adverse events than endoscopic mucosal resection (EMR), especially for novices in colorectal ESD with little experience in gastric ESD.
AIMS & METHODS: We aimed to evaluate the results of colorectal ESD during the clinical learning curve. Colorectal ESD was performed by 2 endoscopists who had expertise in colonoscopy and colonic EMR but had experience of fewer than 5 cases of gastric ESD. A total of 120 cases consisting of the first 60 cases of each endoscopist were retrospectively investigated. The main outcome measurements were procedural time, en bloc resection rate with tumor-free margins (R0 resection rate) and adverse events rate. From among the clinical characteristics obtained before the ESD procedure, factors that affected the main outcome measurements were identified.
RESULTS: (Clinical characteristics) Tumors were located at the rectum, left colon, right colon and junction (dentate line, SD junction, hepatic flexure, splenic flexure, ileocecal valve) in 22, 19, 51 and 28 cases, respectively. With regard to the macroscopic type, 44, 23, 5 and 8 cases were granular-type laterally spreading tumor (LST), nongranular-type LST, depressed and protruding type, respectively. Of the 120 cases, 20 cases had factors which reflected fibrosis of the submucosal layer (sporadic localized lesions with ulcerative colitis, local residual tumors after EMR, etc.). The mean tumor diameter was 38.5±18.3 mm. The histological analysis showed 59 adenocarcinomas and 61 adenomas. (Outcomes) The mean procedural time was 101.7±65.9 min. A total of 113 cases (94.2%) were resected en bloc, and the R0 resection rate was 80.0% (96/120). Perforation and postoperative hemorrhage occurred in 8 (6.7%) and 2 (1.7%) cases, respectively. Multivariate analyses revealed that lesions in junction and lesions with factors reflecting fibrosis were significantly associated with longer procedural time (≥90 min) and a lower en bloc resection rate. Larger lesions (≥40 mm) and lesions resected in the first half (up to 60 cases) were also associated with longer procedural time.
CONCLUSION: Colorectal ESD is feasible and safe when performed by experts in colonoscopy with little experience of gastric ESD. For novices in colorectal ESD, beginning with lesions in junction and lesions with factors reflecting fibrosis may not be advisable.

INTRODUCTION: Total colonoscopy is a potent tool for assessing the large bowel. There are various bowel preparation scale, but few bowel preparation scale have been validated. Diversity in bowel preperation scales can cause a lot of confusion on decisions in the clinical environment and much confounding of results within clinical studies. However there have been no clinical trials that compared 4 types of bowel preparation scales. The aim of this study is to assess the compatibility and reliability of 4 different types of bowel preparation scales.
AIMS & METHODS: This study compared 4 types of bowel preparation scales: Aronchick scale (AC), Boston bowel preparation scale (BBPS), Ottawa scale (OS), Harefield cleansing scale (HCS). 5 trainees read 20 total colonoscopy studies twice, with an interval of 1 month. We used Intraclass correlation coefficient (ICC) to evaluate Intra-observer (test-retest) consistency and inter-observer reliability of the BBPS and the OS. The unweighted kappa statistic was used to assess the reliability of the AC and the HCS.
RESULTS: Total 400 ratings were completed in this study. Inter-observer and intra-observer reliability were assessed by ICC and kappa statistic. ICC for OS was 0.73 (95% CI, 0.52-0.87, $p < 0.0001$), BBPS 0.76 (95% CI, 0.59-0.88, $p < 0.0001$), inter-observer kappa for AC was 0.29 (95% CI, 0.19-0.42, $p < 0.0001$), HCS 0.27 (95% CI, 0.15-0.41, $p < 0.0001$). Intra-observer scores for OS, ICC was 0.79-0.96, BBPS, 0.73-0.89. Intra-observer kappa for AC was 0.51-0.79 and for HCS, 0.36-0.92.
CONCLUSION: Inter-observer agreement values were high in OS and BBPS. This validation analysis showed that OS and BBPS are reliable, coherent scales so that they can provide better standardization to evaluate bowel preparation in both study and clinical practice.

P0187 MANAGEMENT OF LARGE COLONIC POLYPS IN A BOWEL CANCER SCREENING PROGRAMME

H.Y. Lee[1,*], W. Gashau[1], R. Willert[1]
[1]*Department of Endoscopy, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom*
Contact E-mail Address: *huiyann.lee@cmft.nhs.uk*

INTRODUCTION: Bowel cancer is the third most common cancer in the United Kingdom forming up to 13.6% of all newly diagnosed cancers(1). Bowel cancer screening colonoscopy allows early polyp detection at a curable stage. Complete resection and follow-up of large polyps is crucial to prevent malignant progression.
AIMS & METHODS: The aim of this study was to review the management of polyps with diameters ≥ 2 cm, particularly of sessile polyps, to assess the enbloc resection rates, completeness of resection using endoscopic mucosal resection (EMR) vs surgery and the incidence of malignant polyps.
Patients were identified retrospectively from a regional bowel screening programme database. Details of index colonoscopy including polyp characteristics, method of resection and complications were recorded. Histology results were reviewed for all polyps. Outcomes from follow-up endoscopic surveillance were analysed.
RESULTS: One hundred and fifty-eight patients (102 males, 56 females, mean age 66.2 years) with polyps ≥ 2 cm were identified from 2182 screening colonoscopies from January 2010 to August 2013. Caecal intubation rate was 96.8% in this group.
Largest polyp size for each patient ranged from 20 to 60 mm (mean 26.6 mm). The incidence of adenocarcinoma was 11.9% (n = 19), all located within the left colon, with 12 requiring surgical resection.
One hundred thirty nine patients (n = 139) had 155 non-malignant large polyps, mostly tubulovillous or villous histology (n = 110, 79%).
Thirty-six patients had 37 sessile polyps which underwent primary resection by EMR (n = 26) or surgery (n = 11).
Polyp diameter was larger in the surgery group with mean polyp diameter of 40.4 mm vs 28.0 mm ($p < 0.05$).
EMR enbloc resection rate was 11.5% (n = 3 out of 26). Completeness of excision was 38.4% (n = 10) at 3 months and 92.3% (n = 24) at 1 year. EMR complications included 1 perforation, 1 post polypectomy syndrome and 1 bleed.
Surgical resection included: anterior resection in 2, TEMS excision in 7 and right hemicolectomy in 3.
CONCLUSION: Sessile polyps ≥ 2 cm are relatively uncommon in an asymptomatic bowel cancer screening programme (37 in 2182 colonoscopies). They can be successfully resected by EMR without recurrence in 92.3% at 1 year providing a 3 month site check is performed in all piecemeal polypectomies.

P0188 ARE THERE ANY PARAMETERS TO PREDICT BILE DUCT STONES IN BILIARY PANCREATITIS BEFORE ERCP

A. Sayilir[1,*], B. Odemis[1], E. Parlak[1], S. Disibeyaz[1], Y. Beyazit[1], N. Sasmaz[1]
[1]*Gastroenterology, TURKIYE YUKSEK IHTISAS TEACHING AND RESEARCH HOSPI, ANKARA, Turkey*
Contact E-mail Address: *drabdurrahim@gmail.com*

INTRODUCTION: The role of endoscopic retrograde cholangiopancreaticography (ERCP) for the management of acute biliary pancreatitis (ABP) remains a controversial topic. Pre-ERCP detection of biliary stones in patients with ABP may strengthen the indication for a subsequent ERCP.
AIMS & METHODS: The aim of this study was to determine the value of several clinical and laboratory parameters as non-invasive pre-ERCP indicators of bile duct stones. Patients presenting to Türkiye Yüksek İhtisas Teaching and Research Hospital (TYIH) between 1 January 2010 and 31 August 2011 with ABP, who underwent ERCP within 72 hours of the onset of symptoms were screened, and eligible patients were enrolled in the study. Receiver operating characteristic (ROC) curve analysis was used to determine the optimal cut-off value of several parameters, such as AST, ALT, GGT, ALP, bilirubin, common bile duct (CBD) width on USG and duration of syptoms, with the highest sensitivity and specificity for predicting the presence of CBD stones.
RESULTS: A total of 59 patients [20 (33.89%) males and 39 (66.1%) females] were included in the final analysis. Areas under the curve for CBD width, timing of ERCP, AST, ALT, GGT, ALP and bilirubin were 0.753, 0.630, 0.548, 0.370, 0.577, 0.568 and 0.495, respectively. As a predictor of the presence of a biliary stone(s), CBD width was found to have the highest sensitivity, specificity,

negative predictive value (NPV), positive predictive value (PPV) and general accuracy. With a cut-off value of 8.55 mm for CBD width, sensitivity and specificity were 75% with a NPV of 47.4%, PPV of 90.9% and general accuracy of 75. A summary of ROC analyses for the other parameters is provided in table 1.
Table 1. ROC analysis for the value of several labortory and clinical parameters as pre-ERCP indicators of the presence of bile duct stones.

	Cut-off	AUC	Sensitivity (%)	Specificity (%)	NPV (%)	PPV (%)	Accuracy
CBD width (mm)	8.55	0.753	75	75	47.4	90.9	75
Duration (hours)	25.5	0.630	60.9	61.5	30.8	84.8	61
AST (u/L)	224.5	0.548	56.5	53.8	25.9	81.3	55.9
ALT (u/L)	156.2	0.370	43.2	40.0	13.8	76	42.6
GGT (u/L)	263	0.577	69.8	70	35	90.9	69.8
ALP (u/L)	153	0.568	56.8	60	24	86.2	57.4
Bilirubin (mg/dl)	1.54	0.495	54.8	50	20.8	82.1	53.8

CBD, common bile duct; AST, Aspartat Aminotransferase; ALT, Alanin Aminotransferase; GGT, Gama-Glutamyl Transferase; ALP, Alkaline phosphatase; AUC, area under the curve; NPV, negative predictive value; PPV: positive predictive value
CONCLUSION: Determination of CBD width on ultrasonography and serum GGT levels are important parameters that may help predict the presence of biliary stones prior to endoscopic intervention.

P0189 PROCEDURAL DESCRIPTION AND CLINICAL OUTCOMES OF A NOVEL COMBINED RETROGRADE-ANTEGRADE ENDOSCOPIC APPROACH USING ERCP AND EUS FOR THE MANAGEMENT OF POSTOPERATIVE BILE-DUCT TRANSECTIONS

A.L. Vargas[1,*], N. Alemán[1], I. Peñas Herrero[1], C. De la Serna-Higuera[1], C. Almohalla[1], F. García-Pajares[1], G. Sanchez-Antolin[1], M. Pérez-Miranda[1]
[1]*Gastroenterology & Hepatology, Hospital Universitario Río Hortega, Valladolid, Spain*
Contact E-mail Address: *mpmiranda5@hotmail.com*

INTRODUCTION: Postoperative Bile-duct Transections (POBT) are not amenable to endoscopic therapy. Preliminary data from combined percutaneous-endoscopic approaches are encouraging. Isolated reports of successful retrograde canalization are intriguing. We hypothesized that aggressive retrograde (ERCP) and/or antegrade (EUS) attempts at recanalization may salvage POBTs for endotherapy, and subsequent serial stenting would induce remodeling and durable resolution as seen in partial strictures.
AIMS & METHODS: To assess the feasibility, safety and efficacy of an endoscopic treatment algorithm of POBTs and to characterize the heterogeneous techniques used to attempt recanalization.
Since September 2010, 248 consecutive ERCPs were performed at a tertiary Unit for postoperative complications (strictures/leaks) in 150 patients (69 Liver Transplant, 81 Other). POBTs were identified in 17 patients (9 Female; age = 59.6 [43-79] years) following liver transplant (LT) /cholecystectomy (CCx) /Other in 7/7/3. Clinical records were retrospectively reviewed for procedural data (success, antegrade Vs retrograde, technique) and clinical outcome (immediate POBT remodeling and mid-term clinical resolution).
RESULTS: Recanalization was achieved in 12/17 POBT (70%), by means of ERCP alone in 5 (4 LT, 1CCx), of ERCP combined with EUS-guided antegrade approach in 6 (2 LT, 3CCx, 1 Other), and EUS alone in 1. Lack of upstream biliary dilation precluded EUS attempts in 4, and recanalization failed in 1 despite EUS-hepaticogastrostomy (EUS-HG). 5 initial failures underwent surgical repair with/without interval external PTBD. 10/12 recanalizations required forced antegrade/retrograde techniques: using the hard end of a stiff guidewire, needle-knife, puncture with intraductal hollow needles, transhepatic peritoneoscopy or magnetic compression anastomosis. A mean (range) of 1.5 (1-5) ERCPs were needed to achieve recanalization. Coincidental bilomas were drained in 2 POBTS (one transpapillary by ERCP and one transmural by EUS each). 11 Patients have completed 12 treatment courses of serial stenting (2 plastic alone & 10 covered metal with/without plastic) after 323(180-503) days of stents in place. After a mean follow-up of 353(30-900) days, there were 3 recurrences (1 surgery, 1 currently undergoing stenting, 1 successfully remodeled endoscopically). Post-procedural or stent related mild cholangitis ensued in 4, and moderate post-sphincterotomy bleeding in 1.
CONCLUSION: 70% of POBTs can successfully be recanalized endoscopically by means of forced mechanical (guidewires, needles), thermal or magnetic techniques. Antegrade EUS approaches allow salvage of 60% of ERCP failures. Mid-term treatment ouctomes using this algorithm for POBTs appear comparable to those seen with partial postoperative strictures.
Disclosure of Interest: None declared

P0190 VALIDATION OF A RISK SCORE FOR PREDICTING POST-ERCP PANCREATITIS BASED ON THE EUROPEAN GUIDELINE

A. Mariani[1,*], M. Di Leo[1], A. Ambrosi[2], M.L. Grazie[1], A. Giussani[1], P.A. Testoni[1]

INTRODUCTION: Post-ERCP pancreatitis (PEP) is an important complication in biliopancreatic endoscopy, associated with morbidity and mortality. While clinical and technical risk factors for PEP have been elucidated, the identification of a simple and valid risk score to predict PEP remains a challenge.
AIMS & METHODS: To develop a model to predict the risk of PEP in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP).
Methods: A risk score was created based on the prognostic factors for PEP identified on the basis of the ESGE Guideline (1) and validated on 1823 ERCPs from an independent, prospectively assembled database (''validation cohort''). The predictive performance of the models was tested by ROC analysis to identify patients at low and high risk of PEP.
RESULTS: A score proportional to its regression coefficient was assigned to each independent prognostic factor: suspected sphincter of Oddi dysfunction (SOD) (4.1 points), female sex (2.2 points), previous pancreatitis (2.5 points), young age (2 points), no chronic pancreatitis (1.9 points), normal serum bilirubin (1.9 points), precut sphincterotomy (2.7 points), pancreatic injection (2.2 points), large number of cannulation attempts (2.9 points), pancreatic sphincterotomy (3.1 points), biliary balloon sphincter dilation (4.5 points), failure to clear bile duct stones (3.4 points). The AUC of the ROC curve showed a predictive score performance of 0.9268 (95% C. I. 0.90-0.95 $p < 0.0001$). We identified 9.5 as the cut-off between low- and high-risk classes, with 88.5% specificity, 81.6% sensitivity. Considering only severe PEP ($n = 12$), there was a significant difference between the two risk classes ($p = 0.001$).
CONCLUSION: We developed and validated a simple risk score to predict PEP. It could be useful to clinicians for predicting the individual risk of PEP and directing prophylactic measures, to researchers for designing and interpreting clinical trials, and to policy-makers for saving healthcare resources.

INTRODUCTION: Use of radiation in endoscopic procedures has been increasing in Gastroenterology, particularly during endoscopic retrograde cholangiopancreatography (ERCP). Safety radiation limits have been defined for persons with occupational exposure to ionizing radiation. Monitoring the efficacy of protection measures and quality of x-ray systems are recommended.
AIMS & METHODS: The objectives of this study were to measure occupational radiation doses during ERCP in a Gastroenterology department and evaluate the impact of a real time individual dosimeter system in staff behavior. A prospective study was performed, during three phases, in which radiation doses were measured with individual dosimeters in health professionals: gastroenterologist, endoscopy and circulating nurses, radiology technician and anesthesiologist. Phase 1 – 25 procedures, dosimeter placed under the protection apron, at thoracic level. Phase 2 – 18 procedures, dosimeter placed outside the protection apron, at cervical level, simulating absence of radiation protection. Phase 3 – 12 procedures, dosimeter placed in second phase position, but with real time exposure levels displayed in a monitor and staff being able to adapt their position.
RESULTS: In phase 2, the following doses were registered: gastroenterologist 6.78 ± 5.99 μSv, endoscopy nurse $7.63 \pm 12.88 \mu$Sv, radiology technician $6.86 \pm 6.27 \mu$Sv, anesthesiologist $6.58 \pm 11.75 \mu$Sv and circulating nurse $4.56 \pm 5.45 \mu$Sv. In phase 1, protection equipment allowed a significant reduction in exposure doses: gastroenterologist 3.37 ± 4.00 μSv, endoscopy nurse $0.09 \pm 0.16 \mu$Sv, radiology technician $0.70 \pm 1.55 \mu$Sv, anesthesiologist $0.43 \pm 0.95 \mu$Sv and circulating nurse $1.15 \pm 3.03 \mu$Sv ($p < 0.05$). In phase 3, with the change of health professionals' position, according to real time values, there was a reduction of 44-71% in radiation levels, except for the gastroenterologist whose change of position was limited by his role in ERCP.
CONCLUSION: The present study showed occupational exposure doses within the recommendations, proving the efficacy of radiation protective equipments. Real time knowledge of radiation doses may have a positive impact in professionals' behavior.

P0192 PALLIATIVE BILIARY DRAINAGE FOR KLATSKIN TUMORS: ENDOSCOPIC OR PERCUTANEOUS?

A.T. Oliveira[1,1,*], S. Campos[1], S. Giestas[1], N. Almeida[1], S. Mendes[1], E. Camacho[1], R. Mesquita[1], D. Gomes[1], A.G. Agostinho[2], V. Carvalheiro[2], C. Sofia[1]
[1]*Gastroenterology,* [2]*Radiology, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal*

INTRODUCTION: At the time of the diagnosis only 20% of patients with Klatskin Tumors have resectability criteria. Thus, the majority will require palliative procedures for maintenance of biliary drainage.
AIMS & METHODS: The aim of this study is to compare two palliative non-surgical methods (endoscopic and percutaneous approach) in terms of therapeutic efficacy and complications.
We performed a retrospective study of patients newly diagnosed with Klatskin Tumors, in the period betwen 2010-2012, undergoing endoscopic biliary drainage (EBD) and/or percutaneous transhepatic biliary drainage (PTHBD). We analyzed the patient characteristics, technical success (insertion of drain/stent through the stenosis), therapeutic success (total bilirubin $\leq$ 4mg/dL after the procedure), duration of patency, complications and need for reintervention.
RESULTS: We included 70 patients with a mean age of 71$\pm$11 years and a male predominance (67.1%), of which 32 were submitted exclusively to PTHBD, 30 to EBD and 8 at both. These eight were initially submitted to EBD, but by impossibility of access to the biliary tract they needed PTHBD, so we considerer 40 patients in the PTHBD group and 30 in the EBD group. The two groups differed regarding the mean age (PTHBD 68 years; EBD 74 years; $p=0.006$). No difference was found in the Bismuth Classification (Type III/IV: PTHBD 82.5%, EBD 70.0%) and technical success rate (PTHBD 75%; EBD 79%). The rate of therapeutic success was PTHBD 57.5%; ERCP 79.3% ($p=0.07$). The terapheutic failure was more common in Bismuth III/IV types, in both groups (PTHBD 48.5%; EBD 30.0%). The complication rate was in the PTHBD group 47.5% (cholangitis in eleven patients and hemorrhage in 8 patients) and in the EBD group 23.3% (cholangitis in four, pancreatitis in two and perfuration in one) $p=0.038$. The patency time was similar: PTHBD 136 days; EBD 133 days. The reintervention rate was 32.4% in the PTHBD group and 48.3% in the EBD group ($p=0.191$).
CONCLUSION: Palliative biliary drainage is possible by endoscopic or percutaneous route, although the success rate is limited, especially in patients with Bismuth types III/IV. Endoscopic biliary drainage seems to show a trend toward greater treatment success, and it is associated with fewer complications.

P0193 ERCP CANNULATION; EVALUATION OF A WIRE-LED TECHNIQUE FOR BILIARY ACCESS IN A TRAINING CENTRE

C. Shekhar[1,*], S. Shetty[1], N.C. Fisher[1]
[1]*Gastroenterology, Russells Hall Hospital, Dudley, United Kingdom*
Contact E-mail Address: *drcshekhar@gmail.com*

INTRODUCTION: A range of techniques have been described to achieve successful cannulation at ERCP, and when training in ERCP it is often difficult to select the optimum approach [1]. There are potential advantages to a wire-led approach and we have evaluated this in our unit in a training setting.
AIMS & METHODS: To evaluate cannulation success rates for trainers and trainees using a wire-led technique as the default approach.
A prospective evaluation was done with 2 experienced trainers and 2 trainees (previous experience of 50-100 ERCPs each). The sphincterotome was pre-loaded with a hydrophilic wire (in limited cases loop tip wire was used) and cannulation started with the wire extending 3-5mm out of cannula. Attempts were then made to advance the wire deep into the bile duct before injecting any contrast or pushing the cannula through the ampulla. Trainees were allowed 6 minutes for cannulation attempts. If the wire-led approach failed then other techniques were used. Wire-led cannulation was considered successful only if no other techniques were required. Only cases with a 'virgin ampulla' were including in this study.
RESULTS: 100 cases were included over a 5 month period. Trainees were present in 62 (62%) cases. Overall biliary cannulation success was 93 (93%). Success rate was 54/62 (87%) if a trainee was present and 37/38 (97%), if no trainee was present. Independent success for trainees was 34/62 (55%), mostly using the wire-led technique 29/34 (85%). In cases where a trainer took over from a trainee, the wire-led approach was still successful in 14/28 (50%). Overall success with the wire-led approach alone was 31 (69%); other approaches used in remaining cases included pre-cut sphincterotomy, locked PD wire, and PD stent. A peri-ampullary diverticulum was the most common cause for failure of wire-led technique; other common causes included stricture, floppy ampulla, or an impacted stone. Median cannulation time was 6.5 minutes (IQR 4-10min) overall and 5 minutes (IQR 3-10min) for consultant-only cases. Immediate complications included false passage of wire (1 case, no further clinical events) and late complications: post ERCP pancreatitis (1 case, hospital stay 3 days, no further clinical events).
CONCLUSION: Wire-led biliary cannulation, with selective usage of additional techniques, may allow a cannulation rate of >90% in cases with a virgin ampulla. The technique appears to be a useful training tool and has a low complication rate.

P0194 DOUBLE-BALLOON OVERTUBE-ASSISTED ENTEROSCOPY ERCP IN PATIENTS WITH BILLROTH II GASTRECTOMY: A LARGE SERIES REPORT

C.-L. Cheng[1,*], C.-H. Lin[1], J.-H. Tang[1], M.-C. Yu[2], Y.-N. Tsui[1], N.-J. Liu[1]
[1]*Gastroenterology,* [2]*General Surgery, Chang Gung Memorial Hospital, Taoyuan County, Taiwan, Province of China*
Contact E-mail Address: *chiliang.cheng@gmail.com*

INTRODUCTION: Data on double-balloon overtube-assisted enteroscopy to facilitate ERCP (DBE-ERCP) in patients with Billroth II gastrectomy is limited.
AIMS & METHODS: The primary aim was to evaluate DBE-ERCP success in patients with Billroth II gastrectomy and suspected pancreaticobiliary disease. The seconday aim was to examine the safety and efficacy of DBE-ERCP. Patients with Billroth II gastrectomy in whom standard ERCP techniques had failed underwent ERCP by using DBE with initial therapeutic intent were identified retrospectively. DBE success was defined as visualizing the papilla, while ERCP success as completing the intended pancreaticobiliary intervention. Clinical success was delineated as a greater than 50% reduction in abdominal pain or level of hepatic enzyme elevations or resolution of cholangitis or complete extraction of bile duct stone.
RESULTS: From April 2006 through December 2011, 77 patients (59-male, mean age 73.5 years, range 50-95 years) had 92 DBE-assisted ERCPs. Overall DBE-ERCP success was 69 of 77 (90%). DBE success was 73 of 77 (95%), of whom 69 of 73 (95%) achieved ERCP success. Reasons for DBE- ERCP failure ($n=8$): tumor obstruction within afferent limb ($n=2$), peritoneal adhesion ($n=2$), cannulation failure ($n=3$), and bowel perforation ($n=1$). Diagnosis in patients with DBE-assisted ERCP success ($n=69$): choledocholithiasis ($n=50$), biliary dilatation ($n=9$), malignant biliary stricture ($n=9$), normal study ($n=1$). Selective interventions included biliary sphincteroplasty (dilation $\pm$ cautery, $n=76$), stone extraction ($n=57$), stenting ($n=20$), nasobiliary drainage ($n=6$), and rendezvous ($n=3$). Complications occurred in 5 of 77 (6.5%). In those patients who underwent therapeutic ERCP ($n=68$), 66 patients (97%) achieved clinical success.
CONCLUSION: DBE permits diagnostic and therapeutic ERCP in patients with Billroth II gastrectomy with a high success and acceptable complication rates. DBE-assisted ERCP should be considered as an effective alternate when standard ERCP failed in such patients.

P0195 OUTCOMES OF THE ENDOSCOPIC DRAINAGE OF PANCREATIC COLLECTIONS ACCORDING TO THE NEW ATLANTA CLASSIFICATION

D. Ruiz-Clavijo [1,*], B. Gonzalez de la Higuera[1], C. Prieto[1], E. Sainza[1], M. Casi[1], F. Bolado[1], J. Urman[1], I. Fernández Urien[1], F.J. Jiménez[1], J.J. Vila[1]
[1]*Complejo Hospitalario de Navarra, Pamplona, Spain*
Contact E-mail Address: *davidruizcla@gmail.com*

INTRODUCTION: Endoscopic drainage is considered a minimally invasive first-line treatment of pancreatic collections (PC). A revision of the Atlanta classification has been recently published but outcomes of endoscopic therapy according to this new classification are scarce.
AIMS & METHODS: Our objective was to evaluate the outcomes of the endoscopic drainage procedures of PC performed in our center during the last 5 years, assessing results with regard to morphological characteristics of the PC, technique used, and type of stent placed. A retrospective review of all endoscopically drained PC at our center from January 2009 to December 2013 was made. Indications for endoscopic drainage were symptomatic or complicated PC. PC were retrospectively classified according to the new Atlanta 2012 classification. Variables analyzed: 1) general variables: sex, underlying pancreatic pathology, PC type, 2) endoscopic technique: endoscopic intervention, type of stent, technical success (successful placement of draining stents), number of endoscopic interventions (including the session to retrieve the stents after PC resolution), complications, and 3) other variables: clinical success (symptom resolution), morphological success (resolution of the PC on computed tomography), and need for subsequent surgery. All drainage procedures were performed under endoscopic ultrasound guidance. Chi-squared and Fisher's exact test were used for analysis.
RESULTS: Endoscopic drainage was performed in 39 PC in 37 patients (33 men). 46.2% of PC developed in the setting of acute pancreatitis, 38.5% in chronic pancreatitis, and 12.5% after pancreatic surgery. PC included 17 pseudocysts (2 infected) and 19 walled-off necrosis (15 infected). We were unable to retrospectively classify 3 PC according to Atlanta 2012. The endoscopic approach was transgastric in 61%, transpapillary in 28%, and mixed in 7.7%. In 50% of transgrastric drainages a covered biliary metallic stent was deployed while the others underwent pigtail stents placement. The treatment approach and stent used were associated with the type of PC since walled-off necrotic PC were preferentially drained via a transgastric approach (17 of 19) and with metallic stents (13 of 19) ($p<0.05$). Nasocystic lavage was performed in 38.5% of drainages (13 infected walled-off necrotic PC and 2 infected pseudocysts). Endoscopic necrosectomy was required in 2 patients. Technical, clinical and morphological success was achieved in 94.9%, 76.9% and 66.7% of cases per

intention to treat analysis. Type, location, or etiology of PC, drainage technique and type of stent did not show a significant influence on technical, clinical, or morphological success. The median number of endoscopic sessions performed were 2 (range:1-6). There were 30% of complications after the endoscopic drainage including migration of the stents in 7 patients, infection in 2, and perforation in 1 case. 3 stent migrations and the perforation required surgery while the infections resolved after new endoscopic drainage procedure.
CONCLUSION: In our series, endoscopic treatment of PC achieved 95% technical success, 76.9% clinical success per intention to treat, and 66.7% morphologic success. The type of PC according to Atlanta classification determined the treatment approach and stent placed.

P0196 CAN INITIAL PRECUT FISTULOTOMY IMPLEMENTATION REDUCE ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY–RELATED COMPLICATION RISK?

D. Kim[1,1,*], G. Song[1], B. Lee[1], D. Baek[1], J. Seo[1], S. Lee[1], **T. Kim**[1], K. Lee[1], J. Lee[1]

[1]*Department of Internal Medicine, Pusan National University School of Medicine, Busan, Korea, Republic Of*

INTRODUCTION: Precut fistulotomy allows biliary access when standard cannulation methods fail. Precut fistulotomy is considered a risk factor for endoscopic retrograde cholangiopancreatography (ERCP)–related complications; however whether the complication risk is due to precut fistulotomy itself or to the prior prolonged attempts is still debated. We aimed at assessing success of cannulation and complications of an initial precut fistulotomy vs. a 'classic strategy' of precut fistulotomy after a difficult biliary cannulation.
AIMS & METHODS: We conducted a retrospective study from January 2011 to December 2012. A total of 152 patients without prior sphincterotomy were enrolled. The patients were classified into two groups: an initial precut fistulotomy (Group A, $n = 72$) or a late precut fistulotomy only after a failed difficult biliary cannulation (precut fistulotomy after $>$ 10 cannulation attempts, $>$ 10 minutes, and $>$ 3 accidental pancreatic duct cannulations, Group B, $n = 80$).
RESULTS: During the study period, total of 1412 ERCPs were performed. Of these, 152 cases (10.7%) underwent precut fistulotomy. Both groups were comparable, with no differences for age, gender or indications and findings. The overall success of cannulation for Group A and Group B was 95.9% vs 95%; mean cannulation time: 5.7 vs. 13.0 minutes ($p < 0.001$). The overall frequency of post–ERCP pancreatitis was 3 patients in Group A vs. 11 patients in Group B ($p = 0.041$). Other complications developed with 1 perforation and 2 bleeding presenting in the Group A and Group B, respectively. All resolved conservatively. Finally, the overall complication rates for Group A and Group B were 8.3% (6 cases out of 72 patients) and 17.5% (14 cases out of 80 patients), respectively.
CONCLUSION: Initial precut fistulotomy provides a higher cannulation success with significantly less time than late precut fistoltomy, although final overall success is similar. Initial precut fistulotomy implementation reduces post–ERCP pancreatitis risk but not the overall complication rate.

INTRODUCTION: Endoscopy is effective in the treatment of pancreatic fistulas due to pancreatitis.
AIMS & METHODS: We aimed to determine the effectivity of endoscopic treatment in patients with pancreatic fistulas due to etiologies other than pancreatitis.
RESULTS: The study group consisted of 44 patients (28 male, 6-80 years). Etiologies were surgery in 30 and trauma in 14 patients. Thirty-seven patients were presented with drainage through the drain, 5 with pancreatic ascites, and 2 with pseudocyst. Pancreatic fistulas were located in the blind end in 22 (50%)and lateral side of the pancreas in 9 (20.5%) patients. Pancreatic fistula could not be visualized during pancreatography in 6 (13.6%) patients. Six patients had disconnected pancreatic duct syndrome. Endoscopic treatments were pancreatic sphincterotomy (PES)+ stenting in 35, PES alone in 6, and PES + nasopancreatic drain insertion in 2 patients. The success of endoscopic treatment could not be determined in 9 patients due to lost to follow up in 6 and exitus in 1 patient. Endoscopic treatment was unsuccessfull in 7 patients due to disconnection in 6 and failure of cannulation in 1 patient. Endoscopic treatment was successfull in 29 patients (65%) and surgically placed drains were withdrawn after a mean time of 27.3 days (5-90) in fistulas located in the blind end, 11.9 (3-28) days in fistulas located in the lateral side, and 9.7 (3-18) days in fistulas with undefined location.
CONCLUSION: Endoscopy is effective in the treatment of pancreatic fistulas due to etiologies other than pancreatitis if the pancreatic duct is not disconnected.
Disclosure of Interest: None declared

P0198 THE RESULTS OF ERCP IN PATIENTS WITH A HISTORY OF FAILED CANNULATION

E. Parlak[1,*], S. Disibeyaz[2], A.S. Koksal[1], B. Odemis[2], B. Cicek[3], H. Yildiz[2], N. Sasmaz[2], B. Sahin[2]

Contact E-mail Address: *koksalas@yahoo.com*

INTRODUCTION: Cannulation of common bile or pancreatic ducts is a prerequisite for biliopancreatic interventions.
AIMS & METHODS: To determine the reasons of failed cannulations and suggest ways to increase the success rate.
We reviewed the data of the patients who were referred to our ERCP unit after failed cannulation at another center.
RESULTS: The study group included 71 patients (40 male, mean age:57.2 years). Sixty-nine patients had biliary and 2 pancreatic pathologies. On admission, 2 patients had retroperitoneal perforation, 1 patient had pancreatitis and cholangitis, each due to the previous ERCP attempt. The reasons of failed cannulation were unsuccessfull pre-cut in 31 (43.6%), failure to reach papilla due to apical stenosis in 8, presence of a peripapillary diverticula in 6, altered anatomy in 6 (3 with Billroth II), distal location of the papilla in 2, and failure to identify papilla in 1 patient. Fifteen patients had no reasons to explain failed cannulation. Cannulation was not attempted in the patient with retroperitoneal perforation. Of the remaining 70 patients, cannulation could be achieved in all of them (68/70, 97.1%) other than 2 with Billroth II gastroenterostomy. Cannulation could be achieved selectively in 50, after pre-cut in 14, dilation of the apical stenosis in 4, and by using either one channel two accessory method or leaving a guidewire in the pancreatic channel in 2 (2.9%) patients with peripapillary diverticula.
CONCLUSION: Performing pre-cut in the appropriate direction, realising the anatomic alterations and anomalies in the location of papilla, and applying advanced cannulation techniques are required to increase the success rate of cannulation.

P0199 PREVENTION OF POST-ERCP PANCREATITIS: A RANDOMIZED CLINICAL TRIAL USING RECTAL DICLOFENAC

G.W. Lua[1,*], R. Muthukaruppan[1], J. Menon[1]
[1]*Medical Department, Ministry of Health Malaysia, Kota Kinabalu, Sabah, Malaysia*
Contact E-mail Address: *guanway@hotmail.com*

INTRODUCTION: Pancreatitis is one of the commonest post ERCP complications. Preliminary research has evaluated several pharmacologic agents for prevention of post-ERCP pancreatitis (PEP) but none has been proven to be effective. Non steroidal anti-inflammatory drugs (NSAIDs) have been shown to reduce the incidence of PEP via inhibition of phospholipase A2. There were various trials using different routes and dosages of NSAIDs. Meta analysis of these trials was carried out but the results were inconsistent. Hence, we conducted a clinical trial to evaluate the efficacy of prophylactic rectal diclofenac for the prevention of PEP in high-risk patients.
AIMS & METHODS: This was a randomized, open-label, two-arm, prospective clinical trial.
Only patients at high risk of developing PEP were selected. This was determined by validated patient- and procedure-related risk factors. All procedures were performed by gastroenterology trainees under the supervision of senior consultants. They were then assigned to either receive 100mg rectal diclofenac or no intervention immediately after ERCP. After the procedure, the patients were admitted to the ward for further observation.
The primary outcome of the trial was the development of PEP, which consisted of new onset of upper abdominal pain, an increase in pancreatic enzymes to at least three times the upper limit of the normal range after the procedure, and requiring at least 2 nights of hospital stay. The patients were also reviewed 1 month after discharge to exclude the occurrence of any adverse event related to the study drug and ERCP procedure. The difference in incidence of post-ERCP pancreatitis between the 2 study groups was analysed using Fisher exact test (2-tailed), with $P < 0.05$ indicating a significant difference.
RESULTS: Among 107 patients who were enrolled and completed follow-up, 62 (57.9%) received diclofenac and 45 (42.1%) were in the control group. Among all the patients, 4 (3.7%) developed PEP, in which 3 were in the diclofenac group (a pancreatic stent was deployed for 1 of the patient in this group) and 1 was in the control ($p = 0.31$). Every cases of PEP was mild. After ERCP, 5 (4.7%) developed cholangitis and 1 (0.9%) had a perforation in which they were treated conservatively. No drug related complications or adverse event were noted for both groups of patients.
CONCLUSION: Among patients at high risk for developing PEP, rectal diclofenac did not significantly decrease the incidence of PEP.

P0200 EUS AND ERCP COMBINED WITH IDUS IN THE DIAGNOSIS OF BILE DUCT STRICTURE

H. Jiang[1,*], S.-Y. QIN[1], L. TAO[1], W. LUO[1], S.-B. SU[1], X.L.[1], H.-J. NING[1], X.-P. LU[1], R.-E. LEI[1]
[1]*The First Affiliated Hospital of Guangxi Medical University, Nanning, China*
Contact E-mail Address: *lihuan@erbechina.com*

INTRODUCTION: A variety of cholongioscopes have been emerged as a new tools for diagnosis of different biliary strictures. But these new techniques are not widely applied clinically because of high price and too easy to damage.
AIMS & METHODS: We evaluated the value of endoscopic ultrasonography (EUS) and endoscopic retrograde cholangiopancreatography (ERCP) combined with intraductal ultrasonography (IDUS) in the diagnosis of bile duct stricture. 36 patients with bile duct stenosis were recruited. The findings by endoscopic ultrasonography and endoscopic retrograde cholangiopancreatography combined with intraductal ultrasonography and the results of bile duct brushing cytology and liquid-based cytology of these patients were analyzed. The final diagnosis was based on clinical data, histopathology and follow-up results (≥6 months).
RESULTS: All of the 36 patients, in whom 21 were diagnosed malignant biliary diseases, including 9 biliary tract carcinomas, 4 duodenal papilla carcinomas, 4 pancreatic cancers infiltrating common bile duct and 4 liver cancers infiltrating common bile duct; 15 were diagnosed as benign biliary diseases, including 9 bile duct stones, 4 liver fluke diseases, 1 cholangitic stenosis and 1 external compression, were shown to have bile duct stricture. The accuracy rate of EUS, ERCP, IDUS and EUS+ERCP+IDUS in the differential diagnosis of bile duct stricture disease were 77.8%, 88.9%, 91.7% and 94.4%, respectively. The accuracy rates of differential diagnosis of bile duct stricture disease between EUS and ERCP were similar; while the accuracy rate of EUS and ERCP combined with IDUS was significantly higher than both EUS and ERCP ($P<0.05$). The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of EUS+ERCP+IDUS were 95.2%, 93.3%, 95.2%, 93.3%, respectively; the sensitivity, PPV, NPV in EUS +ERCP +IDUS were higher than that of EUS, ERCP and IDUS. All of the 36 patients received bile duct brushing cytology and the liquid-based cytology tests, 19 of which were diagnosed as malignant biliary diseases, while 17 were diagnosed as benign biliary diseases. The sensitivity, specificity and accuracy of differential diagnosis of bile duct stricture disease were 90.5%, 100% and 94.4%, respectively.
Table. Comparison of ERCP and EUS in the diagnosis of bile duct stricture

	EUS	ERCP	IDUS	EUS+ERCP+IDUS
sensitivity	71.4%(15/21)	85.7%(18/21)	90.5%(19/21)	95.2%(20/21)
specificity	86.7%(13/15)	93.3%(14/15)	93.3%(14/15)	93.3%(14/15)
PPV	88.2%(15/17)	94.7%(18/19)	95%(19/20)	95.2%(20/21)
NPV	68.4%(13/19)	82.4%(14/17)	87.5%(14/16)	93.3%(14/15)
diagnosis	28	32	33	34
misdiagnosis	8	4	3	2
Accuracy rate (%)	77.8	88.9	91.7	94.4

CONCLUSION: EUS and ERCP combined with IDUS can improve the diagnostic accuracy of bile duct disorders. IDUS is carried out under the guidance of a guide wire, and the operation is simple. It can also make up for the inadequacy of EUS. With the help of ERCP and IDUS, the bile duct could be directedly brushed, which could improve the diagnostic positive rate.

INTRODUCTION: In patients with surgically altered anatomy, endoscopic treatment of pancreatic disease such as pancreaticojejunostomy stricture, pancreatic fistula, and pancreatic duct stones can be challenging.
AIMS & METHODS: We evaluated the efficacy and safety of endoscopic pancreatic interventions using short double-balloon endoscope (DBE) for the treatment of pancreatic disease in patients with surgically altered anatomy.
Between October 2009 and April 2014, we performed endoscopic pancreatic interventions in 12 patients using a short DBE (152 cm in length with a 2.8 mm working channel; EC-450BI5/EI-530B, Fujifilm Medical, Tokyo, Japan), enabling conventional ERCP accessories. Previous surgeries included pancreaticoduodenectomy with Billroth II reconstruction (n = 7), pancreaticoduodenectomy with Roux-en-Y reconstruction (n = 3), and Roux-en-Y gastrectomy (n = 2). Indication for pancreatic interventions were anastomotic stricture (n = 8; with pancreatic duct stones [n = 5]), pancreatic fistula (n = 3), and pancreatic duct stones (n = 1).
RESULTS: Access to the papilla or the end of afferent loop successful in all 12 patients, but anastomosis site could not be identified in 3 patients. Pancreatic duct cannulation was achieved using a straight cannula (0.025-inch ERCP-catheter, MTW Endoskopie, Wesel, Germany) and a 0.035-inch hydrophilic guidewire (Radifocus, Terumo, Tokyo, Japan), or a metal tip cannula (PR-132Q, Olympus, Tokyo, Japan). Pancreatic interventions were successful in 9 patients (75%). Three of 6 patients with anastomotic stricture were treated successfully with balloon dilation, and the remaining 3 patients required repeated balloon dilation and long-term pancreatic stent placement. Two patients with pancreatic fistula were treated successfully with endoscopic nasopancreatic drainage. Pancreatic duct stones were successfully removed in 4 patients. Complications occurred in 3 (25%) patients, including retroperitoneal air (n = 1) and hyperamylasemia (n = 2), but all were asymptomatic.
CONCLUSION: Endoscopic pancreatic interventions using short DBE, although technically demanding, are effective and safe in patients with surgically altered anatomy.

P0202 "SHORT" SINGLE-BALLOON VERSUS DOUBLE-BALLOON ENDOSCOPE FOR PANCREATICOBILIARY INTERVENTIONS IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

H. Kogure[1,*], A. Yamada[1], H. Isayama[1], N. Takahara[1], R. Uchino[1], T. Hamada[1], K. Miyabayashi[1], D. Mohri[1], T. Sasaki[1], S. Matsubara[1], N. Yamamoto[1], Y. Nakai[1], K. Hirano[1], M. Tada[1], K. Koike[1]

INTRODUCTION: With the advent of short double-balloon endoscope (DBE), therapeutic pancreaticobiliary interventions are possible with surgically altered anatomy. However, because the channel diameter of short DBE is 2.8 mm, only limited ERCP devices are available and the exchange of devices is both time-consuming and cumbersome. Recently, a prototype short single-balloon endoscope (SBE) with passive bending and high force transmission, which has a 3.2 mm working channel and a 152 cm in length, was specifically developed for ERCP (SIF-Y0004-V01; Olympus Medical Systems, Tokyo, Japan).
AIMS & METHODS: The aim of this study was to compare the insertability and procedural efficiency of short SBE and short DBE for pancreaticobiliary interventions in patients with surgically altered anatomy. Between March 2013 and Jan 2014, we performed endoscopic pancreaticobiliary interventions using a short SBE in 20 patients who have successfully undergone short DBE-assisted ERCP. Previous surgeries included Roux-en-Y (R-Y) gastrectomy (n = 7), hepaticojejunostomy (n = 5), pancreaticoduodenectomy with R-Y reconstruction (n = 3), Billroth II (B-II) gastrectomy with Braun's anastomosis (n = 2), pancreaticoduodenectomy with B-II reconstruction and Braun's anastomosis (n = 2), and liver transplantation with hepaticojejunostomy (n = 1).
RESULTS: Access to the papilla or anastomosis with SBE failed in 3/20 patients (15%). Among successful patients, the median time (IQR) required to reach the target orifice was 26 min (11–32.5 min) with SBE and 16 min (11–21 min) with DBE ($P = 0.10$). Pancreaticobiliary interventions with SBE were successful in 17/17 patients (100%). Therapeutic procedures using SBE included stone extraction (n = 11), biliary plastic stenting (n = 5), papillary large balloon dilation (n = 3), balloon dilation of anastomotic stricture (n = 3), pancreatic stenting (n = 3), biliary metallic stenting (n = 1), balloon dilation of biliary stricture (n = 1), and endoscopic naso-pancreatic drainage (n = 1). Although almost the same procedures with prior DBE, the median ERCP procedure time (IQR) was shorter with SBE than with DBE [29 min (23–55.5 min) vs 63 min (46.5–93.5 min), $P = 0.03$]. Aspiration pneumonia as procedure-related complication occurred in 1 patient.
CONCLUSION: Insertability of a short SBE is slightly inferior to that of a short DBE. However, a short SBE with a 3.2 mm working channel allows most conventional ERCP devices to be used and reduces ERCP procedure time compared to a short DBE with an only 2.8 mm working channel.

INTRODUCTION: Post-surgical poor differentiation/high grade of pancreatic cancer (PADC) appears to accurately predict an early unfavourable outcome, these patients possibly deserving neo-adjuvant treatment. EUS-guided pancreatic tissue core biopsy (EUS-PTCB) may in theory allow a pre-operative assessment of PADC-grading. To assess inter-observer pathological agreement and accuracy of preoperative PADC-grading based on EUS-PTCB.
AIMS & METHODS: 42 post-surgical PADC-cases with preoperative EUS-PTCB were chosen. Four expert pathologists independently reviewed the EUS-PTCB slides, reporting tumour grading (well-/moderate-/poor-degree of differentiation). Agreement among pathologists for reporting PADC-grading on pre-operative EUS-PTCB material was expressed by using Cohen's/Fleiss' kappa statistic, as appropriate. Post-surgical PADC-grading was used as gold-standard to assess the cumulative accuracy of EUS-PTCB in preoperatively predicting PADG grade.
RESULTS: The k values for PADC-grading on EUS-PTCB material ranged from 0.09 to 0.41. The total agreement among the four pathologists was only fair (k = 0.27; 95% CI: 0.14-0.38). When tumor grades were grouped as well-/

moderately differentiated versus poorly differentiated, kappa values ranged from 0.19 to 0.50, with only a fair overall agreement (k = 0.27; 95% CI: 0.21-0.49). Preoperative EUS-PTCB-based accuracy of preoperative staging was 56% (75/134 readings; 95% CI: 40-65%), with mean sensitivity and specificity to detect a high grade poorly differentiated tumor of 41% (95% CI: 19-54%) and 78% (53/68 readings; 95% CI: 60-99%), respectively.
CONCLUSION: Preoperative EUS-PTCB-based pathological grading of PADC is unreliable, arguing against the use of this information in clinical practice. This appears to be related with both a suboptimal inter-observer agreement among pathologists and an overall low accuracy in predicting post-surgical staging.

INTRODUCTION: A new 25-gauge Procore® biopsy needle has become recently available. Scanty data on its performance are available. We evaluate the yield of this needle in obtaining samples for histologic evaluation (EUS-FNB), its diagnostic accuracy and inter-observer agreement between three pathologists in a large cohort of patients with heterogenous indication.
AIMS & METHODS: Consecutive patients who underwent EUS-FNB using the Procore 25G were retrospectively retrieved. The collected material was placed directly in formalin or in cytolit and sent for histologic evaluation. All samples were independently reviewed by three pathologists and scored for: (i) presence of an histologic, cytologic specimen or no specimen; (ii) presence or absence of neoplasia; (iii) diagnostic or not diagnostic. Diagnostic accuracy and inter-rater concordance among pathologists in the evaluation of the above mentioned parameters were calculated.
RESULTS: 94 patients (median age 71 years; 55 male) underwent EUS-FNB of 101 sites. Mass lesions were located in the pancreas (49 patients), abdomen (6), liver (8), common bile duct (3 masses and 3 wall thickening), stomach (1 sub-epithelial lesion and 2 wall thickening), mediastinum (2), lung (1), and adjacent to the rectum (1). All the remaining 25 sampled lesions were mediastinal (14) and abdominal (11) lymph nodes. The median lesion size was 30 mm (range, 15-67 mm) and a mean of 2.5 FNA passes (range, 1-6; median, 3; IQR, 2-3) per lesion was done. A total of 41 (40.6%) lesions were classified as having a histologic specimen either by at least two of the three pathologists. A presence of a cytologic specimen was found by at least two of the three pathologists in 29 (28.7%) cases. In the remaining 31 lesions no specimen was present according to all three pathologists. There was good agreement among pathologists in determining if EUS-FNB provided cytologic vs. histologic samples (kappa index, 0.82; 95% CI:0.74-0.90). When considering non-diagnostic samples as false negative, the pooled sensitivity of the EUS-FNB for neoplasia was 65% (154 of 237 readings; 95% CI: 54.8-75.1%), whereas specificity was 98% (50 of 51 readings; 95% CI: 89-100%). The pooled accuracy of the procedure was 70.8 (204 of 288 readings; 95% CI: 62.1-79.6%). In the per-protocol analysis, the overall sensitivity and accuracy of the procedure for malignancy was 93.8 (150 of 160 readings; 95% CI: 88.8-96.9) and 93.9% (170 of 181 reading; 95% CI: 89.3-96.9%), respectively. Substantial agreement on the presence (or absence) of neoplasia resulted (kappa index, 0.94; 95% CI: 0.83-1.00). Substantial agreement was seen across the three reviewers in describing diagnostic accuracy, with an overall kappa value of 0.95 (95% CI: 0.85-1.00). At multivariate analysis, histologic samples were more likely than cytologic one to lead to a correct diagnosis (OR, 4.1; 95% CI: 1.2, 15.0; p = 0.027).
CONCLUSION: EUS-guided FNB with the Procore 25G needle provided samples for histologic examination in about 40% of the cases and showed excellent results in term of interobserver variability.

INTRODUCTION: Morphological evaluation of mediastinal masses is essential for diagnostic confirmation and treatment planning of patients (pts) with mediastinal abnormalities. EBUS-TBNA and EUS-FNA is a safe and efficacy method to obtain tissue for morphological diagnosis. The combined approach reduces the need for additional equipment, the operating costs, and the duration of the procedure. However it could be difficult to select the order of preference if both of the techniques are available.
AIMS & METHODS: The aim was to determine the diagnostic value of EBUS-EUS combined approach by using single ultrasound bronchoscope for evaluation mediastinal lymphadenopathy. EUS−FNA and EBUS−TBNA (Olympus Exera II BF-UC160F, Olympus 21g needles) were compared in 166 patients for tissue diagnosis from enlarge (>0.9cm) 7 and 4L group lymph nodes. 110 lesions were sampled from the respiratory tract under moderate sedation as first step. For 56 lesions fine needle aspiration was performed initially from the esophagus under local anesthesia. Cytology examination of the fine needles aspirates was made on site. If EUS-FNA (8pts) gives a negative result (8pts) in the on-site cytological analysis, EBUS-TBNA was performed once.
RESULTS: Diagnosis was proved in 87.3% of cases in EBUS-TBNA group and in 85.7% of cases in EUS-FNA group. Definitive morphology diagnosis was made in 96.4% by the combined approach with rapid on-site evaluation of the fine needles aspirates.
CONCLUSION: Two procedures can be performed with single ultrasound bronchoscope and the combined approach with cytology examination on site has better diagnostic value than either alone. But EUS-FNA with ultrasound bronchoscope is easy, safe and doesn't request moderate sedation. Therefore it can be performed for patients for tissue diagnosis from enlarge 7 and 4L group lymph nodes as the first step of examination.

INTRODUCTION: Therapeutic endoscopic ultrasound (T-EUS) has been undergoing extensive development in recent years. Although previous experience on EUS-FNA and ERCP is considered to be needed, data on learning curves and the potential benefit of animal models training are lacking.
AIMS & METHODS: To train some different T-EUS techniques and to estimate their difficulties and the potential benefit of the swine model in this context.
Prospective data analysis from a T-EUS practical workshop on a biliary obstruction porcine model by OTSC clip®, addressed to endoscopists with previous EUS-FNA and ERCP experience. There were four different T-EUS procedures trained: common bile duct drainage (CBDD), cholecysto-gastrostomy (CGS), transrectal urinary bladder drainage (TUBD), simulating a fluid collection drainage, and gastro-jejunostomy (GJS). All animals were sacrificed after T-EUS procedures and necropsy studies were performed. Local Ethics Committee approval was obtained.
RESULTS: Thirty three procedures were analyzed (11 CBDD, 5 CGS, 7 TUBD, 10 GJS), performed by 12 endoscopists in 10 pigs (2.83 ± 0.58 proc./endoscopist; 3.3 ± 1.42 proc./animal). Main results are shown in Table 1. Together TUBD and GJS were the procedures more frequently and successfully completed versus CBDD and CGS (100% vs. 62.5%, p = 0.007 and 82.4% vs. 37.5%, p = 0.011). Among the different procedural steps, guidewire management (31.8%), stent insertion (25%) and cystotome use (20%) were the most troublesome ones.
Table 1. Results by procedure

	CBDD	CGS	TUBD	GJS	Total	*p
N	11	5	7	10	33	
Mean time duration (min.)	51.3 ± 14.5	48 ± 7.6	31.3 ± 5.9	21.2 ± 17.2	34.7 ± 18.5	*0.000*
Completed	63.6%	60%	100%	100%	81.8%	*0.007*
Final succes	45.5%	20%	85.7%	80%	60.6%	*0.011*
Trainer intervention needed	18.8%	20%	14.3%	20%	18,8%	*0.608*
Inmediate complications	10%	40%	14.3%	10%	15.6%	*0.437*

CONCLUSION: Our model appears to mirror the challenges of T-EUS even for endoscopists experienced in EUS-FNA and ERCP.
Ethical and cost concerns can be minimized by optimizing the number of T-EUS drainage procedures, up to 4 per animal.
CGS and CBDD, both longer and with higher number of steps and instrument requirements, are more challenging than TUBD or GJS, which suggests more demanding training is needed.
This kind of training based on animal model simulation may allow a safer and probably quicker learning curve on T-EUS.

INTRODUCTION: Treating pancreatic cancer represents a major objective in research, as it still remains the fourth leading cause of cancer deaths among men and women, with approximately 6% of all cancer-related deaths. Radiofrequency ablation uses electromagnetic energy deposition causing thermal lesions and overheating tissue which leads in a final stage to necrosis.
AIMS & METHODS: We studied the assessment of an EUS-guided RFA probe through a 19-gauge needle, in order to achieve a desirable necrosis area in the pancreas. Radiofrequency ablation of the head of the pancreas was performed using a RITA Medical System device on 10 Yorkshire pigs with a weight between 25 to 35 kg. Using an EUS-guided RFA experimental probe we ablated an area of 2 to 3 cm wide at 5-10-15-20 watts for one minute a time.
RESULTS: No major complications were noted. High levels of amylase, lipase, aspartate transaminase and alanine transaminase were found within 3 days from the ablation. Necropsy pointed out a very well limited area with minimal invasion and inflammatory tissue at about 2 cm surrounding the lesion. No nearby fibrosis or adhesions were found and no major vessel injuries or adjacent organ damage was produced. The pathology examination revealed coagulative necrosis, a local acute inflamatory reaction with structured necrosis of the glandular parenchyma, steatonecrosis, and recent thrombosis of blood vessels.
CONCLUSION: EUS-Guided RFA of the pancreas may be a feasible procedure, however more studies are necessary.

INTRODUCTION: Gastric remains one of the most common causes of cancer-related death. Recent studies reveal that neoadjuvant treatment of locally advanced gastric cancer improves survival of these patients. Endoscopic ultrasonography (EUS) staging is recommended in several guidelines, particularly in the assessment of the T and N stages. However, its role in identifing patient candidates to neoadjuvant therapy is not known.
AIMS & METHODS: The purpose of the study was to evaluate the accuracy of EUS in selecting patients for neoadjuvant therapy of gastric adenocarcinoma. We conducted a retrospective analysis of patients with gastric adenocarcinoma who underwent EUS staging and were submitted to primary gastrectomy between 2011 and 2013. We determined the agreement (kappa – k) between EUS and pathological TNM staging and the accuracy (AUROC, sensitivity and specificity) of EUS to identify patients with indication for neoadjuvant therapy (defined as stages II and III in the pathological analysis of the surgical specimen).
RESULTS: Between 2011 and 2013 were performed 141 USE, of which 66 were excluded (37 patients did not undergo underwent gastrectomy, 16 patients underwent neoadjuvant therapy, 7 USE were re-staging examinations and 6 cases weren't adenocarcinomas). Of the 75 patients enrolled, the median age was 66 years, 65% were male and 60% had intestinal type adenocarcinoma. The distribution of patients according to the EUS and pathological staging was: 50.7% and 46.6% for stage I, 31.1% and 33.3% for stage II, 16% and 21.3% for stage III. The agreement between EUS and pathologic stages for T, N and TNM was good (k = 0.61), moderate (k = 0.44) and fair (k = 0.36), respectively, while for stages II + III was good (k = 0.63). The accuracy of EUS for stages II + III was high (AUROC 0.82, sensitivity 78% and specificity 86%), especially for intestinal type adenocarcinoma (AUROC 0.84, sensitivity 86% and specificity 85%).
CONCLUSION: Endoscopic ultrasonography has an important role in the staging of gastric cancer, showing a good performance in the selection of patients for neoadjuvant treatment, especially in intestinal type adenocarcinoma.

INTRODUCTION: Liver abscesses and bilomas are conventionally managed by means of percutaneous drainage or surgical approach. However, both procedures have been reported on high morbi-mortality rates. Transgastric EUS-guided drainage of both entities with plastic stents or nasocystic catheters have been exceptionally performed. We describe our experience using self expandable metal stents (SEMS) – tubular and lumen–apposing metal stents (LAMS) in this setting.
AIMS & METHODS: The aim of the study was to assess the technical feasibility and clinical outcomes of EUS-guided drainage of liver abscesses and bilomas using SEMS under mixed fluoroscopic, endoscopic and ultrasonographic guidance.
Retrospective analysis involving eight consecutive patients (March'12 to Oct '13) with liver abscesses/bilomas not accesible to percutaneous approach and/or discarded for surgery by means of age or comorbidities (Table 1). Procedures were performed by using linear echoendoscopes, 19G needles under EUS & fluoroscopic control, 0.035" guidewires, 8.5F cystotome and tract dilation with 4 mm biliary balloon. Aspiration of fluid was routinely performed for culture. Finally, cSEMS were placed, either tubular or lumen-apposing metal stents (LAMS: AXIOS^{TM}- Xlumena Inc).
RESULTS: Six patients with liver abscesses and 2 bylomas were included (Table 1) EUS-guided transgastric approach was performed in 6/8 cases (75%) in correspondence with abscesses located on the left hepatic lobe. 6 patients were managed with LAMS (5 abscesses, 1 biloma). Median diameter of abscesses was 80.05 mm (range 52.70 - 99). Drainages were successful in all cases and there were no procedure-related complications. Stents were removed after a mean of 7 weeks (range 4-12). There were no relapses after a mean follow-up of 7.5 months (range 1-18)
CONCLUSION: EUS-guided drainage of hepatic abscesses and bilomas by means of SEMS appears to be a safe, effective and useful procedure in patients not suitable for radiologic drainage or surgery. However, larger, prospective and multicenter studies are needed.

P0210 COULD QUANTITATIVE AND QUALITATIVE EUS-ELASTOGRAPHY RESULTS BE AFFECTED BY THE COMPRESSION RATE AND THE DIAMETER OF THE REGION OF INTEREST?

C. Robles-Medranda[1,*]
[1]*ENDOSCOPY, INSTITUTO ECUATORIANO DE ENFERMEDADES DIGESTIVAS, UNIVERSITY HOSPITAL OMNI, ESPIRITU SANTO UNIVERSITY, Guayaquil, Ecuador*
Contact E-mail Address: *carlosoakm@yahoo.es*

INTRODUCTION: EUS-elastography (EUS-e) is an alternative method to evaluate tissue stiffness (elasticity-index) of solid pancreatic masses, which may be related to histopathology tissue features (hard = blue = neoplastic / soft = red-yellow-green = non-neoplastic). Recently publications show different results using EUS-e and a lack of data exist regarding the compression rate of the probe (CRP) and the diameter of the region of interest (d-ROI) under analysis.
AIMS & METHODS: Based on the hypothesis that EUS-e could be affected by CRP and the d-ROI this study aimed to evaluate the quantitative strain ratio (q-SR) and qualitative color (q-C) EUS-e results determined by the CRP and the d-ROI in normal pancreatic tissue (NPT). After approval by the ethics committee and signing of an informed consent, a prospective study was performed in 45 patients undergoing for upper-EUS from Oct-Nov 2013. Inclusion criteria: EUS for evaluate submucosal tumors. Exclusion criteria: age < 18 or > 55; pregnancy, history of: pancreatic disease, choledocolitiasis, symptoms of maldigestion, alcohol abuse, increased serum levels of pancreatic enzymes, smokers and EUS signs of chronic pancreatitis (Rosemont classification). EUS–e was performed using linear Pentax-EUS and Hitachi-Avius. The q-SR and q-C EUS-e was measured in the body of the pancreas taking in consideration the curve of the CRP high: +0.4 (H-CRP), middle: 0 (M-CRP), low: -0.4(L-CRP) in the largest (LROI) and smaller ROI (SROI) diameters. Analysis for q-C was obtained by the predominant color of the pancreatic area studied. Pictures where recorded and q-SR data

were calculated comparing EUS-e of pancreatic tissue with soft tissue (normal mucosal layer: red). Finally, a comparative analysis was performed between the results with the mean normal value (NV) of 1.68 for q-SR previously published for NPT, and between the different CRP.
RESULTS: 60 images were analyzed and 10 patients were included, 6 females, mean age 50 (ranges: 32-55). LROI q-C analysis: showed a predominant green (G) color in H-CRP in 90%, M-CRP in 50% and L-CRP in 70% of cases. SROI q-C analysis: showed a predominant G-color in H-CRP in 100%, L-CRP in 50% and M-CRP in 66.6% of cases. In LROI-quantitative showed a mean SR of 7.2 (range: 2.7-24) for H-CRP, 11.03 (range: 3.3-42) for M-CRP and 8.8 (range: 2.6-36) for L-CRP being $p<0.05$ for H-CRP and L-CRP when compared with NV q-SR, and for H-CRP when comparing with M-CRP. For SROI q-SR analysis showed a mean SR of 6 (range: 5.5-6.6) for H-CRP; 8 (range: 5-12) for M-CRP and 77 (ranges: 2.3-224) for L-CRP, being $p<0.05$ in all cases when compared with NV q-SR.
CONCLUSION: EUS-e (q-C and q-SR) results in NPT could be affected by CRP and d-ROI. These data suggest that a standardization of the measurements parameters is required to determine the best results and application of this technology in pancreatic diseases.

P0211 ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION (EUS-FNA) IN PANCREATIC LESIONS: PREDICTIVE FACTORS OF ACCURATE DIAGNOSIS

C. Leitão[1,*], A. Santos[1], H. Ribeiro[1], J. Pinto[1], A. Caldeira[1], E. Pereira[1], A. Banhudo[1]

Contact E-mail Address: *catia.f.leitao@gmail.com*

INTRODUCTION: Endoscopic ultrasound (EUS) has taken on an important role in the diagnosis of benign and malignant pancreatic disease. Due to the proximity of the transducer and reduced acoustic interference, EUS provides high-resolution ultrasound images of the pancreas with subtle anatomical detail and has the unique ability to obtain specimens of the pancreas and peripancreatic structures for cytohistological diagnosis.
AIMS & METHODS: The aim of this study is to identify the predictive factors for an accurate EUS-FNA diagnosis. **Methods:** Retrospective analysis of medical records of patients submitted to an EUS-FNA for evaluation of a pancreatic mass, from January of 2008 to December of 2013. All procedures were performed by 2 operators, using a linear echoendoscop Pentax® EG3870UTK and Hitachi HI Vision Preirus or EUB-6000 US. Collection of demographic data, ultrasonographic characteristics, technical information on EUS-FNA and cytohistological results.
RESULTS: A total of 1420 EUS examinations were performed during the period. 88 patients (with a mean age of 64±14 years; 54.5% female) diagnosed with pancreatic masses underwent EUS-FNA. 81.8% of them had this symptoms: epigastric pain (34%), weight loss (23.9%) and jaundice (23.9%). 51.5% of the lesions were located in head of pancreas and 67% were solid masses. The median size of the lesion was 31.8±12.5mm. The mean number of passages was 2.35±0.97. EUS-FNA was performed with 19 G needle in 7.1% of patients, 22G needle in 70.6% and with 25G needle in 22.4% of patients. The overall diagnostic accuracy was 82.9%. In 10 patients procore needle (19G-1;22G-1;25G-5) was used and the diagnostic accuracy was 100%, although not a statistically significant difference. Adenocarcinoma was the most common cytological diagnosis (62.9%), followed by inflammatory pancreatic disease (21%), endocrine neoplasm (6.5%), mucinous neoplasm cystic (6.5%) and IPMN (1.6%). There were no procedure-related complications. The predictors of diagnostic accuracy ($p< 0.05$) were: appearance of lesion (solid mass 90.6% vs. cystc mass 54.4%), size of lesion (diagnostic 32.6 mm vs non diagnostic 23.6 mm) and location of the lesion (body 100% vs. head 86.6% vs. neck 70.2% vs. tail 40%). The size of needle and number of passages did not significantly influenced the diagnostic accuracy of the procedure.
CONCLUSION: EUS-guided FNA is a safe and reliable technique for establishing a diagnosis in pancreatic mass lesions, especially in solid mass, located in body or head and with a greater dimension.

P0212 LEARNING CURVE FOR ENDOSCOPIC ULTRASONOGRAPHY IN GASTRIC CANCER T STAGING USING CUMULATIVE SUM METHOD

C.H. Park[1,*], **J.C. Park**[1], E.H. Kim[1], D.H. Jung[1], H. Chung[1], S.K. Shin[1], S.K. Lee[1], Y.C. Lee[1]

INTRODUCTION: One of the most studied tools for the loco-regional staging of gastric cancer is endoscopic ultrasonography (EUS). The American Society for Gastrointestinal Endoscopy guideline set 75 examinations as a minimum number of EUS procedures for mucosal cancer including esophageal, gastric, and rectal cancer before competency can be determined. The learning curve in the staging of gastric cancer, however, has not been evaluated.
AIMS & METHODS: We retrospectively reviewed the clinical records of patients who underwent EUS examinations for gastric cancer, which were performed by trainees, at Severance Hospital, Seoul, Korea, between March 2011 and February 2012. Cumulative summation analysis was applied to assess the learning curve for EUS T staging in each trainee.
RESULTS: A total of 553 initial EUS examinations for naïve gastric cancer performed by 4 trainees were enrolled in the study. Final EUS T staging was determined by experts in 332 gastric cancers, while EUS T staging of other 221 lesions was determined by trainees. Accuracies of EUS examinations performed by trainees and experts were 72.6% and 84.3%, respectively. Required EUS examinations for reaching a 1st plateau in each trainee were 20, 41, 60, and 65, respectively. In addition, poor predictive factors for accurate T staging of gastric cancer were 20–30 mm and 30–50 mm of size compared to 20 mm or less of size, pT2–pT4 stages compared to pT1 stage, and EUS T staging by trainees.
CONCLUSION: A threshold number of 75 which is suggested by guidelines may be acceptable for achieving competency of gastric cancer T staging by EUS.

P0213 PROGNOSTIC SIGNIFICANCE OF EUS NON-TRAVERSABILITY IN PATIENTS WITH LOCALLY ADVANCED SQUAMOUS ESOPHAGEAL CANCER RECEIVING PREOPERATIVE CHEMORADIOTHERAPY

C.J. Cho[1,*], H.J. Song[1], J.S. Lee[1], J.Y. Ahn[1], J.H. Lee[1], D.H. Kim[1], K.-S. Choi[1], K.D. Choi[1], G.H. Lee[1], **H.-Y. Jung**[1], J.-H. Kim[1]

Contact E-mail Address: *formidable1981@gmail.com*

INTRODUCTION: Although endoscopic ultrasonography (EUS) is the most accurate loco-regional staging modality for squamous esophageal cancer (EC), approximately 30% of patients cannot complete EUS due to malignant stenosis (EUS non-traversability). Malignant stenosis has reportedly been associated with advanced tumor stage. However, to date, no study has assessed clinical implications of EUS non-traversable EC stenosis in patients with locally advanced EC receiving preoperative chemoradiotherapy (CRT).
AIMS & METHODS: This study aimed to examine the clinical implications and prognostic significance of EUS non-traversability in locally advanced EC patients treated with preoperative CRT. Data from 89 consecutive patients with locally advanced and resectable EC (stage II or III) planning preoperative CRT followed by esophagectomy were retrieved. Relevant clinical and cancer-specific parameters were reviewed retrospectively. Univariate and multivariate analysis with a Cox model were performed to determine significant factors for survival.
RESULTS: EUS scope could not pass through EC in 26 of 89 (29.2%) patients. Between EUS non-traversable and traversable group, dysphagia (88.5% vs. 52.4%; $P=0.001$), need for stent insertion (30.8% vs. 1.6%; $P<0.001$), median serum albumin level (3.6 vs. 3.9 g/dL; $P=0.028$), tumor length (6.0 cm vs. 4.0 cm; $P=0.002$), and percentage of stage III disease (65.4% vs. 38.1%; $P=0.019$) were significantly different. 79 (88.8%) patients completed preoperative CRT; 22 (84.6%) in non-traversable group and 57 (90.5%) in traversable group ($P=0.426$). 70 (78.7%) attained CR or PR. CRT response rates were not different between non-traversable and traversable group (76.9% vs. 79.4%; $P=0.798$). 53 (59.6%) patients underwent esophagectomy; 16 (61.5%) in non-traversable and 37 (58.7%) in traversable group ($P=0.806$). Median OS of all patients was 32.8 months (95% CI, 0–68.2 months) with 5-YSR of 43.8%. Stage III ($P=0.079$), non-response to preoperative CRT ($P<0.001$), incompletion of esophagectomy ($P<0.001$), weight loss ≥10% ($P=0.047$), serum albumin level <3.8 g/dL ($P=0.035$), EUS non-traversability ($P=0.025$) and tumor length ≥5 cm ($P=0.069$) were negative prognostic factors on univariate analysis. Weight loss ≥10% ($P=0.042$), EUS non-traversability ($P=0.007$), non-response to preoperative CRT ($P=0.003$), and incompletion of esophagectomy ($P=0.002$) remained significant negative prognostic factors of survival in multivariate analysis. EUS non-traversable EC patients had a significantly lower 5-YSR than those with EUS traversable EC (30.8% vs. 49.3%, $P=0.023$). 5-YSR was 50.0% for EUS non-traversable EC patients who attained a clinical response to CRT and also underwent esophagectomy (vs. 64.5% in EUS traversable EC patients; $P=0.153$).
CONCLUSION: EUS non-traversability is a significant negative prognostic factor in patients with locally advanced, resectable EC receiving preoperative CRT. The clinical implication may arise from incomplete loco-regional EC staging and larger tumor burden. We suggest that treatment should not be discontinued for the patients with EUS non-traversable EC stenosis, given the acceptable compliance to multimodality therapy and the survival of the patients who attained a clinical response to CRT and underwent surgery.

P0214 IS THE CORE BIOPSY NEEDLE (PROCORE TM COOK NEEDLE) THE ALMIGHTY SOLUTION FOR EUS-GUIDED TISSUE ACQUISITION? A COMPARISON WITH STANDARD EUS-FNA NEEDLES

C. De Angelis[1,*], S. Gaia[1], S.F. Manfre'[1], A. Andrealli[1], M. Bruno[1], P. Carucci[1], D. Pacchioni[1], A. Cassenti[1], R. Senetta[1], L. Molinaro[1], G. Gatti[1], A. Sapino[1], M. Rizzetto[1]

INTRODUCTION: Fine Needle Aspiration (FNA) under Endoscopic UltraSound (EUS) guidance is an efficient and safe method to obtain tissue samples from gastro-intestinal tract and from the nearest structures. Whereas EUS-FNA provides samples of cells without any tissue structure information, EUS-Fine Needle Biopsy (FNB) has the theorethical advantage to collect tissue specimens for histological evaluation. The aim of this study is to compare feasibility and diagnostic yield of the newly-developed FNB device (Cook EchoTip ProCore) with the standard FNA needles.
AIMS & METHODS: 134 patients (75/59 M/F; 62±13.5 years) were consecutively enrolled between April 2011 and June 2013, for a total of 137 lesions (mean size 33.5±16 mm, range: 6-100 mm): 81 pancreas, 31 lymph nodes, 8 stomach, 7 gut (including 1 papilla), 4 esophagus, 5 aspecific abdominal masses, 1 nervous ganglia. For each lesion EUS-guided tissue sampling was performed both with standard needle and with ProCore needle. An expert cytopathologist evaluated the material giving out a score (0-4) about the adequacy of the samples and assessing the feasibility of the diagnosis on the samples from the two types of needle.
RESULTS: A mean of 3.2±1.1 (range 1-6) and 2.8±1.1 (range 1-7) needle passes per lesion were performed with standard needles and ProCore respectively (p:ns). A core sample adequate for histological assessment from ProCore biopsy was achieved in 29% lesions (mean length 1.37±0.7 mm, range 0.5-3.0 mm), with no difference among the 22, the 19 and the 25 Gauge needle (25%, 46.7% and 33.3% respectively; p: ns). 37% of lesions however fitted for cytological evaluation, whereas 34% were inadequate. There were no statistical difference in the pathologists' adequacy score between the standard needle and the ProCore needle (2.3±1.4 and 2.3±1.4 respectively, p:ns). A final diagnosis was reached 84% cases; 66% of the ProCore samples and 67% of the standard needle samples (p:ns; Standard Echo alone versus both: p 0.009; ProCore alone versus both: p 0.005). In 16.5% the diagnosis was reached only on the ProCore sample. No complications were observed.
CONCLUSION: EUS-FNB is feasible and safe, but only in 29% of cases a core sample adequate for histological evaluation was obtained. The success rate in reaching the diagnosis is similar with standard needles and with ProCore needles. However the best results could be reached significantly better with the combination of the 2 type of needle than with EchoTip alone or with ProCore alone (p: 0.009 and p:0.005 respectively) and it seems that the ProCore needle could be useful especially on fibrotic or hard lesions.

P0215 NATURAL HISTORY OF PANCREATIC INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS: CLINICAL EVALUATION OF SENDAI CRITERIA IN A LARGE COHORT OF PATIENTS

E. Dabizzi[1,*], M.C. Petrone[1], M.E. Traini[1], S.G. G. Testoni[1], P.A. Testoni[1], P.G. Arcidiacono[1]
[1]*Gastroenterology and Digestive Endoscopy, San Raffaele Scientific Institute-Università Vita e Salute, Milano, Italy*
Contact E-mail Address: *dabizzi.emanuele@hsr.it*

INTRODUCTION: Intraductal papillary mucinous neoplasms (IPMN) are mucin-producing, pancreatic cystic tumors, with a long-term potential for progression to adenocarcinoma. The revised "Sendai criteria", based on imaging features, can differentiate the lesions into high and low risk of progression, influencing the patient management. However, few data are still available about clinical management and a better understanding in natural history is critical.
AIMS & METHODS: To evaluate the natural history of IPMN throughout clinical follow-up. Second end-point was to assess the clinical correlation between endoscopic ultrasound features and malignant histology, in order to validate the "Sendai Criteria" in our clinical practice. All the patients with pancreatic IPMN, referred to our tertiary referral center between March 2003 and April 2013 were enrolled in the study. We divided patients into 3 groups, according to Sendai criteria: patients with cysts without signs of malignancy (1), patients with cysts with worrisome features (2) and patients with cysts with high risk stigmata (3). Data were analyzed using uni variate and multivariate logistic regression, to assess the risk factors of malignant progression at diagnosis (T0) and at 2 years of follow up (T2).
RESULTS: 371 patients were enrolled in the study period (171 M, mean age 67 years), with a mean follow up of 38 months from 1 up to 106 months (mean 38 mo). 191/371 (52%) pts presented cysts without signs of malignancy, 105/371 (28%) pts cysts with worrisome features and 75/371 (20%) pts cysts with high risk of malignancy. At multivariate analysis, the features significantly associated with a higher risk of progression at diagnosis included mass size, pancreatic duct dilation ($p < 0.001$), with an accuracy of 78% and a specificity of 88%. Whereas, the features with a significantly higher risk of progression at 2 year-follow up included the pancreatic dilation and the presence of mural nodules (OR 40.01) ($P < 0.001$), with an accuracy of 84% and a specificity of 93%.
CONCLUSION: Our results validated Sendai Criteria in clinical practice. Therefore, patients with no sign of malignancy and unchanged EUS imaging can be followed up with a lengthened interval. Due to a high progression rate, a strict follow up is recommended in pts with worrisome features. Patients with high risk stigmata need surgery at diagnosis.

P0216 AUTOMATIC DETECTION OF 'SUSPICIOUS' CAPSULE ENDOSCOPY VIDEO SEGMENTS

A. Koulaouzidis[1,*], S. Tsevas[2], D.K. Iakovidis[3]
[1]*Centre for Liver & Digestive Disorders, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom,* [2]*Department of Computer Engineering, Technogical Educational Institute of Central Greece,* [3]*Department of Computer Engieering, Technological Educational Institute of Lamia, Lamia, Greece*

INTRODUCTION: Manual review and annotation of capsule endoscopy (CE) videos requires a considerable amount of reviewing time. Furthermore, the diagnostic accuracy of this process – over lengthy reviewing sessions – may decrease due to reviewer's tiredness. Recent studies showed an average detection rate – for the clinically significant findings – as low as 40%.[1] We present a generic computational framework for automatic detection of abnormalities in CE videos.
AIMS & METHODS: A CE video (MiroCam®, InrtoMedic Co Ltd, Seoul, Korea), depicting inflammatory changes (aphthae, mucosal breaks, ulcers, erythema) was reviewed and manually annotated by experienced CE reader. A total of 1,984 frames, depicting any type of pathology, were thumbnailed. The proposed framework considers video frames as members of a vector space represented by their colour information. An unsupervised data reduction algorithm,[2] which does not require any prior knowledge about the data, was then applied on each segment. This algorithm clusters together frames that exhibit similar characteristics e.g. colour distributions. Its output is a subset of video frames extracted from each cluster by applying a threshold to the clustering result. The extracted frames are characteristic of the particular video segment and as a result representative of possible lesions.
RESULTS: The evaluation of the proposed framework aimed to determine its accuracy, in terms of the ratio of the neighbourhoods represented by at least one frame in the system's output and the neighbourhoods that were manually annotated as suspicious for containing lesions. The parameters considered include clustering from 2 to 6 clusters and thresholds[2] varying from 0.004 to 0.6. The obtained accuracy ranged between 76% and 98% depending on the desired sensitivity level of the algorithm, controlled by the threshold. Furthermore, the automatic selection of the representative CE video segments performed by the proposed approach, the number of video frames to be thoroughly examined can be reduced from 30% to 60% of the original video, depending on the clustering and threshold settings.
CONCLUSION: The application of the proposed framework to the evaluation of CE videos may reduce the rate of false negative evaluations by attracting the attention of the reviewer to automatically identified video segments (or single frames) of interest which are likely to contain lesions.

P0217 WIRELESS CAPSULE ENDOSCOPE LOCALIZATION BASED ON VISUAL ODOMETRY

A. Koulaouzidis[1,*], D.K. Iakovidis[2], E. Spyrou[2]
[1]*Endoscopy Unit, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom,* [2]*Dept of Computer Engineering, Technological Educational Institute of Central Greece, Lamia, Greece*

INTRODUCTION: The localization of a wireless capsule endoscope (WCE) within the small-bowel is typically performed by wearable radiofrequency sensors triangulation. The accuracy of this approach is low.[1] Only a few approaches have been proposed for localisation of WCE based on visual features. These include methods addressing the estimation of the rotation angle of the capsule [2,3] & temporal video segmentation methods.[4] We present a WCE localization method, based only on visual information extracted from conventional WCE recording.
AIMS & METHODS: to check the accuracy of visual odometry in WCE with ex-vivo data.
Methods: Automatic detection of points of interest (POI) in WCE video frames, matching of the detected POI between consecutive frames, and determination of actual correspondences between subsets of these POI based on the random sample consensus (RANSAC) algorithm was performed. Instead of the speeded up feature extraction (SURF) algorithm, a maximally stable extremal regions (MSER) algorithm was used. Based on the scaling & the rotation of the content of the consecutive WCE frames, it is possible to estimate the displacement & the rotation of the capsule within the GI tract.
For the ex-vivo experiment a standard simulated intestinal environment was created. Markers were sewn onto the luminal surface of porcine small-bowel through which a capsule endoscope (MiroCam®, IntroMedic Co Ltd, Seoul, Korea) was propelled.
RESULTS: Comparative experiments using both SURF and MSER features, which indicated the superiority of the former over the latter, were conducted. We worked on a corpus of 1070 WCE frames (634 indicating forward motion, 436 indicating backward motion). The accuracy using SURF features was 81.5%

(87.2% on forward motion, 73.2% on backward motion), while using MSER was 67.2% (79.8% on forward motion, and 48.9% backward motion). Noteworthy, the proposed algorithm often fails when using MSER (6.7% of frames while <0.1% when using SURF) and a transform is not estimated due to the lack of adequate correspondences between POI.

CONCLUSION: Visual odometry is a promising technique and -potentially- a feasible alternative to other localization approaches in WCE.

P0218 UTILITY OF THREE-DIMENSIONAL IMAGE RECONSTRUCTION IN THE DIAGNOSIS OF OESOPHAGEAL VARICES

A. Koulaouzidis[1,*], A. Karargyris[2], Y.L. Ang[3], S. Douglas[1], E. Rondonotti[4], A.J. Bathgate[1], P.C. Hayes[3], J.N. Plevris[1,3]
[1]*Endoscopy Unit, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom,* [2]*National Library of Medicine, National Institutes of Health, Bethesda, MD, United States,* [3]*Medical School, The University of Edinburgh, Edinburgh, United Kingdom,* [4]*Gastroenterology Unit, Ospedale Valduce, Como, Italy*

INTRODUCTION: Oesophagogastroduodenoscopy (OGD) remains the gold standard for the diagnosis of oesophageal varices (OVs). Oesophageal capsule endoscopy (OCE) is a non-invasive alternative. However, recent studies showed that OCE is lagging behind OGD in diagnostic accuracy [1]; it can be an acceptable alternative though in certain situations such as those who cannot tolerate OGD or are at risk of variant Creutzfeldt–Jakob disease (vCJD)[2]. Application of innovative 3D reconstruction software may improve OCE accuracy in the diagnosis of OVs [3].

AIMS & METHODS: 14 patients, intolerant or with contraindications for conventional OGD e.g. risk for vCJD (for public health purposes), underwent OCE with PillCam®ESO1/2. The OCE video recordings (from one of the 2 CE domes) from the entry in the oesophagus to exit in the stomach were deconstructed to individual frames. Following 3D reconstruction, the frames were stitched back to 3-D videos. Ten reviewers; 6 GI trainees (novice in CE review), 3 GI specialists with experience between 20 and 100 CE reviews and 3 expert CE reviewers read the OCE first in 2-D and then in a GUI (graphic user interface) offering (side-to-side) 2-D & 3-D. Furthermore, the consensus opinion of 3 senior hepatologists, with wide endoscopy experience in patients with liver disease, who reviewed the OCEs with the GUI was used as reference standard (RS). Interobserver agreement for each of the above groups was checked with kappa (κ) statistics.
When the RS for C2 (i.e. varices requiring treatment) was taken into account, the negative predictive value (NPV) of the entire group (10 reviewers) for C2 variceal diagnosis with2-D and 2D+3D was calculated.

RESULTS: The interobserver agreement for the entire group, novice, experienced and experts CE reviewers with 2-D was 0.145, 0.118, 0.125 and 0.025, respectively. The interobserver agreement for the entire group, novices, experienced and expert reviewers with 2-D & 3-D was 0.215, 0.104, 0.222 and 0.372, respectively. For C2 varices diagnosis (RS), the NPV of 2-D and 2-D & 3-D review was 66.6% and 80%, respectively.
Limitations: the use of subjective RS.

CONCLUSION: In oesophageal capsule endoscopy, the use of a GUI that incorporates 2-D and 3-D reconstructed videos leads to improved diagnostic agreement; furthermore, it improves significantly he NPV of OCE for C2 varices.

Acknowledgement: we thank all those in the 3-D in capsule endoscopy assessment group.

P0219 LATERAL-VIEWING CAPSULE ENDOSCOPY EXPERIENCE FROM AN ACADEMIC CENTRE IN SCOTLAND

A. Koulaouzidis[1,*], L. Bartzis[1], S. Douglas[1], J.N. Plevris[1,2]
[1]*Endoscopy Unit, The Royal Infirmary of Edinburgh,* [2]*Medical School, The University of Edinburgh, Edinburgh, United Kingdom*

INTRODUCTION: CapsoCamS®V1 represents a major departure from conventional 'wireless' capsule endoscopy (CE). This CE system utilises on-board data storage, which necessitates retrieval of the device for data collection. Four lenses in the middle of the device, offering panoramic views of the bowel lumen, have replaced a forward-facing lens. Battery life is also increased to ~15h by virtue of a variable image capture rate. Furthermore, the reviewing software provides 4 rectangular panels in a linear sequence, departing from conventional CE reading software.

AIMS & METHODS: Aim: To report our experience on the clinical use of CapsoCam®SV1 CE.

Setting: An academic hospital, tertiary referral-centre for CE for the South-East of Scotland.

Methods: Retrospective, single centre, observational study.

RESULTS: Since May 2012, 12 patients (4M/8F, mean age: 67.75 ±13.5 years; 8 inpatients) underwent CE with CapsoCam following the standard protocol of our unit. In 80% of patients, the examination was performed for obscure GI bleeding.
The mean time from capsule ingestion to data upload was 5.6 ±8.5 days. Two patients underwent successful endoscopic placement with the AdvanCE® delivery device. The gastric transit time (GTT), small-bowel transit time (SBTT) was 50.9 ±51.2 min and 5.46 ±3.15 h, respectively. The mean total working time for CapsoCam® was 14 ±3 h. Caecal entry was confirmed in 10/12 examinations. The ampulla of Vater (AoV) was visualised in 2/12 i.e. 20% of cases after correcting for quality of bowel prep (10 good). Diagnostic yield for findings was 33.3%.

CONCLUSION: A significant time interval between capsule ingestion and data upload is noted. However, capsule retrieval eliminates the need for radiologic confirmation of capsule excretion in cases of incomplete enteroscopy. The AdvancCE® delivery can be used for CapsoCam® endoscopic placement. The diagnostic yield and the rate of identification of the AoV is comparable to forward-viewing CE devices.

INTRODUCTION: Video capsule endoscopy (VCE) is crucial examination for diagnosis of small bowel bleeding. But diagnostic yield of VCE is 38% to 83% in overt obscure gastrointestinal bleeding (OGIB). For an accurate diagnosis of cause of overt OGIB, the timing to perform VCE is the valuable factor. This study is to investigate the diagnostic yield, rate of therapeutic intervention, and prognosis according to the timing of VCE in the overt OGIB patients.

AIMS & METHODS: We conducted a single center, retrospective study at Korea University Medical Center Anam Hospital from April 2008 to February 2014. Patients who presented overt OGIB with negative result of initial upper and lower endoscopy were enrolled. We compared the diagnostic yield, rate of therapeutic intervention, length of hospital stay, and rate of re-bleeding between patients with VCE performed in ≤48hrs and >48hrs after the occurrence of overt OGIB. We defined positive finding as active bleeding or any cause of small bowel bleeding.

RESULTS: In 111 patients, VCE were performed to evaluate overt OGIB during the period. Among them, 90 patients were included and 21 patients who lacked of medical records were excluded. Diagnostic yield was 65.51% in ≤48hrs group and 35.59% in >48hrs group ($p=0.037$). Therapeutic intervention was done in 45% of the ≤48hrs group and 14% of >48hrs group ($p=0.006$). The average day of hospital stay was 5.48 days in ≤48hrs group and 8.18 days in >48hrs group ($p=0.005$). Re-bleeding rate between the ≤48-hrs group and >48-hrs group was not significantly different.

CONCLUSION: Early VCE deployment within 48hrs of last overt OGIB may improved the diagnostic yield, rate of therapeutic intervention and decreased the length of hospital day.

INTRODUCTION: Small bowel capsule endoscopy (SBCE) may identify small bowel lesions in a large proportion of patients with Crohn's disease (CD).
AIMS & METHODS: To identify predictive factors of small bowel involvement in a cohort of patients with CD. Transversal multicenter study including consecutive patients with CD affecting the small bowel over a period of eight years. Small bowel inflammatory activity at SBCE was assessed with the Lewis Score (LS), and it was considered clinically relevant if LS≥135. Univariate analysis and multivariate regression of patients' baseline clinical, analytical and endoscopic (index ileocolonoscopy) variables were performed to identify pre-test predictors of relevant (LS≥135) lesions at SBCE in patients with known or suspected CD.
RESULTS: A total of 158 patients were included, 58% female, mainly with ileal (42%) or ileocolic (39%) location at ileocolonoscopy, non-stricturing non-penetrating behaviour in 74% of cases. SBCE lesions were non-significant (LS < 135) in 34 (22%) patients, mild (135≤LS < 790) in 68 (43%) and moderate to severe (LS > 790) in 55 (35%). Lesions were located in the first tertile of the small bowel in 38 (24.1%) patients, second tertile in 48 (30.4%) and third tertile in 113 (71.5%) patients. Multivariate regression identified thrombocytosis [OR 1,012 (95% CI: 1.002-1.022), p = 0.019] and low serum albumin [OR 0.803 (95% CI: 0.663-0.971), p = 0.023] as independent variables predictive of small bowel CD, [ROC = 0.846 (0.767-0.925)]. Clinical features, endoscopic distribution of the disease at ileocolonoscopy, and biomarkers such as anaemia or C-reactive protein were not predictive of SBCE lesions.
CONCLUSION: In patients with known or suspected CD, thrombocytosis and/or hipoalbuminemia are predictive of active small bowel inflammation at SBCE. Whether these biomarkers should play a role in the selection of patients for SBCE warrants further prospective evaluation.

INTRODUCTION: ALICE (Augmented Live-body Image Color-spectrum Enhancement) refers to a spectral imaging technique for the MiroView (TM) system to perform medical tests through capsule endoscope (CE) system, where light of specific blue, green, and red wavelength is used to enhance the detail of certain aspects of the surface of the mucosa, but the data was limited.
AIMS & METHODS: This study is to evaluate the visibility of CE-ALICE depending on type of small bowel lesions.
A total of 50 patients who underwent CE at Soon Chun Hyang Bucheon Hospital from August 2008 to November 2011 were enrolled in this study. The lesions were classified as elevated (tumor and polyp, n = 5), flat (angiodysplasia and erosion, n = 18), depressed (ulcer, n = 27) lesions. Two experienced endoscopists analyzed CE-ALICE images obtained at setting 1-10 (setting 1: red 415 nm, green 415 nm, blue 540 nm; setting 2: red 415 nm, green 445 nm, blue 500 nm; setting 3: red 420 nm, green 470 nm, blue 500 nm; setting 4: red 400 nm, green 445 nm, blue 450 nm; setting 5: red 420 nm, green 480 nm, blue 540 nm; setting 6: red 420 nm, green 480 nm, blue 500 nm; setting 7: red 400 nm, green 500 nm, blue 450 nm; setting 8: red 455 nm, green 455 nm, blue 500 nm; setting 9: red 500 nm, green 455 nm, blue 455 nm; setting 10: red 455 nm, green 500 nm, blue 455 nm) compared with conventional images. Physicians rated the visibility of the lesions on ALICE images as follows: _2(improved visibility), _1 (somewhat improved visibility), 0 (visibility equivalent to that of conventional video CE visibility), _1 (somewhat decreased visibility), and _2 (decreased visibility). Scores for each lesion were totaled (per ALICE setting) and evaluated. Intraobserver agreement was also examined.
RESULTS: In elevated lesion (n = 5), with setting 2, 3, 4, 5, 6, 7, 9, 10, improvement was achieved but not significantly statistical (NS). In flat lesion (n = 18), with setting 3, 5, 10, improvement was achieved statistically for 100% (18/18), 100% (18/18), 100% (18/18) (p < 0.01). In depressed lesion (n = 27), with setting 2, 3, 6, 10, improvement was achieved statistically for 89% (24/27), 93% (25/27), 93% (25/27), 85% (23/27)
CONCLUSION: CE-ALICE improves visibility of flat and depressed lesion in small bowel.

INTRODUCTION: Small bowel capsule endoscopy (SBCE) is an expensive but useful imaging method in the diagnosis and extension of Crohn's disease (CD). Symptomatology and acute phase reactants (CRP and ESR) are not correlated with the presence of endoscopic activity in small Bowel. Fecal calprotectin (FC) is a biomarker that correlates well with small bowel inflammation.
AIMS & METHODS: The aim of our study is to assess if fecal calprotectin correlates with the presence of endoscopic activity in small Bowel, evaluated by capsule endoscopy (Lewis Score).
We included prospectively patients with suspected or diagnosed Crohn's disease referred for capsule endoscopy. All of them were submitted to SBCE and a measure of FC, ESR, and CRP. CDAI was also registered.
RESULTS: For this preliminary analysis, 30 patients were included (17 females and 13 males), mean age 38 +/- 13 years. The indication for capsule endoscopy was suspected CD (7 patients), extension study of the illness and/or lack of response to treatment (21 patients) and mucosal healing assessment (2 patients). One patient was excluded for the analysis because of the capsule was retained in stomach temporarily. Only 10% of patients had FC levels less than 100 mcg/g, two of them with no lesions in capsule endoscopy. FC levels higher than 100 mcg/g correlated more closely with the presence of lesions in capsule endoscopy (p = 0.006).
In our study, there is a slight but positive correlation between FC levels and Lewis Score (r = 0.4; p = 0.02). There is no correlation between clinical symptoms, CRP or ESR, and the presence of lesions in the capsule endoscopy.
CONCLUSION: Fecal Calprotectin seems to be useful in identifying patients with Crohn's Disease and small bowel involvement. It can be a good tool to select patients for performing capsule endoscopy

INTRODUCTION: Capsule endoscopy (CE) has recently become one of the most important tools for small bowel investigation. Once swallowed by the patient, Mirocam capsule transmits images from the gut to an external recorder by the Human Body Communication (HBC) system. HBC uses the capsule itself to generate an electrical field and uses the human body as the conductor for data transmission. Because of the creation of an electric field, a potential electromagnetical interference with implantable cardiac devices has been postulated, so their presence is considered a relative contraindication for CE. Whereas some safety data are available about Given M2A capsule in patients with pacemakers (PM) and automatic implantable cardiac defibrillators (AICD), studies in this field regarding Mirocam capsule are lacking.
AIMS & METHODS: We report the use of Mirocam video capsule system (Intromedic Co Ltd, Seoul, Korea) in 6 patients with PM and in a patient with AICD over a 2-years period. Patients swallowed the capsule in the morning after a overnight fast; a bowel cleansing with 2 litres of polyethylene glycol (PEG) solution was administered in the afternoon before the procedure. All patients gave their written informed consent. Three different type of PM from 2 manufacturers (Altura and Insignia Ultra from Boston Scientific Corporation, Esprit from Sorin) and Atlas AICD from St. Jude Inc. were tested. A full technical control of the cardiac devices was performed by electrophysiologists before CE examination, using a manufacturer-specific programmer. This technical control included the evaluation of the following parameters: battery charge, shock impedance, leads impedance and sensing, leads pacing threshold, arhythmic events. After a cardiac visit and electrocardiogram (ECG), each patient was placed in Cardiac Care Unit. AICD electrical therapies were switched off just before capsule ingestion. During CE the patients were continuously monitored with cardiac telemetry, performed by Mortara X12 device (Mortara Instrument Inc., U. S. A.). At the end of the endoscopic procedure, before discharge, the patients repeated cardiac evaluation, ECG and a complete cardiac device check. The following characteristics were analyzed: changes in device parameters, inappropriate shocks, inappropriate anti-tachycardia therapy, inappropriate sensing or pacing, noise detection, device reset, programming changes, permanent electrical damages. CE records were reviewed by a skilled endoscopist.
RESULTS: For 6 patients indication for CE was obscure gastrointestinal bleeding (OGIB), in one was follow up of intestinal polyposis. Mean age was 74 years; all the patients were males. Capsule reached ileo-cecal valve in all except two cases. No complications related to capsule transit were observed. No technical problems related to imagine transmission were recorded. Causes of OGIB were found in 50% of cases. No polyps were found in patient with polyposis. No cardiac devices malfunctions nor interference in sensing or pacing were recorded; conversely, no malfunctions of CE caused by PM or AICD were registered.
CONCLUSION: Our results suggest that Mirocam capsule endoscopy can be safely performed in patients with different types of implantable cardiac devices.

P0225 SELF-EXPANDABLE METAL STENTS VERSUS PLASTIC STENTS FOR MALIGNANT BILIARY OBSTRUCTION: CLINICAL OUTCOME AND COST-EFFECTIVENESS IN POLISH ECONOMIC CIRCUMSTANCES

A. Budzynska[1,*], E. Nowakowska-Dulawa[1], T. Marek[1], M. Hartleb[1]
[1]*Dept. of Gastroenterology&Hepatology, Medical University of Silesia, Katowice, Poland*
Contact E-mail Address: *budzynskaagnieszka@poczta.onet.pl*

INTRODUCTION: Most patients with malignant biliary obstruction are suited only for palliation of jaundice by endoscopic placement of a plastic stents (PS) or self-expandable metal stents (SEMS). The initial higher cost of the SEMS is considered to be balanced by a decreased need for repeated interventions.
AIMS & METHODS: To compare the clinical outcome and costs of biliary stenting with SEMS and PS in patients with malignant biliary strictures. A total of 114 pts (63F, 51M) who underwent 366 endoscopic retrograde biliary drainage (ERBD) for palliation of unresectable malignant biliary obstruction between 2009 and 2014 were retrospectively enrolled into the study.
RESULTS: ERBD with placement of PS was performed in 80 patients, with one-step SEMS insertion (direct placement without a prior plastic stent) in 20 patients and two-step SEMS insertion (placement of SEMS at second or consecutive endoscopic retrograde cholangiopancreatography following plastic stent placement, e.g. SEMS after PS) in 14 patients. Significantly less endoscopic procedures were performed in patients with one-step SEMS than PS alone and two-step SEMS technique (2.0±1.12, 3.1±1.7 and 5.7±2.1 respectively, $p<0.0001$). The median hospitalization time was similar for three groups of patient. The patients survival was longest in SEMS after PS group in comparison to SEMS group and PS group (596.2±270d, 276.1±141d and 207.5±219d, $p<0.001$). Overall median stent patency was 89.3±159 d for PS and 120.6±101 for SEMS ($p=0.01$). Stent dysfunction occurred more frequently in PS group than in SEMS groups (76.8% vs. 62.8%, $p=0.05$). No significant difference between the two stent types in terms of technical success and complications was observed. The mean total cost of hospitalization with drainage procedures was higher for SEMS group, then for SEMS after PS group and finally for PS group (1448±312€, 1152±135€ and 977±156€, $p<0.0001$). Estimated annual cost of subsequent ERBD due to recurrent biliary obstruction would be still higher for SEMS group than for PS group (4618€ vs. 3995€). Metal stents would be cost-effective if their patency exceed 202 days.
CONCLUSION: Biliary decompression by metal stents in patients with malignant jaundice is associated with longer patency and reduced number of additional biliary procedures, but repeated plastic stents' drainage is still more cost-effective strategy.

INTRODUCTION: Self-expandable metal stents (SEMSs) can be used for palliation of combined malignant biliary and duodenal obstructions. However, the results of the concomitant stent placement for the duration of the patients' lives, as well as the need for and efficacy of endoscopic revision, are unclear.
AIMS & METHODS: This study evaluated the clinical effectiveness of SEMS placement for combined biliary and duodenal obstructions throughout the patients' lives and the need for endoscopic revision. This study is a retrospective multicenter study of 50 consecutive patients who underwent simultaneous or sequential SEMS placement for malignant biliary and duodenal obstructions. The data were collected to analyze the sustained relief of obstructive symptoms until the patients' death and the efficacy of endoscopic revision, as well as stent patency, adverse events, survival and prognostic factors for stent patency.
RESULTS: Technical and immediate clinical success was achieved in all of the patients. Duodenal stricture occurred before the papilla in 35 patients (70%), involved the papilla in 11 patients (22%) and was observed distal to the papilla in 4 patients (8%). Initial biliary stenting was performed endoscopically in 42 patients (84%) and percutaneously in 8 patients. After combined stenting, 30 patients (60%) required no additional intervention until the time of their death. The remaining 20 patients were successfully treated using endoscopic stent reinsertion: 9 patients needed biliary revision, 3 patients needed duodenal restenting and 8 patients needed both biliary and duodenal reinsertion. The median duodenal stent patency and median biliary stent patency were 34 weeks and 27 weeks, respectively. The median survival after combined stent placement was 12 weeks. A Cox multivariate analysis showed that duodenal stent obstruction after combined stenting was a risk factor for biliary stent obstruction (Hazard ratio = 6.85; 95% CI = 1.43-198.98; $P=0.025$).
CONCLUSION: Endoscopic bilio-duodenal bypass is clinically effective, and the majority of the patients need no additional intervention until their death. Endoscopic revision is feasible and has a high success rate.

P0227 TEMPORARY ENDOSCOPIC INSERTION OF UNILATERAL OR BILATERAL COVERED SELF-EXPANDABLE METAL STENTS (CSEMS) ABOVE THE HEPATIC DUCT CONFLUENCE FOR BENIGN BILE-DUCT DISEASE

P. Gil-Simon[1], N. Alemán[2], **I. Peñas Herrero**[1,*], A. Vargas[2], R. Sanchez-Ocaña[2], F. Santos[1], C.de la Serna[1], M. Pérez-Miranda[2]
[1]*endoscopy,* [2]*Hospital Universitario Río Hortega, Valladolid, Spain*
Contact E-mail Address: *pgpaula@hotmail.com*

INTRODUCTION: cSEMS appear to enhance therapeutic efficacy for benign distal bile-duct strictures and leaks. Concerns over the use of cSEMS above the hepatic duct confluence remain since clinical data are very limited. Aim: To assess the feasibility and efficacy of cSEMS placement proximal to the hepatic duct confluence in benign disease.
AIMS & METHODS: Retrospective analysis of prospectively databased patients undergoing ERCP over a 10-month period at referral Unit. 34 Consecutive Patients (17 female; age 59 [32-87] years) underwent biliary cSEMS placement across the hilum for benign disease. Underlying diagnosis, number and type of cSEMS, presence of associated plastic stents, indication for cSEMS (primary vs. failed prior plastic stenting), duration of stenting, ease of removal, procedural & stent related complications, and final therapeutic outcome were determined.
RESULTS: Diagnoses: 28 biliary strictures (13 postcholecystectomy, 11 post-liver transplant, 4 undetermined) and 6 miscellaneous (2 high output fistulas, 2 with prior embedded uncovered SEMS, 1 sump syndrome, 1 primary sclerosing cholangitis). In 19.4%, 2 or 3 biliary cSEMS were placed. The contralateral hepatic duct was stented with a plastic stent in 80.6%. Transhilar biliary cSEMS were indicated primarily in 14 (41%) and as salvage of prior standard plastic stenting in the remainder 20. CSEMS used were all 10mm in diameter, Hanaro 23, Wallflex 8, Bonastent 2, Taewoong 1. There were 2 procedural complications related to cSEMS, one moderate cholangitis secondary to hepatic branch occlusion (requiring cSEMS removal), and one mild (pain requiring IV analgesia >24 hours). After a mean duration of stenting of 5.3 (1-15) months, removal was attempted in 64.3% and was technically successful in all 20 cases despite 4 partial migrations (3 proximal/ 1 distal; 2 with cholangitis, 2 asymptomatic). Strictures/leaks were successfully remodeled/controlled upon removal in 19/20 (1 persistent leak), pending long-term follow-up. 11 patients are still undergoing cSEMS replacement. Transient enlargement of the intrahepatic bile-duct was documented in 12/31, without any adverse clinical consequences. Overall complication & short-term success rates are 13% & 95%.
CONCLUSION: If the contralateral hepatic duct is stented and ipsilateral secondary radicals spared, transhilar cSEMS placement appears safe. Refractory benign disease can successfully be salvaged with this aggressive approach, with an acceptable safety profile. Transient intrahepatic duct enlargement was noted. This encouraging preliminary data warrant further study as the long-term efficacy and reproducibility of this approach remain in question.

Contact E-mail Address: *95970@schmc.ac.kr*

INTRODUCTION: Early biliary decompression is indicated for cholangitis in patients with malignant biliary obstruction (MBO). However, preoperative biliary drainage using plastic stents may increase the need of reintervention and perioperative complications. We evaluated the usefulness of a removable fully covered self-expandable metallic stent (FCSEMS) modified to minimize stent-induced complications in preoperative biliary drainage for potentially resectable distal MBO.
AIMS & METHODS: From January 2009 to Agust 2013, a total of 51 patients underwent biliary drainage using a modified FCSEMS (BONASTENT M-Intraductal, Standard Sci Tech Inc, Seoul, Korea) for suspicious distal MBO that was potentially resectable or on stage work-up. Further treatment was decided according to the final assessment; (1) curative intent surgery, (2) neoadjuvant chemoradiation, (3) palliative treatment with/without chemoradiation, or (4) removal of stent for finally proved benign biliary stricture.
RESULTS: The overall technical and clinical success rates of the biliary drainage using a modified FCSEMS were 100% (51/51). Complications related with stenting were developed in 5 patients (1 mild pancreatitis and 4 stent migrations). Final diagnosis was 46 MBS (24 pancreatic head cancers, 18 CBD cancers, 3 gallbladder cancers and 1 ampullay cancer) and 5 benign biliary strictures (3 chronic pancreatitis and 2 autoimmune pancreatitis). 19 patients had undergone curative intent pancreaticoduodenectomy. 3 patients had undergone surgical resection after neoadjuvant chemotherapy. No stent-induced postoperative complication occurred. The median stent patency in patients who had undergone palliative treatment was 148 days (range, 73-256). Removal of the stent was successful in all patients confirmed finally benign biliary strictures.
CONCLUSION: The modified FCSEMS may be effective for first line of biliary drainage in patients with potentially resectable distal MBO without interfere for further intervention.

INTRODUCTION: Metallic stents for malignant distal biliary stricture have become one of the best palliative treatments in inoperative cases who were generally treated by chemotherapy; however its influence in stent patency has not been investigated and consensus is not established.
AIMS & METHODS: From 2002 to 2013, we have inserted metallic stents in totally 259 cases with malignant distal biliary stricture, and treated 164(63%) caes with chemotherapy and remaining 95(37%) cases with best supportive care (BSC). We investigated the efficacy of chemotherapy in its stent patency etc. retrospectively.
RESULTS: Subjects in this study were consisted of 206 (80%) pancreas cancers, 45(14%) biliary cancers, and 8(3%) papillary cancers. Metallic stents we used were 152(59%) partially covered Wallstents (P-WS), 54(21%) partially covered Wallflexs (P-WF), 34(13%) fully covered Wallflexs (F-WF), and 19(7%) fully covered Bonastents (F-BS). There was no significant difference on base line characteristics between chemotherapy group and BSC group except for age (68 vs 74 years olds). Chemotherapy we employed was Gemcitabine (GEM) alone, GEM +TS-1, and GEM+TS-1+CDDP etc. The median stent patency was 328 days in total, and the median stent patency of chemotherapy group was significantly longer (354 days vs188 days in BSC, $p = 0.001$). The median stent patency of biliary cancer in chemotherapy group was significantly longer (341 days vs 119 days in BSC, $p = < 0.001$), whereas the median stent patency of pancreas cancer in chemotherapy group was not significant.
CONCLUSION: We concluded that chemotherapy prolong the stent patency in malignant distal biliary stricture, especially biliary cancers.

Contact E-mail Address: *fmocciaro@gmail.com*

INTRODUCTION: Patients with malignant gastroduodenal obstruction often have coexistent biliary obstruction and require simultaneous endoscopic treatment. The use of self-expandable metal stents (SEMS) is an effective palliative treatment in patients with unresectable malignant gastroduodenal and biliary obstructions.
AIMS & METHODS: The aims of this study are to evaluate the efficacy and safety of double SEMS placement in a large consecutive series of patients with malignant inoperable gastroduodenal and biliary obstruction. From March 2007 to March 2014 we collected data on all consecutive patients treated with double SEMS placement (Wallflex Enteral and Biliary by Boston Scientific, Niti-S Biliary by Taewoong). SEMS were placed under fluoroscopic and endoscopic guidance. First the scope was allowed to reach the duodenal stricture, then a guidewire equipped with an imaging catheter was passed through the stricture allowing the deployment of the duodenal SEMS. The duodenoscope was passed through the duodenal stent for accessing the papilla through the mesh of the SEMS. After common bile duct cannulation and cholangiography a guidewire was placed across the papilla. A balloon dilation to enlarge the spacing of the tight mesh of the duodenal stent was performed allowing the placement of the biliary SEMS. If possible balloon dilation of the duodenal stricture was performed allowing the deployment of the biliary SEMS before duodenal SEMS placement. Technical and clinical success, and adverse events were recorded.
RESULTS: 31 patients (20 male [65%]), with a mean age of 73.6±9.8 year, were treated: 27 had pancreatic head cancer (87%), 2 antro-bulbar cancer (7%), 1 cholangiocarcinoma (3%), 1 duodenal obstruction due to colon cancer (3%). The mean baseline bilirubin level and the median gastric outlet obstruction scoring system (GOOSS) score were 16.7±3.8 mg/dL and 1 (range 0-3) respectively. Technical success was achieved in all patients with significant reduction in bilirubin levels (8.4±3.2 mg/dL) and a satisfactory oral feeding at discharge (GOOSS score 3 [range 2-3]). No complications related to the SEMS placement were recorded. Biliary stent occlusion occurred in 2 patients (6%) after 3 and 10 months. In 1 patient (3%) migration of the biliary stent was recorded after 5 months. The median hospital stay was 4 days (range 3-8) with a median survival time of 6 months (range 3-8). All deaths were due to the natural course of underlying malignancy.
CONCLUSION: Endoscopic management of malignant gastroduodenal and biliary obstructions with double SEMS placement is the treatment of choice in advanced unresectable gastroduodenal tumors with biliary involvement too. It is a safe procedure and it enhances patients' quality of life. In advanced diseases or in frail patients palliative surgery should be considered only in case of endoscopic failure.

INTRODUCTION: The optimal biliary decompression method in resectable perihilar-cholangiocarcinoma has been authorized as percutaneous transhepatic biliary drainage (PTBD). In case of locally advanced perihilar-cholangiocarcinoma, malignant biliary obstruction is judged to have palliation of jaundice by placement of an internal stents or PTBD. We aimed to investigate the efficacy of internal placement of biliary stent compared with PTBD for patients planned CRT in locally advanced perihilar-cholangiocarcinoma.
AIMS & METHODS: The patients who are histologically proven locally advanced perihilar-cholangiocarcinoma between Jan. 1995 and Dec. 2013 at single tertiary medical center in Korea, analyzed as prospective observational study. The perihilar cholangiocarcinoma was defined as disease occurring above the junction of the cystic duct up to the secondary branches of the hepatic duct.
RESULTS: Among one hundred seventy six locally advanced perihilar-cholangiocarcinoma patients, CRT was performed in 79 patients; endoscopic biliary decompression was forty six patients (26.14%), and PTBD was thirty three patients (18.75%). The mean period of internal stent indwelling is 152 days whereas 222 days in PTBD group ($p = 0.675$). The R0 operative rate after the CRT was 23.9% in endoscopic stenting group, and 12.1% in PTBD group ($p = 0.174$). The median overall survivals were 463 days at endoscopic stenting group and 439 days in PTBD group, respectively ($p = 0.874$). Repeated biliary decompression procedure was performed at endoscopic decompression group 26 patients (56.5%), 12 patients in PTBD group (36.4%) ($p = 0.077$).
In the subgroup analysis of endoscopic stenting group, there were 25 cases of SEMS, and 21 cases of biliary drainage using the plastic stent. The stent dysfunction was found in 20 patients (80.0%) with plastic stent and 6 patients (28.6%) in SEMS group ($p = 0.001$). Median stent patency time was 111 days and 402 days in the plastic stent and SEMS, respectively ($p = 0.002$). Post-operative major complications were not seen in both cases.
CONCLUSION: The endoscopic placement of internal stent might be useful method for biliary decompression in patients with planed CRT for locally advanced perihilar-cholangiocarcinoma, compared to PTBD. In case of biliary endoscopic drainage, the pre-CRT SEMS had lower rate for repeated endoscopic procedure than plastic stent in perihilar-cholangiocarcinoma.

P0233 ENDOSCOPIC OESOPHAGEAL STRICTUROTOMY AS PROMISING MODALITY IN THE TREATMENT OF BENIGN RESISTANT OESOPHAGEAL STRICTURES

A.A. Monged[1,*], G. Mohamed[1], C.B. O'Suilleabhain[2], M. Buckley[1] on behalf of Gastroenterology depatment, mercy university hospital, cork, Ireland
[1]*Gastroenterology,* [2]*Mercy University Hospital, Cork, Ireland*
Contact E-mail Address: *amongid@yahoo.com*

INTRODUCTION: The majority of benign oesophageal strictures result from long-standing gastroesophageal reflux disease. Treatment usually involves dilation combined with acid-suppressive therapy. Other causes of resistant strictures include post radiation, oesophageal sclerotherapy, caustic ingestions and surgical anastomosis. In the majority of patients, this can be accomplished with oesophageal dilation, though in cases of refractory strictures, additional therapy is required. There is little published data on the treatment of resistant esophageal strictures (ROS).
AIMS & METHODS: To describe our experience with Endoscopic Oesophageal Stricturotomy (EOS) for resistant oesophageal strictures. From January 2012 to July 2013 all patients with oesophageal strictures resistant to treatment with balloon dilatation +/- bougienage were selected for EOS. Data on Age, sex, co-morbidity, clinical presentation, procedural details, and outcome were retrospectively collected, anonymized, and analized. Endoscopic Oesophageal Stricturotomy procedures were exclusively done by an experienced endoscopist (M. B.). Patient with resistant strictures were assessed for suitability for Stricturotomy. Using Needle knife stricturotome (RX Needle Knife Boston scientific/ 5.5 F/1.8mm) Four quadrant incisions were made and tissue excised. Stricturotomy was followed by hydrostatic balloon dilatation if residual stenosis was present.
RESULTS: A total of five male dysphagic patients, median age 58, (range 29-81), with resistant oesophageal strictures were treated with EOS, during the study period. Two patients had strictures due to peptic fibrosis, two due to exposure to radiotherapy, and one had post surgery for oesophageal atresia. 80% (4/5) had multiple previous trials of unsuccessful balloon. One session of Stricturotomy was enough for 80% of patients, however, for one patient (20%) EOS were needed to be repeated 5 times. Only 40% (2 patients) needed balloon dilatation following the EOS. In all patients, successful response following initial EOS was obtained.
CONCLUSION: EOS is highly effective in treating selected patients with resistant benign oesophageal strictures. Initial response has been achieved to all five patients, refractory oesophageal stricture was noted in one patient, that has finally showed good response after the 5th Stricturotomy session. Short focal strictures may be more suitable for EOS. The risk of perforation following EOS is not yet known, and needs to be elucidated in longer studies. Stricturotomy is a valuable method in the treatment of patients with resistant oesophageal strictures.

Contact E-mail Address: *bcm.bruno@gmail.com*

INTRODUCTION: Self-expandable metallic stents (SEMS) are considered the best palliative treatment of dysphagia of patients with advanced esophageal cancer. Complications are a major concern, especially in patients with better prognosis and longer survival.
AIMS & METHODS: The aim of this study was to assess the prevalence of SEMS-related complications in the follow-up of patients with advanced esophageal cancer who survived longer than 6m. We performed a retrospective analysis of a prospective collected database of patients with advanced esophageal cancer submitted to SEMS palliation between February 2009 and December 2012 at the Cancer Institute of the University of São Paulo. Patients with follow-up longer than 180 days were included in this study.
RESULTS: Of the 145 patients from the database, 32 were selected. There was a predominance of male patients (78.1%), mean age of 60 years with squamous cell carcinoma (78.1%). The lesions were mainly located in the middle esophagus (53.1%). Twenty-nine stents were partially covered (90.6%) and three completely covered (9.4%). Twenty-two (68.7%) patients received chemo and/or radiotherapy before and 26 (81.2%) patients after SEMS insertion. Complications occurred in 20 patients (62.5%): migration (n = 9), overgrowth (n = 8), ingrowth (n = 4), fistula (n = 3), pulmonary infection (n = 2), food impaction (n = 2), GERD (n = 1), bleeding (n = 1) and intractable pain (n = 1). Most complications could be managed endoscopically. Fatal complications occurred in 2 (6.2%) patients: 1 bleeding and 1 pulmonary infection. The median survival after prosthesis was 305 days (range 182-630 days). A mean of 0.9 procedures per patient (range 0-10) were performed to maintain stent patency. At the end of the follow-up, 20 patients still had a functional stent, while 12 patients had either retrieved the stent or received a nasogastric tube.
CONCLUSION: The use of SEMS in patients with advanced esophageal cancer who live longer than 6m is associated with high complication rate. Most complications are usually nonfatal and are managed endoscopically.

INTRODUCTION: Migration is one of the most common complications after stent placement to palliate dysphagia in patients with inoperable esophageal neoplasia. It occurs in up to 36% of the cases, so it would be useful to recognize risk factors associated with this complication as preventive measures could be taken to prevent it.
AIMS & METHODS: The aim of this study was to identify risk factors for esophageal stents migration in patients with advanced esophageal cancer.
From 2009 to 2012, patients with advanced esophageal neoplasia who underwent SEMS placement were followed prospectively and data were collected to evaluated risk factors associated with stent migration. Patients with less than 1 month follow-up were excluded from the study.
RESULTS: A total of 145 patients with a median age of 63 years (SD±10) and male predominance (79.3%) were enrolled in the study. The most common histology was squamous cell carcinoma (109 cases, 75%) followed by adenocarcinoma (24 cases, 16.5%), and extra-esophageal cancer (12 cases, 8.5%). The lesion was located in the distal third of the esophagus in 54 (37.2%), in the mid-esophagus in 70 (48.3%) and in the proximal esophagus in 21 (14.5%) patients. Mean tumors length was 7.5cm (SD = ±2.8cm). Fifty-nine (40.7%) patients received chemoradiation prior and 13 (9.0%) after the stent implantation. Partially covered stents were placed in 135 (93%) pts and fully covered SEMS were placed in 10 (7%) pts. Evolution (n = 69, 47.5%), Hanaro (n = 44, 30.3%), Endoflex (n = 13, 9%), Wallflex (n = 12, 8.2%), Plastimed (n = 6, 4.2%) and Ultraflex (n = 1, 0.8%) stents were used. After a median follow-up of 156 days (range: 31– 630 days), the migration rate was 13.1% (19 patients, range: 1-323 days). The mean survival rate after the procedure was 146 days. Univariate analysis showed that fully covered stents (p = 0.049) and body stent diameter measuring less than 20mm (p = 0.004) were significantly associated with higher migration rate.
CONCLUSION: Fully covered stents and stents with body diameter measuring less than 20mm are associated with higher migration rate.

P0236 ENDOSCOPIC ULTRASOUND (EUS) GUIDED SELF EXPANDING METAL STENTS (SEMS) PLACEMENT FOR GASTRIC OUTLET OBSTRUCTION

C. Shekhar[1,*], S. Hebbar[2], B. Mahon[1]
[1]*Radiology, Queen Elizabeth Hospital, Birmingham,* [2]*Gastroenterolgoy, University Hospital of North Staffordshire, Stoke on Trent, United Kingdom*
Contact E-mail Address: *drcshekhar@gmail.com*

INTRODUCTION: SEMS placement is an effective way of relieving gastric outlet obstruction, majority of them done endoscopically under fluroscopy guidance. This is known to be superior to surgical bypass with lower morbidity, mortality, and shorter hospital stay[1,2]. At times, despite direct vision through the endoscope and fluroscopy guidance, it can be difficult or unmanageable to position a SEMS
AIMS & METHODS: To evaluate use of EUS as an adjunct to safely and effectively delineate lumen through the obstructing lesion and place SEMS through EUS scope with / without fluroscopy guidance. All procedures were done using Olympus linear scope (GF-UCT240) and Evolution (Cook Medical) SEMS were used (22x 60-120mm).
RESULTS: Between February 2010 to November 2011, 15 patients had duodenal/enteral SEMS placement using EUS. All patients had prior CT scan and endoscopy. All had successful stent placement using EUS technique, when it was not possible to be done by endoscopic view supplemented with fluroscopy guidance in previous or done as tandem procedures in same sitting. One patient had 2 stents placed, one in afferent loop endoscopically and another one in efferent loop with help of EUS.
One patient had perforation, stent was placed successfully across a tight angulated stricture but caused tear as it expanded across the angulated obstruction, which was managed surgically.
Endoscopic implantation of SEMS in a malignant gastric outlet obstruction is a safe and effective method. However, any obstruction beyond direct access of scope, presence of food/liquid debris and some times contact bleeding obscuring views are impediments in successful implantation of a stent. Most of the time this is due to inability to visualise/delineate the lumen beyond direct vision even with help of fluroscopy. There is high risk of false passage formation/perforation if wire/catheter are advanced blindly. EUS has an added advantage of visualising lumen even in above circumstances, especially when endoscopic views are poor.
CONCLUSION: This is first ever case series reporting use of EUS in gastroduodenal SEMS placement. We believe this is useful adjunct to existing techniques. However, this needs to be evaluated further in larger comparative studies. As with any other complex intervention, this is highly dependent on experience of the operator in endoscopic stent placement as well as EUS modality.

INTRODUCTION: Duodenal stent placement has emerged as an effective and safe palliative treatment for patients with malignant gastroduodenal obstruction. The uncovered enteral stent is susceptible to re-stenosis due to tumor ingrowth. Although covering an enteral stent with a membrane almost solves the problem of tumor ingrowth, stent migration continues to be a major unresolved problem. Recently, a partially covered metallic stent was introduced for gastroduodenal obstruction.
AIMS & METHODS: Duodenal stent placement has emerged as an effective and safe palliative treatment for patients with malignant gastroduodenal obstruction. The uncovered enteral stent is susceptible to re-stenosis due to tumor ingrowth. Although covering an enteral stent with a membrane almost solves the problem

of tumor ingrowth, stent migration continues to be a major unresolved problem. Recently, partially covered metallic stent was introduced for gastroduodenal obstruction. Twenty patients with malignant gastroduodenal obstruction received palliative treatment with partially covered duodenal stents. Technical success was defined as the placement of the stent successfully. Clinical success was defined as the relief of obstructive symptoms and/or improvement of the Gastric Outlet Obstruction Scoring System score to ≥ 2 after the procedure.
RESULTS: A total of 20 patients (11 men and 9 women; median age 64.5 years, range 39-85 years) were enrolled in this study. Ten patients had pancreatic cancer, four patients had gallbladder cancer, two had cholangiocarcinoma, one had advanced gastric cancer, one had metastatic rectal cancer, one had liver sarcoma, and one had ampulla of Vater cancer. Stent placement was successful in 20 of 20 patients (technical success, 100%). Symptoms improved in 19 patients after stent placement (clinical success, 95%). The Gastric Outlet Obstruction Scoring System score improved significantly (P-value < 0.001). Tumor overgrowth developed in eight patients during patients' survival period (40%). Stent migration did not occur in any case. Median stent patency was 79.5 days (range 13-198 days). Adverse events occurred in 3 patients, comprising two cases of transient bacteremia, and one of asphyxia due to impaction of food material into the stent.
CONCLUSION: Partially covered duodenal stent was effective and safe for the malignant gastroduodenal obstruction and can prevent tumor ingrowth and stent migration.

P0238 A NOVEL REINFORCEMENT METHOD FOR THE SURFACE OF GASTOINTESTINAL METAL STENT: GAS PLASMA TREATMENT

H.S. Choi[1,*], E.S. Kim[1], B. Keum[1], Y.T. Jeen[1], H.S. Lee[1], H.J. Chun[1], C.D. Kim[1], J.-J. Park[1], S.W. Lee[1], H.B. Kim[2]
[1]*Internal Medicine, Korea University College of Medicine, Seoul,* [2]*Institute of Interventional Medicine, M. I. Tech Co., Ltd, Pyeongtaek, Korea, Republic Of*

INTRODUCTION: A gastrointestinal (GI) stent, which is made of Nickel-Titanium (NiTi) alloy coating with a silicone polymer, has been using for the relief of obstructive symptom in malignant stenosis of gastrointestinal tract. But the corrosion and fatigue failures of nitinol devices have been constant subjects of discussion. Recently, GI nitinol stent use is increasing abruptly, and fractures of GI stents have been reported. Although coating with the silicone polymer on the stent plays a key role in corroding, corrosion properties may differ along the surface of the NiTi alloy wire. The surface modification with plasma etching technology is a way to improve the physical properties of the target. We systematically investigated a reinforcement of nitinol alloy and surface modification to stick the silicone employing gas plasma treatment.
AIMS & METHODS: The fifteen NiTi alloy stents were treated in a few conditions of the plasma treatment, in which mixture rates of Ar and O_2 gas, applied voltages and duration of exposing time were varied. We prepared three kinds of stents; normal stent (product by normal process, sample 1), slightly etched normal stent (product by plasma treatment, sample 2) and natural oxide layer-eliminated normal stent (product that removed natural oxide regions by plasma treatment, sample 3). The stents were analyzed with a transmission electron microscope (TEM) and scanning electron microscope (SEM) to examine surface topographies of the stents and the interlocking state between wire and silicone polymer. We performed a potentiodynamic test to compare the corrosion state of each stent in GI state.
RESULTS: The surface profile of the samples showed that some content of the oxide layer for the normal stent was formed in thickness of about 100nm, while the others was 60~70nm by TEM analysis. Moreover, the oxide layer for normal product and slightly etched normal stent was likely to exhibit deposition of oxygen without interlocking that enhances cohesion, whereas natural oxide layer-eliminated normal stent showed behavior of strong interlocking between oxide and nickel. SEM image showed effective modification of nitinol wire to stick the silicone polymer by plasma etching technology. In a potentiodynamic test, the sample 3 removed natural oxide regions by plasma treatment, indicating the strongest corrosion resistance.
CONCLUSION: This result implies that an interlocking between nickel and oxide layer plays a significant role in corrosion resistance. Natural oxide layer by normal manufacture process induced micro-crack of nitinol GI, stent and removing the natural oxide layer by plasma treatment improved reinforcement and surface modification of nitinol GI stent. These results revealed that the plasma treatment could be employed to improve the surface property of GI stent for malignant outlet obstruction.

P0239 ENDOSCOPIC ELECTROCAUTERY DILATION OF POST-SURGICAL BENIGN ANASTOMOTIC COLONIC STRICTURES: A SINGLE CENTER EXPERIENCE

I. Bravi[1,*], D. Ravizza[1], G. Fiori[1], D. Tamayo[1], C. Trovato[1], G. De Roberto[1], L. Laterza[1], C. Crosta[1]
[1]*Division of Endoscopy, European Institute of Oncology, Milan, Italy*
Contact E-mail Address: *ivana.bravi@ieo.it*

INTRODUCTION: Benign anastomotic colonic stenosis sometimes occur after surgery and usually requires surgical or endoscopic dilation. Endoscopic dilation of anastomotic colonic strictures by using balloon or bougie-type dilators has been demonstrated to be safe and effective in multiple uncontrolled series. However, few data are available on safety and efficacy of endoscopic electrocautery dilation.
AIMS & METHODS: Aim of our study was to retrospectively investigate safety and efficacy of endoscopic electrocautery dilation of post-surgical benign anastomotic colonic strictures.
Patients with post-surgical benign anastomotic colonic strictures treated with endoscopic electrocautery dilation between June 2001 and February 2013 were considered. Anastomotic stricture was defined as a narrowed anastomosis through which a standard colonoscope could not be passed. Only annular anastomotic strictures were considered suitable for electrocautery dilation which consisted of radial incisions performed with a precut sphincterotome. Treatment was considered successful if the colonic anastomosis could be passed by a standard colonoscope immediately after dilation. Recurrence was defined as anastomotic stricture reappearance during follow-up.
RESULTS: Sixty-eight patients (43 women and 25 men, median age 63.6 yrs (22.6-81.7)) were included. Nine had undergone adiuvant radiotherapy and chemotherapy, 25 adiuvant chemotherapy only. Forty-four patients had a colorectal, 19 had a colo-colic and 5 an ileo-rectal anastomosis. Five patients had a colostomy and 12 an ileostomy. Two patients were referred for subocclusive symptoms, nine for stipsis and six for stool shape modification. The time-interval between colorectal surgery and the first endoscopic evaluation or symptoms development was 7.3 months (1.3-60.7). Electrocautery dilation was successful in all the patients. There were no procedure-related complications. Median follow-up was 35.5 months (2.0-144.0). Anastomotic stricture recurrence was observed in two patients who were successfully treated with electrocautery dilation and Savary dilation, respectively.
CONCLUSION: Endoscopic electrocautery dilation is a safe and effective treatment for annular benign anastomotic post-surgical colonic strictures.

P0240 BIODEGRADABLE STENTS IN PATIENTS WITH ACUTE LARGE BOWEL OBSTRUCTION SECONDARY TO A RECTAL TUMOR AND INDICATION FOR FURTHER NEOADJUVANT THERAPY: OUTCOMES AND SAFETY

J. Jimenez-Perez[1,*], I. Fernández-Urien[1], J. Vila[1], E. Albéniz[1]
[1]*GASTROENTEROLOGY, COMPLEJO HOSPITALARIO DE NAVARRA, Pamplona, Spain*
Contact E-mail Address: *jjimenezpster@gmail.com*

INTRODUCTION: Colorectal stenting is the first choice treatment in patients with acute large bowel obstruction due to the presence of a malignant tumor in the left colon. After colon decompresion, stenting allows accurate tumoral staging and patient preparation for further surgery. However, stenting is controversial in rectal tumors. The presence of a metallic stent in a patient undergoing neoadjuvant therapy increases disperse radiation and collateral inflammation in surrounding tissues, leading to a higher complication rate and poorer surgical results.
AIMS & METHODS: The aim of this study was to assess the outcomes of biodegradable stents in patients with obstructing rectal tumors undergoing neoadjuvant therapy. A prospective observational study was conducted including patients with acute large bowel obstruction due to a rectal cancer and candidates to neoadjuvant therapy. After large bowel obstruction was diagnosed, a CT scan was performed to confirm the etiology of the obstruction and, in patients with a rectal tumor, to characterize the lesion and to assess the indication of further neoadjuvancy. A biodegradable stent was inserted in these cases. Patients were followed until surgery or until death if surgical treatment was dismissed. Technical success at stent insertion, clinical success, stenting complications and surgical findings and outcomes (primary anastomosis and postoperative complications) were documented.
RESULTS: 8 patients [4 men/4 women; mean age: 62.6 yr (51-77)] were enrolled in the study. Once further neoadjuvant therapy was considered indicated, a polydioxanone monofilament biodegradable stent (Ella-CS. Czceh Rep) was successfully inserted in all patients (100%) [31/25/31 mm; 6 cm (n = 2), 8 cm (n = 6) length]. Initial colon decompression was achieved in every case (100%) but the stent migrated in one patient (12.5%) and a second stent was inserted. Patients underwent neoajuvant therapy [RT: 50.4 Gy in 28 sessions + capecitabine (825 mg/m2/12 h)] and were reevaluated with a CT scan at the end of treatment. 3 patients did not go for surgery after tumoral staging, received chemotherapy and did not present occlusive symptoms until death (mean follow-up: 220 days). 5 patients were operated 96 days after stent insertion (66-123 days). Primary anastomosis was performed in 3 (60%) whereas colostomy was performed in 2 (40%) due to severe local inflammation in one case and a silent perforation in the other. The only post surgical complication was a pneumonia in one patient (12.5%). No wound or anastomosis complications were registered
CONCLUSION: 1. Biodegradable stents are effective in patients with rectal tumors and secondary large bowel obstruction. 2. Association with neoadjuvant therapy causes local inflammation but allows primary anastomosis in 60% of cases and is not followed by an increased post surgery complication rate.

INTRODUCTION: Tumoral obstructions in almost the entire gastrointestinal tract can be treated with interventional digestive endoscopy techniques. The use of self -expanding metal stents (SEMS) is a minimally invasive procedure providing a relatively simple and effective first- line treatment for the relief of obstructive symptoms.
AIMS & METHODS: To report data from a single center study on self-expandable metal stent (SEMS) placement for malignant colorectal obstruction. One hundred and six patients (64 males, mean age of 71±14 years), in a period of 96 months, were retrospectively evaluated and data on type and size of stent, complications, lesion location, and survival after the procedure were analyzed.
RESULTS: Most lesions were located in the rectum (50%, n = 53), 36% (n = 38) in the sigmoid colon, descending colon in 8.4% (n = 9) and 5.6%(n = 6) in the transverse colon. The mean length of the lesions was 65 ± 36mm. Most procedures were performed with palliative intent and in 4 patients two or more stents were placed. The stent was uncovered in 92% of cases and partially covered in 8% of the procedures. Complications were 4 neoplastic ingrowths, 3 stent migrations and 1 perforation. Seventy-five percent of patients were dead by the time of data collection, with a median interval between stenting and death of 105 days.
CONCLUSION: Colonic obstruction may be treated using endoscopic techniques. The placement of SEMS seems to be a safe and effective treatment.

P0242 WHAT SWEDISH SURGEONS DO WHEN DETECTING COMMON BILE DUCT STONES DURING CHOLECYSTECTOMY

F. Swahn[1,*], L. Enochsson[1], U. Arnelo[2], M. Löhr[2], R. Noel[2]
[1]*CLINTEC, Division of surgery,* [2]*KAROLINSKA INSTITUTET, Stockholm, Sweden*
Contact E-mail Address: *fredrik.swahn@ki.se*

INTRODUCTION: About 11,000 cholecystectomies are done annually in Sweden, most of which are completed laparoscopically (about 90%). Management strategies for common bile duct stones (CBDS) have been discussed in to an extreme extent and new options are rapidly emerging.
AIMS & METHODS: The aim of the study was to describe the current strategies applied in routine clinical practice in Sweden. A survey questionnaire was mailed to all hospitals (70) offering cholecystectomies and we obtained responses from all of them (100%). The questionnaire captured information on the details of clinical management strategies in a variety of different clinical manifestations of CBDS.
RESULTS: 35 (50%) of the hospitals reported a predefined policy regarding the management of CBDS. 65 (93%) hospitals used intra-operative cholangiography as a routine, 2 in selective cases and 2 did not. Management of a 3 mm large CBDS received that; 38 (54.3%) left it untreated, 23 (32.8%) performed some kind of intra-operative procedure, 3 (4.3%) preferred a post-operative ERCP; In case of a 6 mm large CBDS, the corresponding figures were; 3 (4.3%), 38 (52.2%), 17 (24.2%) respectively; In case of a 17 mm large CBDS: 23 (32.9%) preferred open CBD exploration and 4 (4.3%) a laparoscopic CBD-exploration, 6 (8.6%) post-operative ERCP. 40 (57.1%) of the hospitals used intra-operative ERCP with some kind of rendezvous cannulation technique.
CONCLUSION: Half of Sweden's surgical units do not follow a predefined policy regarding the intra-operative management of CBDS. Intra-operative ERCP with rendezvous cannulation technique is currently the strategy that is gaining popularity.

Contact E-mail Address: *j.k.wiggers@amc.nl*

INTRODUCTION: The purpose of this study was to determine survival and independent prognostic factors after resection of perihilar cholangiocarcinoma (PHC).
AIMS & METHODS: Patients with PHC resected between 1991 and 2012 were identified from prospectively maintained databases from two institutions (in Europe and USA). Patients with final pathology other than PHC or in-hospital mortality were excluded. Prognostic factors were evaluated using univariate Kaplan-Meier survival analysis with log-rank test and multivariable cox-proportional hazards modelling using backward selection with likelihood ratio test.
RESULTS: 307 patients underwent resection for PHC. The median overall survival was 38 months, and 5-year survival 37%. In multivariable analysis four factors were independently associated with a poor prognosis: a positive resection margin, HR 1.69 [95% CI: 1.25-2.28], p = 0.001, one or more positive lymph nodes, HR 2.31 [1.66-3.23], p < 0.001, perineural invasion, HR 1.59 [1.13-2.23], p = 0.008, and moderate or poor differentiation, HR 1.64 [1.15-2.33], p = 0.006. Other traditional factors were associated with a poor prognosis only in univariate analysis, including lymphovascular invasion, non-papillary tumor, T-stage (7^{th} edition), and AJCC stage (7^{th} edition). Patients with at least 3 out of 4 poor prognostic factors (n = 90) had a median survival of 19 months [95% CI: 16-22] versus 52 months [95% CI: 40-64]. Analyzing R0 patients separately resulted in the same independent prognostic factors.
CONCLUSION: A positive resection margin, one or more positive lymph nodes, perineural invasion and moderate or poor differentiation are independent prognostic factors after resection of PHC. Based on these poor prognostic factors we will derive and validate a prognostic nomogram for resected perihilar cholangiocarcinoma.

P0244 SUCCESSFUL ENHANCED RECOVERY PROGRAMME IN MAJOR LIVER SURGERY

J. Savikko[1,*], M. Ilmakunnas[2], H. Mäkisalo[1], A. Nordin[1], H. Isoniemi[1]
[1]*Department of Transplantation and Liver Surgery,* [2]*Department of Anaesthesiology and Intensive Care Medicine, Helsinki University Central Hospital, Helsinki, Finland*
Contact E-mail Address: *johanna.savikko@helsinki.fi*

INTRODUCTION: Enhanced recovery protocols after surgery accelerate patients' recovery and shorten hospital stay as a result of the optimization of perioperative care. In colorectal surgery these protocols show high-level evidence on reducing primary and total hospital stay without compromising the patient safety. This increased knowledge of perioperative pathophysiology and care has also been slowly implemented into liver surgery. However, in liver surgery the experience of optimized protocols is still limited.
AIMS & METHODS: Here we studied in a prospective way the implementation of multimodal rehabilitation protocol in a tertiary liver surgery unit within a one year period. This study involves the first 134 consecutive patients who were treated according to the enhanced recovery principles in open or laparoscopic liver surgery. An opioid-sparing pain treatment regimen was chosen for these patients together with early mobilization and oral feeding as well as avoidance or quick removal of drains and catheters shortly after surgery. Primary pain control was achieved either with epidural or locally inserted wound catheter analgesia. Peroral combination of pregabalin, ibuprofen and slow-release tramadol was also routinely administered shortly after the operation for pain relief.
RESULTS: All investigated liver resections were performed between April 1st, 2013 and March 31st, 2014. Most of the resections (72%) were major liver surgery involving 2 or more liver segments. Operations were done due to colorectal livers metastases (55% of cases), other liver metastases (9%), hepatocellular carcinoma (13%), gall bladder carcinoma (7%), peripheral cholangiocarcinoma (6%), and the rest 10% were done for benign liver tumors. Operations requiring hepatobiliary reconstructions were excluded from this study. 125 of the operations were open and 9 laparoscopic surgery.
56 of the operated patients were female, 78 male. Age median was 63 years (range 26-86 years). Only 2 patients were admitted to intensive care unit postoperatively; 1 planned admission, 1 due to perioperative pulmonary embolism. Median postoperative hospital stay was 4 days (range 2-11 days). 80% of all patients were discharged by the 5th postoperative day: 35% at the 3rd, 29% at the 4th and 15% at the 5th postoperative day. Two of the laparoscopically-operated patients were discharged at the 2nd, 6 at the 3rd and 1 patient at the 5th postoperative day. 5% of all patients were discharged via their own district hospitals.
Only 3 patients were readmitted back to the liver surgery ward; 1 patient (discharged at the 3rd day) because of pain problems and 2 patients (both discharged at the 5th day) because of elevated liver enzymes seen at the scheduled control visit few days after discharge.
CONCLUSION: Enhanced recovery protocol for perioperative care was introduced safely and effectively after major liver surgery. Routine discharge 2-3 days after laparoscopic resection and even 3-4 days after open resection is realistic and achievable.

INTRODUCTION: Assessment of future remnant liver (FRL) function is crucial in resectable hilar cholangiocarcinoma (HCCA) while complete biliary drainage of the FRL is considered essential for postoperative function and regeneration in extended resections. ^{99m}Tc-mebrofenin-hepatobiliary-scintigraphy (HBS) provides segmental, quantitative information on parenchymal function in the uptake phase, while the excretion of ^{99m}Tc-mebrofenin depends on drainage of the biliary system.
AIMS & METHODS: The aim of this study was to evaluate the value of HBS in the preoperative work-up of patients undergoing resection for HCCA.
From 2008 to 2013, 67 patients suspected of HCCA underwent resection (7/67 (10.4%) hilar resection and 60/67 (89.6%) hilar resection in combination with liver resection). Preoperative HBS was used to generate time-activity curves from regions-of-interest (total liver and FRL). The excretion rate was calculated as decrease in mebrofenin activity in time (%/min) in the FRL.

RESULTS: HBS was performed in 51 of 67 patients. Preoperative biliary drainage had been performed in 44/51 patients. HBS showed sufficient function in 30/44 patients (group A), whereas 14/44 patients required additional procedures (group B), consisting of revision of biliary drainage (n = 8; 18.2%), portal vein embolization (n = 2; 4.5%) or a modified (parenchyma sparing) technique (n = 8; 18.2%). Overall excretion rate in group A was 2.17%/min (IQR25-IQR75 1.03-2.36) vs. 1.15%/min (IQR25-IQR75 0.81-1.50) in group B (p = 0.03).
Overall mortality in 67 patients was 7.5%. Morbidity was 50.0% and 42.9% in group A and B, respectively (p = 0.75). Two patients died due to postoperative liver failure: 1/30 (3.3%) in group A with sufficient FRL-function but low excretion rate and 1/14 (7.1%) in group B despite revision of biliary drainage (p = 0.54).
CONCLUSION: HBS provides combined quantitative assessment of parenchymal function (uptake phase) and biliary decompression (excretion phase) of the FRL enabling identification of patients who require additional or modified procedures prior to resection of HCCA.

INTRODUCTION: Iatrogenic biliary injuries are considered as the most serious complications during cholecystectomy. Better outcomes have been shown in cases managed in a specialized center.
AIMS & METHODS: To evaluate the management and outcome of biliary injuries by multidisciplinary team in major referral hepatobiliary center. From January 2002 to January 2012,472 patients (302 females & 170 males) with post-cholecystectomy biliary injuries were managed with multidisciplinary team at National Liver Institute using endoscopy in 232 patients, in addition to percutaneous techniques in 42 patients and surgery in 198 patients.
RESULTS: Endoscopy was very successful initial treatment of 232 patients (49%) being less invasive in comparison to surgery in treatment of mild/moderate biliary leakage (68%) and biliary stricture (47%) with increased success by addition of percutaneous (Rendezvous technique) in 18 patients (3.8%). Surgery was needed in 198 (42%) for major duct transection, ligation, major leakage and massive stricture. Surgery was urgently in 62 patients and electively in 156 patients. Hepaticojejunostomy was done in most of cases (96) patients with transanastomatic stents. There was only one mortality after surgery due to biliary sepsis, and postoperative stricture was in 3 cases (1.5%) treated with percutaneous dilation and stenting.
CONCLUSION: Management outcome of biliary injuries becomes better with a multidisciplinary care team, with initial minimal invasive technique to major surgery in major complex injury encouraging for early referral to highly specialized hepatobiliary centers.

Contact E-mail Address: *r.j.coelen@amc.nl*

INTRODUCTION: Loss of skeletal muscle mass, sarcopenia, reflects the frailty status of patients and has recently been associated with worse outcomes following surgery for malignancies of gastrointestinal origin. The aim of this study was to investigate the impact of sarcopenia on postoperative morbidity and survival following resection of perihilar cholangiocarcinoma (pHCCA).
AIMS & METHODS: Data were retrospectively collected from a prospectively maintained database including all patients in our institute undergoing major liver resections for suspected pHCCA between 1998 and 2013. Sarcopenia was assessed in patients in whom an adequate preoperative CT scan was available, by measuring total skeletal muscle mass at the level of the third lumbar vertebra. Sex-specific cut-off values for sarcopenia were determined by optimum stratification. Clinicopathological data, postoperative morbidity (Clavien-Dindo grade ≥3), mortality and long-term survival were analysed.
RESULTS: Sarcopenia was present in 41 (42%) of 97 patients with pHCCA and was correlated with lower body mass index. Sarcopenia was associated with 30-day/in-hospital mortality (24% vs. 9%, p = 0.037). Overall postoperative complication rate (Clavien-Dindo grade ≥3) was higher in sarcopenic patients (66% vs. 46%), though this was not statistically significant (p = 0.058). However, sarcopenia was predictive for sepsis (OR 6.77, 1.67 to 27.43, p = 0.007). Estimated five-year overall survival rate was lower for sarcopenic patients (18 vs. 36%, p = 0.024). After correction for lymph node status, resection margin status, tumour differentiation grade and postoperative complications in multivariable analysis, sarcopenia was revealed as an independent predictor for worse overall survival (HR 1.93, 1.08 to 3.43; p = 0.026).
CONCLUSION: Sarcopenia has a negative effect on postoperative outcome and overall survival following resection of pHCCA and should therefore be considered in preoperative risk assessment.

P0248 RESECTION AND RECONSTRUCTION OF THE HEPATIC ARTERY FOR ADVANCED CHOLANGIOCARCINOMA: COULD ARTERIOPORTAL SHUNTING ALTER MICROVASCULAR RECONSTRUCTION?

T. Noji[1,*], T. Tsuchikawa[1], T. Nakamura[1], E. Tamoto[1], K. Okamura[1], T. Shichinohe[1], S. Hirano[1]
[1]*Gastroenterological Surgery II, Hokkaido University, Graduate School of Medicine, Sapporo city, Japan*

INTRODUCTION: The anatomic features of the hepatic hilum facilitate invasion of the hepatic arteries by cholangiocarcinoma. To accomplish curative resection, hepatic artery resection and reconstruction is sometimes required for such advanced cases. One small study suggested that arterioportal shunting (APS) might be useful in these patients. Surgical results with more cases and the survival impact of APS for cholangiocarcinoma have not yet been investigated.
AIMS & METHODS: The aim of this case controlled study was to evaluate the safety of APS and whether APS could be an alternative to microvascular reconstruction.
Patients and Methods: Thirty nine patients with intra- or extra-hepatic cholangiocarcinoma who underwent hepatic arterial resection were evaluated. There were 18 patients with APS (APS group) and 21 patients with microvascular arterial reconstruction (MVR group).
RESULTS: Preoperative statuses of the patients from both groups were similar, except for a number of patients with preoperative portal embolization. There were no significant differences in incidences of postoperative complications (Clavien-Dindo ≤ IIIa) between the two groups. However, the incidence of liver abscess formation was significantly higher in the APS group (38.9% vs 4.8% p = 0.02). Treatments for these liver abscesses were complicated. Mortality (hospital death) was 6% in APS group, 0% in MVR group, respectively (p = 0.46). Cumulative 3- and 5-year survival rates were 53.1% and 22.1%, respectively, in the MVR group, and22.2% and 11.1%, respectively, in the APS group (p = 0.11).
CONCLUSION: Microvasucular arterial reconstruction should be used as the first-line strategy for patients with intra/extra-hepatic cholangiocarcinoma. APS is indicated when the artery cannot be microscopically anastomosed.

P0249 SURGICAL OUTCOME OF "HILAR PLATE RESECTION": EXTENDED HILAR BILE DUCT RESECTION WITHOUT HEPATECTOMY

T. Noji[1,*], T. Tsuchikawa[1], T. Nakamura[1], E. Tamoto[1], K. Okamura[1], T. Shichinohe[1], S. Hirano[1]

INTRODUCTION: In the treatment of hilar cholangiocarcinoma, several studies have advocated en bloc major hepatectomy to achieve negative histologic margins and improved survival. However, we know that there are some patients with distal cholangiocarcinoma with longitudinal spread remaining in the hilar portion, without infiltration beyond the bile duct wall. We also know that there are a few patients with Bismuth type I hilar cholangiocarcinoma without infiltration beyond the bile duct wall. These tumors are likely to have superficial spreading, which would be difficult to accurately diagnose preoperatively. It remains unknown whether, for patients with such a non-invasive tumor, extended hepatectomy would be appropriate. We have done extended extrahepatic bile duct resection at the level of the hilar plate with curative or palliative intention for selected patients with or without hilar malignant tumors, calling this procedure "hilar plate resection" (HPR).
AIMS & METHODS: The results of a retrospective study evaluating the clinical benefits in patients who underwent HPR for biliary malignancies are reported.

Surgical procedure of HPR: Nodal clearance around the pancreatic head and skeletonization of the portal vein and the hepatic artery were performed first. The portal vein and the hepatic artery were then separated from the surrounding tissue upward to the hilar plate, where the duct cannot be further separated from the vasculature. This was considered "the limit of ductal transection without hepatectomy", which is at the right edge of the posterior portion of the right portal vein and the right edge of the umbilical portion of the left portal vein. Then, the gallbladder with the "cystic plate" was resected toward the hepatic hilum. Finally, the extrahepatic duct at the hilar plate was resected.
Patients: Fifty-two patients with cholangiocarcinoma underwent HPR. The procedure was performed in 28 patients with curative resection (cHPR group) and in 24 patients with palliative intention (pHPR group). In the same period, one hundred twenty-eight patients with cholangiocarcinoma underwent major hepatectomy with intrahepatic cholangiojejunostomy (Hx group). We compared with these groups in term of post operative complications and survival.
RESULTS: There were no significant differences in the number of patients with postoperative complications and in postoperative hospital stay. The overall cumulative survival rates of each procedure (Hx group, cHPR group, and pHPR group) were 40%, 38%, and 11% at 5 years, respectively. There was no significant difference between Hx and cHPR group in survival rates ($p = 0.87$). But the survival rate of the pHPR group was significantly lower than that of the Hx group ($p = 0.03$). The survival rate of the pHPR group was lower, but not significantly, than that of the cHPR group ($p = 0.08$).
CONCLUSION: HPR appears to be safe and feasible for selected patients with cholangiocarcinoma. However, the indications for HPR should be restricted.

P0250 LAPAROSCOPIC GASTRECTOMY FOR GASTRIC CANCER: RESULTS OF IMPLEMENTATION OF A NEW TECHNIQUE

E.J. Jongerius[1], M. I.van Berge Henegouwen[1], S.M. Lagarde[1], **S.S. Gisbertz**[1,*]
[1]*surgery, AMC, Amsterdam, Netherlands*
Contact E-mail Address: *s.s.gisbertz@amc.nl*

INTRODUCTION: Although different (neo)adjuvant strategies are being developed, surgical treatment remains the cornerstone of curative treatment for gastric cancer. Standard operative procedure has traditionally been an open (sub)total gastrectomy with a modified D2-lymphadenectomy. In an attempt to lower perioperative morbidity, we designed and standardized a laparoscopic technique to perform a (sub)total gastrectomy for the treatment of patients with potentially curable gastric cancer.
AIMS & METHODS: Aim of this study was to describe the short-term results of the first series of laparoscopic gastrectomies in patients with potentially curable gastric cancer.
In this prospective cohort trial we evaluated the first series of consecutive patients with potentially curable gastric cancer who underwent a laparoscopic (sub)total gastrectomy with a modified D2-lymphadenectomy the first year following introduction of the laparoscopic technique. Primary endpoint was perioperative morbidity and mortality. Secondary endpoints were hospital length of stay, number of harvested lymph nodes and radicality of surgery (R0 resection rate).
RESULTS: From February 2013 until April 2014 28 patients out of a total of 38 patients underwent a laparoscopic gastrectomy (73.7% of all gastrectomies). Eighteen patients (64.3%) underwent a total gastrectomy and 10 patients (35.7%) a subtotal gastrectomy. In 5 patients (17.9%) at least 6 cm of esophagus was co-resected. 18 patients (64.3%) received neo-adjuvant chemotherapy. There were 3 conversions (10.7%). Reasons for conversion were tumor involvement of the duodenum with a narrow relation to the pancreatic head in 2 cases and tumor ingrowth in the left hemidiafragm necessitating partial diaphragm resection in 1 case. The median operation time was 320 min (SD 66.8), median blood loss 200 cc (SD 269.6) and median hospital stay 8 days (SD 6.3). The overall complication rate was 21.4% (6 patients). There were 2 complications requiring re-intervention (7.1%). Both patients had an anastomotic dehiscence for which surgical drainage was performed. One of these patients eventually died of the septic consequences (total hospital mortality 3.6%). In 1 patient peri-operatively peritoneal metastases were detected and a palliative resection was performed. In 26 patients the tumor was radically removed (R0 resection rate 96.3%). Median lymph node count was 25 (SD 8.5).
CONCLUSION: Laparoscopic surgery for gastric cancer is feasible with good oncologic results and acceptable peri-operative morbidity and mortality. Implementation of this technique was evaluated as successful and therefore it is now standard surgical strategy at our center.

P0251 SUBMUCOSAL TUNNEL FOR PERITONEAL ACCESS ASSOCIATED WITH AN OVER-THE-SCOPE CLIPS (OTSC) CLOSURE: COMPARISON WITH TWO OTHER METHODS OF GASTROTOMY CLOSURE AFTER NOTES PROCEDURES

J.-M. Gonzalez[1,2,*], K. Saito[1], C. Kang[1], M. Gromski[1], M. Sawnhey[1], R. Chuttani[1], K. Matthes[1]
[1]*Gastroenterology, Beth Israel Medical Center, Harvard Medical School, Boston, MA, United States,* [2]*Gastroenterology, Aix-Marseille University, North Hospital, Marseille, France*

INTRODUCTION: Safe transgastric NOTES procedures require a reliable closure of the gastrotomy. Recently a novel peritoneal access method via a submucosal tunnel has been described with encouraging preliminary results.
AIMS & METHODS: The aim was to compare a submucosal tunnel access plus over-the-scope clips (OTSC) for closure with two other closure modalities. It was a prospective ex-vivo study on forty-two specimens equally randomized in three groups and carried out in an Academic medical center. Fourteen procedures were performed in each group including: 1.) Tunnel (6 cm) + endoclips; 2.) Knife + balloon dilation access + OTSC; 3.) Tunnel + OTSC. The main outcome measurements were: pressurized air-leak test was realized to evaluate the strength of the closure. Stomach volumes, procedure times, number of clips, and incision sizes were also registered.
RESULTS: The mean air leak pressure was statistically higher in group 3 than in groups 1 and 2: 95.2 ± 19.3 mmHg vs. 72.5 ± 35.2 and 79 ± 24.5 mmHg ($p < 0.05$). The gastrotomy creation times for groups 1, 2 and 3 were 28.0 ± 10.1, 4.3 ± 1.4 and 20.1 ± 10.6 minutes, respectively, with significantly lower time in the group 2 ($p < 0.001$). The closure times were 16.1 ± 6.1, 6.5 ± 1.2 and 5.3 ± 3.0 minutes, respectively, and significantly longer in the endoclip group ($p < 0.001$). There was no difference in the volumes and the incision sizes between the three groups.
CONCLUSION: The combination of a submucosal tunnel access and OTSC offers a stronger closure than the other methods studied.

P0252 NEW MULTICOLORED MULTIMATERIAL BIOELASTIC ORGAN REPLICATION USING HYBRID MDCT AND 3D PRINTING TECHNOLOGY FOR TANGIBLE DIGESTIVE SURGERY SIMULATION

M. Sugimoto[1,*]
[1]*Gastroenterology, Kobe University, KOBE HYOGO, Japan*
Contact E-mail Address: *sgmt@med.kobe-u.ac.jp*

INTRODUCTION: Our new technology of Bio-Texture Modeling by hybrid MDCT and 3D printing system enabled manufacturing patient-specific 3D organ replicas. We developed the latest generation of 3D printer by simultaneous jetting of different types of model materials.
AIMS & METHODS: The objective was to develop and evaluate patient-specific, anatomically accurate, bioelastic 3D replica for simulation, navigation and training of digestive surgery in 40 clinical cases. Based on DICOM data from MDCT, after generating its surface polygons using OsiriX application, the inkjet 3D printer created life-size copies of the 3D organs, blood vessels, and abdominal cavity. We programmed a printer to create clear models made from acrylic resins that allowed us to visualize and understand the gastrointestinal and hepatobiliary pancreatic complex internal structures and blood vessels or the exact tumor locations. We printed liver models compounding the polyvinyl alcohol (PVA) to make the model a realistic stand-in for ultrasonic diagnosis, hepatic intervention and surgical simulation.
RESULTS: The patient individual multicolored 3D printed models were useful for visible and tangible surgical simulation and navigation to plan and guide the successful gastrectomy, colectomy, hapatobiliary pancreatic surgeries in total of 40 patients including 20 laparoscopic surgeries. The 3D objects using a combination of transparent and soft materials allowed creation of translucent medical models that show visceral organs and other details that can be handled, overcoming the limitation of the conventional image-guided navigation. The gel-like support material, which is specially designed to support complicated geometries, is easily removed by hand. This provided realistic simulation of suturing and dissection to provide specific values of bio-texture in gastrointestinal hepatobiliary pancreatic organs for tensile strength and elongation to break. The PVA was available for wet tissue simulation in ultrasonography and intervention in hepatic surgery.
CONCLUSION: New 3D printing techniques delivered tangible and safe surgery training and could help younger, less experienced surgeons practice with accurate copies for digestive surgery. Its combines the advantages of conventional 3D modeling and precise virtual 3D planning and can be applied advantageously in personalized surgical simulation and navigation.

P0253 TRANSRECTAL NOTES VERSUS LAPAROSCOPIC AND OPEN CHOLECYSTECTOMY IN AN ANIMAL MODEL OF CALCULOSE CHOLECYSTITIS

O. Ryska[1,*], Z. Serclova[1], J. Martinek[2], R. Dolezel[3], J. Kalvach[3], T. Henlin[4], E. Laszikova[4], S. Juhas[5], J. Juhasova[6], **M. Ryska**[3]
[1]*Department of Surgery, Horovice Hospital, Horovice,* [2]*Hepatogastroenterology department, Institute for Clinical and Experimental Medicine,* [3]*Department of Surgery,* [4]*Department of Anesthesiology, Central Military Hospital, Prague,* [5]*Institute of Animal Physiology and Genetics, Libechov,* [6]*Institute of Animal Physiology and Genetics, Prague, Czech Republic*

INTRODUCTION: Natural-orifice transluminal endoscopic surgery (NOTES) as an evolving concept has been studied in several experimental trials. However, randomized experimental study evaluating NOTES in the area of calculose cholecystitis is missing. Transrectal compared to more frequently used transvaginal access offers good manipulation in the upper abdomen and is not limited to the female population. Also the physiologic impact during NOTES may differ from laparoscopy and open procedures because of presumed longer operation and need of extensive body positioning.
AIMS & METHODS: The aim of the study was to compare transrectal NOTES, laparoscopic and open approach to cholecystectomy in animal with calculose cholecystitis.
Laparoscopy (3-ports) was performed, bile was aspirated from the bladder and 4 gallstones obtained by human cholecystectomy were inserted via cholecystotomy in all 42 animals four week prior planned intervention. Animals were than randomized into NOTES ($N = 14$), open ($N = 11$), laparoscopic ($N = 11$), and sham groups ($N = 6$). In NOTES cholecystectomy a double channel endoscope was used to enter the abdominal cavity via rectotomy performed by needle knife

and balloon dilatation. A standard laparoscopic grasper was advanced to grip the fundus. Cystic duct and cystic artery were clipped and the preparation finished with a hook knife. The access site incision was endosutured by OVESCO clip. Small (5-6cm) subcostal incision and 3-ports laparoscopy were performed in open and laparoscopic groups. For hemodynamic monitoring using LiDCO, central venous and arterial catheter were introduced. After a follow-up period of 30 days, the animals were euthanized and necropsies were performed.
RESULTS: The procedure time was significantly longer in NOTES than in open and laparoscopic groups 145 (90-240) vs. 40 (25-65) vs. 63 (40-90) minutes, $p < 0.001$. In 3 animals from NOTES group the bladder dissection was complicated by severe bleeding, which was not treatable endoscopically. NOTES technique was indicated as unfeasible and these animals could not be evaluated afterwards. Perforation of the gall bladder occurred in 9/11 in NOTES versus 1/11 (RR: 9.0; 1.36-59; $p = 0.02$) and 4/11 (RR: 2.3; 1.1-5.2; $p = 0.04$) in open and laparoscopy groups. All followed hemodynamic parameters including heart rate, mean arterial pressure, cardiac index, central venous pressure and systemic vascular resistance did not differ from sham animals in all groups. Gallstones with wall inflammation confirmed histologically were present in all extracted bladders. All rectotomies were healed, however intraabdominal infection occurred more frequently in NOTES (4/11) than in open (2/11) and laparoscopic (1/11) groups.
CONCLUSION: Despite the technical difficulties and longer operational times, NOTES did not affect hemodynamic parameters. However, the feasibility rate of NOTES in the area of calculose cholecystitis did not reach conventional approaches. There were more intraoperative and postoperative complications in NOTES group. Transrectal access can be used universally and closed safely but risk of intraabdominal contamination during the procedure remains an issue.

INTRODUCTION: Immunosuppressants and biologicals are considered the mainstay of therapy for inflammatory bowel disease (IBD) thanks to the possibility of inducing remission and preventing disease progression. However, the growing and earlier use of these medications predisposes the patients to an increased risk of opportunistic infections, which represent an important cause of morbidity and mortality. Human Cytomegalovirus (HCMV) and Epstein-Barr virus (EBV) play a prominent role in the development of acute colitis in immune-compromised patients. In a previous study, our group has defined the spectrum of conditions associated with infection by HCMV and EBV, associating their presence with the refractory to conventional therapies and identifying the main risk factors for reactivation, as well as to detect in quantitative real-time PCR (RT-PCR), performed on fresh intestinal biopsies, the most sensitive method for diagnosis.
AIMS & METHODS: We investigated the role of these viruses in IBD pathogenesis by evaluating the presence of viral DNA within the cells of the intestinal mucosa, in particular in enterocytes and lamina propria mononuclear cells (LPMCs). We enrolled 7 IBD patients (5/2 M/F, mean age 47), 1 patient with profound combined immunodeficiency (M, 28 years) and 8 healthy controls (HC). All patients underwent lower endoscopy with multiple biopsies. Enterocytes were separated on a Percoll density gradient and LPMCs obtained by enzymatic digestion. The viral load was assessed by quantitative RT-PCR on mucosal specimens, enterocytes and LPMCs. Wilcoxon and Mann-Whitney tests were applied for statistical analysis.
RESULTS: Viral DNA was found in the mucosa of all the patients and in 2 control subjects, with double positivity for HCMV and EBV DNA in 6 patients, while EBV DNA alone in the remaining 2 patients and HC. In different colonic locations, 6 patients showed peak values for EBV DNA above 10^3 copies/10^5 cells in at least one location, while only 2 patients had similarly high values for HCMV DNA. No HC showed peak values exceeding 10^2 copies/10^5 cells. Viral DNA was found within enterocytes in 5 patients and in none of the HC, while inside of LPMCs was evidenced in all patients and 3 HC. HCMV DNA was found in enterocytes of only 2 patients, while 6 patients had detectable DNA in LPMCs; instead 5 patients had EBV DNA in enterocytes and in all cases in LPMCs. EBV DNA median values in healthy and injured mucosa, both in the enterocytes (223.5 copies/10^5 cells) and in LPMCs (3348.5 copies/10^5 cells), were significantly higher when compared to the levels of HCMV DNA (0 copies/10^5 cells; 6.5 copies/10^5 cells in enterocytes and LPMCs respectively) of both patients and HC. Finally, in inflamed areas EBV DNA median values were higher than in healthy mucosa.
CONCLUSION: Our data demonstrated the presence of EBV DNA in colonic LPMCs and enterocytes of patients with IBD, with higher loads observed in the first population. We also observed high levels of EBV DNA in enterocytes and LPMCs in the presence of mucosal inflammation. This shows a preponderant role of EBV compared with HCMV, with further studies needed to improve the knowledge of the relationship between this virus and clinical manifestations.

P0255 AIEC-RECEPTOR CEACAM6 ABNORMAL EXPRESSION IN CROHN'S DISEASE DEPENDS ON HYPOXIA RESPONSIVE ELEMENTS METHYLATION STATUS AND CHROMATIN REMODELLING

J. Denizot[1], **A. Agus**[1,*], A. Desrichard[2], N. Uhrhammer [2], A. Darfeuille-Michaud[1], N. Barnich[1]
[1]*UMR1071 INSERM, Université d'Auvergne,* [2]*Department of Oncogenetics, Department of Breast Oncology, Centre Jean Perrin, Clermont-Ferrand, France*
Contact E-mail Address: *allison.agus1@udamail.fr*

INTRODUCTION: Abnormal expression of CEACAM6 is observed at the apical surface of the ileal epithelium in Crohn's disease (CD) patients. This allows Adherent-Invasive *Escherichia coli* (AIEC) to colonize gut mucosa, leading to development of inflammation. Our aims were to understand the regulation of CEACAM6 expression in ileal mucosa of CD patients at the baseline and to investigate molecular mechanisms involved in AIEC infection-dependent CEACAM6 overexpression. Since changes in DNA methylation patterns were reported in CD patients, we analyzed whether epigenetic mechanisms are involved in the up-regulation of CEACAM6 expression in intestinal epithelial cells.
AIMS & METHODS: Protein expression and localization were analyzed before and after AIEC infection using immunofluorescence staining and Western-blot analysis. HIF-1α and histone H3 Serine 10 phosphorylation (H3S10p) levels were measured in CEACAM6 promoter region by chromatin immunoprecipitation (ChIP) in intestinal epithelial cells (IEC). Transgenic CEABAC10 mice expressing human CEACAM6 were orally challenged with 10^9 AIEC LF82 bacteria. At 3 days post-infection, ileum-associated AIEC were quantified, and mRNA levels were measured in isolated enterocytes.
RESULTS: Higher expression of CEACAM6 was observed in T84 cells compared to Caco-2 cells. This was associated to high binding of HIF-1 on the CEACAM6 gene promoter in an open chromatin state region characterized by increased in H3S10 phosphorylation level. In contrast, Caco-2 cells expressed low levels of CEACAM6 due to a compact chromatin state in CEACAM6 promoter (low level of H3S10p). AIEC infection led to increased CEACAM6 expression related to enhance HIF-1 binding to CEACAM6 promoter. Abnormal H3S10 phosphorylation in CEACAM6 promoter following AIEC infection in IEC enhanced HIF-1 binding, and subsequent CEACAM6 expression. In vivo, increased levels of CEACAM6 and HIF-1α proteins were measured in ileal enterocytes of AIEC-infected CEABAC10 mice, which could be due to high H3S10 phosphorylation enabling HIF-1α binding to CEACAM6 promoter.
CONCLUSION: AIEC bacteria increased CEACAM6 expression in ileal enterocytes of CEABAC10 mice by stabilizing HIF-1α transcription factor and by opening chromatin in CEACAM6 promoter. This allowed HIF-1α binding and subsequent gene transactivation, indicating that abnormal CEACAM6 expression in ileal mucosa of CD patients could be related to AIEC colonization-induced epigenetic regulation.

P0256 WESTERN DIET IN CEACAM6 EXPRESSING MICE: IMPACT ON SHORT-CHAIN FATTY ACIDS PRODUCTION AND HOST SUSCEPTIBILITY TO INTESTINAL INFLAMMATION

A. Agus[1,*], J. Denizot[1], J. Thévenot[1], S. Massier[1], E. Billard[1], S. Denis[1], A. Darfeuille-Michaud[1], N. Barnich[1]
[1]*UMR1071 INSERM, Université d'Auvergne, Clermont-Ferrand, France*

INTRODUCTION: Recent advances have shown that abnormal inflammatory response observed in Crohn's disease (CD) involves interplay between intestinal microbiota, host genetic and environmental factors. The escalating consumption of fat and sugar in Western diets parallels an increased incidence of CD during the latter 20th century. Western lifestyle could explain the increasing prevalence of new diseases such as CD.
AIMS & METHODS: We aimed at understanding the multifactorial etiology of CD by evaluating the modulation of host physiology in response to nutrition. We analyzed the impact of a High-Fat/High-Sugar (HF/HS) diet in mice on gut micro-inflammation, selection of *E. coli* population, concentration of short-chain fatty acids (SCFA) and expression of their free fatty acid-receptors such as G-protein-coupled receptor 43 (GPR43). Mouse sensitivity to DSS-induced colitis was assessed to evaluate the impact of nutrition in the sensibility to chemically-induced colitis. Mice fed a conventional or a HF/HS diet during 18 week-period, fecal lipocalin-2 (Lcn-2) was measured by ELISA to detect low-grade inflammation during the course of treatment, *E. coli* populations associated to colonic and ileal mucosa were quantified, production of SCFA by microbiota were measured by gas chromatography in fecal samples. GPR43 receptor was visualized by confocal microscopy after immunostaining of colonic mucosa tissues. The severity of DSS-induced colitis (1% of DSS in drinking water, 10 days) was evaluated by disease activity index (DAI) measurement, histological score and cytokine release.
RESULTS: HF/HS diet increased Lcn-2 level in stools from 5 weeks until 18 weeks of treatment, showing that HF/HS diet creates a specific inflammatory environment in the gut. Interestingly, abnormal proportions of *E. coli* bacteria were recovered from colonic and ileal mucosa of mice under HF/HS diet, compared to mice under conventional diet. SCFA concentrations (acetate, propionate, butyrate) were significantly decreased in fecal samples from mice under HF/HS diet compared to mice fed a conventional diet. Combination of HF/HS diet led to dysbiosis with an overgrowth of pro-inflammatory *E. coli* bacteria and a decrease in protective SCFA producing bacteria. GPR43 receptor expression was reduced in mice treated with an HF/HS diet compared to mice under a conventional diet. In addition, HF/HS diet led to an exacerbation of gut inflammation

following DSS-induced colitis, with an increase of DAI, histological score and release of pro-inflammatory cytokines.
CONCLUSION: Western diet creates a low-grade inflammation in the gut with a decrease of protective SCFA producing bacteria, leading to overcolonization by *E. coli* opportunistic pathogen bacteria which could aggravate the inflammatory process resulting in chronic inflammation. Together, these findings support the multifactorial etiology of CD and highlight the importance of nutrition factors in CD pathogenesis.

INTRODUCTION: Epithelial barrier function is primarily regulated by the tight-junction proteins (TJ). Ulcerative colitis (UC) is characterized by Th2 immune response with inflammation and epithelial barrier dysfunction, including an elevation of claudin-2 protein function (1).
In UC, epithelial leaks appear early due to micro-erosions resulting from upregulated epithelial apoptosis and from a significant IL-13-dependent arrest in epithelial restitution (2).
Vitamin D is traditionally associated with bone metabolism. Importantly, recently studies support an important role of vitamin D in the pathogenesis as well as potential therapy of IBD. Vitamin D deficiency is in fact common in patients with IBD (3).
AIMS & METHODS: Our aim was to determine whether vitamin D could affect IL-13 and IL-6 levels, and regulate the activity of tight-junction proteins Claudin-1, -2, -4 and -7 in the inflamed and non-inflamed colonic mucosa of UC patients.
Methods: Biopsies from the colon (rectum, sigma) of patients with active UC were studied. Non-inflamed (NI) and inflamed (I) intestine tissues, obtained from the same patient, were cultured with 10 nM $1,25(OH)_2D_3$. After 24 h incubation the medium was removed and used for the determination of IL-13 and IL-6 levels by ELISA test. The lysates of biopsies were used to determine the levels of TJ protein by Western blot analysis.
RESULTS: Claudin-1 and Claudin-2 proteins were up-regulated in active UC. The treatment with $1,25(OH)_2D_3$ increases the Claudin-1 levels in the NI tract and decreases their level in the I tract, while the treatment with $1,25(OH)_2D_3$ remarkably decreases the Claudin-2 protein level in both I and NI tract. Claudin-4 and Claudin-7 proteins were down-regulated with Western Blot Analysis and their levels increase when both NI and I tract were cultured in the presence of the $1,25(OH)_2D_3$. IL-13 and IL-6 levels decrease incubating the biopsies with $1,25(OH)_2D_3$.
CONCLUSION: Our study reports a down-regulation of claudin-4 and claudin-7, and an up-regulation of claudin-2, that might lead to altered TJ structure and be related to the impaired epithelial function in active UC.
Our results, indicating the inhibition of cytokine levels and the regulation of Claudin-2, Claudin-4 and claudin-7 by $1,25(OH)_2D_3$, suggest that vitamin D may represent a potential target for the treatment of IBD.

INTRODUCTION: Smoking seems to be a risk factor for microscopic colitis and smokers develop the disease more than 10 years earlier than non-smokers. However, the impact of smoking on clinical activity and outcome has not been elucidated.
AIMS & METHODS: In a post-hoc analysis from pooled data of two randomized controlled trials (BUC-60/COC and BUC-63/COC) we assessed the association of demographical (gender, age, smoking habits, previous and/or concomitant medication, family history of inflammatory bowel disease) and clinical variables (duration of symptoms, mean number of stools/watery stools per day, abdominal pain, clinical remission). Moreover, we analyzed the predictive value of baseline parameters on clinical outcome in a logistic regression model.
RESULTS: Pooled data from 202 patients with active collagenous colitis (CC) were available thereof 36% current smokers, 29% former smokers and 35% non-smokers. Current smokers had an increased number of watery stools at baseline compared to non-smokers ($p = 0.05$). 20/137 (15%) patients treated with budesonide did not achieve clinical remission. The majority of these (85%) were either smokers or former smokers. An association was found between smoking status (current smokers vs. non smokers: OR 0.37, 95% CI: 0.14-0.96, $p = 0.041$; former smokers vs. non smokers: OR 0.21, 95% CI: 0.07-0.60, $p = 0.004$), mean number of watery stools per day (OR 0.77, 95% CI: 0.66-0.90, $p = 0.001$) and decreased likelihood to obtain clinical remission. All other variables showed no significant association.
CONCLUSION: Smoking is associated with increased number of watery stools and decreased likelihood to achieve clinical remission in collagenous colitis. Smoking seems to have an impact on disease activity and treatment outcome in patients with CC.

INTRODUCTION: Intermediate filaments (IF) are one of the main components of the human cell cytoskeleton, which mainly consist of keratins (K). K8, K18 and K19 constitute the main keratins in the intestinal epithelial cells. Keratin alteration may play a role in the pathophysiology of ulcerative colitis (UC). K8 -/- mice develop chronic colitis (1). Heritable predispositions to UC were mapped to the K8/18 loci in human (2). K8 and K18 play a role in TNF-α induced-apoptosis (3). We have previously shown reduced expression of insoluble K8, K18 and K19 in active UC (ACT) relative to un-inflamed proximal colonic mucosa (INACT) using mass spectrometry (MS) analysis in the IF fraction of pooled patient samples from these two groups. The aim of this study was to use antibody-based relative quantification of K8, K18 and K19 in individual patient samples to validate MS results and describe variation in expression across the cohort.
AIMS & METHODS: IF proteins were extracted from rectal biopsies in patients with active colitis ($n = 9$) as well as endoscopically and histologically un-inflamed proximal colonic mucosa in each individual. IF proteins extracted from the sigmoid colon of a normal individual was used as an internal control. Each sample was dot-blotted on a membrane followed by immunoblotting for identification and quantification of keratins (8, 18 &19) sequentially. A control MCF-7 sample was included in all immunoblots to allow normalisation between sample groups. Relative keratins concentration for each dot- blotted sample was inferred by determining its signal intensity relative to the MCF-7 keratins signal intensity measured in turn by densitometry. Statistical analysis to compare the two groups was made separately for K8, K18 and K19 using Mann-Whitney U test.
RESULTS: Median relative IF protein levels from the active mucosa were 0.18, 0.28 and 1.48 for K8, K18 and K19, respectively were significantly lower than those from the un-inflamed inactive mucosa: 1.21, 1.16 and 3.59 for K8 ($p = 0.02$), K18 ($p = 0.03$) and K19 ($p = 0.02$), respectively. Median Baron's endoscopy score in ACT and INACT biopsy samples were 2 (range 2-3) and 0 (range 0-1), respectively. Median histological activity index in ACT and INACT were 2 (range 1-3) and 0 (range 0). Median disease duration was 5 years in the cohort.
CONCLUSION: This study confirms reduced expression of insoluble keratins in the active colonic epithelial cells relative to the un-inflamed proximal colonic mucosa and validates our previous MS observations. Insoluble keratin expression may be used as a tissue marker of disease activity.

INTRODUCTION: It is not uncommon that patients with ulcerative colitis report symptoms such as diarrhea, bloating and abdominal discomfort despite a complete absence of biochemical and endoscopic signs of disease activity. One possible explanation to this phenomenon is that these patients may suffer from pancreatic exocrine insufficiency (PEI). One previous study has indicated that the prevalence of PEI may be as high as 17% in patients with inflammatory bowel disease (IBD) (1). However, most studies on PEI in IBD including the aforementioned have used fecal elastase (Fel-1) as the only method to investigate pancreatic exocrine function. Concerns have been raised about the diagnostic accuracy of Fel-1 to diagnose PEI in IBD due to dilution effects and increased degradation.

Hence, studies on the prevalence of PEI in IBD patients using more specific tests of exocrine pancreatic function are warranted. The 13C-mixed triglycerides (MTG) breath test is a non-invasive pancreatic function test that can be used to confirm the diagnosis of PEI with high sensitivity and specificity.
AIMS & METHODS: The aim of the present study was to investigate the prevalence of PEI and clinical factors associated with PEI in patients with ulcerative colitis. Cases with ulcerative colitis seen at the out patient clinic of Sahlgrenska University Hospital were included in the study. Ulcerative colitis disease activity was evaluated by the Mayo scoring system for assessment of ulcerative colitis activity, fecal calprotectin, and sigmoidoscopy. Patients were screened for PEI using the Fel-1 test. Subjects with low Fel-1 were further examined using the 13-CMTG breath test. Computed tomography (CT) was used to evaluate pancreatic morphology in cases where the 13C-MTG breath test could confirm the PEI diagnosis.
RESULTS: In total 192 patients with ulcerative colitis were included in the study (mean age 44 years, 110 (57%) male, 93 (48%) with active disease). Fel-1 below the lower limit of normal (200 μg/g stool) was observed in 15 (7.8%) patients. There was no difference in age, ulcerative colitis disease activity, stool frequency or azathioprine use between patients with low and normal Fel-1 (Table 1). Further examination of patients with low Fel-1 with the 13C-MTG breath test revealed normal pancreatic exocrine function in all but one patient. This patient had signs of atrophy of the pancreas on CT.
Table 1

	Fecal elastase <200 μg/g	Fecal elastase >200 μg/g	p-value
Age, median (inter quartile range)	43 (39-61)	43 (33-54)	0.21
UC, active disease (Mayo score >0)	8/15 (53%)	85/177 (48%)	0.79
Self-reported increased stool frequency	6/15 (40%)	59/177 (33%)	0.58
Calprotectin, median (inter quartile range)	120 (52 to 390)	64 (18 to 260)	0.30
Azathioprine use	1/15 (7%)	27/177 (15%)	0.70

CONCLUSION: Fel-1 values below normal can be found in a minority of patients with ulcerative colitis but the vast majority of these patients have no signs of PEI when further tested with the 13C-MTG breath test. Our diagnostic strategy using Fel-1 as a screening test followed by the 13C-MTG test as a confirmatory test indicated that clinically significant PEI is rare in patients with ulcerative colitis.

INTRODUCTION: Accumulating data demonstrate that under physiological conditions, enteric glial cells (EGC) positively regulate the intestinal epithelial barrier (IEB). EGC are necessary for IEB homeostasis, increase IEB healing and decrease IEB permeability, identifying EGC as a source for soluble factors able to reinforce the IEB. The most recently discovered prostaglandin 15dPGJ2 is produced by EGC to regulate intestinal epithelial cell (IEC) proliferation and differentiation. However nothing is known considering other polyunsaturated fatty acid (PUFA) metabolites that could also be produced by EGC.
AIMS & METHODS: The PUFA signature of the JUG embryonic cell line as well as rat adult primary cultures of EGC were established using high sensitivity liquid chromatography tandem mass spectrometry. Immunohistochemistry was used to detect the 15-LOX producing enzyme of 15-HETE on rat and human EGC cultures and on human sub-mucosal plexus. Pharmacological approach was used to determine 15-HETE impact on Caco-2 monolayer cultivated or not in presence of EGC. Direct injection of 15-HETE into the colon wall was used to measure its impact on IEB permeability *in vivo*.
RESULTS: Among the 24 PUFA metabolite measured, rat EGC mostly produced 5- and 15-HETE. They also expressed the 15-lipoxygenase 2 (15-LOX2), whereas the 15-lipoxygenase 1 was undetectable. 15-HETE increased IEC spreading, IEB resistance and decreased IEB permeability without affecting IEC proliferation. In addition, 15-LOX2 was expressed in human EGC in culture but also *in situ* in EGC from submucosal ganglia. Interestingly, 15-HETE production by EGC from CD patients was significantly reduced compared to EGC from control patients. At the same time, CD EGC were unable to decrease IEB permeability, but addition of 15-HETE backed up the permeability to control conditions. *In vivo*, 15-HETE also reduced the IEB permeability, showing the potential of 15-HETE to reinforce IEB.
CONCLUSION: This study not only presents the first evidence for EGC functional abnormalities in CD, but also reveals that 15-HETE can reduce IEB permeability

Contact E-mail Address: *digcsb@humv.es*

INTRODUCTION: Several studies have concluded that patients with inflammatory bowel disease (IBD) are at increased risk of osteoporosis. The increase of proinflammatory cytokines, as TNF-α and interleukins (IL) appear to mediate, as a pathogenic mechanism, in the loss of bone mass density (BMD) in these patients. However, the influence of anti-TNF drugs on the bone metabolism of patients with IBD is not well known. Our aim is to evaluate the influence of anti-TNF drugs on bone mineral density and markers of bone remodeling in IBD patients.
AIMS & METHODS: Prospectively we have enrolled 8 patients (2 men and 6 women) with active IBD, 2 ulcerative colitis and 6 Crohn's disease, all with indication for treatment with anti-TNF drugs. Clinical data were collected on standardized data forms. BMD values were measured by dual-energy X-ray absortiometry (Hologic QDR 4500) at the lumbar spine (L1-L4) and femoral neck (FN) baseline visit and after a year of treatment. We determined serum 25-hydroxyvitamin D3 (25OHD ng/ml) and intact parathyroid hormone (PTH pg/ml). Bone turnover markers were measured by fully automated electrochemiliminescence system (Elecsys 2010, Roche Diagnostic, Germany): aminoterminal propeptide of type collagen (P1NP) and C-terminal telopeptide of type I collagen (CTX) at baseline visit, 8 week, 6 month and a year after treatment.
RESULTS: In our study, mean age was 42 years (age range 24-54). Two patients were treated with infliximab and 6 with adalidumab. All of them had been treated previously with 5-ASA, Azathioprine in 50% and corticoids in 20%. Mean basal weight (61 kg) did not change over treatment. The BMD in lumbar spine was 1.031 (0.112) g/cm^2 at baseline and 1.037 (0.127) g/cm^2 a year after. The BMD in FN was 0.755 (0.131) g/cm^2 and 0.774 (0.120) g/cm^2 respectively. The percentage of change in lumbar spine was 1% ($p=0.77$) and in FN 2.5% ($p=0.15$). Data table show biochemical parameters and different percentages over basal state.

	Baseline	8 week	6 month	Year
25OHD ng/ml	21 (9)	21 (9) [0%]	24 (12)[14%]	23 (12) [9%]
iPTH pg/ml	27 (11)	37 (13) [37%]*	30 (11) [11%]	38 (19) [40%]
P1NPmg/L	49 (26)	66 (26) [34%]*	61 (17) [24%]	43 (23) [-13%]
β-CTX ng/ml	0.421 (0.210)	0.380 (0.328) [-9%]	0.488(0.326) [15%]	0.419(0.332) [-2%]

CONCLUSION: 1. Bone mass in IBD patients with TNF- α inhibitors treatment were similar at baseline and after a year of treatment.
2. P1NP was increased 8 week after the beginning of treatment but P1NP returned to basal level after a year. Parathyroid hormone levels seem to increase early after the beginning of treatment and remains above basal levels over time. β-CTX and vitamin D, bone resorption markers, were stable during treatment.
3. Further studies are required to analyze the relationship between this therapeutic agents and bone metabolism in IBD.

P0263 EDUCATION OF PATIENTS WITH CROHN'S DISEASE ON THE RISKS OF SMOKING REMAINS CHALLENGING

C. De Bie[1,*], V. Ballet[1], G.Van Assche[1], S. Vermeire[1], M. Ferrante[1]
[1]*Department of Gastroenterology, UNIVERSITY HOSPITALS LEUVEN, Leuven, Belgium*

INTRODUCTION: The detrimental effect of smoking on development and progression of Crohn's disease (CD) is generally accepted. Although health care professionals undoubtedly spend a lot of time in education of patients, the actual awareness of smoking risks in CD patients is unclear.
AIMS & METHODS: We assessed several smoking behaviour parameters and patients' awareness on different consequences of smoking, through a simple questionnaire in a single referral centre. During the outpatient clinic of gastroenterology, 625 consecutive patients with CD, 238 patients with ulcerative colitis (UC) and 289 patients without an inflammatory bowel disease (non-IBD controls, NC) were requested to participate. Questionnaires included questions on former and actual smoking behaviour, cessation attempts, nicotine dependence (Fagerström score), and willingness to quit smoking. Patients were questioned on their awareness of smoking-related risks on several aspects of health, including detrimental effects on CD (Table 1).
RESULTS: Participation rates were 92% for CD ($n=575$, 46% male, 44 years, 44% never smoked), 93% for UC ($n=238$, 57% male, 45 years, 50% never smoked) and 76% for NC ($n=221$, 48% male, 48 years, 55% never smoked). At diagnosis, more CD patients were active smokers compared to UC patients (40% vs. 17%, $p<0.001$). Previous attempts to stop smoking and nicotine dependence were similar in all groups. Remarkably, smoking cessation rates after

diagnosis were not higher in CD compared to UC (both 56%, p = 0.997). In contrast, more CD than UC patients started smoking after diagnosis (12% vs. 6%, p = 0.050). As shown in Table 1, the majority of patients recognized dangers of smoking on general health (98-99%), lung cancer (95-97%), myocardial infarction (89-92%), and stroke (78-87%). Although CD patients more frequently acknowledged risks of smoking on their disease, only 37% were aware of the link with CD development, 30% of increased surgical rates, and 27% of increased postoperative recurrence rates. Of note, within the CD population, awareness was unrelated to actual smoking behaviour. Increased surgery rates were acknowledged by 30% of active, 32% of former and 29% of non-smokers (p = 0.783). Active smokers not willing to quit smoking, most often denied a potential bad influence of smoking on their disease. Previous surgery, level of education and employment did not influence awareness. Finally, UC patients were more frequently aware of an inverse relationship between smoking and UC development (39% UC, 16% CD, 4% NC, p < 0.001).

Smoking increases the risk of	Certainly not	I don't think so	I don't know	I think so	Certainly
bad general health					
CD	0%	0%	2%	13%	85%
UC	1%	0%	0%	12%	87%
NC	0%	0%	0%	6%	94%
lung cancer					
CD	0%	1%	4%	18%	77%
UC	0%	1%	4%	16%	79%
NC	0%	0%	3%	12%	85%
myocardial infarction					
CD	0%	1%	10%	28%	61%
UC	0%	1%	9%	31%	59%
NC	0%	0%	8%	25%	67%
stroke					
CD	0%	2%	17%	30%	51%
UC	0%	2%	20%	29%	49%
NC	0%	0%	12%	27%	61%
CD					
CD	4%	14%	45%	19%	18%
UC	2%	19%	61%	10%	8%
NC	0%	5%	71%	14%	10%
CD surgery					
CD	1%	10%	59%	20%	10%
UC	1%	10%	72%	12%	5%
NC	0%	4%	77%	11%	8%
postoperative CD recurrence					
CD	2%	9%	62%	18%	9%
UC	0%	12%	74%	10%	4%
NC	0%	3%	81%	9%	7%
UC					
CD	4%	12%	67%	13%	4%
UC	10%	29%	48%	8%	5%
NC	1%	3%	76%	13%	7%

CONCLUSION: Although CD patients were better informed on the detrimental effects of smoking, the awareness rate was still low. These data may also suggest more denial for the adverse consequences of smoking in active smokers. More efforts need to be done on informing and educating patients regarding the risks of smoking.

INTRODUCTION: Mucosal healing, which has been established as a target goal in inflammatory bowel disease, involved the coordinated regulation of several signaling pathways, including Notch signaling which plays an essential role in differentiation. Macrophages constitute one of the central components of the inflamed mucosa, and have the ability to modulate epithelial cell function. We have previously reported[1] HIF-1α stabilization in macrophages from the mucosa of IBD patients and we aim to analyse here the expression of Notch ligands by macrophages and the role of HIF-1.

AIMS & METHODS: U937 cells were subjected to hypoxia (3% O_2) or normoxia (21% O_2) and protein levels of HIF-1α were analysed by Western blotting and the mRNA expression of *Dll4* and *Jag1* ligands by real time PCR (n = 5). In some cases, cells were subjected to transient transfection of HIF-1α with miRNA or with an empty vector (mock, n = 5). Analysis of the *Jag1* gene promoter was performed using a ChIP assay (n = 3). Colonic surgical resections from both damaged and non-damaged mucosa were obtained from IBD patients (n = 11). In both cases, macrophages were isolated from the mucosa and the expression of *Dll4* and *Jag1* ligands was determined by real time PCR. HIF1, CD68 and Jag1 immunofluorescence experiments were performed in the mucosa of IBD patients.

RESULTS: In mock U937 cells, hypoxia induced HIF-1α stabilization and a time-dependent increase in *Dll4* and *Jag1* mRNA expression, which starts to be significantly different from normoxia 5 h later (4.1 ± 0.4 and 18.5 ± 2.1 fold induction vs macrophages in normoxia, respectively). The increase induced by hypoxia was significantly decreased when macrophages had been treated with *miHIF-1α* (0.94 ± 0.34 and 4.3 ± 2.4 fold induction vs macrophages in normoxia, respectively). ChIP assay showed HIF-1α binding to the proximal promoter region of *Jag1* gene in hypoxia through the HREs sequences located between positions -106 and -638. Immunofluorescence experiments revealed that CD68-positive cells were co-localized with HIF-1α and Jag1 in the damaged mucosa of IBD patients. The mRNA expression of *Dll4* and *Jag1* was significantly higher in macrophages isolated from damaged mucosa than from non-damaged (1.5 ± 0.2 and 3.2 ± 0.7 fold induction vs macrophages from non-damaged mucosa, respectively).

CONCLUSION: HIF-1α mediates the increase in the expression of Dll4 and Jag1 induced by hypoxia in macrophages. Jag1 expression co-localizes with HIF1α in macrophages of the mucosa of CD patients and it is higher in macrophages from damaged than from non-damaged mucosa.

P0265 THE MACROPHAGE PHENOTYPE DIFFERENTIALLY MODULATES NOTCH SIGNALING PATHWAY IN EPITHELIAL CELLS: RELEVANCE IN DISEASE CROHN'S

D. Ortiz-Masia[1,*], J. Cosin-Roger[1], S. Calatayud[1], C. Hernandez[2], D. Barrachina[1]

INTRODUCTION: Crohn's disease (CD) is associated with impaired epithelial barrier function. Restoration of mucosal integrity involves proliferation and differentiation of intestinal epithelial cells and Notch signaling has been shown to be central in the regulation of these processes. Macrophages are present in the microenvironment surrounding the crypts in the intestine and may modulate the behavior of epithelial cells. We have previously reported presence of both M1 and M2 macrophage phenotypes in the mucosa of ulcerative colitis patients[1]. We aim to determine the role of different macrophage phenotypes on epithelial Notch signaling and the relevance of this pathway in CD.

AIMS & METHODS: U937 cells were polarized towards a M1 phenotype with IFNγ and LPS (24h) or M2 phenotype with IL-4 (72h) and these cells were co-cultured with HT29 cells for 24h. Next we determined in epithelial cells, the expression of HES1 by static cytometry and alkaline phosphatase activity. Damaged mucosa of patients with CD was obtained. Protein levels of HES1 and the expression of CD86 (M1 marker) or CD206 (M2 marker), were quantified in the mucosa.

RESULTS: Immunofluorescence experiments show that M1 macrophages co-cultured with HT29 cells did not significantly modify the expression of HES1 (87.4 ± 5.4% vs the basal expression in HT29 cells) but induce a significant (P < 0.05) increase in AP activity in epithelial cells (125.4 ± 3.0% vs the basal activity in HT29 cells). In contrast, M2-macrophages significantly (P < 0.05) reduced in HT29 cells both, HES1 expression (62.1 ± 11.1% vs the expression in HT29 cells) and AP activity (62.5 ± 4.1% vs the activity in HT29 cells). A quantitative analysis of the number of CD86-and CD206-positive cells in the damaged mucosa of CD patients as well as protein levels of HES1, reveal a negative and significant correlation between the ratio of M2/M1 macrophages and HES1 protein levels (Pearson r -0.6775, P value 0.031, n = 10).

CONCLUSION: M2 macrophages induced a profound reduction in epithelial Notch signaling and impair enterocyte differentiation while M1 macrophages failed to do that. In the damaged mucosa of CD patients, the prevalence of M2 macrophages, through diminution of both epithelial Notch signaling and enterocyte differentiation, may impair epithelial regeneration.

INTRODUCTION: Mucosal healing has been established as a key treatment goal in Crohn's disease (CD) that predicts sustained clinical remission and resection-free survival of patients. This process depends on the proper reconstruction of the intestinal epithelium that depends on proliferation and differentiation of progenitor cells, a process that is tightly regulated by activation of the Notch signalling. We aim to determine the regulation of the Notch pathway and epithelial differentiation in the mucosa of CD patients.
AIMS & METHODS: Colonic surgical resections from both damaged and non-damaged mucosa were obtained from CD patients (n = 11). Human intestinal crypts were isolated from mucosa by using a non-enzymatic dissociation technique based on short-term EDTA treatment. Protein levels of IAP (marker of enterocyte differentiation) and HES1 (a specific Notch target gene) were analyzed by Western blotting and immunohistochemistry (HES1). The expression of MUC2 (a marker of goblet cell differentiation), CDX2 (a transcriptional activator of intestine specific genes involved in differentiation) and Math1 (a gene that is repressed by HES1) was analyzed in epithelial cells by real time PCR. The quantitative analysis of goblet cells was performed in the mucosa stained with PAS.
RESULTS: A comparative study (fold induction vs crypts from non-damaged mucosa) revealed a significant ($P < 0.05$) diminution in protein levels of HES1 (0.28 ± 0.07) and IAP (0.20 ± 0.10) and a significant increase in mRNA levels of MUC2 (11.8 ± 2.3), CDX2 (2.1 ± 0.8) and Math1 (3.4 ± 0.8) in crypts from damaged mucosa. Immunostaining for HES1 revealed lack of this protein in epithelial cells of the damaged mucosa. The percentage of goblet cells vs. total nuclei in the crypt was significantly ($P < 0.05$) higher in the damaged ($47.8 \pm 4.4\%$) than in the non-damaged mucosa ($29.2 \pm 2.4\%$).
CONCLUSION: The diminished Notch signaling and impaired enterocyte differentiation detected in epithelial cells from damaged mucosa of CD patients may mediate the weakened mucosal healing observed in these patients.

P0267 HUMAN INTESTINAL FIBROBLASTS ARE NOVEL TARGET CELLS FOR ALPHA-MELANOCYTE-STIMULATING HORMONE – POSSIBLE IMPLICATIONS FOR THE TREATMENT OF STRICTURING CROHN'S DISEASE WITH MELANOCORTIN PEPTIDES AND DERIVATIVES

D. Bettenworth[1,*], A. Stegemann[2], P.R. Tepasse[1], E. Rijcken[3], M. Apel[2], M. Böhm[2]
[1]*Department of Medinice B,* [2]*Department of Dermatology,* [3]*Department of General and Visceral Surgery, University Hospital Münster, Münster, Germany*

INTRODUCTION: Efficient treatment against fibrotic complications like intestinal strictures is still an unmet need in patients with Crohn's disease. In dermal fibroblasts, melanocortin peptides such as a-melanocyte-stimulating hormone (a-MSH) were shown to modulate collagen synthesis. Moreover, in the bleomycin scleroderma mouse model this peptide had anti-fibrotic effects. Thus, we wondered if human intestinal fibroblasts are also target cells for melanocortins in the context of extracellular matrix synthesis.
AIMS & METHODS: Human intestinal fibroblasts were isolated from macroscopically normal colonic specimens of patients undergoing scheduled colonic surgery (n = 5) and were characterized by immunohistochemistry with anti-desmin, anti-vimentin and anti-alpha-smooth muscle actin antibodies. Melanocortin receptor (MC) expression was determined by RT-PCR. Intracellular Ca2+ mobilization indicating functional coupling of the detected MC was assessed by FURA-2AM loading and fluorescence analysis. Collagen type I expression was determined by RT-PCR and secretion of procollagen type I C-terminal peptide by ELISA.
RESULTS: Immunocytochemistry with anti-desmin, anti-vimentin and anti-alpha-smooth muscle actin antibodies confirmed a myofibroblast phenotype of isolated cells. MC expression profiling proved that these cells exclusively express MC_1. Truncated transcripts for proopiomelanocortin (POMC), the precursor of a-MSH, were also detected but no functional full-length POMC mRNA. In accordance, cells lacked POMC protein expression ruling out an autocrine loop for alpha-MSH. No Ca^{2+} mobilization was detected by FURA-2AM loading, after stimulation with a-MSH and fluorescence analysis. However, a-MSH at doses between 10^{-6} and 10^{-10} M significantly suppressed procollagen type I C-terminal peptide secretion induced by TGF-b1. This effect was not paralleled by reduction in corresponding COL(I) mRNAs – indicating a posttranscriptional mechanism of the regulatory effect of a-MSH on collagen synthesis.
CONCLUSION: These findings demonstrate that human intestinal fibroblasts are novel targets for alpha-MSH. It will be intriguing to assess the effect of other melanocortins and derivatives in these cells on collagen synthesis as well as the impact of them in animal models of intestinal fibrosis.

INTRODUCTION: IBD has many characteristics of autoimmune diseases. Sensorineural hearing loss has been reported in many autoimmune diseases. Little is known about hearing loss in patients with IBD.
AIMS & METHODS: A prospective blinded comparative study was conducted over a 3 year period. IBD patients and controls underwent a complete otorhinolaryngeal examination and eudiometry test.
RESULTS: Altogether 105 participants (76 patients and 29 controls) took part in this study. 59(77%) had Crohn's disease (CD) and 17(23%) had ulcerative colitis (UC). Mean age was 36, 51% were males and 40% of the patients were presently hospitalized due to IBD exacerbation. 16/76(21%) of the IBD patients complained of hearing loss since first IBD diagnosis and 13% had current hearing disabilities. Audiometric examination revealed that any hearing loss (mild to severe) was found in 23(30%) of the IBD population, compared to 3 (10%) of the control group ($p < 0.05$). Sensironeural was the hearing deficiency type in 93% of them. Out of 46 patients, whose extraintestinal manifestation (EIM) status was clearly documented, 43% (n = 20) had EIMs. Hearing loss was present in 5/20 (25%) of these patients, compared to 0/23 who did not have EIMs ($p < 0.01$). IBD phenotype (inflammatory vs. obstructive/fistulary), current hospitalization and disease type (CD vs. UC) was not different between these groups.
CONCLUSION: Sensironeural hearing loss may be another EIM of IBD. It is found in 30% of IBD patients, and in up to 43% of patients with other EIMs. Early hearing evaluation should be recommended to IBD patients who have other EIMs

INTRODUCTION: IBD, and in particular Crohn's disease, is chronic inflammatory condition characterized by an abnormal immune response towards self microbiota and by an abnormal gut microbiota composition, as determined by new molecular techniques. Anti-TNF-a is one of the strongest therapeutical options available, able to induce mucosal healing and restore mucosal immune homeostasis. Little information exists on the ability of antiTNF-a to modulate gut microbiota composition.
AIMS & METHODS: Aim of our study was to evaluate gut microbiota composition in Crohn's disease patients before and after 6 weeks after anti-TNF-a therapy.
Fecal samples were collected in 3 consecutive CD patients, the first day of the first dose of anti-TNF-a therapy (infliximab) and following 6 weeks: 2 patients displayed colonic CD and 1 ileo-ciecal CD (2 males of 23 and 33 years, and 1 female of 53 years), no-one took any antibiotic 2 weeks before starting anti-TNF-a therapy or during the active treatment. Harvey Bradshaw scores at baseline and after 6 weeks were respectively 4 and 3, 7 and 3 and 4 and 1.
Microbiota composition was assessed by Metagenomic, a technique assessing 16S rRNA (Roche 454 GS Junior), following DNA isolation from stool samples stored in –80°C. Data obtained were analyzed by suite Qiime.
RESULTS: Bacteria amplicons were detected in all samples. Prevalent classes of bacteria were: Bacteroidia (min 18% - max 95%), Firmicutes (min 2% - max 58%%) and Proteobacteria (min 2% - max 22%). Following anti-TNF-a therapy, bacteroidetes reduced in all patients (min from 3% – max from 67%). Firmicutes, on the contrary, increased in levels. In 2 patients also proteobacteria increased. Species Faecalibacterium was not present in 2 out of 3, but in one patient, Fecalibacterium increased from 17% before therapy to 23% after therapy.
CONCLUSION: Anti TNF-a treatment is associated with active modulation of intestinal microbiota, including decrease in bacteroidetes and increase in firmicutes. Metagenomics seems a promising technique whose real application in clinic is still under development.

Contact E-mail Address: *ahmir.ahmad@nhs.net*

INTRODUCTION: Inflammatory bowel disease is a chronic disorder, affecting 240,000 people in the UK. The long-term impact of recent advances in IBD management on hospital admissions and surgery is uncertain.
AIMS & METHODS: Our aim was to investigate trends in hospital admission, fatality rates, surgery, endoscopy and cytokine inhibitor infusions for CD and UC in England between 2001-02 and 2010-11.
We used admissions data from Hospital Episode Statistics, a national administrative database of all National Health Service hospital admissions and population data from the Office for National Statistics, England.
RESULTS: From 2001-02 to 2010-11, age-sex standardised day-case admission rates increased by 460.4% ($p<0.001$) and 127.0% ($p<0.001$) for CD and UC respectively. There was no significant change in inpatient admission rates for CD and UC. Both inpatient and day-case rates of surgery and endoscopy fell for both CD and UC [inpatient: CD surgery -8.9% ($p<0.001$) CD endoscopy -14.4% ($p<0.001$) UC surgery -6.8% ($p<0.001$) UC endoscopy -10.5% ($p<0.01$); day-case: CD surgery -75.3% ($p<0.001$) CD endoscopy -55.9% ($p<0.001$) UC surgery -66.7% ($p<0.001$) UC endoscopy -17.2% ($p<0.001$)]. Day-case infusions, including cytokine inhibitor treatment, rose in both CD and UC, by 308.9% (14.8% to 60.6%, $p<0.001$) and 3475.0% (0.4% to 15.4%, $p<0.001$) respectively.
CONCLUSION: Over the past decade inpatient admission rates for IBD have remained static, but day-case admission rates have risen whilst the requirement for surgery and endoscopy has fallen. The reduction in surgical and endoscopic activity and the switch towards day-case activity may reflect recent advances in IBD management, notably, the substantial increase in anti-TNF therapy.

P0271 EPIDEMIOLOGY AND TEMPORAL TRENDS (2000-2012) OF INFLAMMATORY BOWEL DISEASE IN ADULT PATIENTS IN A CENTRAL REGION OF SPAIN

A.J. Lucendo[1,*], D. Hervías Cruz[2], Ó. Roncero[3], R. Lorente[4], A. Bouhmidi[5], T. Angueira[1], C. Verdejo[4], I. Salueña[5], S. González-Castillo[1], A. Arias[6] on behalf of The Ciudad Real province IBD working group
[1]*Gastroenterology, Hospital General de Tomelloso, Tomelloso,* [2]*Gastroenterology, Hospital Virgen de Altagracia, Manzanares,* [3]*Gastroenterology, Hospital General Mancha Centro, Alcázar de San Juan,* [4]*Gastroenterology, Hospital General Universitario de Ciudad Real, Ciudad Real,* [5]*Gastroenterology, Hospital Santa Bárbara, Puertollano,* [6]*Research Support Unit, Hospital General Mancha Centro, Alcázar de San Juan, Spain*

INTRODUCTION: A growing incidence of IBD in southern Europe has been recently reported, with records of pediatric cases confirming these tendencies in Spain. Data on adult population however, has not been provided for over 10 years and needs to be updated.
AIMS & METHODS: This study has two main objectives: (1) to estimate the current prevalence of IBD in central Spain, and (2) to examine recent trends in disease prevalence. A further goal was to characterize changes in disease presentation over time.
A multicenter retrospective registry of all adult patients with a diagnosis of IBD, including both Crohn's disease (CD) and ulcerative colitis (UC), attended in 5 public hospitals covering a population of 514,368 inhabitants was carried out.
RESULTS: In 2012, the prevalence of CD and UC in adults was 137.17/100,000 inhabitants [95% confidence interval (CI): 114 – 160] and 99.84/100,000 inhabitants (95% CI: 79 –119), respectively. The mean incidence rate during 2000-1012 period of CD and UC was 8.9 and 5.6/100,000 inhabitants per year, respectively. Most of our patients (75.55%) were diagnosed during the last 13 years. CD affected equally both genders; a trend to progressive increase in the age at diagnosis, ileal location and inflammatory behavior was documented for CD patients. In contrast, UC affected with a higher frequency to male subjects (57.8%, $p=0.015$), specifically at an age over 40 years old. Age at UC onset trended to progressively increase from 2000 to 2012 ($p<0.001$), but the extension on the disease remained unchanged.
CONCLUSION: A significant increase in the prevalence of IBD, especially for CD, was documented in our region regarding previous estimation in Spain. CD incidence reached similar figures to those provided for Northern Europe, increasing the burden of IBD over the health system.

P0272 HEPATOBILIARY DISEASES IN A PROSPECTIVE POPULATION BASED COHORT WITH INFLAMMATORY BOWEL DISEASES (ICURE)

A. Rönnblom[1,*], T. Holmström[1], H. Tanghöj[1], F. Rorsman[1], D. Sjöberg[1]
[1]*Dpt of Medical Sciences, Uppsala, Sweden*
Contact E-mail Address: *anders.ronnblom@akademiska.se*

INTRODUCTION: The relation between hepatobiliary diseases and IBD has been the focus for scientific research for many years. There are, however, few prospective population based cohort studies in this area. Between 2005 and 2009 all newly diagnosed cases of IBD in all age groups in the Uppsala Health Care Region were registered. The cohort consists of 790 individuals corresponding to an average incidence of 20.0 new cases of UC/100 000/year and 9.9 new cases of Crohn's disease/100 000/year (REFERENCES JCC. 2013 Oct 1;7(9):e351-7. and JCC. 2014 Mar 1;8(3):215-22.)
AIMS & METHODS: During the winter 2013/14 all medical records were scrutinized and the results were collected. Liver function tests and investigation of hepatobiliary diseases were collected. Liver function tests had been checked at least once in 97.1% of the cohort. The main method for the diagnosis of PSC was magnetic resonance cholangiopancreaticography (MRCP), or endoscopic retrograde cholangiopancreatography (ERCP) when the results were ambiguous. Parenchyma diseases were investigated with liver biopsy and biochemical tests. IBD was classified according to the Montreal classification.
RESULTS: Seventeen patients with PSC were diagnosed corresponding to an overall prevalence of 2.15% (for UC 1.90% and for Crohn's disease 2.65%). The average age of these was 25,0 years. Among the 92 paediatric patients (<17 years old) three patients had autoimmune hepatitis, but none PSC. Three patients have undergone liver transplantation and one has died of colonic carcinoma. Eleven patients have demonstrated persistent elevation of ALP but have had a normal MRCP or refused further investigation.
CONCLUSION: In this prospective population based cohort consisting of 526 patients with UC and 264 with Crohn's disease, 17 cases of PSC was found, among whom ¼ so far have been liver transplanted or have died because of carcinoma. The average age of those affected by PSC is considerably lower than usually is reported. Forthcoming study of ICURE will reveal if more patients will be affected by liver disease.

P0273 CELIAC DISEASE IN IBD. OBSERVATIONS FROM A POPULATION BASED COHORT OF IBD (ICURE)

A. Rönnblom[1,*], T. Holmström[1], H. Tanghöj[1], A. Wanders[1], D. Sjöberg[1]
[1]*Dpt of Medical Sciences, Uppsala, Sweden*
Contact E-mail Address: *anders.ronnblom@akademiska.se*

INTRODUCTION: IBD and celiac disease are diseases with worldwide distribution and an increased incidence of them have been reported from many areas. There is a shortage of studies investigating the possible concomitant appearance of these diseases in the same individual and whether those affected by both diseases demonstrate any particular phenotype. ICURE (IBD Cohort Uppsala health Region) is a population based cohort of individuals with ulcerative colitis ($n=526$, JCC. 2013 Oct 1;7(9):e351-7) Crohn's disease ($n=264$, JCC. 2014 Mar 1;8(3):215-22) and microscopic colitis ($n=272$). We have previously reported the occurrence of celiac disease among patients with microscopic colitis (Scand J Gast 2013;48:825-830) and we now aimed to study the patients with UC and Crohn's disease in the same respect.
AIMS & METHODS: In 790 individuals diagnosed with ulcerative colitis or Crohn's disease between 2005 and 2009, the possible concomitant occurrence of celiac disease was investigated. Medical notes were scrutinized and pathological specimens were re-examined.
RESULTS: Three hundred and ninety-nine of the 790 patients had been examined for the possibility of celiac disease, corresponding to an investigation of 49.4% of the total cohort. Sixteen patients with celiac disease were found, representing 2.05% of the cohort. Two patients with IBD and celiac disease developed collagenous colitis 5 and 7 years later and one PSC after 3 years. A young man with UC developed collagenous sprue. Compared with the non-celiacs the patients with both IBD and celiac disease were younger (22.5 vs. 34.5 years, $p=0.0015$) and those with colitis more often had an extensive disease (9/3 vs. 163/328, $p=0.0026$) and 76% were women.
CONCLUSION: Celiac disease is sufficiently common among patients with IBD to motivate screening for this condition in the regular workup of patients with ulcerative colitis and Crohn's disease. Those affected by both diseases are predominantly young women with extensive colitis.

INTRODUCTION: The IBD is a chronic and potentially debilitating disease course can represent a heavy burden for patients, impacting every aspect of the affected individual's life.
AIMS & METHODS: To assess work disability (WD) rates in an inflammatory bowel disease (IBD) cohort involving patients with Crohn's disease (CD) or ulcerative colitis (UC) cohort and to identify possible clinical or demographic factors associated with WD. Data from 443 (M/F: 202/241, CD/UC: 260/183, mean age: 35.5 (CD) and 40.5 (UC) years, biological drug exposure 31.2% / 11.5%) consecutive patients were included. WD data were collected by questionnaire and the Work Productivity and Activity Impairment (WPAI) instrument. Disability pension (DP) rates in the general population were retrieved from public databases.
RESULTS: The overall DP rate in this IBD population was 32.3%, with partial disability in 24.2%. Of all DP events, 88.8% were directly related to IBD. Overall, full DP was more prevalent in IBD (RR:1.51, $p<0.001$) and CD (RR:1.74, $p<0.001$) but not in UC compared to the general population and also in CD compared to UC (OR: 1.57, $p=0.03$). RR for full DP was increased only in young CD patients ($RR_{<35\ year\ olds}$: 9.4; $RR_{36\text{-}40\ year\ olds}$: 9.4 and 5.6, $p<0.01$ for both). In CD, age group, previous surgery, disease duration, frequent

relapses, and the presence of arthritis/arthralgia were associated with an increased risk for DP. Among employed patients, absenteeism and presenteeism was reported in of 25.9% and 60.3% patients, respectively, leading to a 28% loss of work productivity and a 32% activity loss, and was associated with disease activity and age group. Average cost of productivity loss due to disability and sick leave with human capital approach was 1450 and 430 €/patient/year, respectively (total productivity loss 1880 €/patient/year).

CONCLUSION: Risk of DP was highly increased in young CD patients (six to nine fold). Previous surgery and presence of arthritis/arthralgia was identified as risk factor for DP. Work productivity is significantly impaired in IBD and is associated with high productivity loss.

P0275 INCREASED INTESTINAL PERMEABILITY AMONG FIRST-DEGREE RELATIVES OF CROHN'S PATIENTS IS NOT ASSOCIATED WITH INCREASED MUCOSAL ULCERATIONS ON SMALL BOWEL VIDEO CAPSULE ENDOSCOPY

C. Teshima[1,*], M. El Kalla[2], S. Turk[3], W. El Matary[4], R. Valcheva[1], R. Danchak[2], M. Gordon[2], P. Ho[1], A. Mullins[2], D. Wong[1], J. Meddings[5], H. Huynh[2], L. Dieleman[1]

[1]Medicine, [2]Pediatrics, University of Alberta, Edmonton, Canada, [3]Medicine, Free University Amsterdam, Amsterdam, Netherlands, [4]Pediatrics, University of Manitoba, Winnipeg, [5]Medicine, University of Calgary, Calgary, Canada

INTRODUCTION: First-degree relatives (FDR) of Crohn's disease (CD) patients have the highest risk for developing CD. CD patients and a substantial portion of FDR have increased intestinal permeability. It is unclear whether FDR have abnormal permeability because of early, asymptomatic CD or whether this occurs without mucosal inflammation. Video capsule endoscopy (VCE) is the most sensitive means of imaging the small intestine and can identify mucosal lesions suggestive of subclinical CD. The purpose of our study was to determine if abnormal small intestinal permeability in healthy FDR is associated with small bowel mucosal abnormalities detected by VCE.

AIMS & METHODS: 342 CD patients consented to have their FDR between 10-45 years of age contacted regarding study participation. Eligible FDR underwent small bowel permeability testing as measured using the lactulose/mannitol (L/M) test that is based on the fractional urinary excretion of these sugars. FDR with abnormal permeability (defined as ≥ 0.030) were compared to FDR with normal small permeability (<0.025) by VCE to assess for small bowel inflammatory changes. The primary outcome was the number of mucosal ulcerations seen on VCE in each permeability group.

RESULTS: 223 FDR consented to participate and completed the intestinal permeability test. 40 (17.5%) had abnormally increased permeability. Subsequently, 59 subjects with normal and 29 subjects with abnormal permeability underwent VCE. On VCE, there was no difference in small bowel mucosal abnormalities with a mean of 2.27 (range 0-16) ulcers in the normal and 2.52 (range 0-15) ulcers in the abnormal permeability groups respectively (NS). Surprisingly, 23.5% of asymptomatic FDR had more than 3 small bowel lesions as shown by VCE, irrespective of their intestinal permeability. These lesions were significantly associated with fecal calprotectin of $>$ 50 mg/g stool.

CONCLUSION: There is no association between small bowel ulcerations seen on VCE between asymptomatic FDR of Crohn's patients with abnormally increased intestinal permeability and FDR with normal permeability. Thus, the increased small bowel permeability in FDR does not seem to be caused by subclinical CD, but is likely an intrinsic gut barrier defect. Surprisingly, over 23% of these FDR had 3 or more small bowel ulcers, associated with increased fecal calprotectin levels.

P0276 PRE-POUCH ILEITIS: A MORE TREATMENT REFRACTORY SUB-GROUP OF POUCHITIS

D.C. de Jong[1,*], M.A. Samaan[1], S. Sahami[2], G.van den Brink[1], M. Löwenberg[1], C. Ponsioen[1], W.A. Bemelman[2], G.R. D'Haens[1]

[1]Inflammatory Bowel Disease Unit, Academic Medical Centre, Amsterdam, [2]Department of Surgery, Academic Medical Centre, Amsterdam, Netherlands

Contact E-mail Address: *markasamaan@gmail.com*

INTRODUCTION: Following restorative proctocolectomy (RPC) with ileal pouch-anal anastomosis (IPAA) for ulcerative colitis, (UC) up to 50% of patients will develop pouchitis. Moreover, a subgroup will also develop inflammation in the pre-pouch ileum (pre-pouch ileitis, PI). Endoscopically, PI can mimic Crohn's disease (CD) but evidence suggests that PI may be a distinct disease entity. PI has been reported more frequently in UC patients with primary sclerosing cholangitis (PSC) undergoing IPAA. This group is also known to have higher rates of backwash ileitis and certain similarities have also been described between this and PI[1].

AIMS & METHODS: Our aim was to assess the incidence, predictive factors and response to treatment in a single centre cohort of pouch patients. We retrospectively collected data on 246 consecutive UC patients who underwent RPC and IPAA over the last 15 years. Endoscopic and histological records were used to identify individuals with PI, defined as ulceration seen in the afferent limb at endoscopy and evidence of active inflammation in biopsy samples.

RESULTS: Seventy-nine (32%) of the 246 patients were found to have had pouchitis. Twelve patients were found to have concurrent PI, representing 5% of the total cohort. No patients had PI in the absence of pouchitis. Of those with PI, 6 patients (50%) had antibiotic-refractory, chronic pouchitis (as previously defined[1]): four of whom required steroids/immunomodulators and two required treatment with anti-TNF agents. One had antibiotic-dependent pouchitis. The remaining 5 were antibiotic responsive and did not require long-term treatment for their symptoms. A higher proportion of patients in the PI group had PSC (2 of 12, 17%) compared to the non-PI group (11 of 234, 5%) though this difference did not reach statistical significance ($p = 0.07$).

Table 1: Showing demographic data for patients with and without pre-pouch ileitis (PI)

	PI (n = 12)	Non-PI (n = 234)
Gender (female:male)	4:8 (33%:66%)	109:125 (47%:53%)
Smoker	1 (8%)	26 (14%, n = 185)
Pouchitis	12 (100%)	67 (30%, n = 227)
PSC	2 (17%)	11 (5%, n = 234)
EIM	1 (8%)	21 (10%, n = 219)

CONCLUSION: Compared with pouchitis, PI is a rarer and less well-defined condition. Its recognition is relevant to clinicians as the inflammation involved is more extensive and can be more treatment refractory than isolated pouchitis. Our study demonstrates high rates of antibiotic-refractory, chronic pouchitis among those with concurrent PI when compared with published pouchitis cohorts[2]. An alternative possibility is that PI is a distinct clinical entity with different pathophysiology to isolated pouchitis. The diagnosis of PI should be considered in all patients with ulceration of the afferent limb rather than making the assumption that Crohn's disease is the underlying condition.

INTRODUCTION: The incidence of vaccine-preventable disease is increasing. Current practice guidelines recommend annual influenza vaccination for all inflammatory bowel disease (IBD) patients.

AIMS & METHODS: We aimed to determine the annual uptake of influenza vaccine in UC patients. Using the Business Objects database of Clalit Health Services in the Tel Aviv district we identified all patients over 18 years old with a diagnosis of Ulcerative colitis (UC) on 31.12.2005. This cohort was followed until 31.12.2012. Subjects over age 50 without IBD who are also targeted for influenza vaccination served as controls. The uptake of annual influenza vaccination was recorded.

RESULTS: 470 UC patients were included (241 (51.3%) males, age 50.4±18.4 years, disease duration 158.9±86.5 months), and 2960 controls. During the years 2006, 2007, 2008, 2009, 2010, 2011 and 2012 the uptake of influenza vaccination was 101 (21.5%), 122 (26.0%), 147 (31.3%), 181 (38.5%), 177 (37.7%), 170 (36.2%) and 178 (37.9%) amongst UC patients, and 993 (33.5%), 1360 (45.9%), 1524 (51.5%), 1611 (54.4%), 1446 (48.9%), 1576 (53.2%) and 1557 (52.6%) amongst controls ($p<0.0001$ for every year). Independent predictors of vaccination included age (OR, 1.05; 95% CI, 1.03-1.06; $p<0.001$) and cardiovascular risk (OR, 1.81; 95% CI, 1.31-2.49; $p<0.01$).

CONCLUSION: Although uptake influenza vaccination is consistently lower in UC compared to controls, an upward trend was observed over the study period. Public health initiatives should target this high-risk population to promote immunization.

P0278 UK IBD TWIN AND MULTIPLEX REGISTRY: CONCORDANCE AND ENVIRONMENTAL RISK FACTORS OF TWINS WITH IBD

H. Gordon[1,*], T. Orchard[2], A. Steel[1], M. Harbord[1]
[1]*Gastroenterology, Chelsea and Westminster Hospital,* [2]*Gastroenterology, St Mary's Hospital, London, United Kingdom*

INTRODUCTION: Twins offer insight into the relative importance of genetic and environmental factors in disease development. Twin studies to date show concordance in monozygotic twins with CD and UC to be 20-55% and 6.3-17% respectively. Dizygotic concordance rates are 0-3.6% (CD) and 0-6.3% (UC) (1). The UK IBD Twin and Mutliplex Registry is a research database established in October 2013; this study reviews disease patterns and environmental risk factors of twin pairs recruited.
AIMS & METHODS: Data subjects were recruited via clinician referral, IBD charities and retracing members of a database dormant since 1996. Adult twin pairs discordant and concordant for IBD were recruited. Data subjects completed a questionnaire regarding demographics, disease history and environmental exposure. Medical records were reviewed when available.
RESULTS: Demographics, Concordance and Zygosity: 100 twin pairs were recruited. Mean age 57 years 5 months, range 21-83 years. 31 monozygotic:69 dizygotic. Ratio CD:UC = 48:52. Concordance of twin pairs classified by zygosity and disease type is as follows:

	Crohn's Disease	Ulcerative Colitis
Monozygotic	**53.3%**	**25%**
Dizygotic	**10%**	**19.4%**

Early Environment: Higher rates of exclusive breastfeeding were reported in concordant compared with discordant pairs (27.3% n = 22 pairs vs 16.7% n = 78 pairs). Self reports of perceived childhood illness did not show any difference between IBD and healthy twins of discordant pairs (16.7%, 13/78 vs 19.2%, 15/78). However, the IBD twin more often recalled frequent gastrointestinal infection prior to IBD onset in comparison with their healthy twin (10.3%, 8/78 vs 3.8%, 3/78).
Diet: IBD twins from discordant pairs reported higher rates of consuming "ready made" meals at least weekly before disease incidence (12.8%, 10/78 vs 5.1%, 4/78).
Smoking: On review of discordant twin pairs (n = 72), there was no significant difference in numbers of current, ex and non smokers between subjects with UC (n = 41), CD (n = 32) and their healthy twin at time of symptom onset.
Medication and Stress: On review of all IBD sufferers, 7.1% (8/112) and 13.4% (15/112) used NSAIDS and antibiotics within 3 months preceding onset. 48.2% (54/112) reported significant stress within the year preceding onset.
Time of onset in concordant pairs: The mean lag between diagnosis of concordant pairs was 7 years 5 months.
CONCLUSION: Concordance of twin pairs with CD is in keeping with previous studies. However UC concordance is greater than expected; in particular 19.4% dizygotic twin pairs with UC are concordant. This is 4 fold expected rates of non-twin sibling concordance(2), suggesting early environment to be important in pathogenesis. This study supports an associaton between diet, stress and gastrointestinal infection with IBD onset. The lack of associatoin with smoking at incidence may reflect sample size.

INTRODUCTION: The incidence of Crohn's disease is continuing to rise in several countries and in others it appears to have already levelled off. We updated our previous population based study[1] by retrieval of additional information on patients diagnosed with Crohn's disease between 1963 and 1987, and included patients diagnosed with Crohn's disease up to 2010.
AIMS & METHOD: The aim was to assess temporal trends in incidence, prevalence and disease phenotype at diagnosis. Patients of all ages with a potential diagnosis of Crohn's disease were identified retrospectively by evaluation of medical notes of all current and previous patients at the Colitis clinic, Örebro University Hospital amended by computerised search in the inpatient, outpatients, primary care and histopatological records. The medical notes were reviewed and patients were included if they lived within the catchment area at any time during their disease course, were diagnosed between 1963-2010 and fulfilled the Lennard-Jones criteria for Crohn's disease. Disease phenotype was defined according to the Montreal classification.
RESULTS: The mean incidence for the period 1988-2010 was $7.6/10^5$ (95% CI: $6.7\text{-}8.4/10^5$). A comparison with the earlier period 1963-1987 showed increased age and sex standardised incidence rates of Crohn's disease, with an incidence rate ratio of 1.32 (1.11-1.57). The median (range) age at diagnosis increased from 28 (3–79) years to 37 (5–87) years (p = 0.0002). Similarly, the point prevalence increased from $178/10^5$ (157-199) on 31 December 1987 to $267/10^5$ (244 – 291) on 31 December 2010. Non-stricturing, non-penetrating disease at diagnosis increased from 12.2% in 1963-1987 to 32.3% in 2005-2010.
CONCLUSION: The incidence of Crohn's disease during the last two decades increased. A striking increase in non-stricturing, non-penetrating disease at diagnosis was observed, suggesting earlier diagnosis or phenotypic change. The observed point prevalence in 2010 is among the highest reported.

Contact E-mail Address: *dorota.cibor@gmail.com*

INTRODUCTION: Interleukin 6 (Il-6) plays an important role in the development of inflammatory process in IBD patients. The 174 G/C IL-6 promoter polymorphism affects IL-6 transcription. The GG genotype seems to induce higher IL-6 levels while the C allele (GC or CC) seems to be associated with decreased transcription and secretion of IL-6.
AIMS & METHODS: Our study aimed to evaluate the effect of single nucleotide polymorphism of IL-6 (174 G/C) on the disease course in patients with UC and CD.
Material and methods: 105 patients (aged 18-75 years) with diagnosed IBD: 50 with CD and 55 with UC were involved in the study. The controls consisted of 124 healthy individuals. In all patients were evaluated following parameters: disease duration, disease location, presence of complications, present pharmacotherapy, past surgical procedures, BMI, cigarette smoking. In all subjects morphology, biochemical parameters, CRP, fibrinogen, IL-6 level and IL-6 polymorphism were assessed.
RESULTS: No statistically significant differences in IL-6 polymorphism were observed between patients with UC, CD and controls. Patients with GG genotype were significantly younger at the disease onset. In IBD patients with GG genotype higher mean IL-6 level was noticed as compared to other genotypes (4.685 +/- 5.9 vs 2.715 +/- 5.1 in GC and 3.186 +/- 3.6 in CC). In both UC and CD patients with GG and GC genotype a positive correlation between IL-6 and fibrinogen level as well CRP was found. In IBD patients with CC genotype no correlation between IL-6 and fibrinogen was found (p = 0.48).
CONCLUSION: The risk of developing IBD is not connected with IL-6 polymorphism. However, IL-6 variation might have an influence on the course of the disease in IBD patients.

P0281 THE TPMT AND ABCB1 POLYMORPHISMS IN IBD PATIENTS IN CRETE: IMPACT ON DISEASE AND RESPONSE TO TREATMENT

C. Coucoutsi[1], A. Voumvouraki[1], O. Sfakianaki[1], G. Emmanuel[1], E. Digenakis[1], I. Koutroubakis[1], **E. Kouroumalis**[1,*]
[1]*Gastroenterology, University of Crete Medical School, Heraklion Crete, Heraklion, Greece*
Contact E-mail Address: *kouroum@med.uoc.gr*

INTRODUCTION: It is well known that polymorphisms of the TPMT gene (coding for thiopourine methyl-transferase), influence response to treatment with azathioprine. Polymorphisms of the ABCB1 gene (coding for p-glycoprotein 170) has been associated with IBD and resistance to treatment but results are conflicting.
AIMS & METHODS: The aim of this study was to determine the frequencies of TPMT and ABCB1 gene polymorphisms in IBD patients from Crete, a population genetically homogeneous, and how these polymorphisms might influence response to treatment and disease behaviour. A total of 222 IBD patients, records were reviewed for intake of azathioprine, possible adverse reactions, response to treatment and need for colectomy. All patients were genotyped for TPMT gene polymorphisms, that have been related to intolerance to azathioprine (G238C, G460A and A719C) as well as ABCB1 gene polymorphisms (G2677T/A and C3435T), using a PCR-RFLP method. The same polymorphisms were also determined in 119 age and sex healthy controls.
RESULTS: Allele frequencies of TPMT gene in our study population were found to be in concordance with those reported in other Caucasian populations. 76 IBD patients were identified receiving azathioprine, of whom 16 were discontinued (10 CD, 6 UC) due to adverse reaction. 2 of them were found to carry the G460A and A719G alleles (TPMT 3A genotype) (12.5%). For the ABCB1 gene, G2677T/A allele frequencies were found to be similar to those reported in the literature. There was no association of G2677T/A or C3435T with clinical phenotype, or resistance to treatment. However, 77.3% of 22/222 patients who did not respond to therapy and required surgery, were found to carry both the C3434T and the G2677T mutation
CONCLUSION: Our study was conducted in a genetically homogenous population in the island of Crete. No correlation of any single SNP was found with

either clinical activity or response to treatment. However, most patients who carried both the G2677T and C3435T mutations were refractory to treatment, a finding which implies that resistance to treatment in IBD patients is a more complex issue, which requires the presence of a genetic locus rather than a single SNP.

INTRODUCTION: A total of 20-30% of patients with active Crohn's disease (CD) do not respond to anti-TNF-α treatments and up to 40% of patients in chronic therapy experience a loss of response. Furthermore about 50% of patients with ulcerative colitis (UC) experience a loss of response to anti-TNFα therapy after one year. The cause of this limited efficacy is unclear, but past studies hypothesized that the individual variation of drug metabolism may play an important role. Thus, given the limited data available, the role of Fcγ IIIa receptor (i.e. one of the four receptors involved in the catabolic pathway of anti-TNF-α drugs) polymorphisms should be further explored.
AIMS & METHODS: The aim of this prospective, long-term follow up study was to evaluate the correlation between Fcγ IIIa receptor polymorphisms and clinical outcome in IBD patients undergoing biologic therapy.
We enrolled consecutive IBD patients who achieved clinical remission by anti-TNF-α therapy. Blood samples were collected at the beginning of biological therapy. The assessment of IBD activity was based on the Harvey-Bradshaw Index score (HBI, remission <5, mild disease 5-7, moderate disease 8-16, severe disease >16) for CD patients and on the Mayo score (Mayo <2 remission, mild disease 2-5, moderate/severe disease 6-12) for UC patients. Biochemical evaluation and clinical score were assessed every 8 weeks. For the genotyping analysis we used a Light Snips (Tib-Molbiol, Genova, Italy) and the Real-Time PCR Technique developed by Light Cycler 480 Instrument (Roche, Mannheim, Germany).
RESULTS: We prospectively included 39 patients (12UC/27 CD, 16F/23M) with a median follow-up of 66.8 weeks (10-112). A total of 25 (64.1%) (10UC/15CD) patients kept in remission during the whole follow up period, while 14 (35.9%) (2UC/12CD) experienced disease relapse. As shown in the Table, four out of 14 (28.6%) (1UC/3CD) patients who experienced disease relapse, had FcγIIIa-158 V/V receptor polymorphism, while the remaining 10 (71.4%) (9CD/1UC) had FcγIIIa-158 F/V or F/F receptor polymorphisms. Out of 25 patients who kept in remission, 3 (12%) (1CD/2UC) had FcγIIIa-158 V/V receptor polymorphism, whereas the remaining 22 (88%) (14CD/8UC) showed FcγIIIa-158 F/V or F/F receptor polymorphisms. Patients in remission tended to have more often FcγIIIa-158 V/V receptor polymorphism compared to patients who relapsed, but statistical significance was not reached.

	Patients in Remission (n = 25)	**Relapsers (n = 14)**	*p value*
Polymorphism **V/V**	3 (12%)	4 (28.6%)	0.2251
Polymorphism **V/F +F/F**	22 (88%)	10 (71.4%)	

CONCLUSION: The evaluation of Fcγ IIIa-158 V/V receptor polymorphism does not seem useful in identifying patients who are more likely to lose anti TNF-α response during long term period. However, further larger studies are necessary to investigate the role of Fcγ IIIa receptor polymorphisms.

P0283 GENOME-WIDE STUDY OF ANTI-TNF RESPONSE IN INFLAMMATORY BOWEL DISEASES

M. Hübenthal[1,*], A. Franke[1], V. Andersen[2,3] on behalf of The Danish anti-TNF study group
[1]*Christian-Albrechts-University of Kiel, Kiel, Germany,* [2]*South Danish University, Odense,* [3]*South Jutland Hospital, Aabenraa, Denmark*
Contact E-mail Address: *vandersen@health.sdu.dk*

INTRODUCTION: Biomarkers predictive of treatment response will help select the optimal treatment for the individual patients. Genome-wide association studies (GWAS) on anti-TNF response in patients with Crohns Disease (CD) and ulcerative colitis (UC) are limited.
AIMS & METHODS: We performed a GWAS using ImmunoChip on a clinically-based cohort of anti-TNF treated patients with CD and UC. Data on the first treatment of anti-TNF was sampled retrospective from 18 medical departments in Denmark by young medical doctors from the patient records. Efficacy was evaluated using a simple 3-step scale (full/partial/non-responds) based on the information in the patient records. Efficacy reflected the maximum response within 26 weeks after anti-TNF treatment initiation. In total, 130061 autosomal single nucleotide polymorphisms (SNPs) pass quality control QC) (62341 failed QC) in 592 unrelated individuals (+ 34 failing QC). SNPs were assessed for full versus non-responders (partial responders were omitted).
RESULTS: In total, 364 cases had CD (270 full, 41 partial, and 53 non-responders) and 197 cases had UC (124 full, 23 partial, and 50 non-responders) and 31 cases had undetermined disease and/or response. Loci previously published to be risk factors for CD or UC could be shown to be significantly associated with differences in anti-TNF response in CD (full vs. non-response) and UC (full vs. non-response), respectively.
CONCLUSION: This is the first GWAS of anti-TNF treatment response in IBD. Power for detecting associated markers was limited. Collaboration between owners of anti-TNF treated cohorts e.g. in the regi of the International Inflammatory Bowel Disease Genetic Consortium (IIBDGC) may increase the power for identifying SNPs associated with treatment response.

INTRODUCTION: The genetic basis of inflammatory bowel disease (IBD) is incompletely understood and it has been suggested that rare genetic variants contribute to the heritability of IBD.
AIMS & METHODS: Here, we aimed to study rare variants involved in the pathogenesis of IBD. We performed exome sequencing and detailed immunological profiling in a patient with early onset Crohn's disease (CD). The coding region of the gene encoding X-linked inhibitor of apoptosis protein (XIAP) was sequenced in samples of 275 paediatric IBD patients and 1047 adult-onset CD patients. XIAP genotyping was performed in samples of 2680 IBD patients and 2864 healthy controls. Functional effects of the identified variants were investigated in primary peripheral blood mononuclear cells (PBMCs) and cultured cell lines.
RESULTS: A novel, de novo, nonsense mutation in the gene encoding XIAP, a gene previously linked to primary immunodeficiency, was identified in a male patient with early-onset CD. Sanger sequencing of XIAP in large cohorts of paediatric IBD and adult-onset CD revealed several additional XIAP variants. XIAP variants were detected in four percent of male patients with paediatric-onset CD and were confined to this subset of IBD patients without detection of XIAP variants in either UC or adult-onset CD. CD in patients harbouring XIAP variants was characterized by small and large intestinal involvement, perianal disease, and stricturing behaviour. Functional studies in primary PBMCs and cultured cell lines revealed that the majority of identified XIAP variants were associated with selective defects in NOD1 and NOD2 signalling. NOD1/2 defects occurred as a consequence of impaired association of mutant XIAP with RIPK2 and/or altered XIAP-dependent ubiquitylation of RIPK2 thus uncoupling NOD1/2 from its downstream mediator NF-κB.
CONCLUSION: Our studies reveal the frequent occurrence of XIAP variants in male, pediatric onset CD. Moreover, our data provide a mechanistic basis to the previously unexplained observation of functional NOD2 defects in the absence of genetic variants in NOD2. Finally, given the known association of XIAP mutations with primary immunodeficiency and the observed defect in NOD1/2 signaling, our data lend further support to the concept of primary immunodeficiency in a subset of CD patients.

INTRODUCTION: According to current guidelines, all IBD patients should be screened regularly for malnutrition with a validated tool (focusing on BMI, weight loss and food intake). In a previous screening study conducted in hospitalized patients (n = 1252) malnutrition was as observed up to 20% using the body mass index (BMI) calculation, while it was high as 40% according to the validated malnutrition universal screening tool (MUST). We hypothesized that even MUST is not the sufficient method to evaluate the risk of malnutrition of an IBD patient.
AIMS & METHODS: 173 consecutive IBD (126 with Crohn's disease – CD and 47 with ulcerative colitis – UC) patients were enrolled into the study. Body composition was measured by InBody 720 body analyser device, using the bioelectrical impedance method. BMI and MUST were also calculated and compared to main results of BIA (skeletal muscle mass – SMM, body fat mass – BFM fat free mass-FFM).
RESULTS: Rate of malnutrition in IBD patients was detected in 16%, 32% and 44% in patients using BMI, MUST and BIA, respectively. Almost half of the CD patients have a high risk of malnutrition based on the BIA parameters (48%), while it was lower using the MUST criteria (34%) or the simple BMI calculation (17%).
We compared patients' body composition regarding their ranking on MUST scale. We found that UC patients' SMM and FFM altered significantly in the

MUST cathegories (SMM p = 0.032, FMM p = 0.034 S, BFM p = 0.083 NS), while we found no significant changes among CD patients. (SMM p = 0.823, FMM p = 0.815, BFM p = 0.660 NS).
Although the differences weren't significant, highest risk of malnutrition was detected in stenosing CD patients (57%, 43% and 29% with BIA, MUST and BMI, respectively). High portion of CD and UC patients was underweighted (48% vs. 34%). Fat tissue deficiency was more pronounced in CD than in UC (52% vs. 23%), even in patients with stenosing disease phenotype (57%).
CONCLUSION: BMI calculation is not the appropriate method to estimate the risk of malnutrition in IBD patients. MUST score calculation is able to detect a higher portion of endangered subjects. Although the availability is not as wide as it should be, the BIA method is the most accurate test to evaluate the risk of malnutrition. According to our findings it is a useful tool to plan the dietary therapy of the patients, and it can be a recommended method especially in UC patient care.

Contact E-mail Address: *milagn422@gmail.com*

INTRODUCTION: The assessment of ulcerative colitis (UC) activity is based on a combination of symptoms, clinical examination and endoscopic finding. The most important goals of the recent therapies of UC are to induce and maintain clinical remission and to achieve mucosal healing. Mucosal healing is defined as Mayo endoscopy subscore of 0 or 1 in the majority of the studies. Interestingly, rate of endoscopic remission has been shown to be higher than that of clinical remission in some trials.
AIMS & METHODS: The **aim** of our study was to evaluate the correlation between clinical and endoscopic disease activities of UC defined by activity scores. Clinical activities were defined by two activity indices: the Rachmilewitz Activity Index (CAI) and the partial Mayo score. Every patient underwent colonoscopy performed by 3 experienced gastroenterologists and endoscopists. They graded the findings both according to the endoscopic part of the Rachmilewitz Activity Index (EI) and the Mayo endoscopic subscore. Mucosal healing was defined as Mayo endoscopic subscore and EI of 0. Histological activity was scored by Riley score.
RESULTS: 100 UC patients were enrolled in the study (49 males, 51 females; mean age at diagnosis: 32.5 years). They were diagnosed on the basis of standard clinical, endoscopic and histologic criteria. Clinical and endoscopic activities showed strong correlations using both scoring systems (p = 0.0029 and p = 0.0001). Endoscopic disease activity also correlated with the histological activity (p≥0.001). Significant correlation was shown between the clinical activity and mucosal healing (p = 0.0012 and p≥0.001). No association was showed with the extension of the disease and clinical or endoscopic activity.
CONCLUSION: Assessment of mucosal healing is very important for guiding therapy and for evaluation of remission in patients with UC. Our result showed that the correlation between the clinical, endoscopic and histological activities is very good in UC. Mucosal healing highly associated with clinical remission.

P0287 DIAGNOSTIC DELAY IN PEDIATRIC CROHN'S DISEASE PATIENTS IS LONGER THAN IN PEDIATRIC ULCERATIVE COLITIS PATIENTS

A. Schoepfer[1,*], E. Safroneeva[2], N. Fournier[1], G. Rogler[3], J. Ezri[1], A. Nydegger[1], S. Vavricka[4], C. Braegger[3] on behalf of Swiss IBD Cohort Study Group
[1]*University Hospital Lausanne / CHUV, Lausanne,* [2]*University of Bern, Bern,* [3]*University Hospital of Zurich,* [4]*University Hospital Zurich, Zurich, Switzerland*
Contact E-mail Address: *alain.schoepfer@chuv.ch*

INTRODUCTION: We have recently shown that the median diagnostic delay (time from first IBD symptoms until IBD diagnosis is established) was 9 months in adult Crohn's disease (CD) patients and 4 months in adult ulcerative colitis (UC) patients in Switzerland. Of note, 25% of CD patients had a diagnostic delay >24 months. We also showed that the length of diagnostic delay in CD patients represents a risk factor for complicated disease course and intestinal surgery. There is a lack of data regarding diagnostic delay in pediatric IBD patients.
AIMS & METHODS: We aimed to assess the diagnostic delay in pediatric CD and UC patients and to identify risk factors for long diagnostic delay. Data from the Swiss IBD cohort study were analyzed. Patients were recruited from university centers (80%), regional hospitals (19%), and private practices (1%). Data on diagnostic delay was provided by parents and physician questionnaires. Diagnostic delay was further divided into the time interval from first symptoms to the first consultation with the physician (patient-related interval) and the interval from first physician consultation until IBD diagnosis was established (physician-related interval). Long diagnostic delay was defined as delay lying avove the 75th percentile. Non-normal data are presented as median, interquartile range [IQR] and range.
RESULTS: A total of 100 pediatric CD (37% females) patients and 75 pediatric UC patients (56% females) were included. Age at disease onset was 12 [10-14] years in CD and 11 [7-13] years in UC patients. Diagnostic delay in CD was 4 [2-8] (range 0-82) months with the interval form first symptoms to physician visit of 1 [0-3] (range 0-24) months and from physician visit to diagnosis of 3 [1-9] (range 0-82) months. In UC patients the median diagnostic delay was 2 [1-7] (range 0-52) months with an interval from first symptom onset to physician visit of 0 [0-3] (range 0-36 months) and from physician visit to diagnosis of 2 [1-4] (range 0-20) months. Diagnostic delay in CD patients was significantly longer than in UC patients (median 4 vs. 2 months, p = 0.011). Long diagnostic delay was defined as period of >8 months in CD and >7 months in UC patients. Neither gender, age at diagnosis, disease location, positive IBD family history, nor provenience (rural vs. non-rural) were associated with long diagnostic delay.
CONCLUSION: the median diagnostic delay in pediatric CD and UC patients in Switzerland is 4 and 2 months, respectively. However, one fourth of pediatric CD patients needs >8 monhts and one fourth of pediatric UC patients needs >7 months from first symptom onset to IBD diagnosis.

P0288 BEHAVIOR OF P-GLYCOPROTEIN 170 (P-GP) FUNCTIONAL ACTIVITY IN PERIPHERAL BLOOD LYMPHOCYTES (PBL) OF IBD PATIENTS DURING TREATMENT WITH ANTI-TNFS

A.M. Sambuelli[1,*], C. Cortada[2], A. Gil[1], S. Negreira[1], S. Huernos[1], S. Goncalves[1], B. Maricel[1], T. Pablo[1]

Contact E-mail Address: *asambu@fibertel.com.ar*

INTRODUCTION: Pgp, encoded by the MDR1 gene is a transmembrane, ATP-dependent, efflux pump, expressed in cells with barrier function and PBL, removing drugs, toxins, xenobiotics. IBD share drugs Pgp influenced with other diseases (as steroids, 6-MP in leukemia cells). Pgp overexpression was implicated in highly active resistant RA (Tsujimura, *Ann Rheum Dis* 2008) induced by IL2 and TNF, influencing steroid efflux from lymphocytes, reporting that a single infliximab (IFX) infusion overcame refractoriness with elimination of Pgp high expressing CD4+lymph and recovery of dexametasone in PBL with Ppg marked decrease. Pgp measure in PBL could be an early marker of AntiTNFs efficacy and Pgp activity could modify the efflux of concurrent Pgp substrates drugs.
AIMS & METHODS: We aimed to study Pgp activity in PBL of IBD pts. treated with antiTNFs, investigating a potential role in IBD management. Pgp functionality was evaluated in PBL of IBD and healthy controls (HC: n30), studied in 5 groups of IBD pts. (n123 recruited) with at least 10 CD/10 UC each: - Before and after 20 days of AntiTNF (IFX or ADA) in steroid refractory (group 1) or thiopurine refractory (group 2), - Before and after 3 mo of 6-MP in steroid refractory (group 3), - In Thiopurine sensitive (group 4) and Steroid sensitive (group 5). Response criteria: at 45 days of AntiTNFs or 3 mo. of 6-MP (CDAI: a 70 points drop, Mayo score 3 points+30% drop) categorized in: remission (CDAI≤150, Mayo Sc.≤2) and partial response. Rhodamine123 (fluorescent Pgp substrate) efflux was studied by flow cytometry, expressed by the behaviour of 2 markers defined by % of cells with different fluoresc. levels: M1 (high fluoresc./low Pgp pump activity), M2 (low fluoresc./Pgp high activity, used for the results).
RESULTS: Basal Pgp values (mean±SD) in total PBL (M2) were: Group 1: 41.4 ±18.5, Group 2: 32.1 ±13.6, Group 3: 44.1±19.8, Group 4: 36.1±16.9, Group 5: 37.5±16.4 and HC 39.0±12.3. Major finding was a significant decrease of Pgp after AntiTNFs in IBD in most of responder pts. (Δ -difference- in refractory vs remission p: 0.030018, and 0.0023 for groups 1 and 2, and vs. partial response p = 0.014 in group 2, Mann Whitney). Initial Pgp values of pts. with available Pgp post AntiTNFs measures according response were: Group 1 (n 20) 38.0±17.7, 44.6±8.4, 38.6±21.0, Group 2 (n 23) 35.9±16.0, 34.8±9.9, 23.1±7.1 for remission, partial response and refractory. Post AntiTNFs: 26.2±16.0, 29.0±12.1, 47.0±19.3 (Group 1) and 21.0±11.6, 22.3±11.5, 36.0±11.7 (Group 2). Pts. with 6-MP monotherapy (n23) did not show signif. changes in Pgp. A signif. decrease of Pgp in CD3 lymph. (only group 2 p < 0.003) after AntiTNFs was observed in remission vs refractory pts. In B lymph. lower values post AntiTNFs (group 1) were shown in responders as a trend. Values of post-treat. IBD were lower than HC (p < 0.04).
CONCLUSION: 1) We found that AntiTNFs decreased Pgp activity in PBL of IBD pts., significantly associated with treatment response; 2) AntiTNFs could modify the transport of concurrent Pgp substrates. MDR1 polymorphism typing is ongoing. Longer follow-up and larger size sample are needed to verify the value of Pgp activity measurement in IBD management.

P0289 PREDICTIVE FACTORS FOR CHRONIC INFLAMMATORY BOWEL DISEASES IN PATIENTS PRESENTING WITH NEW ONSET DIARRHEA

A.-M. Singeap[1,*], A. Trifan[1], I. Girleanu[1], O.C. Stoica[2], C. Stanciu[2]
[1]*INSTITUTE OF GASTROENTEROLOGY AND HEPATOLOGY IASI, GR T POPA UNIVERSITY OF MEDICINE AND PHARMACY,* [2]*INSTITUTE OF GASTROENTEROLOGY AND HEPATOLOGY IASI, Iasi, Romania*
Contact E-mail Address: *anamaria.singeap@yahoo.com*

INTRODUCTION: The diagnosis of chronic inflammatory bowel diseases (IBD) requires chronic changes over time (colonoscopic inflammatory changes lasting at least 6 months and chronic histological inflammation). The onset of chronic IBD may mimic acute diarrhea (defined as having sudden onset and lasting less than four weeks); on the other hand, acute diarrhea may be mistaken with a new case of chronic IBD. Our aim was to find clinical or biological predictive factors for the diagnosis of chronic IBD.
AIMS & METHODS: A prospective study was conducted on all cases of new onset diarrhea which presented in our Gastroenterology Unit during 2012. Their

initial evaluation included clinical exam, complete biological picture and colonoscopy. All cases of new onset diarrhea with uncertain etiology were followed and the final diagnosis was established at least 6 months after the onset, by repeating colonoscopy with biopsy. The final diagnosis was correlated with clinical and biological parameters evaluated at the first presentation.
RESULTS: A total of 120 patients with new onset diarrhea presented to our unit in 2012. After the initial work-up, 82 patients had a positive diagnosis (infectious colitis, colorectal cancer, radiation colitis, ischemic colitis). The remaining 38 patients, including both patients with inflammatory changes at colonoscopy and patients with normal colonoscopy were reevaluated by colonoscopy and biopsies after 6 months. For 11 patients, results were conclusive for chronic IBD, 5 patients had collagenous or lymphocytic colitis, and 22 patients were diagnosed with acute self-limiting colitis or irritable bowel syndrome (IBS). Among the parameters we analysed, anemia and hypoalbuminemia in the onset of the symptomatology were significantly correlated with the subsequent diagnosis of chronic IBD; elevated levels of inflammatory parameters like C-reactive protein and erythrocyte sedimentation were present in similar proportions in the different types of final diagnosis except IBS; other biological parameters were not contributive; non-significant correlation was found with respect to age, weight loss and clinical history or associated symptoms.
CONCLUSION: Anemia and hypoalbuminemia are predictive factors for chronic inflammatory bowel diseases in patients presenting with new onset diarrhea; a more extensive initial work-up applied in these patients could bring an early diagnosis for IBD.

INTRODUCTION: Recent epidemiologic studies have shown that patients with inflammatory bowel disease (IBD), in particular those with ulcerative colitis (UC) are at increased susceptibility for *Clostridium difficile* infection (CDI) compared with the general population.
AIMS & METHODS: The objectives of this study were to assess the incidence and risk factors for CDI in UC patients in a tertiary center from North-Eastern Romania.
Data of all UC patients admitted at the Institute of Gastroenterology and Hepathology, Iasi, Romania, between January 2012 and October 2013 were analyzed. In patients with concomitant CDI, risk factors for CDI were identified.
RESULTS: A total of 70 UC patients were included in this prospective study, amongst which eight (11.5%) were identified as having a concomitant CDI. On univariate analysis, age $>$ 65 years (OR = 1.53, CI = 0.93-16.27; p = 0.048), male gender (OR = 1.38, CI = 0.30-14.91; p = 0.032), hemoglobin $<$9 g/dL (OR = 1.93, CI = 0.19-18.52; p = 0.043), severe UC disease (OR = 1.22, CI = 0.14-10.5; p = 0.037), and serum albumin $<$3 g/dL (OR = 1.86, CI = 1.12-10.14; p = 0.012) were associated with CDI. However, on multivariate analysis, only severe disease and serum albumin retained statistical significance.
CONCLUSION: CDI was detected in one of eight patients admitted with a UC flare; severe UC disease and low serum albumin were independent risk factors for CDI.

P0291 ASSESSMENT OF WALL INFLAMMATION AND FIBROSIS IN CROHN'S DISEASE AND ITS CORRELATION WITH BOWEL SONOGRAPHY AND MRI-ENTEROGRAPHY

A. Rispo[1,*], P.P. Mainenti[2], G.D. De Palma[3], D. Musto[1], L. Bucci[4], F.P. D'Armiento[5], A. Testa[1], M. Rea[1], F. Sasso[1], N. Caporaso[1], F. Castiglione[1]
[1]Gastroenterology, [2]Radiology, [3]General Surgery, [4]Colorectal Surgery, [5]Pathology, AOU Policlinico Federico II of Naples, Naples, Italy

INTRODUCTION: Crohn's disease (CD) is a chronic inflammatory bowel disorder which is relapsing and remitting in nature and is characterised by transmural inflammation. About the therapeutical management of CD, it is believed to be particularly important to differentiate between active inflammation and fibrotic lesions in CD patients. Bowel sonography (BS) and MRI-enterography (MRI) are procedures widely used for diagnosing CD and its complications.
AIMS & METHODS: to define the features of the CD strictures, also correlating BS and MRI with histopathology.
We performed an observational prospective study including all CD patients undergoing surgery for strictures. Pre-operative assessment was performed by BS and MRI. BS investigated for: bowel wall thickness (BWT), bowel wall stratification, power-Doppler vascular pattern of the bowel wall, mesentery hypertrophy and enlarged lymphnodes. MRI study included: BWT, T1-weighted gadolinium-based contrast uptake, enhancement pattern, mural and lymph node/cerebrospinal fluid (CSF) signal intensity ratios on T2-weighted fat-saturated images, mesenteric signal intensity on T2-weighted fat-saturated images. Histopathological inflammation was graded by the acute inflammatory score (AIS); the semi-quantitative degree of fibrosis was performed according to the literature. Statistical analysis was performed using chi-square, Mann–Whitney U test and Cohen's k measure.
RESULTS: The study included 20 CD patients. The indications to surgery were: obstructive symptoms in 13 patients, penetrating complications in 7 patients. All but 3 strictures (87%) showed acute inflammation coexisting with fibrosis while only 3 strictures were predominantly fibrotic On BS, the presence of a layered bowel wall stratification was the only variable associated with the presence of fibrosis (k = 0.72; p $<$ 0.03). About MRI, AIS correlated with mural thickness and mural/CSF signal intensity ratio on T2 sequences (p = 0.04, p = 0.02) but not with mural enhancement on T1 images (p = 0.62).
CONCLUSION: The majority of strictures in CD patients treated by surgery are consistent with a mixed type inflammation (acute inflammation plus fibrosis). The presence of stratified BS pattern shows a significantly higher degree of fibrosis while the evidence of high mural signal intensity on T2-weighted fat-saturated images on MRI reflects histological features of acute inflammation. Even if the ideal definition of the type of the strictures in CD still remains significantly out of reach, the combined use of BS and MRI can offer useful information in a sub-group of patients needing surgery for complicating CD.

INTRODUCTION: Inflammatory bowel diseases (IBD) are immune-mediated disorders resulting in chronic, relapsing inflammation of the gastrointestinal tract. A prominent feature of inflammation in IBD is the involvement of effector cells such as neutrophils, eosinophils and mast cells. Neutrophil volume distribution width (NVDW) generated by VCS technology is a new marker which reflects neutrophil activation.
AIMS & METHODS: We sought to investigate the value of NVDW parameter in monitoring disease activation in IBD patients. Neutrophil VCS parameters were measured in IBD patients admitted to our outpatient clinic. Age and sex matched healthy subjects were taken as the control group. Patients with acute or chronic infection and accompanying inflammatory disease were excluded. Pediatric Crohn Disease Activity Index (PCDAI) and Pediatric Ulcerative Colitis Activity Index (PUCAI) were used to define disease activation. Complete blood count, albumin, eritrocyte sedimentation rate, C-reactive protein ve fecal calprotectin were studied routinely at each visit.
RESULTS: A total of 34 pediatric patients with IBD and 29 controls were enrolled in the study. NVDW was significantly higher in patients with IBD compared to healthy controls (p $<$ 0.001). An increased NVDW level was observed in IBD patients with activation (22.42±2.13) compared to those in remission (19.22±1.63) (p $<$ 0.001). There was no statistically significant difference between IBD patients in remission and healthy controls (p = 0.115). A significantly increased NVDW was observed in CD patients with activation compared to CD patients in remission (22.87±2.19 vs 19.68±1.85, p = 0.002). NVDW was significantly higher UC patients with activation compared to UC patients in remission (22.07±2.08 vs 18.53±0.93, p $<$ 0.001). NVDW was correlated with WBC count (r:0.712), platelet count (r:0.347), ESR (r:0.471), CRP (r:0.699), fecal calprotectin (r:0.812), PUCAI (r:0.852) ve PCDAI (r:0.670). The best cut-off of NVDW for prediction of disease activation in CD and UC in this series was 20.39 with a sensitivity of % 90.9 and a specificity of %75 (AUC:0.852 CI 0.698-1.000 p = 0.002) and 19.74 with a sensitivity of % 92.9 and a specificity of % 90.9 (AUC:0.961, CI:0.889-1.000, p $<$ 0.001) respectively.
CONCLUSION: As a quantitative, objective, and sensitive parameter, NVDW has a potential to be an additional predictor for disease activation in IBD.

P0293 IBS-LIKE SYMPTOMS ARE COMMON IN PATIENTS WITH ULCERATIVE COLITIS IN DEEP REMISSION BUT THEY DO NOT SEEM TO BE CAUSED BY LOW GRADE INFLAMMATORY ACTIVITY

B. Jonefjäll[1,*], L. Öhman[1,2], M. Simrén[1,3], H. Strid[1]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Acadamy, University of Gothenburg, [2]Department of Microbiology and Immunology, Sahlgrenska Acadamy, University of Gothenburg, Institute of Biomedicine, [3]University of Gothenburg Centre for Person-Centred Care (GPCC), Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

INTRODUCTION: Gastrointestinal (GI) symptoms compatible with Irritable Bowel Syndrome (IBS) are common in patients with ulcerative colitis (UC). It has been suggested that these symptoms are a reflection of occult inflammation rather than coexisting IBS.
AIMS & METHODS: The aim was to investigate possible factors correlating with IBS-like symptoms in UC patients in deep remission by assessing inflammatory markers, other GI symptoms, psychological symptoms and quality of life (QOL). In total, 297 patients with UC were included at a regular outpatient clinic visit. The patients completed self-administrated questionnaires to assess diagnostic criteria for IBS (Rome III), severity of GI symptoms (Gastrointestinal Symptom Rating Scale (GSRS)), QOL (IBDQ), psychological symptoms (Hospital Anxiety and Depression scale (HAD)), stress (QPS Nordic) and non-GI somatic symptoms (PHQ-12). Fecal calprotectin was used as inflammatory marker. Patients with a normal rigid sigmoidoscopy and calprotectin $>$200 μg/g were further investigated with flexible sigmoidoscopy. Deep remission was defined as a total Mayo-score $\leq$2 (endoscopic findings, rectal bleeding and physician global assesment subscores = 0), with no relapse during the three-month period prior to visit. Comparisons where made between patients in deep remission with (UCR+IBS) and without (UCR-IBS) IBS-like symptoms and patients

with active disease (UCA). Comparisons between the three groups were performed with Kruskal-Wallis test and thereafter post-hoc tests with Mann–Whitney U test and Bonferroni correction, with p-value <0.017 considered significant.

RESULTS: Among the patients, 46% (n = 138) met the criteria for deep remission and 18% (n = 25) of these patients experienced IBS-like symptoms. There was no difference in fecal calprotectin levels between the UCR+IBS and the UCR-IBS patients. The UCR+IBS patients reported significantly more severe GI symptoms in general, lower QOL scores, higher levels of anxiety, stress and non-GI somatic symptoms than the UCR-IBS patients (see table). The level of somatic and psychological symptoms did not differ between the UCR+IBS patients and the UC patients with active disease (see table).

Median (IQR) Level of sign p < 0.017	UCR+ IBS (n = 25)	UCR- IBS (n = 113)	UCA (n = 159)	UCR+ IBS vs UCR-IBS	UCR+ IBS vs UCA	UCA vs UCR-IBS
Calprotectin (μg/g)	18 (7-30)	32 (13-64)	280 (80-715)	p = 0.044	**p < 0.001**	**p < 0.001**
GSRS Total	2.5 (2.1-3.1)	1.5 (1.2-1.9)	2.5 (1.8-3.1)	**p < 0.001**	p = 0.701	**p < 0.001**
Anxiety (HAD)	5.0 (3.5-8.0)	2.0 (1.0-5.0)	4.5 (2.0-8.0)	**p = 0.001**	p = 0.291	**p < 0.001**
Depression (HAD)	2.0 (1.0-7.5)	1.0 (0.0-3.0)	3.0 (1.0-6.0)	p = 0.048	p = 0.941	**p < 0.001**
Stress (QPS Nordic)	2.0 (1.0-3.0)	1.0 (0.0-2.0)	2.0 (1.0-3.0)	**p = 0.003**	p = 0.281	**p = 0.001**
Non-GI Sympt (PHQ)	6.0 (3.5-8.5)	3.0 (1.0-5.0)	4.0 (2.0-7.0)	**p < 0.001**	p = 0.132	**p < 0.001**
QOL (IBDQ)	183 (163-198)	205 (192-213)	167 (144-195)	**p < 0.001**	p = 0.142	**p < 0.001**

CONCLUSION: IBS-like symptoms in UC patients in deep remission are common. Psychological factors rather than low grade inflammatory activity seem to be of importance for symptom generation. Interestingly, UC patients in deep remission with IBS-like symptoms experience GI symptoms, reduced psychological well-being and QOL compatible with UC patients with active disease.

P0294 THE SEVERITY OF ABDOMINAL PAIN AT ONSET OF ULCERATIVE COLITIS IS ASSOCIATED WITH IBS-LIKE SYMPTOMS DURING CLINICAL REMISSION

B. Jonefjäll[1,*], H. Strid[1], L. Öhman[1,2], J. Svedlund[3], A. Bergstedt[3], M. Simrén[1,4]
[1]*Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Acadamy, University of Gothenburg,* [2]*Department of Microbiology and Immunology, Institute of Biomedicine, Sahlgrenska Acadamy, University of Gothenburg,* [3]*Department of Psychiatry, Institute of Neuroscience and Physiology, Sahlgrenska Acadamy, University of Gothenburg,* [4]*University of Gothenburg Centre for Person-Centred Care (GPCC), Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

INTRODUCTION: Symptoms compatible with Irritable Bowel Syndrome (IBS) are common in patients with ulcerative colitis (UC) in clinical remission. It has been suggested that these symptoms might arise due to postinflammatory changes comparable with postinfectious IBS. Factors that increase the risk for developing IBS-like symptoms in patients with new onset of ulcerative colitis are not known.

AIMS & METHODS: The aim was to study factors in patients with new onset of UC that predicts development of IBS-like symptoms during clinical remission. In total, 98 patients with new onset of UC were followed prospectively during three years with yearly follow up visits. The patients completed self-administrated questionnaires at each visit to assess diagnostic criteria for IBS (Rome II), severity of gastrointestinal (GI) symptoms (GI Symptom Rating Scale (GSRS)) and psychological symptoms (Hospital Anxiety and Depression scale (HAD)). Fecal calprotectin, ESR and CRP were used as inflammatory markers. The Mayo score was used to evaluate clinical disease activity. Remission was defined as a total Mayo score ≤ 2 and an endoscopic subscore ≤ 1, with no relapse during the three-month period prior to visit. Data from the first visit at the onset of UC were compared between the group of patients that fulfilled the criteria for IBS while in remission (UCR+IBS) during follow-up and the group that did not (UCR).

RESULTS: Among the UC patients, 87 met the criteria for clinical remission, and 25 (29%) of these reported IBS-like symptoms in remission, on at least at one of the three follow-up visits. The UCR+IBS patients suffered from more severe GI symptoms including abdominal pain (see table) during their primary flare than the UCR patients. The patients that experienced mild to severe abdominal pain had an increased risk for developing IBS-like symptoms during follow-up (OR = 3.1 (95% CI 1.1-8.4) p = 0.03), this occurred in 39% (n = 17) of these patients compared to 20% (n = 8) of the patients that reported none or minor abdominal pain. Female gender (p = 0.10), being unmarried/single (p = 0.05) and higher depression scores (HAD p = 0.09) tended to be more common among UCR+IBS patients. There was no difference in clinical disease activity (Mayoscore p = 0.42), inflammatory markers (Calprotectin p = 0.29, CRP p = 0.36, ESR p = 0.58) or disease extension (p = 0.57) between the two groups.

Table to abstract P0294

GSRS - Median (IQR)	**UCR+IBS**	**UCR**	**p - value**
Total	3.5 (2.2-4.0)	2.7 (2.1-3.3)	**<0.05**
Diarrhea	5.0 (3.3-6.3)	5.3 (3.8-6.7)	0.56
Constipation	2.3 (1.7-2.8)	2.0 (1.7-2.7)	0.30
Abdominal Pain	2.7 (1.8-2.8)	2.0 (1.7-3.0)	**<0.05**
Indigestion	3.8 (2.8-4.6)	3.3 (2.4-4.1)	0.09
Reflux	1.0 (1.0-2.0)	1.0 (1.0-1.5)	0.07

CONCLUSION: Patients with ulcerative colitis that develop IBS-like symptoms during follow-up experience more severe GI symptoms, including abdominal pain, at disease onset, despite no difference in inflammatory disease activity. This might indicate a more sensitive GI tract in this category of patients.

P0295 NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN AS A POTENTIAL BIOMARKER FOR AXIAL INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE PATIENTS

C. Gonen[1,*], D. Kurtulus[2], K. Kochan[1], A. Yesil[1]
[1]*Gastroenterology, Istanbul Haydarpasa Numune Training and Research Hospital,* [2]*Physical Therapy and Rehabilitation, Umraniye Training and Research Hospital, Istanbul, Turkey*
Contact E-mail Address: *drcgnn@yahoo.com*

INTRODUCTION: Axial arthropathy associated with inflammatory bowel diseases (IBD) includes isolated sacroiliitis, inflammatory back pain and ankylosing spondylitis. There is no reliable laboratory test that can be used as a diagnostic tool in the management or diagnosis of axial arthropathy in IBD. Neutrophil gelatinase associated lipocalin (NGAL) is a recently identified molecule, which has tissue destructive effects by protecting matrix metalloproteinase-9 from autodegradation. This represents an important mechanism by which NGAL may contribute to the degradation and remodelling of the extracellular matrix, leading to rheumatologic manifestations of IBD. Previously, we showed that serum NGAL levels in IBD patients were significantly higher than healthy controls.

AIMS & METHODS: To investigate serum NGAL levels in IBD patients with or without axial arthropathy. A total of 83 patients (64 with IBD, 19 with IBD and axial arthropathy), and 40 age- and sex-matched healthy controls (HC) were included in this study. Patients with peripheral joint involvement were excluded. Serum NGAL levels were measured using ELISA.

RESULTS: The patients were aged between 16 and 74 years, and their mean age was 39.1 ± 11.5 years. Age, gender, and disease-year distributions were not statistically significantly different among the groups. Serum NGAL levels were elevated significantly in IBD patients with axial artropathy [median 234 U/L, range (122-312) ng/ml] compared to IBD patients without axial involvement [168 U/L (57-310 ng/ml] (p:0.001) and HC group [122 (45-234) ng/ml] (p:0.004). NGAL levels of the IBD group were significantly higher than those of the control group (p:0.001). There was no significant difference between the IBD group and IBD with axial involvement group in Hgb, WBC, CRP, and ESR values.

CONCLUSION: Serum NGAL levels were found to be elevated in IBD patients with axial involvement when compared to IBD patients without involvement, suggesting a partial pathophysiologic role in this particular extraintestinal manifestation. NGAL seems to be a promising biomarker for the diagnosis and management of axial arthropathy in IBD.

P0296 ANORECTAL STRICTURE IN CROHN'S DISEASE: NATURAL FATE OR CHALLENGING TARGET TO TREAT?

C. Brochard[1,*], L. Siproudhis[1], T. Wallenhorst[1], P.N. D'Halluin[1], J.F. Bretagne[1], G. Bouguen[1]
[1]*Service des maladies de l'appareil digestif, Rennes, France*
Contact E-mail Address: *charlene.brochard@chu-rennes.fr*

INTRODUCTION: The natural history of non-fistulising perianal Crohn's disease (PCD) remains unknown.

AIMS & METHODS: This study aimed to assess the long-term outcome of anorectal strictures. Between January 2005 and October 2013, a tertiary referral centre prospectively recorded each clinic of patients with PCD with detailed data about the phenotype and disease activity of luminal and anal CD, medical treatment and surgery. At each visit, CD and PCD were assessed using the Harvey-Bradshaw Score, the Cardiff-Hughes classification and with the Perianal Disease Activity Index. Follow-up was determined by the duration between the diagnosis of anorectal stricture and the last visit. Cumulative incidence of stricture healing (disappearance of the anal stricture) was estimated using a Kaplan-Meier method

and factor associated with an unfavourable course (persistent stricture S2, persistent stoma or proctectomy) with non-parametric test.
RESULTS: A total of 102 patients (M/F: 37/65) were included. The duration of CD at diagnosis was 8.9 years. After a median follow-up period of 2.8 years, 52 of the 88 followed patients (59%) achieved anorectal stricture healing. Two patients (2%) developed anal adenocarcinoma. Female gender (HR 2.05 [1.1-4.03], p = 0.0221), disease duration of CD of less than 10 years (HR 1.94 [1.01-3.63], p = 0.0271), and anal fistula at stricture diagnosis (HR 2.36 [1.21-5.05], p = 0.0106) were significantly associated with anorectal stricture healing in a multivariate analysis model. Twenty-eight patients (32%) had an unfavourable course at the end of follow-up. Gender and introduction or optimisation of TNFα antagonist treatment decreased the risk of unfavourable course in multivariate analysis. Conversely, the Luminal B2 phenotype at CD diagnosis was the only factor associated with unfavourable course.
CONCLUSION: Anorectal stricture does not imply a non-reversible and complicated condition related to severe perianal Crohn's disease. However, both diagnosis of cancer and sepsis drainage remain challenging in this situation.

P0297 REDUCING UNNECESSARY COLONOSCOPY – A COST MINIMIZATION ANALYSIS OF NEW DIAGNOSTIC STRATEGIES FOR EXCLUDING ORGANIC BOWEL DISEASE IN PRIMARY CARE PATIENTS

C. Helsper[1,*], L. Kok[1], S.G. Elias[1], H.E. Koffijberg[1], K.G. Moons[1], N.J. de Wit[1]
[1]*Julius Center for Health Sciences and Primary Care, UNIVERSITY MEDICAL CENTER UTRECHT, Utrecht, Netherlands*
Contact E-mail Address: *c.helsper@gmail.com*

INTRODUCTION: In general practice, complaints of the lower digestive tract are frequently presented. Of those affected, only an estimated 7% suffers from organic bowel disease (OBD), such as inflammatory bowel disease, diverticulitis and cancer. [1] These patients should be referred for colonoscopy without delay. Unfortunately, OBD is found in only one third of referred patients, indicating a considerable number of unnecessary referrals in primary care.[2] Our research group developed several diagnostic strategies to optimize colonoscopy referral policy.
AIMS & METHODS: We aim to assess the benefits and costs of the diagnostic strategies developed to reduce unnecessary colonoscopy referrals in primary care. The diagnostic strategies combine patient history and physical examination with two point of care tests (POCT); calprotectine and/or iFOBT. We evaluated the benefits and costs of three diagnostic strategies, each at three cut-off points. Strategies are: 1. iFOBT added to history and physical examination (iFOBT), 2. calprotectine added (Calpro), and 3. both POCT added (CiF). The three different cut-off points are based on OBD risk for referral. Benefits are prevented costs and prevented unnecessary referrals for colonoscopy. Costs are additional costs and missed diagnoses.
RESULTS: A reduction of 0.5% (iFOBT), 5.4% (Calpro) and 5.9% (CiF) in the number of colonoscopies cover the additional testing costs. The largest cost-savings are achieved by iFOBT and CiF. At the 2.5% cut-off, these strategies provide a modest cost reduction (1.3 and 0.2mln Euros, respectively) with 84 (2%) and 0 (0%) patients incorrectly not referred for colonoscopy annually in the Netherlands. At a referral threshold of 5% OBD probability, a cost reduction of €5.8 (iFOBT), €2.3 million (Calpro) and €4.7(CiF), Euros would be achieved at an annual cost of 720 (4%), 720 (4%) and 306 (3%) incorrectly averted referrals in the Netherlands, respectively. Cost reduction for all strategies even increased at 7.5% OBD risk, but this threshold yielded much higher incorrectly referred patients for all three strategies, above 1000 patients annually in the Netherlands.
CONCLUSION: Implementation of the diagnostic strategies as developed in the CEDAR study are likely to reduce the colonoscopy related costs at a burden of incorrectly averted referrals for colonoscopy. Implementation of the CiF and iFOBT strategies at the lowest threshold value for referral, is likely to be safe and modestly cost-saving. The CiF and iFOBT strategy at the 5% OBD probability threshold, might also be a valuable alternative in current practice given the substantial costs savings and relative safety. The most appropriate threshold and the resulting cost savings needs to be determined for the health care setting in which it will be used.

INTRODUCTION: Crohn's disease (CD) and Ileocolonic Tuberculosis (ITB) mimic each other in clinical, endoscopic and histologic features. In an ITB endemic country like India differentiating one from the other remains a challenge.
AIMS & METHODS: The aim of our study was to revalidate the existing clinical, laboratory and histological parameters that aid in differentiating Ileocolonic Tuberculosis from Crohn's disease.
Methods: We prospectively included patients with Ileocolonic ulcers. Patients were diagnosed as either ITB or CD based on established criteria. All patients were evaluated for Extra Intestinal Tuberculosis. Patients were followed up and a repeat colonoscopy was performed at 3 months and at of 6 months of treatment; diagnosis was revised if the patient did not demonstrate mucosal healing when compared to the previous colonoscopy. Patients who completed follow up were included in final analysis.
RESULTS: Sixty patients were included in the study of which fifty-five patients completed follow up and were included in the analysis. A final diagnosis of CD was made in 37 patients (67%), ITB in 18 patients (33%). Differentiating features of ITB and Crohn's are summarised in table -1. Quantiferon TB Gold in Tube test was positive in 94.4% of ITB patients versus 19.3% of Crohn's disease patients (P- <0.001). The Sensitivity, Specificity, Positive predictive value, Negative predictive value for Quantiferon TB Gold in tube test was 94.44%, 83.78%, 73.91% and 96.88% respectively.

Variables	CD (n = 37)	TB (n = 18)	P value
Mean Age (in years)	32.5	45	0.1
Male/ Female	20/17	8/10	0.7
Mean Duration of illness (Months)	13.6	8	***0.026***
Bleeding PR	7 (18.9%)	0 (0)	***0.04***
Fever	4 (10.8%)	8 (44.4%)	***0.004***
TB QuantiferonGold in Tube			***<0.001***
Positive	6	17	
Negative	31	1	
Granuloma Characteristics			
Caseation	0 (0)	5 (28%)	
Large	5(13%)	12 (66.6%)	
Confluent	7 (19%)	13(72.2%)	
More than 5 granulomas/hpf	8 (21%)	10 (55.5)	
Band of epitheloid Histiocytes	71(19%)	8 (44.4%)	
Lymphoid cuff	19 (51%)	11 (61%)	
Pericryptal	21(56.7%)	3 (16.7%)	
Microgranulomas	30 (81.1%)	3 (16.7%)	
Focally enhanced colitis	15 (40.5%)	2 (11.1%)	
Histology abnormal in endoscopically normal sites	23 (60.5%)	1(5%)	

CONCLUSION: Longer duration of illness, bleeding per rectum, pericryptal granuloma's, microgranuloma's, focally enhanced Colitis, histological changes in antrum and histological abnormality in endoscopically normal sites favored Crohn's disease. Presence of fever, large granulomas, caseating granulomas, confluent granulomas, favored ITB. Quantiferon TB Gold in Tube test had good sensitivity but poor specificity in differentiating ITB from Crohn's disease.

INTRODUCTION: Serologic nuclear and anti microbial antibodies have been recognized as predictive markers of disease course and complications in ulcerative colitis (UC) and Crohńs disease (CD). The stability of serologic titers over time of these markers has been questioned.
AIMS & METHODS: The aim of the present study was to compare antibody titers before and after treatment in newly diagnosed treatment naive pediatric patients with inflammatory bowel disease (IBD). Patients aged <18 years, (N = 57) diagnosed with IBD were included between 2005-2007 and followed prospectively. Blood specimens were analyzed for antibodies (Prometheus labs, San Diego) at diagnosis, and repeatedly after 1-2 years of treatment.
RESULTS: Among the 19 UC patients 68% were ANCA-positive versus 32% of the 38 CD patients (p = 0.02). In CD and UC patients respectively, the median titers in EU/ml at baseline against I2, 249 and 257, Anti-Omp C, 3.1 and 3.6, ASCA IgA, 8.4 and 3.1, ASCA IgG, 11.9 and 3.1 and CBir, 27 and 16, were not significantly different at follow- up. The titers against ASCA IgA and IgG were significantly higher in the CD patients versus UC patients both at diagnosis and at follow-up (p = 0.01 and p < 0.01, respectively) with post-treatment ASCA IgA 7.5 and ASCA IgG 12.8 in CD versus 3.1 and 6 in UC respectively (p < 0.01 and 0.03). There were no statistically significant differences for gender, or between the different treatments of CD patients, in whom 18 of 38 patients had received infliximab.
CONCLUSION: UC patients were significantly more frequently ANCA positive, whereas the CD patients had significantly higher titers against ASCA IgA and IgG both at diagnosis and at follow-up. The present study demonstrates a general reproducibility of the presence and titers of serologic antibodies from the

time of diagnosis until 1-2 years of follow- up for IBD, indicating that serologic markers measured at diagnosis may be applied as prognostic markers even after years of treatment.

INTRODUCTION: Crohn's disease (CD) is a relapsing inflammatory disease. Many patients experience intestinal strictures that require surgery if non amenable to medical therapy. Moreover, there is an unmet need to objectively assess new treatment endpoints such as disease modification, structural damage and restitution. Real time ultrasound elasticity imaging has not been systematically developed yet to evaluate the viscoelastic properties of the human gut in vivo.
AIMS & METHODS: In this prospective, controlled and partially blinded study unaffected and affected gut segments of 10 CD patients (male = 6, median age = 49, median Harvey Bradshaw index = 6) were examined pre-, intra- and postoperatively with ultrasound including real time elastography (RTE) to assess strain. Following surgical resection strain of full gut wall segments was analyzed by direct tensiometry. Histopathological scoring of fibrosis with two independent, specific stains, molecular quantification of collagen content as well as morphometrics were performed. Data were aggregated at patient level and non-aggregated at segment level prior to statistical analysis including a non-linear model where appropriate.
RESULTS: RTE strain was significantly different between unaffected and affected segments (mean ± SD 169.0 ± 27.9 vs. 43.0 ± 25.9; $p<0.001$). Moreover, mean RTE strain per patient was completely different in unaffected (all > 132) compared with affected (all < 87) segments. An RTE strain cut point of 110 reliably distinguished segments. Tensiometry strain in segments with an RTE strain of >110 was significantly greater than in those with < 110 (mean ± SD 77.1 ± 21.4 vs. 12.9 ± 9.5; $p<0.001$). These findings were further corroborated by morphometrics, collagen content and fibrosis score.
CONCLUSION: RTE allows bedside assessment of gut tissue mechanical properties in CD.

INTRODUCTION: The correlation between clinical activity and intestinal inflammation in Crohn's Disease (CD) is modest. Biomarkers and imaging techniques are objective tools able to assess the biological activity.
AIMS & METHODS: Our aim was to objectively evaluate disease activity in patients in clinical remission (CR) with small bowel CD (SBCD) by using capsule endoscopy (CE), magnetic resonance enterography (MRE) and correlate the findings with laboratory parameters of inflammation.
Thirty-five consecutive patients with known SBCD in CR were prospectively recruited and underwent MRE, followed by Agile patency capsule (PC), and if patency was proven, a video capsule. The Lewis score was calculated for each tertile. C-reactive protein (CRP) and fecal calprotectin (FC) were evaluated for their association with clinical activity, MRE and CE findings.
RESULTS: Eight of 35 cases with abnormal passage of PC were excluded, all of which were predicted by MRE (NPV 100%). All video capsules reached the cecum, including 9 additional cases predicted to be retained by MRE which proved to be false positives (53%) by the PC. CE detected active disease in the proximal-mid SB in 44% of the patients and in the distal SB in 48%. MRE detected proximal-mid SB disease in only 18% and distal disease in 67% of patients. Most (81%) of patients with SB lesions detected by CE had elevated FC (cutoff, 30μg/g) while CRP (cutoff, 5mg/l) was increased in 19% of these patients. FC modestly correlated with Lewis score ($r=0.4$). There was no correlation between CRP and Lewis score. Similarly, 78% of patients with active disease on MRE had increased FC, while CRP was elevated in 22% of the patients.
CONCLUSION: 1. A PC prior to the CE procedure diminished the likelihood of CE retention, and was superior to MRE in prediction of capsule retention. 2. Despite CR active inflammation was detected in > 50% of patients by CE. 3. Proximal SB disease was better detected by CE than MRE. 4. FC associated better than CRP with disease activity found by CE or MRE. 5. When used properly, CE is a safe procedure in patients with SBCD.

INTRODUCTION: There is a lack of studies having systematically assessed in a large cohort of patients with ulcerative colitis (UC) the disease location over time as well as risk factors associated with progression or regression of disease extent.
AIMS & METHODS: We aimed to assess disease location over time and to evaluate associated risk factors. Data from the Swiss IBD cohort study were analyzed. Patients were recruited from university centers (68%), regional hospitals (14%), and private practices (18%). Disease locations over time were analyzed and risk factor analysis for a change in disease location was performed using logistic regression modeling. Non parametric data are illustrated as median and interquartile range [IQR].
RESULTS: A total of 1,016 UC patients (45.6% females, median age at diagnosis 31 [23.3-40.5] years) were included. At diagnosis, UC patients presented with the following disease locations: 199 (19.6%) proctitis, 338 (33.3%) left sided colitis, 381 (37.5%) extensive colitis/pancolitis, and 98 (9.6%) unknown. During a median of 9 [5-16] years disease duration, a disease progression was documented in 145/1016 (14.3%) of patients, a regression in 176/1016 (17.3%) of patients, whereas 624/1016 (61.4%) of patients had a stable disease location (7% of patients with unknown evolution of disease location over time). Logistic regression modeling identified the following factors associated with disease progression in UC patients presenting with proctitis or left-sided UC at diagnosis: treatment with systemic steroids (OR 2.077, 95% > CI 1.359-3.174, $p=0.001$), treatment with immunomodulators (azathioprine, 6-MP, methotrexate) (OR 1.647, 95% > CI 1.119-2.424, $p=0.011$), treatment with TNF-antagonist(s) (OR 1.668, 95% > CI 1.077-2.581, $p=0.022$), and treatment with calcineurin-inhibitors (OR 3.159, 95% > CI 1.679-5.943, $p < 0.001$). Neither gender, age at UC diagnosis, body mass index, presence of extraintestinal manifestations, smoking status at diagnosis, positive UC family history, nor 5-ASA treatment were associated with disease progression. No specific factors were found to be associated with regression in UC patients with extensive colitis/pancolitis or left-sided colitis at diagnosis.
CONCLUSION: Over a median of 9 years disease duration about two-thirds of UC patients maintained the initial disease location whereas one-third either had a progression or a regression of the initial disease location. Treatment with systemic steroids, immunomodulators, TNF-antagonists, or calcineurin-inhibitors was significantly associated with disease progression.

INTRODUCTION: Psoriasis has been associated with Inflammatory Bowel Disease (IBD). However, whether IBD is associated with specific phenotypes of psoriasis is unknown.
AIMS & METHODS: In a case-control prospective study, we aimed to assess psoriasis phenotype in IBD patients (pts), when using a non-IBD patients population as controls (non-IBD C). From January 2011 to November 2013, dermatological assessment was performed in 251 IBD pts under follow up. Dermatological assessment was focused in detecting the presence of psoriasis (present/absent) and in defining its characteristics (localization, phenotype), including severity (mild/moderate/severe). In order to define psoriasis phenotype in IBD, each IBD pt with psoriasis was matched for gender, ethnicity and age (±5 years) with one non-IBD pt with psoriasis, referring to the same centre. Data were expressed as median (range) and differences between groups assessed by the T test or the chi-squared test, as appropriate.
RESULTS: Dermatological assessment was performed in 251 IBD pts (115 F, age 46 yrs, range 16-85; IBD duration 9 yrs, range 1-46): 93 UC (42 M, age 50, range 22-85; UC duration 7 yrs, range 1-41; UC extent: proctitis 33, left 13, extensive 42, ileal pouch 3, ileostomy 1, ileo-rectal anastomosis 1) and 158 CD (91 M, age 43, range 16-80; CD duration 10 yrs, range 1-46; CD colitis 13, ileocolitis 32, ileitis 51, neo-terminal ileum 56, ileostomy 2, distal ileum + jejunum 4). Non-IBD C included 62 pts (35 M, age 47, range 18-75). Among the 251 IBD pts, psoriasis was detected in 62 (25%; 36 CD, 26 UC). In the IBD group, the median age and IBD duration were comparable in pts with or without psoriasis (years:

age 50 range 23-72 *vs* 47 range 16-85; IBD duration 9.5, range 1-46 *vs* 9, range 1-41; p = ns for both). Mild plaque type psoriasis was detected in a higher proportion of IBD pts (52/62; 84%) than non-IBD C (33/62; 53%; p < 0.001). Scalp psoriasis and sebopsoriasis were the more common psoriasis phenotype in IBD (21/62; 84%), followed by palmo-plantar psoriasis (9/62; 14%) and by inverse psoriasis (8/62; 13%). Psoriatic arthritis was detected in 10/62 (16%) non-IBD-C and in 6/62(10%) IBD patients (p = n.s.). Among the 62 IBD pts with psoriasis, psoriasis developed after anti-TNFs in 6 (10%), including palmo-plantar (n = 4), sebopsoriasis (n = 1), inverse psoriasis (n = 1).
CONCLUSION: Results from a cohort of IBD patients matched with non-IBD control patients suggest that specific phenotypes of psoriasis may be associated with IBD.

INTRODUCTION: Crohn's disease (CD) is associated with penetrating complications such as phlegmons and intra-abdominal abscesses. As the management of the patients is influenced by the presence of such complications, a readily available tool for the diagnosis of extramural complications in CD is needed. Preliminary findings suggest that the assessment of vascularity within intra-abdominal masses may distinguish between phlegmons and abscesses.
AIMS & METHODS: Aim of our study was to evaluate the use of contrast enhanced ultrasound (CEUS) to distinguish between phlegmons and intra-abdominal abscesses in CD patients as a point-of-care technique. From November 2011, consecutive patients with complicated CD were enrolled. Indications of patient assessments by CEUS were symptoms, signs and biochemical exams indicating penetrating behavior (abdominal pain, mass, fever, elevated CRP and leukocytosis). A total of 22 CD pts (14 M; median age 27 yrs, range 18-75; disease duration: median 54 mos, range 1-564; CD site: ileal in 13 pts, ileocolonic in 9 pts; CD behavior: penetrating in 20 pts, stricturing in 2 pts; previous ileocolonic resection in 9 pts) were included. Clinical evaluation by an IBD expert and other cross sectional imaging techniques (MR and CT) were considered as the standard.
RESULTS: CEUS detected abscesses in 9 and phlegmons in 12 pts. One patient had an unspecified lesion that was diagnosed as metastasis by PET. Six out of 9 abscesses were confirmed by CT-Enteroclysis and these pts underwent surgery during the follow up. The remaining 3 pts with abscesses were treated with antibiotics and are still in follow up (17.5 mos). In the phlegmon group, 4 out of 12 patients were evaluated by CT or MRI that confirmed CEUS findings in 3 cases but in one patient a deep abscess was identified and surgery was scheduled. Eight out of 12 pts were clinically followed up (median: 16 mos). Two of these patients developed an abscess after one week from CEUS despite medical treatment. Overall CEUS correctly identified 19 out of 22 lesions (86%) on the basis of cross sectional imaging modalities and clinical follow up used as final diagnosis.
CONCLUSION: CEUS is a non-invasive, radiation-free and point-of-care technique able to differentiate phlegmons from abscesses driving a prompt clinical management in complicated CD patients.

INTRODUCTION: Small intestine contrast ultrasonography (SICUS) can detect intestinal damage in patients with Crohn's disease (CD).
AIMS & METHODS: We evaluated the diagnostic accuracy of SICUS in determining the site, extent, and complications of CD, compared with magnetic resonance (MR)-enterography as the standard. We performed a retrospective analysis of 59 patients with CD [(M = 34; median age: 46, CD site: ileal 36 (61%), ileocolonic 18 (30%), jejuno-ileal, 3 (5%), colonic 1 (2%); behaviour: non-stricturing non-penetrating 10 (17%), structuring 31 (53%), penetrating 18 (30%); previous surgery 25 (42%)] evaluated by SICUS and MR-enterography 3 months apart, between January 2011 and March 2014. We evaluated disease site (based on bowel wall thickness), extent of lesions, presence of complications (stenosis, prestenotic dilation, abscess, or fistulas) using MR-Enterography as the standard. Sensitivity, specificity, and diagnostic accuracy were calculated. We determined the correlations in maximum wall thickness and disease extent in the small bowel between results from SICUS and MR-Enterography.
RESULTS: SICUS identified the site of small bowel CD with 96% sensitivity, 71% specificity, and 93% diagnostic accuracy; it identified the site of colon CD with 73% sensitivity, 93% specificity, and 88% diagnostic accuracy. Results from SICUS and MR-enterography correlated in determination of bowel wall thickness (rho = 0.51) and disease extent (rho = 0.75; P < .0001 for both). SICUS detected ileal stenosis with 90% sensitivity, 94% specificity, and 91.5% diagnostic accuracy, and pre-stenotic dilation with 66% sensitivity, 83% specificity, and 73% diagnostic accuracy. SICUS detected abscesses with 75% sensitivity, 100% specificity, 98% diagnostic accuracy, and fistulas with 82% sensitivity, 81% specificity, and 81% diagnostic accuracy.
CONCLUSION: SICUS identified lesions and complications in CD patients with high levels of sensitivity, specificity, and accuracy compared to MR-enterography. SICUS might be used as an imaging tool as part of a focused diagnostic and follow up examination of patients with CD.

Contact E-mail Address: *EZittan@mtsinai.on.ca*

INTRODUCTION: The current approach to managing loss of response to anti-TNF agents is based on clinical symptoms and empirically increasing the dose or shortening the treatment interval as opposed to tailoring the drug concentrations in individual patients. The primary objective of this study was to evaluate adalimumab drug levels (ADL) and antibodies to adalimumab (ATA) in relation to disease activity.
AIMS & METHODS: A cohort of 61 patients with Crohn's disease (CD) treated with adalimumab between 2005-2013 were recruited to the study. Demographic and clinical information was obtained from chart reviews and patient interview. Disease activity was determined by Harvey-Bradshaw Index (HBI), ileocolonoscopy reports, and CRP levels. Clinical remission was defined by HBI≤4. Mucosal healing was defined by the disappearance of all ulceration in all ileocolonic segments. ADL and ATA were tested using a liquid phase assay. ATA ≤ 1 U/mL were considered low titer.
RESULTS: 61 CD patients were included in the analysis. 39 of the patients were previously on infliximab. 37 were on doses of adalimumab greater than 40mg every other week. 18 of the patients were on concomitant immunosuppressant therapy (methotrexate or azathioprine). 40 of the patients were in clinical remission. 11 (18%) subjects exhibited elevated ATA titers (>1 U/mL). 14 had any detectable ATA (> 0 U/mL). ADL levels were significantly higher in patients with low ATA compared to those with elevated ATA titers (p = 0.001). ADL levels were not associated with CRP levels or with clinical remission (p = 0.07 and p = 0.93, respectively. However, high median ADL drug level (≥5.8 μg/mL) was associated with complete mucosal healing (p = 0.017).
CONCLUSION: Adalimumab levels are not significantly associated with clinical remission or CRP levels in Crohn's disease patients. However, high adalimumab drug levels were associated with complete mucosal healing. Further evaluation with larger, prospective studies is required to further assess the important of drug level monitoring in this setting, however, this study suggests that achieving adequate adalimumab levels may be important toward realizing the goal of mucosal healing. Our results also demonstrate the importance of using endoscopic assessment rather than clinical or laboratory assessments to assess therapy response.

INTRODUCTION: Faecal calprotectin (CALf) is fairly correlated with clinical and endoscopic activity in ulcerative colitis (UC), and it has also been demonstrated to be a good predictor of relapse. However, the routine use of CALf measurement is constrained by the need for the patient to carry stool samples, as well as handling and processing them in the laboratory. The availability of hand held, single-use devices for CALf measurement that could be performed by the patient himself, might spread the use of CALf in clinical practice.
AIMS & METHODS: Aim: To evaluate the usefulness of a rapid semi-quantitative test of CALf in predicting relapse in patients with UC in remission.
Patients and Methods: A prospective, multicentre study that included patients with left-sided or extensive UC in clinical remission for ≥6 months on maintenance treatment with mesalazine. At baseline and every 3 months, patients were evaluated clinically and semi-quantitative CALf was measured using a monoclonal immunochromatography rapid test (*PreventID Caldetect*™, Immunodiagnostic AG, Germany) without manipulation of stools or laboratory analysis, until relapse or 12 months of follow-up.
RESULTS: At least one determination of CALf with clinical follow-up was available in 192 out 206 patients initially included in the study. 55% with extensive UC, 62% required corticosteroids in the past, and 88% were non-smokers. From a total of 695 measurements of CALf, 81 (12%) were above the upper

threshold of normality of the test (>60 μg/g) and 57 (8%) had limiting values (15-60 μg/g). During follow-up, 32 relapses (17% of patients) occurred. Having a CALf >60 μg/g was significantly associated with relapse at follow-up (35% *vs.* 12%, p<0.0001), with a PPV of 35% and a NPV of 88%. 644 CALf determinations with a three-month follow-up were available; undetectable CALf was significantly associated with absence of recurrence, with a PPV of 100% and a NPV of 93% (0% *vs.* 6%, p=0.002).

CONCLUSION: Rapid semi-quantitative measurement of CALf, with no need for laboratory analysis and faecal samples handling, may be useful for monitoring patients with UC in remission.

INTRODUCTION: The pathogenesis of inflammatory bowel disease (IBD) is still incompletely understood and patient-tailored therapy is an unmet need. Thus, biomarkers are needed to follow the course of disease; however, sensitive non-invasive markers to monitor the disease activity are still missing. Previously, we could demonstrate a significant increase of microRNA-320 (miR-320) expression in murine DSS-induced colitis. Aim of this study was to evaluate the potential of miR-320 to monitor the course of inflammation in immunological and bacterial driven experimental colitis as well as in IBD patients.

AIMS & METHODS: MiR-320 expression was assessed by qRT-PCR in murine colonic tissue after induction of T cell transfer colitis as well as *Salmonella* and *Citrobacter (C.) rodentium*-induced colitis. Additionally, miR-320 level was measured in human blood and stool samples from patients with Crohn's disease (CD; n=8) or Ulcerative colitis (UC, n=4) in remission or during acute flare and in healthy controls (n=11). Disease activity was assessed by Crohn's disease activity index (CDAI; active disease: CDAI>220; inactive disease: CDAI<150) in CD patients and the clinical activity index (CAI; active disease: CAI>4; inactive disease: CAI<3) in UC patients.

RESULTS: MiR-320 level in tissue samples from the transfercolitis was significantly increased in animals with severe colitis (>10% loss of body weight) as compared to controls (0.18±0.01 (colitis) vs. 0.11±0.03 (control);$P=0.05$) whereas there was no significant increase of miR-320 in samples from *C. rodentium*-induced colitis (0.6±0.3 (control) vs. 1.1±0.7 (colitis);$P=0.2$) and *Salmonella*-induced colitis (0.6±0.4 (control) vs. 0.06±0.02 (colitis);$P=0.3$). MiR-320 expression in blood of CD patients was significantly increased in acute flare (mean CDAI=231±7.2) as compared to remission (mean CDAI=97±33.9) and healthy controls (x-fold increase:435.4±152.7 (flare) vs. 70.1±28.7 (remission);$P=0.05$; vs. 24.6±8.8 (control);$P<0.001$). Moreover, miR-320 level of controls was significantly lower as compared to CD patients in remission ($P=0.01$). Furthermore, miR-320 expression in blood as well as stool from CD patients revealed a strong correlation with the CDAI ($r^2=0.78$ (blood);$r^2=0.81$ (stool)). In UC patients, miR-320 expression in blood obtained during acute flare (mean CAI=6) or quiescent disease (mean CAI=1.5) also revealed a significant increase of miR-320 expression as compared to healthy controls (182.15±111.4 vs. 24.6±8.8;$P=0.03$). As opposed to CD, miR-320 level in blood from UC patients was not significantly increased in acute flare as compared to quiescent disease. However, miR-320 expression in stool from UC patients was significantly enhanced in acute flare as compared to quiescent disease (225.35±35.4 (flare) vs. 68.5±40.6 (remission);$P=0.02$) showing a strong correlation with the CAI ($r^2=0.68$).

CONCLUSION: Our preliminary results indicate that miR-320 expression is increased in classical IBD models but not significantly altered in bacterial-induced colitis. Furthermore, miR-320 expression in human blood and stool samples follows the course of disease activity in IBD patients. Future studies are needed to elucidate the potential of miR-320 to predict relapse and disabling courses of disease.

P0309 THE APPROPRIATENESS OF TESTING AND INTERPRETATION OF ANTI-TNF DRUG AND ANTIBODY CONCENTRATIONS: WHEN SHOULD THEY BE ORDERED, AND WHAT TO DO WITH THE RESULTS?

G.Y. Melmed[1,2], **P.M. Irving**[1,*], G.G. Kaplan[1], B. Bressler[1], J. Jones[1], P.L. Kozuch[1], M.P. Sparrow[1], F.S. Velayos[1], L. Baidoo[1], A.S. Cheifetz[1], S.M. Devlin[1], L.E. Raffals[1], N. Vande Casteele[3], D.R. Mould[4], M.C. Dubinsky[2], J.-F. Colombel[5], W.J. Sandborn[3], C.A. Siegel[1] on behalf of BRIDGe (Building Research in IBD Globally)

INTRODUCTION: The availability of drug concentration and antibody testing for anti-TNF therapy promises optimized drug dosing and informed decision-making for patients with inflammatory bowel disease (IBD) treated with these agents. However, there is no consensus on when to test and how to interpret the results for various clinical scenarios. We applied the RAND/UCLA Appropriateness Method toward establishing the appropriateness of when these tests should be obtained, and how to act upon their results.

AIMS & METHODS: A comprehensive literature review was conducted on the topic of drug concentration and anti-drug antibodies in patients with IBD for all approved anti-TNF therapies. This review was presented to an expert panel including clinician and pharmacokinetic experts who have published on the topic, and the Building Research in Inflammatory Bowel Disease Globally group, a globally diverse panel of 13 gastroenterologists clinically experienced in IBD treatment and therapeutic drug monitoring. A total of 35 scenarios assessed the appropriateness of obtaining these tests, and 143 additional scenarios addressed the appropriateness of various clinical strategies in response to test results. Panelists used a modified Delphi method to rate each scenario through a web-based survey, and then met in-person to discuss and anonymously re-rate appropriateness on a 1-9 scale (1-3 inappropriate, 4-6 uncertain, 7-9 appropriate). Disagreement was assessed using a validated index.

RESULTS: Assessment of anti-TNF drug and antibody concentrations was rated appropriate at the end of induction therapy in primary nonresponders, in secondary nonresponders, at least once during the first year of therapy, in patients experiencing immune-related side effects, and when restarting a drug following a drug holiday (before 2nd infusion). Routine assessment in responders at the end of induction was rated uncertain. Panelists rated the appropriateness of various clinical management options including changing therapy within-class, switching out of class, adjusting drug dose/interval, adding/adjusting concomitant immunomodulators, and "doing nothing" for each of 6 permutations of high/low drug concentration and high/low/undetectable antibody concentrations. These ratings were highly dependent on the specific clinical scenario for which the test was obtained. For example, switching out of class when drug and high antibody concentrations were detected was "appropriate" at the end of induction in nonresponders, "uncertain" at the end of induction in responders, and "inappropriate" during maintenance in responders.

CONCLUSION: The appropriate timing and how to respond to anti-TNF drug and antibody testing for IBD was determined through a modified Delphi panel based on expert interpretation of the literature. The time to test and clinical action on the results is dependent on the specific clinical scenario. These recommendations can help guide clinicians to best optimize anti-TNF therapy.

P0310 IBD RECURRENCE AFTER STOPPING ANTI-TNF-ALPHA THERAPY: A PROSPECTIVE RANDOMIZED CONTROLLED STUDY COMPARING MESALAMINE AND AZATHIOPRINE – AD INTERIM RESULTS

G. Bodini[1,*], V. Savarino[1], P. Dulbecco[1], I. Baldissarro[1], E. Savarino[1]

Contact E-mail Address: *bodini.giorgia@gmail.com*

INTRODUCTION: The advent of tumor necrosis factor (TNF) antagonists has dramatically changed the management of patients with inflammatory bowel diseases (IBD). However, despite more than a decade of clinical experience, there is still debate about the optimal exit strategies from biologic therapies. Indeed, an important issue concerns how to manage patients with long-standing remission after stopping anti-TNF-α drugs. Data on different maintenance strategies are lacking.

AIMS & METHODS: We aimed to assess the efficacy of mesalamine (MESA) vs. azathioprine (AZA) as maintenance therapy in IBD patients who withdrew biological therapy after obtaining deep remission (i.e. clinical remission, biomarker remission and mucosal healing). Consecutive IBD patients who achieved deep remission due to anti-TNF-α therapies withdrew them and were prospectively randomized to two different maintenance treatments: MESA 2.4 gr/die in ulcerative colitis (UC) and 3 gr/die in Crohn's Disease (CD) patients or AZA 2.5 mg/kg/die. Then, patients were followed up every two months or before in case of relapse, by means of routine biochemistry, clinical examination and endoscopy at 1-year or before in case of relapse. The Harvey-Bradshaw Index (HBI; remission <5) and Mayo score (remission <3) was used to evaluate clinical activity for CD and UC, respectively, whereas endoscopy activity was assessed by means of Mayo endoscopic score (endoscopic remission <2) or CD endoscopic index (CDEIS; endoscopic remission <3).

RESULTS: We prospectively enrolled 16 patients with IBD [6UC/10CD; 8F/8M; median age 44 (25-57)] who were followed-up for a median period of 48 (20-78) weeks after achieving deep remission due to anti-TNF-α therapy. Ten patients [2UC/8CD; 5F/5M; median age 37.5 (25-53)] were randomized to MESA 2.4 gr/die or 3gr/die and 6 patients [1UC/5CD; 3F/3M; median age 41.2 (21-47)] to

AZA 2.5 mg/kg/die. All AZA-treated patients (100%) kept in remission during the entire follow up period [median period of 55.5 weeks (20-76)], whereas 3/10 (30%) MESA-treated patients [1UC/2CD; 0F/3M; median age 42 (29-52)] experienced clinical relapse after a median period of 14 weeks (8-26). The latter three patients were shifted to AZA and clinical remission was restored.
CONCLUSION: Our preliminary data showed that AZA is more effective than MESA in maintaining clinical remission in IBD patients who stopped biological therapy after obtaining deep remission. Moreover, we observed that disease recurrence due to mesalamine failure occurs a few weeks after biologic withdrawal and can be successfully treated with AZA.

P0311 MRI AND CLINICAL ASSESSMENTS FOR PERIANAL CROHN'S DISEASE: GAIN AND LIMITS

A. GARROS[1], L. SIPROUDHIS[1], B. TCHOUNDJEU[1], T. ROHOU[2], C. BROCHARD[1], T. WALLENHORST[1], **G. BOUGUEN**[1,3,*]
[1]*Service des Maladies de l'Appareil Digestif,* [2]*Service de radiologie et imagerie médicale, CHU Pontchaillou,* [3]*INSERM U991, Université de Rennes 1, Rennes, France*

INTRODUCTION: Assessment of perianal Crohn's disease (PCD) remains challenging. ECCO guidelines recommended Magnetic resonance imaging (MRI) as a gold standard but both accuracy and advantage of MRI remain scarce as compared to systematic clinical assessment. The aim of the study was to define diagnosis values of both assessments.
AIMS & METHODS: Between January 2006 and April 2012, consecutive patients with PCD assessed by MRI and clinical exam were prospectively recorded. At each visit, perianal activity (Perianal Disease Activity Index) and perianal phenotype (Cardiff-Hughes classification) were notified. MRI analyses were independently reviewed and interpreted according to Cardiff-Hughes and Van Assche classifications.
RESULTS: Overall, 122 combined evaluations were assessed in 70 different patients. MRI failed to show superficial ulcerations in 20 of 21 patients as well as severe ulcerations in 13 of 15 patients. MRI constantly failed to diagnose anal stenosis (n = 21). According to fistulizing lesions, the global agreement between clinic and MRI was 60% to assess complex fistula. Clinical assessment underestimated 52% of multiple or ramified fistula tracts. Clinical exam (including induration) failed to diagnose half abscesses described on MRI.
Table. Overall value of clinical or MRI assessment for each items

Items		test	G-S	Se	Sp	Youden Index**	Pos LR	Neg LR	C
Ulceration		MRI	Clinic	0.08	0.94	0.02	1.33	0.98	0.68
Stenosis				0	1	0	-	1	0.83
Fistula	Cardiff*	Clinic	MRI	0.94	0.15	0.09	1.12	0.40	0.58
	Induration			0.4	0.86	0.26	2.86	0.70	0.28
	Abscess			0.14	1	0.14	-	0.86	0.70

CONCLUSION: ECCO guidelines for assessment of PCD should be applied with some caution because of the low sensitivity of MRI for the diagnosis of non-fistulizing PCD. Concomitant clinical and MRI assessments should be recommended.

INTRODUCTION: Ulcerative colitis (UC) is a chronic inflammatory bowel disease of unknown etiology(1), affecting patient's quality of life, and increases cancer colon. Its incidence and prevalence are growing all over the world (2). Its conventional therapy commonly fails to give satisfactory results and may cause serious side effects(3). So, new treatment is needed**.** In UC, both damaged intestinal tissue and the immune system need to be repaired. Only stem cells (SCs) can do this(4). Among adult SCs, adipose derived SCs can be easily obtained with less heterogeneity in their immunophenotype and multilineage differentiation ability than do bone marrow derived MSCs(5). Several papers had reported the efficacy of systemically infused MSCs in treating experimental UC, but some trapped in liver and lung, decreasing their effect in local injury site (colon) and increasing required dose(4). Meanwhile, some papers reported the use of MSCs on experimental external wounds and reported some efficacy(6).
AIMS & METHODS: Evaluate effectiveness of stem cell therapy through local enema & intravenous approaches. Induction of UC in sprague dawley (SD) rats by 5% dextran sulphate sodium (DSS). Isolation of MSCs from adipose tissue was done under sterile conditions. Cells were characterized using cell surface markers by fluorescence-activated cell sorting analyses. First group was control healthy group. Second group received 5% DSS for 7 days with no therapy. Third group received local $1x10^6$ ADMSCs enema. Fourth group received systemic iv $1x10^6$ ADMSCs. Disease activity index (DAI) was assessed daily. On day 7 colon was examined macroscopically & microscopically.
RESULTS: All groups received DSS had DAI higher than healthy control group with statistically significant difference ($p < 0.05$). Both groups receiving stem cells showed less DAI, macroscopic & microscopic score than control diseased group ($p < 0.05$). Local enema group and systemic iv groups had no statistically significant difference in DAI, macroscopic nor microscopic scores.
CONCLUSION: Stem cell therapy via enema is a potential future therapy with expected low side effects than systemic route for treating UC.

Contact E-mail Address: *akter.hossain@karolinska.se*

INTRODUCTION: Infliximab is effective in inducing remission in inflammatory bowel disease and many patients are treated for several years with sustained clinical remission.
AIMS & METHODS: To evaluate the long-term outcome of maintenance infliximab (IFX) treatment in inflammatory bowel disease (IBD), regarding inflammatory activity, concomitant medication, quality of life (QoL) and whether reduced intestinal surgery could be observed after initiation of treatment. Patients with Crohn's disease or ulcerative colitis, responding to IFX treatment during one year and thereafter on continuous maintenance treatment, were eligible. Two hundred patients with Crohn's disease (CD; n: 164), or ulcerative colitis (UC; n: 36), were involved. Median age at diagnoses was 22 (3-64) years. Five mg /kg body weight IFX was usually administered every eight week. Inflammatory activity was assessed by Harvey Bradshaw index (HBI) in Crohn's disease. Concomitant medications were followed during the study period, and Short Health Scale (SHS), a validated short questionnaire, was used for measuring QoL. Hb, LPK, Albumin, CRP and calprotectin were monitored. Side effects and reasons for discontinuation were recorded. In this retrospective study the observation period ended in March 2014. Parameters and treatment duration were estimated by last observation carried forward.
RESULTS: Median disease duration at start of treatment was 5.0 (0.2 - 44) years. Median duration of IFX treatment was 3.4 (1.0-13.9) years. Table 1: Parameters of inflammatory activity before and after start of IFX treatment

	HBI (n:164)	CRP (n: 196)	Alb (n:199)	WBC (n:198)	Calprotectin (n:50)
Before	8.04	29.23	34.98	8.70	3135 (1872-6200)
After	2.76	8.45	37.28	7.54	158 (30-1503)
P-value	<0.0001	<0.0001	<0.0001	<0.0291	<0.0012

SHS (n:60) was significantly improved in all QoL dimensions. Steroid treatment and immunosuppression at start of IFX treatment were 51% and 62%, respectively. Corresponding figures at latest infusion were 10% and 43%. No opportunistic infection has been diagnosed. Ten infusion related moderate to severe side effects were observed, leading to treatment discontinuation. Loss of response occurred in 42 patients. Of those, 20 needed intestinal surgery. Twelve changed anti-TNF therapy, one patient received alternative biological treatment and 9 continued without biological treatment. Surgery before initiation of IFX therapy was necessary in 27% compared to 11% after treatment. Sixteen patients in remission decided to stop treatment and 13 of those are still in remission with only 4 on immunosuppression. One patient died several years after stopping treatment from lung cancer and the remaining 2 were restarted on anti-TNF. Twenty-four patients moved, while on therapy. Three patients were lost to follow up and two stopped treatment because of malignancies.
CONCLUSION: Almost three-quarters of the patients demonstrated clinical benefit from IFX treatment. Use of steroids was dramatically reduced with less influence on the use of immunosuppression. SHS showed significant improvement of QoL. During the studied time period, surgery was less frequent after initiation IFX treatment.

P0314 MEAN PLATELET VOLUME AND NEUTROPHIL-TO-LYMPHOCYTE RATIO AS NEW BIOMARKERS OF SUSTAINED RESPONSE TO INFLIXIMAB THERAPY IN CROHN'S DISEASE PATIENTS

A. Sobolewska[1,*], M. Włodarczyk[1], K. Stec-Michalska[1], J. Fichna[2], M. Wiśniewska-Jarosińska[1]
[1]*Department of Gastroenterology,* [2]*Department of Biochemistry, Medical Univeristy of Lodz, Łódź, Poland*
Contact E-mail Address: *dr.mwlodarczyk@gmail.com*

INTRODUCTION: The loss of response to infliximab (IFX) in Crohn's disease (CD) patients is currently an important clinical problem. Therefore, searching for predictors of maintenance or loss of response to anti-tumor necrosis factor-α (anti-TNF-α) agents has become the aim of current studies in the field. Recently, the neutrophil-lymphocyte ratio (NLR) and mean platelet volume (MPV) have been proposed as new biomarkers of subclinical inflammatory process. Here we hypothesized that NLR or MPV may be used as cost-effective biomarkers of subclinical inflammation during 52-week IFX therapy in CD patients responding to induction treatment.
AIMS & METHODS: The study aimed at establishing whether NLR or MPV at baseline and pre-infusion at week 14 are good predictors of sustained response after week 14 in CD patients undergoing 52-week IFX therapy. 30 adult patients with CD (11 women and 19 men; mean age±SD 32.0±8.6 years), who underwent a 52-week course of treatment with IFX and achieved response to induction treatment evaluated at week 14 were enrolled to the study. The control group consisted of 12 healthy subjects. The association between NLR or MPV, baseline disease parameters and maintained clinical response or remission during IFX therapy was assessed.
RESULTS: Fifteen of CD patients (50%) have not reached full one year maintenance IFX treatment without loss of response. The analysis showed a statistically significant higher NLR (4.62±2.43 vs. 1.49±0.76; $p<.001$) and lower MPV (10.25±0.99 vs. 11.29±1.08 fL; $p=.003$) in CD patients compared to controls. Higher NLR at baseline (5.85±2.71 vs. 3.39±1.28; $p=.003$) and at week 14 (4.79±2.61 vs. 2.58±1.23; $p=.006$) were observed in CD patients with loss of response to IFX maintenance treatment than in those with sustained response. NLR lower than 4.068 at baseline predicts sustained response with 80% sensitivity and 87% specificity. NLR lower than 3.667 at week 14 predicts sustained response with 67% sensitivity and 80% specificity. MPV at week 14 in CD patients with loss of response was significantly higher (11.31±1.16 fL vs. 10.19±0.52 fL; $p=.001$) than in CD patients with sustained response. In patients with sustained response to maintenance IFX treatment higher ΔMPV between baseline and week 14 was calculated (0.78±0.34 fL vs. 0.23±0.39 fL; $p<.001$). MPV higher than 10.3 fL at week 14 predicts sustained response with 67% sensitivity and 80% specificity. ΔMPV between baseline and week 14 higher than 0.4 fL predicts sustained response with 87% sensitivity and 93% specificity.
CONCLUSION: In CD patients with loss of response to IFX therapy higher NLR and lower MPV were observed. It can be suggested that NLR and MPV may serve as good predictors of sustained response to IFX maintenance treatment in CD patients as well as may allow selection of the most appropriate therapy based on the individual approach. Further studies are warranted to confirm our observations and to establish the cut-off points in a larger cohort.

INTRODUCTION: Infliximab (IFX) trough levels (TL) as well as c-max levels have been positively associated with its efficacy and negatively with IFX immunogenicity in patients with IBD. Clearance of IFX is increased in the presence of anti-drug antibodies (ADA). However, to what extent ADAs impact the binding and neutralization of soluble TNF-alpha *in vivo* remains largely unknown. In this study we assessed the relationship between IFX-, ADA- and TNF-alpha levels at a mid-infusion visit and at trough in patients with IBD on maintenance therapy.
AIMS & METHODS: Serum samples from 90 consecutive patients with IBD (Crohn's disease: $n=66$, ulcerative colitis: $n=24$) on IFX maintenance therapy were obtained at mid-infusion visits and at trough. IFX and ADA were measured by a homogeneous mobility shift assay from Prometheus, which allows detection of ADA in the presence of IFX. Serum TNF-α was measured by a Collaborative Enzyme Enhanced immuno-Reactive (CEER) Assay.
RESULTS: Patients had received a median number of 11 IFX infusions (range 3 - 71) with a median dose of 5.5 mg/kg (4.1- 10.9 mg/kg) before study entry. ADAs were detected in 18 pts at mid-infusion and in 21 pts at trough. In ADA positive pts median serum concentration of IFX was significantly lower than in ADA negative pts both at mid-infusion and at trough. Inversely, significantly higher serum concentrations of TNF-α were detectable in ADA positive pts at both visits (see Table). At trough the TNF-α/IFX ratio was significantly higher in ADA positive patients than in those without ADA ($p<0.0001$). No difference was seen in TNF-α levels when segregated by IFX serum levels alone.

	Mid-infusion			Trough		
	ADA neg. n = 69	ADA pos. n = 21	p-value	ADA neg. n = 69	ADA pos. n = 21	p-value
IFX (μg/ml) median (range)	13.59 (3.2-35.2)	0.75 (0.08-16.37)	<0.0001	6.36 (range)	0.42 (range)	<0.0001
TNF-α (pg/ml) median (range)	5.5 (range)	10.2 (range)	0.04	7.5 (range)	25.6 (range)	<0.0001

Interestingly, 3/10 (30%) ADA negative pts at mid-infusion with an IFX concentration below 8 μg/ml turned ADA positive at trough versus 1/36(3%) pts with an IFX concentration ≥8 μg/ml.
CONCLUSION: ADA detected in patients with IBD on IFX maintenance therapy impairs neutralization of soluble TNF-α and is associated with lower serum concentrations of IFX and higher levels of TNF-α both at mid-infusion and at trough. Our finding favours a strategy of a pre-emptive dose optimization in ADA positive patients due to insufficient control of inflammation.

P0316 INFORMATION NECESSARY TO PREDICT INDIVIDUAL INFLIXIMAB (IFX) PHARMACOKINETICS (PK) IN PATIENTS WITH IBD

A. Eser[1,*], H. Vogelsang[1], G. Novacek[1], S. Reinisch[1], C. Primas[1], C. Lichtenberger[1], S. Brehovsky[1], D. Mould[2], W. Reinisch[1]

INTRODUCTION: The increasing interest in monitoring serum IFX concentrations for purposes of therapeutic dose adjustment (TDA) has led to the availability of various assays whose validity remains to be determined. Only population-based approaches to determine individual IFX PK are used so far.
AIMS & METHODS: Objectives: 1) Evaluate the performance of 3 different IFX assays and 2) Determine how many samples are needed in order to estimate individual PK accurately and precisely.
Serum samples were collected after the 3rd IFX infusion for measurement of IFX and anti-drug antibodies (ADA) in 117 patients with IBD (87 = CD, 30 = UC). The mean IFX dose was 5.84 mg/kg for patients with a mean weight of 68.37 kg (ADA positive $n=19$, ADA negative $n=98$). For each patient, at least 2 samples from within the same infusion interval were available. 41 patients had >2 IFX concentrations. IFX serum concentrations were measured with ELISA assays provided by Theradiag (France) (TD) and Immundiagnostik (ID, Bensheim, Germany). IFX and ADA were also determined by a homogeneous mobility shift assay from Prometheus. Assay performance was evaluated by running a population PK model using Nonmem (version 7.2 Icon Dublin Ireland). Estimated clearance, between subject variability (BSV) and residual error were compared with literature values. Bayesian updating and forecasting was conducted using individual patient data and forecasting with different subsets of information for each subject. Initially, only subject demographics (age, weight, gender, albumin, ADA status and planned dose) were used. Forecast concentrations based only on this information were compared with the first observed concentration value. Subsequent evaluations included progressively more PK observations. Agreement between observed and forecast concentrations was evaluated graphically and via root mean square error (RMSE) and concordance.
RESULTS: Ability of assays to estimate clearance was variable with Prometheus and ID performing better than TD, but all provided reasonable estimates. The number of observations needed to accurately and precisely estimate individual PK was similar for all 3 assays. If no serum concentrations are available the precision of the prediction of subsequent IFX concentrations is poor (RMSE = 0.46, concordance = 0.43) which is reflective of high BSV in IFX PK. With more serum IFX concentration per patient, precision of forecast concentrations increased. With 3 observations (RMSE = 0.15, concordance = 0.86), PK estimates were markedly improved. With 4 observations the predicted concentration was within the assay error (RMSE and concordance). Two vs. one observation within a dose interval does not substantially impact precision, but does impact time required to collect enough observations to obtain precise estimates of future IFX PK.
CONCLUSION: Assay quality is important for precisely estimated IFX clearance in IBD patients. TDA according to patient demographics and patient factors is imprecise. At best 3 to 4 measurements of IFX would be taken early on. Based on this information it becomes feasible to dose to a target concentration and to determine the dose necessary. It further provides tools to prospectively determine which concentrations are leading to most favourable responses.

INTRODUCTION: Around 50% of IBD patients do not respond to the HBV vaccine. To increase the success rate, different vaccination protocols have been proposed although no study has been able to establish the optimal strategy for IBD patients.
AIMS & METHODS: Aims: To compare the success rate between two HBV vaccines in IBD patients: traditional (Engerix®) and a new vaccine with adjuvant (Fendrix®). Secondary aim was to identify predictor factors of response to the vaccine.
Methods: IBD patients with negative HBV serology and without previous vaccination against HBV were randomized to receive Fendrix® or double doses of Engerix® at months 0, 1, 2 and 6. Anti-HBs concentration was measured 2 months after the 3rd and 4th doses (EUDRA CT number:2010-023947-14).
RESULTS: 170 patients had been included: 55% male, 52% with Crohn's disease, 30% under immunosuppressants and 37% under anti-TNF treatment. 54% of patients received Engerix® and 46% Fendrix®; the main characteristics of patients (age, gender, type of IBD and treatment) were similar between the 2 groups. Overall, 44% of patients had response (anti-HBs^3 100 IU/l) after the first 3 doses (161 patients have already received 3 doses), and 71% after the completion of the vaccination (134 have completed the vaccination). The response rate after the 4 doses was 67% with Engerix® vs. 76% with Fendrix® ($p = 0.2$); considering anti-HBs^{3}10 IU/l (the standard threshold), the response rate was higher with Fendrix® than with Engerix® (87 vs. 73.6%, $p = 0.04$). In patients under immunosuppressants or anti-TNF drugs, the response (anti-HBs^{3}100 IU/l) after the 4 doses was 55% with Engerix® vs. 69% with Fendrix® ($p = 0.12$). In the multivariate analysis, older age (odds ratio [OR] = 0.9, $p < 0.0001$) and immunosuppressants or anti-TNF concomitant treatment (OR = 0.04, $p < 0.0001$), but not the type of vaccine (OR = 1.9, $p = 0.1$), were associated with the response rate to the vaccination. 7.7% of patients flared up during the study period, and 13% suffered adverse events (only 41% related with the vaccine, and all of them mild). The frequencies of flaring up and adverse events were similar between the 2 groups.
CONCLUSION: A statistically significant different response rate to Fendrix® (single dose) or Engerix® (double dose) has not been demonstrated in IBD patients yet (although the trial is still ongoing). A 4-dose schedule increases the response rate around 30% compared with a 3-dose regimen. The older age and the immunosuppressive and anti-TNF treatment decrease the success rate of the vaccine. Both vaccines seem to be safe in IBD patients.

INTRODUCTION: One-third of patients with Crohn's disease (CD) or ulcerative colitis (UC) receiving anti-TNF therapy do not respond to treatment (primary failure), and a relevant proportion experience a loss of response (secondary failure) or intolerance.
AIMS & METHODS: To investigate the efficacy of a second anti-TNF agent after failure or intolerance to a first drug.
METHODS: *Inclusion criteria:* Studies evaluating the efficacy of infliximab (IFX), adalimumab (ADA), and certolizumab pegol (CZP) as the second anti-TNF drug in CD or UC. *Search strategy:* Bibliographical searches in PubMed. *Data synthesis:* Percentage of response/remission; the meta-analysis was performed using the inverse variance method.
RESULTS: We included 42 studies (35 CD, 6 UC, 1 pouchitis). The CD studies comprised 30 switching IFX→ADA, 4 IFX→CZP, and 1 ADA→IFX. Overall, the second anti-TNF in CD induced remission in 43% (95%CI = 38-48%; $I^2 = 75\%$; 27 studies; 2,345 patients) and a response in 65% (95%CI = 57-73%; $I^2 = 92\%$; 26 studies; 1,922 patients) of patients. The remission rate was higher when the reason to withdraw the first anti-TNF was intolerance (61%; 95%CI = 40-82%; $I^2 = 89\%$) than after secondary (45%; 95%CI = 34-57%; $I^2 = 79\%$) or primary failure (30%; 95%CI = 22-37%; $I^2 = 8\%$); response rates were, respectively, 72%, 66%, and 60%. Six UC studies were identified, all of them switching IFX→ADA, and only 4 of them reporting remission rates (151 patients), with figures ranging from 0% to 50%
CONCLUSION: The efficacy of a second anti-TNF in CD patients largely depends on the cause for switching. The remission rate was higher when the reason to withdraw the first anti-TNF was intolerance (61%), compared with secondary failure (45%) and primary failure (30%).

INTRODUCTION: Infliximab is an effective therapeutic option in patients with refractory ulcerative colitis (UC). The optimal timing of infliximab therapy is still one of the outstanding questions in the therapy of UC.
AIMS & METHODS: The aim of our study was to assess whether there is an association between the one-year remission rates and the elapsed time between the diagnosis and the start of infliximab therapy. 116 UC patients treated with infliximab were enrolled in this retrospective study. The time elapsed between the diagnosis and the first biological therapy was assessed in every patient, who was then categorized to groups according to the elapsed time (>5 years and <5 years; 0-2 years, 2-5 years, 5-10 years etc).
RESULTS: The mean elapsed time between the diagnosis and the start of biological therapy was 7 years (0-38 years). 50.4% of patients started infliximab therapy within 5 years after diagnosis. After induction with infliximab 65.6% of the enrolled patients achieved remission and 34.4% achieved response. After one-year treatment period, the remission and response rates remained 67.7% and 21.8%. 10.6% of patients showed loss of efficacy at one year infliximab therapy. Complete mucosal healing was detected in 31.2% and deep remission in 13.9% of the patients at week 52. Response rates to infliximab therapy at one year were significantly lower compared to rates at week 14 ($p = 0.029$). The rate of remission and loss of efficacy did not depend on the elapsed time between the diagnosis and the start of biological therapy. However, response rates were higher in longer elapsed time ($p = 0.036$).
CONCLUSION: Infliximab is effective for drug-refractory UC to induce and maintain clinical remission. Our results did not reveal an association between the remission rates and the elapsed time between the diagnosis and the first biological therapy in UC.

P0320 HEAD-TO-HEAD COMPARISON OF 5 FECAL MARKERS TO PREDICT RESPONSE TO INDUCTION AND MAINTENANCE THERAPY WITH INFLIXIMAB IN ULCERATIVE COLITIS PATIENTS; A PROSPECTIVE STUDY

A.C. Frin[1,*], S. Nancey[2], J. Filippi[1], G. Boschetti[2], B. Flourie[2], J. Drai[3], P. Ferrari[4], X. Hebuterne[1]
[1]*Gastro enterology, CHU Archet 2, Nice cedex 3,* [2]*Gastro enterology,* [3]*Biochemistry, CHU Lyon sud, Hospices civils de Lyon, Pierre Benite, Lyon,* [4]*Biochemistry, CHU Pasteur, Nice cedex 3, France*

INTRODUCTION: The role of faecal markers in monitoring anti TNF alpha therapies has been insufficiently explored. This study aimed to determine the usefulness of five faecal proteins in the prediction of clinical response to Infliximab (IFX) in Ulcerative Colitis (UC): calprotectin (fCal), Lactoferrin (fLac), M2PK (fM2PK), neopterin (fNeo), and zonulin (fZo).
AIMS & METHODS: Thirty-one consecutive patients with an active UC, requiring IFX [5 mg/kg at week 0 (W0), 2, 6 and every 8 W] were prospectively studied. At W0, W2, W6 and W14, clinical activity was recorded and a stool sample collected. Clinical response to induction therapy was defined at W14 as a reduction of at least 3 points and 30% of the Mayo score. In 25 patients, endoscopies were performed at W0 and W12; an endoscopic Mayo subscore of 0 or 1 defined endoscopic remission. Clinical response to maintenance therapy was evaluated at W52 and optimization or discontinuation of IFX were considered as a failure.
RESULTS: At W0 the median partial Mayo Score, the endoscopic Mayo and the UCEIS scores were 7/9 (2-9), 3/3 (2-3) and 8/11 (6-11) respectively. At W14, 19 patients (61%) were clinical responders and 13 (52%) experienced an endoscopic response. The median levels of fCal drop dramatically from W0 to W14 in responders [from 4260 µg/g (96-25051) to 128 µg/g (11-3782); $p = 0.0001$]. In contrast, it did not differ significantly in non-responders [from 9077 µg/g (215-50000) to 2781 µg/g (203-14149); $p = 0.287$]. Same trends were observed for fLac

and fM2PK levels. At W2, fLac and fM2PK predicted accurately clinical response to IFX induction (area under the curve (AUC) = 0.82, 0.84 and 0.88 respectively): cuts-offs of 800 µg/g for fCal, 20000 ng/g for fLac and 50 UI/mL for fM2PK determined by ROC curves allowed to discriminate clinical responders from non responders to induction therapy, with good sensitivities (Se) (82%, 81% and 88%, respectively), and specificities (Sp) (69%, 70% and 80%, respectively). FLac measured at W2 were the more valuable marker to predict endoscopic remission at W12 [(AUC = 0.80, Se and Sp = 72% with a cut-off of 32891 ng/g). At W14, the three previous markers were also reliable to predict clinical response at W52 (AUC = 0.82, 0.86 and 0.75 respectively) with best cut-offs of 146 µg/g for fCal, 3457 ng/g for fLac and 2.25 UI/mL for fM2-PK. FCal, fLac and fM2PK were well correlated with both the endoscopic Mayo subscore and the UCEIS. FNeo and fZo did not show any relevant result.

CONCLUSION: FCal, flac and fM2-PK predicted with a good accuracy the clinical response to induction and maintenance IFX therapy in UC. The measurement of one of these markers at W0 and at the end of induction might distinguish responders from non responders to IFX maintenance therapy within one year.

P0321 ALTERATIONS OF FECAL MICROBIOTA AND METABOLIC LANDSCAPE IN RESPONSE TO ORAL OR INTRAVENOUS IRON REPLACEMENT THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

T. Lee[1], **A. Schmidt**[2,*], I. Lagkouvardos[2], T. Clavel[2], A. Walter[3], M. Lucio[3], K. Smirnov[3], P. Schmitt-Kopplin[3], R. Fedorak[1], D. Haller[2]

INTRODUCTION: Iron deficiency is a common complication in patients with inflammatory bowel diseases (IBD) and oral iron replacement therapy is suggested to exacerbate IBD symptoms. We hypothesized that oral iron may impact the composition of the gut microbiota and thereby affect the disease status.

AIMS & METHODS: An open-labelled clinical trial including patients with Crohn's disease (CD; N = 29) or ulcerative colitis (UC; N = 19) as well as control patients with iron deficiency (iron saturation < 16% and ferritin < 100) (N = 20) was performed to compare the effects of oral (PO; ferrous sulfate) vs. intravenous (IV; iron sucrose) iron replacement therapy over a period of three months. The health status was assed via quality of life (EQ 5D and SIBDQ) and disease activity (HBI and PMS) questionnaires. Stool and sigmoid mucosal biopsies were collected before and after treatment. Gut bacterial diversity and composition were assessed by high-throughput sequencing of 16S rRNA genes (V4 region). Fecal metabolites were analyzed by ESI-FT-ICR-MS.

RESULTS: PO and IV treatments were comparable regarding amelioration of iron deficiency, with superior but not significant levels of ferritin and iron saturation in the IV group. Worsening or improvement of disease activity and quality of life were independent of iron treatments (no difference between PO and IV). Fecal bacterial diversity was significantly different between control, UC and CD patients before and after iron treatment. Samples from IBD patients were characterized by marked inter-individual differences as well as lower phylotype richness and proportions of unknown *Clostridiales*. We identified the presence of 18 CD-specific molecular species (OTUs), many of which matched sequences of facultative anaerobic bacteria. Major shifts in bacterial diversity occurred in approximately half of the participants after treatment, independently of disease. In those samples where bacterial profiles shifted, changes in diversity were significantly higher in IBD patients. However, no consistent changes in the occurrence of specific OTUs relative to iron treatment could be identified, suggesting individual-specific responses to treatment. Metabolite analysis using OSC-PLC classification showed a clear separation of both UC and CD from control patients before the iron treatment. After therapy, metabolite profiles were only different in UC patients indicating a possible convergence of CD patients with control subjects in response to the iron treatment. Separation into IV- and PO-specific metabolite profiles appeared in the control and CD group but not in the UC group.

CONCLUSION: Shifts in bacterial diversity associated with iron treatment are independent of the route of administration and are more pronounced in IBD patients. Efficiency and clinical outcome of both iron therapies are comparable in both IBD patient cohorts.

P0322 DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING PARAMETERS AS PREDICTORS OF REMISSION IN CROHN'S DISEASE PATIENTS TREATED WITH ANTI-TNF THERAPY

A. Buisson[1,2,*], C. Hordonneau[3], J. Scanzi[1], F. Goutorbe[1], M. Goutte[1], B. Pereira[4], G. Bommelaer[1,2]
[1]*Gastroenterology department, CHU Estaing Clermont-ferrand,* [2]*Microbes, Intestine, Inflammation and susceptibility of the host UMR 1071, Inserm/ Université d'Auvergne; USC-INRA 2018,* [3]*Radiology department, CHU Estaing Clermont-ferrand,* [4]*Biostatistics unit, DRCI, CHU Clermont-ferrand, Clermont-ferrand, France*

INTRODUCTION: Anti-TNFα agents are the most effective therapy in Crohn's disease (CD). However, almost one-third of the patients experience primary failure to anti-TNF therapy. Diffusion-Weighted Magnetic Resonance Entero-Colonography (DW-MREC) has shown good accuracy to detect and assess inflammatory activity in CD[1,2].

AIMS & METHODS: We aimed to study the DW-MREC parameters as predictors of advanced remission (clinical remission defined as CDAI <150 AND CRP <5 mg/L), surgery, clinical remission (CDAI <150) or clinical response (ΔCDAI≥70) after induction regimen of anti-TNFα (week 12).

Overall, 28 consecutive CD patients were prospectively included during 1 year. All the patients underwent a DW-MREC[1,2] within 4 weeks before starting anti-TNFα. Adalimumab (ADA) was administered as 160mg at W0, 80mg at W2 and 40mg e.o.w. Infliximab (IFX) was administered as 5mg/kg at W0, W2 and W6. The collected MRI parameters were: Clermont score[1,2], apparent diffusion coefficient (ADC), Magnetic Resonance Index of Activity (MaRIA), presence of stenosis, fistula, abscess, sclerolipomatosis or mesenteric lymph nodes.

RESULTS: Median age and disease duration at inclusion were 37 years (17-71) and 34 months (0-456) respectively. Overall, 14 (50%) were smokers, 7 (25%) underwent previous intestinal resection and 7 (25%) had ano-perineal lesions. 13 patients (46.4%) had ileal CD (L1), 3 (10.7%) colonic CD (L2), 12 (42.8%) ileocolonic CD (L3). CD phenotypes were non-stricturing non-fistulizing (B1), stricturing (B2) and fistulizing (B3) in 9 (32.1%),12 (42.9%), and 7 (25.0%) patients, respectively. While 13 patients were treated with IFX (44.4%), 15 were treated with ADA (55.6%). Among them, 10 (35.7%) patients received concomitant thiopurines. At inclusion, median CDAI was 225 (170-393) and median C-reactive protein value was 17.1 mg/L (2.9-148). 13 patients (46.4%) experienced advanced remission at W12.

Mean ADC seemed lower (1.912 vs 2.162, p = 0.07) and mean MaRIA seemed higher (47.0 vs 41.9, p = 0.13) in the patients treated with anti-TNFα therapy which experienced advanced remission at W12.

Presence of mesenteric lymph nodes was predictive of no need for surgery at W12 in the patients treated with anti-TNFα therapy (p = 0.01). Sclerolipomatosis seemed also predictive of no requirement for surgery at W12 in the patients treated with anti-TNFα therapy (p = 0.13). Presence of mesenteric lymph nodes was predictive of response to anti-TNFα therapy at W12 (p = 0.05).

CONCLUSION: MRI parameters reflecting inflammatory activity (presence of mesenteric lymph nodes, sclerolipomatosis, low ADC) seemed predictors of advanced remission or response to anti-TNFα agents in CD. Despite the lack of power due to small sample size, the intermediary results of our study show that DW-MREC could be a useful and promising tool to predict effectiveness of anti-TNFα therapy in CD.

P0323 PREDICTIVE FACTORS OF EARLY INFLIXIMAB INFUSION REACTIONS IN INFLAMMATORY BOWEL DISEASE

C. Duron[1], **A. Buisson**[1,2,*], M. Goutte[1], B. Pereira[3], G. Bommelaer[1]
[1]*Gastroenterology department, CHU Estaing Clermont-ferrand,* [2] *Microbes, Intestine, Inflammation and susceptibility of the host UMR 1071, Inserm/ Université d'Auvergne; USC-INRA 2018,* [3]*Biostatistics unit, DRCI, CHU Clermont-ferrand, Clermont-ferrand, France*

INTRODUCTION: Anti-TNF agents including infliximab (IFX), a chimeric antibody, are the most effective therapies in inflammatory bowel diseases (IBD). Early IFX Infusion Reaction (EIIR) is rare, but is a serious complication in IBD patients, and could lead to drug withdrawal and consequently impact the therapeutic strategy. The role of premedication remains uncertain.

AIMS & METHODS: We aimed to establish predictors of EIIR in IBD patients and to assess the impact of premedication.

Patients, disease and infusions characteristics, collected for all IFX infusions performed in our IBD Unit, were retrieved from electronic charts from 2008 to 2013. The EIIR were defined as events related to IFX infusions occurring within two hours of the infusion. Univariate and multivariate analysis were performed taking into account the inter-patients and intra-patients variability and interaction test.

RESULTS: Among the 80 included IBD patients, 51 (63.8%) had Crohn's disease (CD). The mean age and disease duration were 38.8 years (±14.1) and 7.4 years (±7.0) respectively.

Overall, 23 IBD patients (28.8%) experienced EIIR. Age, prior history of intestinal resection, atopy or allergy, familial history of IBD, type of IBD, disease location, disease extent or disease duration were not predictive of EIIR. In univariate analysis, non-stricturing non fistulising CD was predictive of EIIR (26.4% vs 52.2%, p = 0.03). This result was confirmed by multivariate analysis. Of 1107 infusions, we observed 38 EIIR (3.4%). In univariate analysis, the first four infusions (26.4% vs 52.6%, p = 0.002) and the resumption of IFX after drug holiday (17.2% vs 29.0%, p = 0.001) were predictive of EIIR. Multivariate analysis confirmed that the resumption of IFX after drug holiday was a major risk factor of EIIR (OR = 24, p < 0.001) but not the first four infusions. Surprisingly, a premedication (anti-histaminic or hydrocortisone) seemed to be a risk factor for EIIR in univariate and multivariate analysis while concomitant therapies did not prevent EIIR. As resumption of IFX after drug holiday was a major risk factor for EIIR, interaction test was performed and showed that the increased risk induced by the premedication was related to resumption of IFX after drug holiday.

The patients who experienced EIIR and those who did not experience EIIR have had to discontinue IFX therapy in 69.6% (16/23) and 50.9% (29/57) of cases, respectively (NS).

CONCLUSION: EIIR is a major event in the history of IBD patients treated by IFX as it leads to drug discontinuation and thus limits considerably the available therapeutic armamentarium. **The resumption of IFX after drug holiday is the major risk of EIIR** and could be predicted in part by the measurement of anti-drug antibodies. Non stricturing non penetrating CD could be also a risk factor.

The efficacy of premedication remains questionable and could be limited to the high risk patients.

P0324 COMPARISON BETWEEN INFLIXIMAB AND ADALIMUMAB FOR THE TREATMENT OF PERIANAL FISTULISING CROHN'S DISEASE

A. Tursi[1], W. Elisei[2], M. Picchio[3], R. Faggiani[4], C. Zampaletta[4], G. Pelecca[4], **G. Brandimarte**[5,*]
[1]*Gastroenterology Service, ASL BAT, Andria,* [2]*Division of Gastroenterology, ASL Roma H, Albano Laziale (Roma),* [3]*Division of Surgery, "P. colombo" Hospital, ASL Roma H, Velletri (Roma),* [4]*Division of Gastroenterology, "Belcolle" Hospital, Viterbo,* [5]*Division of Internal Medicine and Gastroenterology, "Cristo Re" Hospital, Rome, Italy*

INTRODUCTION: Infliximab (IFX) and Adalimumab (ADA) have improved the management of perianal Crohn's disease (CD). However, comparative studies have not been reported previously.
AIMS & METHODS: Our aim was to compare the outcomes of CD patients with perianal fistulising disease treated with IFX or ADA.
A retrospective medical record review of CD patients, who received IFX or ADA for perianal fistulising disease, was conducted. Fistulas were assessed using Magnetic Resonance Imaging (MRI), and seton placement was performed when appropriate. A 36-month follow-up was performed.
RESULTS: Twenty CD patients (9 males and 11 females; median age 31.5 years, range 18-39) were treated (9 with IFX and 11 with ADA). Seton placement was performed in 18 patients (8 in IFX and 10 in ADA group).
The baseline Harvey-Bradshaw index (HBI) and perianal disease activity index (PDAI) significantly decreased after 6 weeks and remained at similar levels for the entire follow-up in both groups.
The complete response rate of fistulas was 75% of patients at 36 months (78% in IFX and 73% in ADA group), with no significant difference between the two study groups.
Setons were withdrawn from twelve patients (5 in IFX and 7 in ADA group), who experienced complete response and showed no radiological evidence of disease at 12-month follow-up.
Two patients with complex fistulas failed to obtain fistula closure under anti-TNFα (one in each groups). Changing the anti-TNFα was useless and both patients underwent to permanent colostomy.
CONCLUSION: Efficacy of IFX and ADA was similar in treating perianal fistulising CD patients.

INTRODUCTION: Current medical treatment options for patients with steroid-dependent, active ulcerative colitis (UC) with insufficient response or intolerance to immunosuppressants (IS) and/or biologicals are limited and not evidence-based. In addition, the recognised related safety profiles are considerable. The clinical use of Granulocyte, Monocyte/Macrophage Adsorptive (GMA) apheresis with Adacolumn® has previously demonstrated a safe and efficacious use in this subgroup of UC patients.
AIMS & METHODS: This study was an uncontrolled, open-label, multicenter trial conducted in the UK, France and Germany (ART, NCT01481142). Consecutive eligible patients (18-75 years, steroid-dependent active UC with a Rachmilewitz (CAI) index $\geq$6 and an Endoscopic Activity Index (EAI) $\geq$4, and insufficient response or intolerance to IS and/or biologicals) were included. Patients received at least 5 weekly GMA apheresis. Evaluation visits were planned at Week 12, 24 and 48. The primary endpoint was the remission rate (CAI $\leq$4) at Week 12 in the Intention-to-treat (ITT) population. We report safety results observed along with the earlier communicated 12 weeks interim efficacy results of 55.9% response and 39.3% remission.
RESULTS: The safety population comprised 85 subjects having received at least one apheresis treatment. 14 out of 85 patients (16.5%) discontinued up to Week 12. 61/85 patients (71.8%) experienced any AE; in 54 patients (63.5%) these were of mild or moderate intensity, all transient, mainly consisting of headaches and problems related to venous access difficulties. Six (7.1%) patients experienced serious adverse events (SAEs), all unrelated to the study treatment. SAEs or AEs that led to discontinuation or withdrawal from the study were either related to the indication being studied (ulcerative colitis), or to poor venous access/ vascular access. There were no clinically significant changes in vital signs. There were few shifts from baseline to week 12 among clinically significant values in safety-relevant laboratory parameters.
CONCLUSION: GMA apheresis with Adacolumn® has shown benefit in more than 50% of patients with moderate to severe, active, steroid-dependent UC and insufficient response or intolerance to IS and/or biological agents. No new safety signals were observed, confirming the safety profile of GMA apheresis even in a difficult-to-treat UC patients group.

Contact E-mail Address: *itoayumi@ige.twmu.ac.jp*

INTRODUCTION: Efficacy of tacrolimus (TAC) as remission induction therapy for refractory ulcerative colitis (UC) has been reported. However, hitherto mid- and long-term outcomes and remission maintenance rates following a prolonged treatment with TAC have not been evaluated.
AIMS & METHODS: In this study, we were interested to evaluate the clinical remission maintenance rate for TAC in patients with UC. For this study, we included 29 patients (15 male and 14 female) who had received a TAC-based induction therapy between April 2009 and December 2013 (mean observation period 728 $\pm$ 311 days). In 10 patients, TAC was administered for 90 days including the period of remission induction, followed by switch to an immunomodulator (azathioprine) to maintain remission (group 1). In 19 patients, TAC was continued beyond the period of remission induction to maintain remission (group 2). The patients in groups 1 and 2 were matched with respect to gender, disease duration, pre-TAC haemoglobin (Hb), C-reactive protein (CRP), clinical activity index (CAI, according to Lichtiger), and endoscopic index (EI) at one month after TAC administration. The total dose of prednisolone administered up to the time when clinical remission was achieved, duration of hospital stay, and the time to recurrence between the two groups were factored into analyses. Remission was defined as a CAI score of 4 or less at week 4 or later after TAC administration. Likewise, recurrence was defined as a case in whom the blood trough level was increased (10 ng/dl or above) by means of intense intravenous regimen of prednisolone, switch to a biological preparation, repeat or dose-escalating TAC administration required to induce remission.
RESULTS: There was no significant difference in gender, disease duration, pre-TAC Hb, CRP, CAI, total dose of prednisolone administered until remission, duration of hospital stay, and the time to recurrence between the two groups. The mean TAC administration period in group 2 was 235 $\pm$ 122 days vs 86 $\pm$ 13 days for group 1. Further, the EI scores at one month after TAC administration were 5.8 $\pm$ 1.6 and 7.8 $\pm$ 2.1 for group 1 and group 2, respectively; the difference was significant ($P < 0.012$). Regarding the treatment safety, finger tremor was observed in 2 patients in group 1 and 5 patients in group 2, renal dysfunction was observed in none of the group 1 patients, but in 3 of group 2 patients.
CONCLUSION: In this study, although no significant difference was found in the time to recurrence, the EI score at one month after TAC treatment was significantly higher in group 2 compared with group 1. This finding suggests that a maintenance dose of TAC is likely to maintain remission even in patients with delayed mucosal healing. However, longer TAC therapy may carry higher risk of adverse side effects.

P0327 STRESS AND NONSTEROIDAL-ANTIINFLAMMATORY DRUGS (NSAID)-INDUCED EXACERBATION OF EXPERIMENTAL COLITIS IS ATTENUATED BY ANTIBIOTIC RIFAXIMIN AND PROBIOTIC SACCHAROMYCES BOULARDII

B. Brzozowski [1,*], M. Zwolinska-Wcislo [1], E. Karczewska [2], A. Ptak-Belowska[3], K. Urbanczyk [4], G. Krzysiek-Maczka[3], M. Strzalka[3], **T. Brzozowski** [3]
[1]*Gastroenterology, Hepatology and Infectious Diseases Clinic,* [2]*Department of Microbiology, Faculty of Pharmacy,* [3]*Department of Physiology,* [4]*Department of Pathomorphology, Jagiellonian University Medical College, Cracow, Poland*

INTRODUCTION: Clinical and experimental studies have indicated that stress plays an important role in the initiation and perpetuation of inflammatory bowel disease (IBD), however, the mechanism of stress-induced alterations in the severity of the inflammatory process of colonic mucosa remains unclear. Colonic microbiota is important component of IBD pathogenesis but its influence on the colonic mucosal barrier under stress conditions as well as the efficacy of treatment with antibiotics or probiotics on experimental colitis have not been fully explained.
AIMS & METHODS: We studied the effect of cold stress on healing of experimental colitis induced in rats by intrarectal administration of 2,4,6- trinitrobenzenosulfonic acid (TNBS) and we assessed the involvement of colonic microflora in healing of TNBS colitis in rats exposed to stress and stress combined with aspirin (ASA) treatment. The efficacy of antimicrobial therapy by antibiotic rifaximin or probiotic *Saccharomyces boulardii* on stress-induced impairment of the healing of experimental colitis in the absence or presence of ASA treatment was investigated. Animals with TNBS-induced colitis and exposed to cold stress for 20 min every second day were treated i.g. daily with 1) vehicle (saline), 2) *Saccharomyces boulardii* (10^8CFU/rat), 3) rifaximin (100 mg/kg), 4) ASA (20mg/

kg) alone or 5) ASA (20 mg/kg) combined with *Saccharomyces boulardii* (10^8CF/rat) or rifaximin (100 mg/kg). At day 10 upon colitis induction, the colonic blood flow (CBF) was determined by H_2-gas clearance technique, the blood was withdrawn for measurement of plasma MPO, IL-1β and TNF-α levels and the expression of proinflammatory markers IL-1β, TNF-α, iNOS, COX-2 and HIF-α were analyzed in colonic mucosa of stressed rats.

RESULTS: Exposure to stress significantly increased the area of TNBS damage and the concomitant administration of ASA further augmented the area of these lesions. This delay in mucosal healing caused by cold stress was accompanied by a significant fall in the CBF, the significant rise in tissue weight, a 4-fold increase in MPO activity and the mucosal overexpression of IL-1β, TNF-α, iNOS, COX-2 and HIF1α. In stressed animals, the significant increase of *E. coli* counts in feces and the spleen were observed and this effect was significantly attenuated by both rifaximin and *Saccharomyces boulardii*. Treatment with rifaximin and to lesser extent with probiotic *Saccharomyces boulardii* significantly decreased the area of colonic lesions while increasing CBF and significantly reducing the plasma IL-1β and TNF-α levels and the colonic expression of proinflammatory markers.

CONCLUSION: 1/ Stress exacerbates experimental colitis due to increase of intestinal pathogenic *E. coli* and this pathogenic bacteria translocation to the extra-intestinal organs such as spleen, and 2/ Modifying of the intestinal microbiota through probiotics or selected antibiotics could be of clinical importance in the limitation of the consequences of environmental factors such as stress and adverse effects of NSAID therapy in patients with lower GI-tract disorders.

Contact E-mail Address: *bernd.bokemeyer@t-online.de*

INTRODUCTION: The nationwide BioCrohn Registry (*Bio*logical Registry with *Crohn*s Disease Patients in Germany) of the German Competence-Network IBD is a five-year prospective registry of about 1,500 patients with Crohn's disease (CD) in Germany. This is a sub-study of the BioCrohn Registry reporting the anti TNF-alpha antibody (TNF) steroid-free remission rates of induction and maintenance therapy in 391 anti-TNF-naïve CD-patients with adalimumab (ADA) or infliximab (IFX) up to 12-months follow-up.

AIMS & METHODS: Within the framework of this non-interventional prospective online documentation, data in respect to the course of disease, psychosocial burden of disease, health economics and the genetic profile were examined. End of 2012 the recruitment was stopped having 1,525 CD-patients included by 59 different gastroenterology practices and hospitals with IBD experience. All patients have a 5 year follow-up period. The databank for baseline and 12-months data has been closed in 03/2013 and after databank cleansing now we have the finalized data including the 6- and 12-months visits.

RESULTS: 391 TNF-naive CD-patients (ADA: n = 264; IFX: n = 127) have been analysed (average age: 36 years; female: 52%; smokers 34%; disease duration: 9.3 years; bowel resection: 33%; prior immunosuppressive therapy: 75%). Baseline characteristics were similar in the two groups. The IBD-therapy followed an accelerated step-up management. Immunosuppressants were used in 19% at 6 and in 21% after 12 months. Accordingly to the TNF therapy, the use of systemic glucocorticoids dropped over time (baseline until 6 and 12 months) from 22.0% to 6.3% and 8.3%, respectively ($p < 0.001$). The remission rate (PGA) at 6 months was 70.9% and 72.1% after 12 months. In spite of the TNF-induced clinical remission (> 70%) the psychosocial impairments with anxiety/depression (EQ-5D) showed only minor improvement and remained on a relatively high level (baseline: 37%, 6 months: 31%, 12 months: 28%). In the induction therapy with TNF we found a steroid-free remission (HBI < 5) in 67.1% at 6 months and in 68.9% at 12 months in the maintenance therapy. Evaluating the efficacy of ADA vs. IFX we did not find any difference in steroid-free remission rates as an induction therapy at month 6 (ADA: 68.2%; IFX: 64.6%; p = n.s.) or as a maintenance therapy at month 12 (ADA: 68.1%; IFX: 70.6%; p = n.s.). In the per protocol TNF-group with regular visits at 6 and 12 months (n = 264) 91.7% of these patients were still on TNF after 12 months. Additionally 5.7% of the ADA-patients switched to IFX and 9.2% of the IFX-patients switched to ADA. This means that 76.8% of the patients starting with TNF were on the same TNF therapy after 12 months.

CONCLUSION: In this real life setting anti-TNF therapy could induce steroid-free remission in about 70% with the relatively early escalation of therapy in IBD-experienced centres. In comparison there is no difference in steroid-free remission rates between ADA vs. IFX.

P0329 PREDICTORS OF HOSPITALIZATION IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS FROM ULTRA 1 AND ULTRA 2

B. Feagan[1,*], W.J. Sandborn[2], W. Reinisch[3], S. Ghosh[4], A.M. Robinson[5], A. Lazar[6], Q. Zhou[5], M. Skup[5], R.B. Thakkar[5]

[1]*Robarts Research Institute and University of Western Ontario, London, Canada,* [2]*UCSD, La Jolla, United States,* [3]*McMaster University, Hamilton,* [4]*University of Calgary, Calgary, Canada,* [5]*AbbVie Inc, North Chicago, United States,* [6]*AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany*

INTRODUCTION: Patients with moderately to severely active ulcerative colitis (UC) are frequently hospitalized due to disease deterioration. The factors associated with hospitalization risk in patients treated with non-biologic therapy for UC are analyzed in patients randomized to placebo (PBO) in ULTRA 1[1] and ULTRA 2[2].

AIMS & METHODS: ULTRA 1 had an 8 to 12 week double-blind (DB) phase followed by an open-label (OL) all adalimumab (ADA) phase to week 52. ULTRA 2 was a 52-week DB trial in which patients with inadequate response could receive OL ADA 40 mg beginning at week 12. Patients with loss of response or intolerance to prior anti-TNF use could enrol in ULTRA 2. Logistic regression was used to determine predictors of all-cause and UC-related hospitalization in PBO randomized patients from ULTRA 1 and ULTRA 2. Baseline variables assessed were age, sex, disease duration, pancolitis, prior anti-TNF use, CRP, albumin, Mayo score, aminosalicylate use, immunomodulator use, corticosteroid use, alcohol use, smoking status, and weight. Model 1 also included baseline endoscopy subscore (2 vs 3) and Model 2 also included stool frequency (SFS, 0-1 vs 2-3), rectal bleeding (RBS, 0-1 vs 2-3), and PGA (0-2 vs 3) subscores. Patients were censored 70 days after moving to OL ADA.

RESULTS: Selected odds ratios for the association of baseline variables with hospitalization for PBO randomized patients from ULTRA 1 and 2 are shown in the table. In both regression models, male sex was a significant predictor for lower risk of all-cause and UC-related hospitalization, whereas lower baseline albumin and higher baseline CRP concentration were significant predictors for higher risk of all-cause and UC-related hospitalization. Alcohol use was associated with UC-related hospitalization in both models. Disease activity at baseline, as measured by Mayo score or individual subscores, disease duration, prior anti-TNF use, pancolitis, or use of aminosalicylates, immunomodulators, or corticosteroids were not associated with hospitalization risk in either model.

Table. Logistic regression odds ratios for hospitalization in PBO-randomized patients from ULTRA 1 and 2

	Model 1		Model 2	
	All-cause	UC-related	All-cause	UC-related
Sex (male)	0.37**	0.41*	0.35**	0.38*
Baseline CRP (mg/L)	1.01*	1.02**	1.01*	1.02**
Albumin (<40 g/L)	2.39*	2.82**	2.50*	3.00**
Current alcohol use	1.82	2.11*	1.82	2.12*

CONCLUSION: In this analysis, factors associated with hospitalization in patients receiving non-biologic therapy for UC were sex, increased inflammation (as measured by CRP) and low baseline albumin. These factors may be useful when evaluating future therapeutic interventions in patients with UC failing conventional therapy.

P0330 DEEP REMISSION IMPROVES CLINICAL OUTCOMES AFTER INFLIXIMAB DISCONTINUATION IN INFLAMMATORY BOWEL DISEASES

C. Felice[1,*], D. Pugliese[1], M. Marzo[1], G. Andrisani[1], O.M. Nardone[1], A. Papa[1], I. De Vitis[1], G.L. Rapaccini[1], L. Guidi[1], A. Armuzzi[1]
[1]*IBD Unit, Internal Medicine and Gastroenterology, Complesso Integrato Columbus, Catholic University, Rome, Italy*
Contact E-mail Address: *carla.felice@virgilio.it*

INTRODUCTION: Recent studies underlined the importance to treat inflammatory bowel diseases (IBD) looking beyond symptoms and considering also tangible indicators of disease remission, such as mucosal healing and normalization of biomarkers. A clear definition of deep remission has not been validated yet. However, the achievement of clinical remission associated to mucosal healing has been demonstrated to improve clinical outcomes during biological treatments. Some studies also showed that high C-reactive protein (CRP) levels at the time of infliximab (IFX) discontinuation may represent a risk factor for clinical relapse. No data are available so far about clinical outcomes of IBD patients who discontinue IFX being in deep remission defined as the combination of clinical remission, mucosal healing and normal CRP.
AIMS & METHODS: This single-centre study included IBD patients who discontinued maintenance treatment with IFX because of sustained steroid-free clinical remission (HBI$\leq$4 for Crohn's disease -CD- and partial Mayo score$\leq$2 for ulcerative colitis –UC-, with no intake of systemic steroids during the last 12 months before discontinuation). Deep remission was defined as sustained steroid-free clinical remission associated to normal CRP ($\leq$5 mg/l) and mucosal healing (defined as absence of ulcers in CD, or endoscopic Mayo score of 0-1 in UC). Primary endpoint was the comparison of clinical relapse between two groups of patients who were in deep remission (group 1) or not (group 2) at the time of IFX discontinuation. Secondary endpoints were endoscopic recurrence, hospitalizations, surgeries and retreatment with anti-TNFα between the two groups.
RESULTS: Sixty-one patients (40 CD, 21 UC) were included in the study (group 1 n = 34, group 2 n = 27). Median follow-up after IFX discontinuation was 36 months (IQR 23-60). No significant differences were found among baseline characteristics. The rate of clinical relapse resulted significantly different between groups: 14/34 (41%) in group 1 relapsed in comparison with 21/27 (78%) in group 2 ($p = 0.009$). Mucosal healing was the only other variable associated to a lower incidence of clinical relapse ($p = 0.03$). Median values of CRP at the time of IFX discontinuation were not associated to a different clinical outcome. Time to clinical relapse was significantly shorter in group 2: patients not in deep remission at the time of IFX discontinuation relapsed after a median of 12 months (IQR 8,25-19.5) in comparison with 36 months (IQR 23-57) of group 1 ($p < 0.001$). No differences were found considering rates of endoscopic recurrence, hospitalization, surgery and need for anti-TNFα retreatment. However, patients in group 2 required hospitalization and retreatment with anti-TNFα significantly earlier in comparison with group 1 ($p = 0.02$ and $p = 0.03$, respectively).
CONCLUSION: IBD patients who discontinue IFX because of sustained steroid-free clinical remission may relapse over time. However, the presence of deep remission (clinical remission associated to mucosal healing and normal CRP) at the time of IFX discontinuation seems to guarantee better clinical outcomes.

INTRODUCTION: Etrolizumab, a humanized antibody to the integrin $\beta7$, blocks $\alpha4\beta7$:MAdCAM-1 and $\alpha E\beta7$:E-cadherin interactions, and has been shown in a Phase 2 study to be effective at inducing clinical remission in patients with moderate-to-severely active ulcerative colitis (UC).[1] Maximal occupancy of $\beta7$ receptors was observed on lymphocyte subsets in peripheral blood and colonic tissue in both dose cohorts (monthly subcutaneous doses of 100mg [low] or 300mg+loading dose [high]), with a corresponding increase in B and T intestinal homing lymphocytes in peripheral blood.[2] Here we present the pharmacodynamic (PD) effects of etrolizumab in colonic tissue and the serum pharmacokinetics (PK) from the Phase 2 study.
AIMS & METHODS: Changes from baseline were assessed in colonic tissue gene expression at weeks 6 and 10 (qPCR, n = 96) and in αE cells at week 10 (immunohistochemistry [IHC], n = 55 & 73 in epithelium and lamina propria, respectively). Serum drug levels were measured at multiple time points following etrolizumab administration.
RESULTS: Etrolizumab displayed linear kinetics, with ~4.4 fold exposure separation between the two dose cohorts. The average serum concentration of etrolizumab at week 10 was 8.5μg/mL and 37.8μg/mL for the low and high dose cohorts, respectively. There were no differences in $\beta7$ gene expression in colonic tissue between the etrolizumab and placebo treated groups. αE^+ cells were decreased in the intestinal crypt epithelium, but not in the lamina propria, in etrolizumab-treated patients compared with placebo. Reduction in multiple markers associated with proinflammatory infiltration and active disease was observed in etrolizumab-treated patients who achieved clinical remission compared to those who did not, including decreases in expression of proinflammatory cytokines, lymphocyte subset markers (CD3, CD19), MAdCAM-1, and epithelial cell-associated αE^+ cells. Although maximal occupancy of $\beta7$ receptors was observed in both low and high dose groups, there were no apparent differences in PD effects between the two etrolizumab-treated cohorts. Furthermore, within the etrolizumab-treated cohorts, there were no observed drug exposure/clinical remission relationships.
CONCLUSION: In this Phase 2 study, we confirmed etrolizumab target engagement and subsequent biological effects, both in peripheral blood and at the site of disease pathobiology. PD effects were consistent with decreased inflammation in the colonic mucosa, particularly in patients who attained clinical remission. These findings contribute to the understanding of the mechanism of action of etrolizumab: blockade of leukocyte homing to, and decreased inflammation in, the colon.

P0332 CLINICAL OUTCOME OF PERIANAL CROHN'S DIESEASE AND IMPACT OF TREATMENT STRATEGIES OVER THE TIME

C. Reenaers[1,*], A. Natalis[1], E. Louis[2]
[1]*CHU Sart Tilman, Liege, Belgium, Liege, Belgium,* [2]*Hepato-Gastroenterology, CHU Sart Tilman, Liege, Belgium, Liege, Belgium*
Contact E-mail Address: *catherinereenaers@hotmail.com*

INTRODUCTION: Perianal Crohn's disease (pCD) is associated with complications leading to recurrent surgery and tissue damage. Immunosuppressive drugs (IS) including anti-TNF have changed the management of pCD.
AIMS & METHODS: Our aim was to describe the management and the natural history of a cohort of patients with active pCD and to identify predictive factors of poor evolution.
Methods: A retrospective study of pCD patients registred in the database of the university hospital of Liège, Belgium. Perianal lesions included abscess, fistulae, anal fissure, anal strictures. pCD treatments included antibiotics, surgical drainage (with or without seton), stoma. Medical treatments including IS and anti-TNF were recorded at pCD diagnosis and over follow-up. pCD relapse was defined as antibiotherapy for recurrent abscess, the need for surgical drainage or stoma. The subroups of patients followed before (old cohort) and after (young cohort) the year 2000 were compared in a subanalysis.
RESULTS: 181 patients with pCD were included. Mean follow-up was 7.9 years Mean time between CD and pCD diagnosis was 6.3 years. Lesions at pCD diagnosis were abscess in 93/181 (51%), fistula in 91/181 (50%; 77/93 of complex fistulae), anal fissure in 28/181 (15%), anal stricture in 18/181 (10%). At diagnosis abscess drainage was performed in 31/181 (17%), drainage + seton in 44/181 (24%), stoma in 18/181 (10%). 132/181 (74%) and 83/181 (47%) had IS and anti-TNF respectively at pCD diagnosis. Relapse rate was 51% within a mean time of 33 months. During follow-up 15% required a stoma. Predictive factors of relapse were perianal abscess ($p<0.0001$, $HR=4.4$), fistula ($p<0.0001$, $HR=4.5$) or surgical drainage at diagnosis ($p<0.0001$, $HR=4.5$), young age at pCD diagnosis (28 versus 31 yo, $p=0.02$), short time between CD and pCD diagnosis (5.7 versus 7 years, $p=0.01$), IS ($p=0.04$, $HR=1.8$) and anti-TNF ($p=0.01$, $HR=1.5$) at pCD diagnosis. Anti-TNF during follow-up, time to introduce them and duration of anti-TNF treatment were not predictive of relapse. The young and old cohort had the same characteristics at pCD diagnosis except a higher use of IS (87% vs 48%, $p<0.0001$) and anti-TNF (3% vs 68%, $p<0.0001$) in the young cohort. Clinical outcome including the time to relapse, type of relapse, need for surgery and stoma was similar in both cohorts.
CONCLUSION: In our cohort of pCD patients half of them had a perianal relapse over the time requiring surgery in more than 2/3 of them. At pCD diagnosis perianal abscess, fistula, surgical drainage, young age, treatment with IS or anti-TNF were associated with a higher risk of relapse. Although higher prescription of anti-TNF and IS in the last years new treatment strategies have not impacted the outcome of pCD.

P0333 BIOMARKER ANALYSES FROM A PHASE 2 STUDY EVALUATING THE ANTI-INTERLEUKIN-13 ANTIBODY TRALOKINUMAB IN PATIENTS WITH ULCERATIVE COLITIS

C. Balendran[1,*], J. Kilhamn[1], S. Pierrou[1], E. Rehnström[1], N. Henderson[1], K. Randall[2], G. Hughes[2], M. Knutsson[1], F. Erlandsson[1], M.B. Hansen[1], S. Danese[3]
[1]*AstraZeneca, Mölndal, Sweden,* [2]*AstraZeneca, Alderley Park, United Kingdom,* [3]*Istituto Clinico Humanitas, Milan, Italy*

INTRODUCTION: Interleukin-13 (IL-13) is a central cytokine effector in the T-helper 2 immune response that has been proposed to be a key driver of ulcerative colitis (UC) pathogenesis. Tralokinumab (CAT-354) is a human immunoglobulin G4 antibody that inhibits binding of IL-13 both to IL-13 receptor (IL-13R) alpha 1 and IL-13R alpha 2.
AIMS & METHODS: The aim of these analyses was to gain insight into the mechanistic action of tralokinumab in a phase 2 study in patients with UC. Overall, 111 patients with moderate-to-severe UC were randomised in a 1:1 ratio to receive tralokinumab 300 mg or placebo subcutaneously every 2 weeks during a 12-week treatment phase. Serum samples were obtained at baseline and at 2-week intervals throughout the treatment phase. Biopsies were taken during colonoscopy at baseline and after 8 weeks of treatment from mucosal areas judged by the endoscopist to represent inflamed and normal colonic mucosa. IL-13 levels were assessed in serum and biopsy homogenates at baseline and following treatment. Changes from baseline to week 8 in colonic mRNA expression were assessed by *in situ* hybridisation for the tight junction protein claudin-2 and by quantitative PCR for selected IL-13-regulated genes. Data were analysed by treatment and treatment response, with clinical response defined as a decrease in total Mayo score of ≥ 3 points and $\geq 30\%$, and a decrease in rectal bleeding subscore of ≥ 1 point or an absolute subscore of 0 or 1.
RESULTS: A time-dependent increase in total IL-13 serum levels was observed with tralokinumab but not with placebo. Free IL-13 was detectable in homogenates of inflamed colonic mucosa; however, there was no consistent trend regarding changes from baseline after 8 weeks' treatment with tralokinumab. At baseline, *in situ* claudin-2 mRNA expression was higher in inflamed versus normal colonic mucosa. Claudin-2 mRNA expression decreased from baseline in clinical responders. There were numerical increases from baseline in colonic mucosal mRNA levels for IL-6, IL-8 and S100 calcium binding protein A8 (a subunit of calprotectin) in clinical responders in the tralokinumab group compared with clinical responders in the placebo group. A numerical decrease from baseline in mRNA for tumour necrosis factor receptor superfamily member 12A was seen in the tralokinumab group compared with placebo. However, gene expression changes were small and would not remain significant after correcting for multiple statistical comparisons.
CONCLUSION: Claudin-2 may be a useful prognostic biomarker for UC. Total IL-13 in serum increased with tralokinumab treatment, supporting systemic target engagement. In colonic mucosa, small expression changes in IL-13-regulated genes were associated with tralokinumab treatment, though measurement of free IL-13 could not confirm target engagement by tralokinumab in colonic mucosa.

INTRODUCTION: Purine analogue azathioprine (AZA) is widely used for induction and maintenance of remission in steroid dependent patients with inflammatory bowel disease (IBD).
AIMS & METHODS: We investigated its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients three years after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985-2012, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10-15 days for the first 3 months and then every 1-2 months following the institution of treatment.
RESULTS: Out of 2472 consecutive IBD outpatients visited in the index period, AZA was prescribed to 360 patients, 189 (52.5%) were affected by Crohn's disease (CD) and 171 (47.5%) by ulcerative colitis (UC). Seventy-eight patients with a follow-up <36 months were excluded from the study. Two hundred and eighty-two patients were evaluated, 152 (53.9%) with CD and 130 (46.1%) with UC. One hundred and fifty-four (54.6%) were male and 128 (45.4%) female (average age of 33.75 ± 13.82 SD years, range 14-76 y.). Three years after the institution of treatment, 170 (60.3%) patients still were in steroid-free remission (101 CD vs 69 UC, 66.4% and 53.1%, respectively, $p=0.0279$), 62 (22%) had a relapse requiring retreatment with steroids (38 UC vs 24 CD, 29.2% and 15.8%, respectively, $p=0.0091$), 50 (17.7%) discontinued the treatment due to side effects (27 CD vs 23 UC, 17.8% and 17.7%, respectively). Loss of response from 1st to 3rd year of follow-up was low, about 12%.
CONCLUSION: Three years after the onset of treatment 60% of patients did not require further steroid courses. After the first year loss of response was low in two subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

P0335 EFFICACY OF AN MMP9-SPECIFIC MONOCLONAL ANTIBODY IN A DSS-INDUCED COLITIS MODEL OF ULCERATIVE COLITIS

D. Marshall[1], R. Spangler[1], C. O'Sullivan[1], J. Adamkewicz[1], **V. Smith**[1,*]
[1]*Gilead Sciences, Inc., Foster City, United States*

INTRODUCTION: Ulcerative colitis (UC) remains a high unmet medical need with no current curative therapies; the majority of patients with UC require life-long treatment to prevent disease progression. UC is characterized by disease-specific upregulation of matrix metalloproteinase 9 (MMP9). MMP9 can exert pathogenic effects both by degrading extracellular matrix (ECM) proteins and participating in tissue destruction and by activating or releasing growth factors and cytokines from the ECM or cell surface. Previous attempts to target MMPs with broad-spectrum or semi-selective inhibitors in oncology and inflammatory diseases have been unsuccessful, partly due to their lack of specificity.
AIMS & METHODS: Here we used immunohistochemistry to confirm MMP9 induction at colitic foci in both human and DSS-exposed mice and evaluated efficacy of a therapeutically-dosed MMP9-specific monoclonal antibody (AB0046) in a DSS-induced colitis model of UC.
RESULTS: MMP9 immunoreactivity was limited in the healthy colon, but was strongly induced and had a similar pattern of expression at active disease sites in human UC and mouse DSS-colitis tissue. In disease, MMP9 was expressed in abscessed and necrotic crypts and regions of cryptitis containing neutrophilic infiltrates as well as by macrophages within the lamina propria. Extracellular MMP9 staining colocalized with regions of destruction in the epithelial crypt basement membrane. Inhibiting MMP9 in established DSS-induced colitis with AB0046 resulted in a significant protection (50%) against body weight loss and endoscopically assessed disease, and a 45% reduction in the incidence of diarrhea. Colons from AB0046-treated animals exhibited less crypt destruction, less inflammatory cell infiltration, and a reduction in MMP9 expression. In concordance with the IHC analysis, AB0046 treatment resulted in a decrease in histopathologic disease scores. Interestingly, AB0046 treatment resulted in reduction of serum markers of inflammation including IL-6, CXCL2, KC/GRO, MPO, LIF, MCP-1/2/5, MIP-3β, and TIMP-1.
CONCLUSION: MMP9 is highly expressed in human UC and in mouse DSS-exposed colons. The ability of MMP9 to degrade basement membrane and to activate or release pro-inflammatory factors from the ECM make this protein a compelling therapeutic target in colitis. Treatment of established DSS-induced colitis with an MMP9-specific monoclonal antibody resulted in improvement in clinical measures of disease, histopathology, as well as in systemic markers of inflammation. These data suggest that an MMP9 specific monoclonal antibody is a promising therapeutic strategy for treatment of UC. Gilead Sciences has developed a humanized MMP9-specific monoclonal antibody that is currently in a Phase 1b clinical trial in UC.

P0336 INFLIXIMAB ONE HOUR INFUSIONS – A GOOD CHOICE FOR IBD PATIENTS?

D. Branquinho[1,*], P. Freire[1], S. Mendes[1], M. Ferreira[1], F. Portela[1], C. Sofia[1]
[1]*Gastroenterology, Coimbra University Hospital (CHUC), Coimbra, Portugal*
Contact E-mail Address: *diogofbranquinho@yahoo.com*

INTRODUCTION: The use of anti-TNF agents as maintenance therapy in IBD patients is well documented. However, administration of Infliximab (IFX) implies long hours at the hospital, with significant costs and inconvenience. A shorter infusion protocol would minimize such drawbacks, maintaining the same safety and efficacy.
AIMS & METHODS: To evaluate the safety and efficacy profile of one hour IFX infusion.
Between November 2012 and December 2013, the occurrence of acute adverse reactions to IFX was prospectively documented. Patients under maintenance therapy, with at least 4 infusions with no history of reactions, received one hour infusions. This was followed by 1-hour surveillance in the next 5 infusions, and 30 minutes from then on.
RESULTS: From a total of 95 patients under IFX therapy (Average age: 38.8 ± 14.2 years old; Female - 58%; Crohn's Disease – 66, Ulcerative Colitis – 25, Unclassified IBD – 4), about 68% (65/95) started receiving one hour infusions (average of 6 per patient, total of 390 infusions), while 31.6% (30/95) were kept under the usual two hour protocol, with two hour infusions followed by one or two hours of surveillance.
In the one hour infusion group, 38.4% were under combined therapy with immunosuppressive agents and 23% received hydrocortisone and/or clemastine as prophylactic medication. There was no adverse reaction noted in this group. In 92.3% of the patients, the therapeutic regimen remained the same, but in the remaining 7.7%, an increase in dosage or interval shortening was needed. One patient had to change to Adalimumab (ADA) due to poor response to IFX.
In the 2-hour infusion group, 56.7% were under combined therapy with immunosuppressants and 43.3% received prophylactic medication. A total of 5 reactions were described (2.46%), 2 of which were severe (0.98%), leading to IFX definitive suspension. Initial regimen was maintained in 93.3% (28/30) of these patients, while 6.7% (2/30) had to increase IFX dosage or shorter intervals between infusions.
CONCLUSION: During maintenance therapy, 1 hour infusions are safe and effective, minimizing costs associated with IFX therapy, and allowing shorter hospital stays and better quality of life to IBD patients.

P0337 BODY MASS INDEX VARIATION IN INFLIXIMAB-TREATED IBD PATIENTS

D. Branquinho[1,*], P. Freire[1], S. Mendes[1], M. Ferreira[1], F. Portela[1], C. Sofia[1]
[1]*Gastroenterology, Coimbra University Hospital (CHUC), Coimbra, Portugal*
Contact E-mail Address: *diogofbranquinho@yahoo.com*

INTRODUCTION: A significant number of patients with IBD present with nutritional deficiencies and malnutrition is relatively common. There are several ways of describing response to Infliximab (IFX). However, nutritional status is rarely used as a tool to evaluate the efficacy of this anti-TNF agent.
AIMS & METHODS: To establish a relation between BMI changes and clinical response in patients treated with IFX.
Patients with IBD treated with IFX for at least a year were included. Their BMI was measured before starting IFX, after remission induction therapy, and then after 1 and 3 years of maintenance therapy. Response to IFX was evaluated through clinical and laboratorial data.
RESULTS: A total of 62 patients were included (average age 37.3 ± 13.8 years old; 71% females; Crohn's Disease – 45, Ulcerative Colitis – 19). Their initial average BMI was 21.4±3.07 (10 patients with BMI < 18.5 – 16.1%; 8 patients with BMI > 25 – 12.9%). After induction, no significant change was noted in BMI, but one year later, a meaningful increase was noted (21.4 to 22.7; $p = 0.049$). After three years of therapy, this tendency was more evident (21.4 to 22.8; $p = 0.026$), as only 2 patients still had BMI < 18,5, whilst 16 had weight excess (26%).
There was a significant increase in BMI in patients who responded to therapy, in contrast to those who maintained clinical activity. The average BMI actually decreased in the latter group (+1,81 *vs.* -0,96; $p = 0.012$). This increase was noted particularly in patients who had initial BMI < 18.5 ($p = 0.032$), as well as in male patients and with small bowel involvement. Factors such as age, disease duration, smoking or other medication did not show significant association with BMI.
CONCLUSION: Nutritional deficits are common clinical issues in IBD patients. Therapy with Infliximab is clearly associated with improved nutritional status in patients who are responders, unlike those who mantained disease activity. This association is more clearly noted in the group with lower initial BMI.
Disclosure of Interest: None declared

P0338 MONITORING VITAL SIGNS DURING INFLIXIMAB INFUSION – IS IT REALLY USEFUL?

D. Branquinho[1,*], P. Freire[1], S. Mendes[1], M. Ferreira[1], F. Portela[1], C. Sofia[1]
[1]*Gastroenterology, Coimbra University Hospital (CHUC), Coimbra, Portugal*
Contact E-mail Address: *diogofbranquinho@yahoo.com*

INTRODUCTION: Monitoring vital signs is part of the surveillance protocol during Infliximab infusions in most IBD reference centers. Despite being innocuous, it is a time consuming task, representing another burden to already strained healthcare professionals. In this era of increasing medical care costs, and with the growing number of IBD patients treated with biological agents, it becomes essential to analyze if this practice is able to predict or identify adverse reactions to Infliximab.
AIMS & METHODS: To evalute the usefulness of monitoring vital signs during Infliximab infusions.
From January 2013 to December 2013, each patient's pulse (HR), systolic blood pressure (SBP), temperature (Temp) and pulse oximetry (SpO2) were registered during Infliximab infusions. Acute adverse reactions were also recorded.
RESULTS: A total of 593 Infliximab infusions were administered to 95 patients (average of 6.2 ± 1.3 infusions per patient; median age: 38.8 ± 14.2 years old; 59% females; Crohn's Disease – 66, Ulcerative Colitis – 29). The overall incidence of acute infusion reaction was 2.2% (13 of 593 infusions), affecting 6 patients (6.3%). Two of them were serious, with bronchospasm and angioedema. Comparing baseline vital signs between groups with and without acute reactions, no relevant differences were noted (HR: 78 *vs.* 81/min, $p = 0.23$; SBP: 106 *vs.* 109 mmHg, $p = 0.12$; Temp: 35.9 *vs.* 36.1°C, $p = 0.68$; SpO2: 98% *vs.* 99%, $p = 0.42$). Vital signs measured immediately before and during acute reactions were also compared. No significant change was noted in most cases, except during the two serious reactions, in which there was an increase in heart rate (67 to 110 beats/min and 86 to 112/min) and a fall in one of the patients' SpO2 (97 to 85%), maintaining stable blood pressure and temperature.
CONCLUSION: Scheduled monitoring of vital signs during Infliximab infusions was unable to predict acute reactions or to identify patients with increased risk of such reactions, though it can help to assess its severity. Such conclusions do not suggest a more distant surveillance, but emphasize that clinical symptoms should be the main focus.

INTRODUCTION: Correlation between histological activity, endoscopic findings, levels of calprotectin and lactoferrin in ulcerative colitis (UC) are not well established. Infliximab can induce remission. Residual microscopic active inflammation may predict relapse. Non-invasive methods such as calprotectin may be appropriate for this purpose.
AIMS & METHODS: The primary aim was to evaluate the histological remission induced by infliximab at week 8 (Geboes <3.0); secondary aims were to evaluate the association between histological remission, mucosal healing, faecal calprotectin and faecal lactoferrin. 20 patients with moderate to severe UC (Mayo score 6-12) with inadequate response to corticosteroids or corticosteroid dependence, all of them anti-TNF naïve, started infliximab in a prospective, open-label, multi-centre study, with 1 year of follow-up, 4 visits assessments (baseline, week 8, week 30, and week 52). Topical treatment was not allowed. In each visit, Mayo score, faecal calprotectin and lactoferrin were evaluated, and sigmoidoscopy with biopsies was performed. The worst sample was used for histological score (Geboes index – GI) and the patients were considered in deep remission when in clinical remission (Mayo score <2) and GI ≤ 3 and calprotectin levels <100mg/L and lactoferrin ≤ 7.25mg/L and mucosal healing at endoscopy (0 or 1).
RESULTS: Out of the 20 patients, 13 had left-sided colitis (E2) and 7 had pancolitis (E3). At weeks 8, 30 and 52, 15%, 30% and 35% of the patients, respectively, were on histological remission. At the same intervals, 10%, 20% and 10% of the patients, respectively, were in deep remission. Sixty-six percent of those on histological remission at week 8 had persistent remission at week 30 and 52, and 100% of those on histological remission at 30 week persisted thereafter. Calprotectin >100mg/L at week 8 predicted histological activity (sensitivity: 76%; specificity: 100%), with a positive predictive value (PPV) of 100% and a negative predictive value (NPV) of 42%. Lactoferrin levels higher than 7.25 mg/L at week 8 predicted histological activity (sensitivity: 94%; specificity: 66%), with a PPV of 94% and a NPV of 66%. The probability of being in histological remission once achieving mucosal healing (PPV) was 55% (weeks 30 and 52) and the probability of endoscopic mucosal healing with calprotectin ≤ 100mg/L was 100% and 75%, respectively, at weeks 30 and 52.
CONCLUSION: Infliximab is able to induce and maintain histological remission in ulcerative colitis patients. High levels of calprotectin and lactoferrin predict persistent histological activity.

P0340 ANTI-TNF HAS A FAVORABLE EFFECT ON INSULIN SENSITIVITY IN NON-DIABETIC, NON-OBESE PATIENTS WITH INFLAMMATORY BOWEL DISEASE

F. Kothonas[1,*], S.A. Paschou[2], A. Myroforidis[1], V. Loi[2], T. Terzi [2], O. Karagianni[2], A. Poulou[1], A. Vryonidou[2], K. Goumas[1]

Contact E-mail Address: *fotiskothonas@gmail.com*

INTRODUCTION: Insulin resistance is very common in autoimmune systemic diseases and recently it was also found in children and adults with inflammatory bowel disease (IBD). Inflammation and insulin resistance are closely linked, and inflammatory cytokines such as tumor necrosis factor alpha (TNFa) may inhibit insulin signaling and promote insulin resistance. The aim of this study was to investigate the effect of anti-TNF therapy on glucose and lipid metabolism in non-diabetic, non-obese patients with IBD.
AIMS & METHODS: We studied 41 patients with IBD (25M/16F, 36.4 ± 11 (19-64) years old, 28 with Crohn's disease and 13 with ulcerative colitis), without known history of diabetes. Eighteen patients (9M/9F, 33.6 ± 8.8 years) were on anti-TNF therapy for more than 1 year, while the other 23 patients (16M/7F, 38.7 ± 12.5 years) were treated with azathioprine and mesalazine (Aza/Mes). Nine of the patients from the second group were then treated with anti-TNF and studied again 6 months after. Fasting glucose, insulin, c-peptide, HbA1c, lipids, and CRP levels were determined and HOMA-IR index was calculated, in all patients. Statistical analysis of the data was performed using SPSS 16.00.
RESULTS: Three of the patients were diagnosed with overt diabetes and were excluded from the analysis. Patients from the two therapy groups were matched for age (anti-TNF: 33.6 ± 8.8 years vs Aza/Mes: 38.7 ± 12.5 years, $p>0.05$) and BMI (anti-TNF: 23.3 ± 3.4 vs Aza/Mes: 23.1 ± 1.7, $p>0.05$), and were not obese. We did not find any statistical differences between the patients from the two therapy groups in the levels of fasting glucose (anti-TNF: 88 ± 10.7 vs Aza/Mes: 93.4 ± 14.9 mg/dl, $p>0.05$), insulin (anti-TNF: 10.9 ± 7.9 vs Aza/Mes: 12.1 ± 6.6 mIU/ml, $p>0.05$), c-peptide (anti-TNF: 1.9 ± 0.9 vs Aza/Mes: 2.2 ± 1.4 ng/ml, $p>0.05$), HbA1c (anti-TNF: 5.2 ± 0.3 vs Aza/Mes: $5.3 \pm 0.4\%$, $p>0.05$), total cholesterol (anti-TNF: 168.6 ± 32.7 vs Aza/Mes: 162.8 ± 34.3 mg/dl, $p>0.05$), HDL (anti-TNF: 57.5 ± 15.7 vs Aza/Mes: 53.8 ± 20.3 mg/dl, $p>0.05$), LDL (anti-TNF: 95.8 ± 28.7 vs Aza/Mes: 90.7 ± 24.4 mg/dl, $p>0.05$), triglycerides (anti-TNF: 75.8 ± 37.6 vs Aza/Mes: 90.8 ± 61.3 mg/dl, $p>0.05$), CRP (anti-TNF: 3 ± 5.4 vs Aza/Mes: 4.9 ± 6.1, $p>0.05$) and in the HOMA-IR index (anti-TNF: 2.77 ± 2 vs Aza/Mes: 3.1 ± 1.9, $p>0.05$). In patients who were treated for 6 months with anti-TNF, a statistically significant decrease in insulin (before: 15.4 ± 5.8 vs after: 10.2 ± 2.7 mIU/ml, $p=0.049$) and c-peptide (before: 2.4 ± 1.2 vs after: 1.4 ± 0.4 ng/ml, $p=0.038$) levels as well as the HOMA-IR index (before: 4.1 ± 2.1 vs after: 2.3 ± 0.7, $p=0.047$) was observed, without any statistically significant changes in weight, BMI, glucose, HbA1c, lipids and CRP levels (in all comparisons $p>0.05$).
CONCLUSION: These preliminary data indicate that anti-TNF therapy may have a favorable effect on insulin sensitivity in non-diabetic, non-obese patients with inflammatory bowel disease.

INTRODUCTION: Free fatty acids (FFAs) are nutritional components and metabolic intermediates that play important roles in a wide range of cellular functions (energy source, membrane structure, signalling). Recently, FFAs have been reported to activate a family of G protein-coupled receptors, which are involved in the pathophysiology of a variety of diseases, including metabolic and inflammatory disorders. GPR84 is activated by medium chain FFA (carbon length C9-C14). The receptor is primarily expressed on white blood cells (PMN, monocyte/macrophage) consistent with a reported role for GPR84 in inflammation.
We identified GLPG1205 as a potent and selective antagonist of GPR84, inhibiting GPR84 activation in HEK cells, as well as GPR84-induced neutrophil migration. In a mouse IBD model (DSS), GLPG1205 dose-dependently decreased the disease activity index, to a similar level as sulphasalazine and cyclosporine. The histological score for colon lesions, neutrophil influx as well as colonic MPO content was substantially reduced.
AIMS & METHODS: To evaluate the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of GLPG1205 in healthy volunteers, and identify a dose for subsequent Proof of Concept studies in inflammatory bowel disease.
GLPG1205 was administered as a liquid suspension, providing maximal dose flexibility, as single doses (10 up to 800 mg) or multiple doses (50, 100 and 200 mg once daily (QD) for 14 days). Each dose level was evaluated in panels of 8 male healthy volunteers, with 6 receiving GLPG1205 and 2 placebo. In order to evaluate target engagement, PD was assessed by a competitive radiolabeled binding assay in whole blood, using a tritiated GPR84 antagonist chemically closely related to GLPG1205.
RESULTS: In healthy volunteers, GLPG1205 was generally safe and well tolerated up to 100 mg QD for 14 days, with no adverse effects on ECG, vital signs or laboratory parameters. The most relevant adverse event was headache. The PK of the compound showed a good oral bioavailability with a long half-life ($>$ one day) and a dose-proportional increase in exposure. Steady state was reached after 8 to 10 days. GLPG1205 showed concentration-dependent target engagement in whole blood (*ex vivo*), showing similar potency as in *in vitro* assays. The single-dose PK/PD data demonstrated a clear relationship between drug exposure and PD effect. Complete target occupancy for 24 hours after once daily dosing in volunteers was observed at doses of 100 and 200 mg QD.
CONCLUSION: GLPG1205, a potent and selective inhibitor of GPR84, is safe and generally well tolerated in healthy volunteers. It shows a favorable PK/PD profile, clearly demonstrating the ability of the compound to antagonize GPR84, a target which might be implicated in several neutrophil- and macrophage-driven inflammatory conditions. At 100 mg once-daily, full 24-hour inhibition was obtained. This dose will be studied in Proof of Concept studies to evaluate the efficacy and safety of GLPG1205 in patients with Crohn's disease and ulcerative colitis.

INTRODUCTION: The FODMAP (fermentable oligo- di- and monosaccharides, and polyols) -restricted diet has previously been proven effective to improve symptoms in patients with irritable bowel syndrome (IBS). FODMAPs are small osmotic active and poorly absorbed short-chain carbohydrates, and include fructose (found in fruit), lactose (found in milk products), fructans (found in grain and vegetables), galacto-oligosaccharides (found in legumes) and polyols (found

in sweetened products). FODMAPs are rapidly fermented by bacteria in the colon and can cause bloating, increased gas production, abdominal pain and altered bowel movements. FODMAPs do not cause IBS, but a FODMAP-restricted diet may improve the symptoms. Patients with inflammatory bowel disease (IBD) often suffer from persistent symptoms even though the inflammatory activity is in remission. This study aimed to investigate the FODMAP-restricted diet in patients with IBD in remission with persistent symptoms consistent with IBS.

AIMS & METHODS: A 6 week intervention was undertaken in 12 IBD-patients (10 ulcerative colitis and 2 Crohns disease, 3M/9W, age 23-57 years) in remission with CRP < 5mg/L and faecal calprotectin < 100mg/kg, and fulfilling the ROME-III criteria for IBS. FODMAP intake was determined by 4 days prospective dietary registrations at 0 and 6 weeks. Instructions and follow-up were given by a clinical dietician. IBS-symptoms and quality of life (QoL) were assessed with questionnaires (IBS-SSS and SF-36). Compliance was assessed by VAS-scales. Colonic fermentation was measured by breath tests with sampling for 180min after intake of 10g lactulose. Statistics: T-tests and ANOVA ($p < 0.05$).

RESULTS: FODMAP intake was significantly reduced from median 6.3g/d to 1.5g/d ($p = 0.0005$). IBS symptoms were significantly reduced from median IBS-SSS score 265.0 to 67.6 ($p < 0.0001$), and resolved in 58% of patients (remission classified as score < 75). Symptoms were reduced in the first 3 weeks and remained stable from 3 to 6 weeks. Mental-related QoL significantly improved from median score 43.8 to 53.3 ($p = 0.039$). There was a positive trend for physical-related QoL with mean score 41.0 vs. 47.1 ($p = 0.05$). QoL improved over the whole 6 weeks of the intervention. The scores for the SF-36 health domains "bodily pain" (53.3) and "vitality" (52.1) improved most, with p-values 0.004 and 0.017, respectively. Gas production did not change (AUC 3488 vs. 3390 ppm x min, $p = 0.8$). Mean compliance with the diet was 93%, and 73% continued the diet one month after the intervention.

CONCLUSION: The FODMAP-restricted diet resolved or improved IBS symptoms and QoL, and should be considered an effective treatment for patients experiencing symptoms in spite of remission from IBD.

P0343 INCREASED EXPRESSION OF T-CELL-ASSOCIATED GENES IN BASELINE BIOPSIES FROM TNF ANTAGONIST NAIVE PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS WHO UNDERGO REMISSION IN RESPONSE TO ETROLIZUMAB IN A PHASE II TRIAL

INTRODUCTION: Etrolizumab is a humanized antibody to the integrin $\beta7$ subunit that blocks $\alpha4\beta7$ and $\alpha E\beta7$ binding to MAdCAM-1 and E-cadherin, respectively. In a recent phase II randomized double-blind placebo-controlled trial (EUCALYPTUS), induction therapy with etrolizumab showed clinically meaningful efficacy compared to placebo at week 10 in patients with moderate to severely active ulcerative colitis.

AIMS & METHODS: RNA sequencing of inflamed colonic biopsies from TNF antagonist naïve etrolizumab-treated patients who took part in EUCALYPTUS was used as a hypothesis-free approach to identify gene expression patterns associated with clinical remission in response to etrolizumab. Gene set enrichment analysis of pre-defined immune cell gene sets was performed. Following this, differentially expressed genes of interest were evaluated in sorted CD4+ or CD8+ $\alpha E\beta7$-positive and -negative T cells from colonic biopsies of non-EUCALYPTUS UC patients and control subjects.

RESULTS: TNF antagonist naïve patients that underwent remission in response to etrolizumab had higher baseline expression of T cell-associated genes in mucosal biopsies, while high baseline expression of neutrophil-associated genes was associated with etrolizumab non-response. Patients with higher than median gene expression levels of the T cell associated genes ITGAE (αE integrin), granzyme A and TMEM200A were enriched for remission in response to etrolizumab. As increased αE gene expression was associated with remission, sort purified $\alpha E\beta7$-positive T cells from biopsies of UC patients were used to test for increased expression of other remission-associated T cell genes. Gene expression of granzyme A in CD4+ and CD8+ T cells ($p < 0.01$) and TMEM200A in CD8+ T cells ($p < 0.05$), along with other effector molecules such as granzyme B and perforin in CD4+ T cells ($p < 0.05$), were found to be increased in $\alpha E\beta7$-positive T cells relative to $\alpha E\beta7$-negative T cells from UC patients but not healthy subjects. Finally, gene expression of the effector molecules granzyme A and B were decreased following etrolizumab treatment in patients achieving remission.

CONCLUSION: Enrichment of T cell associated genes, including αE and granzyme A, was observed in baseline colonic biopsies from TNF antagonist naïve patients that achieved clinical remission in response to etrolizumab. These candidate biomarkers may identify patients whose disease pathobiology is predominantly T cell-mediated and may benefit from etrolizumab treatment.

P0344 QAX576, AN ANTI–INTERLEUKIN (IL)-13 MONOCLONAL ANTIBODY, FOR THE TREATMENT OF PATIENTS WITH FISTULISING CROHN'S DISEASE (CD): RESULTS OF A PROOF-OF-CONCEPT STUDY

G. Rogler[1,*], A. Stallmach[2], S. Fichtner-Feigl[3], S. Schreiber[4], A. Sturm[5], E. Ramsden[6], P. Moulin[6], D. Lee[6], A. Christ[6]
[1]Division of Gastroenterology and Hepatology, University Hospital, Zurich, Switzerland, [2]Department of Internal Medicine IV, Jena University Hospital, Jena, [3]Department of Surgery, University Medical Center Regensburg, Regensburg, [4]Department of Internal Medicine I, University Hospital Schleswig-Holstein, Kiel, [5]Charité Campus Virchow Klinikum, Medical Department, Berlin, Germany, [6]Novartis Institutes for BioMedical Research, Basel, Switzerland

INTRODUCTION: Recent studies have identified IL-13 as a key cytokine driving the tissue remodelling that accompanies fistula formation in CD. This study assessed the effect of QAX576, an anti–IL-13 monoclonal antibody on fistula healing in patients with fistulising CD.

AIMS & METHODS: In this 52 weeks (6 weeks treatment, 46 weeks observation), multi-centre, parallel group, double-blind, active controlled study, 23 patients (≥18 years) were planned to be included. Enrolment was stopped after 10 patients due to slow recruitment. Eligible patients (CD ≥ 6 months, ≥ 1 perianal fistula, ≥ 1 ineffective fistula treatment but no previous anti-TNF α treatment failure) were randomized to receive intravenously either QAX576 10 mg/kg (at baseline, Weeks 3 and 6; placebo at Week 2; $n = 6$) or infliximab (IFX) 5 mg/kg (at baseline, Weeks 2 and 6; placebo at Week 3; $n = 4$). The primary variable was the number of patients (responders) achieving complete closure of all perianal fistulas for ≥ 4 weeks (compared to historical placebo rate of ~13%). Secondary variables included clinical assessments of the fistulas and MRI-based activity scores of the fistula tracts.

RESULTS: Nine patients were included in the pharmacodynamic analysis set (QAX576 = 6; IFX = 3 [one patient excluded due to protocol deviation]). The primary endpoint was achieved by two patients (33.3%; 90% CI: 0.114, 0.656) in the QAX576 group. One patient stopped treatment due to abscess formation (Week 3), one due to lack of efficacy (Week 14). In the QAX576 group, patients had 1-4 secreting fistulas at baseline. Both responders had complete closure with absence of any secretion within 3 weeks, although the MRI activity score remained stable or even increased in these two patients. Fistula secretion remained stable in three patients and fluctuated in one. All patients in the IFX group were responders.

Immunohistochemistry of fistula tissue at baseline confirmed epithelial expression of IL-13Rα2 (but not IL-13Rα1) and de-differentiation of distorted, entrapped crypts; SNAIL expression as marker of invasiveness was not found.

Overall, 35 AEs were reported in four patients (66.7%) in the QAX576 group; 24 AEs were reported in four patients (100%) in the IFX group. Majority of AEs were mild or moderate in severity. No death was reported in this study. One SAE (procedural pain) was reported in the IFX group.
CONCLUSION: In this study, QAX576 was well tolerated. As expected IFX was a powerful agent to induce fistula closure. Blockade of IL-13 may be effective, too, as compared to historical placebo rates, although the very low patient number does not allow a formal assessment.

P0345 THE INFLUENCE OF ANTI-ADALIMUMAB ANTIBODIES ON ADALIMUMAB TROUGH LEVELS, TNF-A LEVELS AND CLINICAL OUTCOME

G. Bodini[1,*], V. Savarino[1], P. Dulbecco[1], I. Baldissarro[1], E. Savarino[1]
[1]*IRCCS San Martino DIMI, genova, Italy*
Contact E-mail Address: *bodini.giorgia@gmail.com*

INTRODUCTION: There is increasing evidence on the role of low trough levels and the development of anti-TNF-α antibodies for the occurrence of lack/loss of response to Infliximab (IFX) therapy in patients with Crohn's Disease (CD). Therefore, several recent papers and guidelines suggested the need for dosing IFX concentrations and anti-IFX antibodies in order to treat better CD patients. To date, there are limited data on the role of Adalimumab (ADA) trough levels and anti-ADA antibodies (AAA) for the management of CD patients.
AIMS & METHODS: We assessed the role of AAA on ADA trough levels, TNF-α concentrations, clinical biomarker (i.e. C-reactive protein) and clinical outcome. In this prospective observational cohort study, performed at a single tertiary referral center, 23 [14M/9F; mean age 41 (range 21-66)] infliximab-naïve patients with CD achieving disease remission and in maintenance treatment with ADA were included and followed-up. Blood samples were drawn at standardized time points (i.e. every 6 months or in case of CD relapse) just before ADA injection. Trough ADA serum concentration and AAA were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Blood samples were considered positive for AAA presence if AAA were $\geq$ 1.7 U/mL and for ADA trough levels if ADA levels were $\geq$ 5 µg/ml. Disease activity was assessed at the same points by means of routine biochemistry and the Harvey-Bradshaw Index (HBI, remission <5, mild disease 5-7, moderate disease 8-16, severe disease >16).
RESULTS: We have data from 189 blood samples. AAA were observed in 42/189 (22.2%) samples, out of whom 16/42 (38.1%) had levels of AAA $\geq$1.7 U/mL. ADA trough levels were found in 183/189 (96.8%) samples, out of whom 168/183 (91.8%) had a value of drug levels $\geq$5 µg/ml. Overall, 5/23 (21.7%) patients had AAA and 22/23 (95.6%) were positive for ADA levels. Blood samples with AAA had lower ADA trough levels [7.54 (0-26.49) vs. 9.45 (0.14-23.62); $p=0.002$] and higher TNF-α concentrations [5.9 (4.1-11.5) vs. 3.6 (0-27.2); $p=0.0007$] than blood samples without evidence of AAA. Moreover, patients with blood samples positive for AAA reported HBI values higher compared to patients without evidence of AAA [10 (3-17) vs. 5 (2-17); $p<0.0001$]. Finally, no difference was found in terms of mean PCR values between patients with AAA and those without [8.1 (3-76.4) vs. 5.2 (2.6-56); $p=0.39$].
CONCLUSION: Development and presence of AAA decreases ADA trough levels and increases TNF-α concentrations in blood samples from CD patients on maintenance treatment with ADA, thus favoring clinical relapse in them as demonstrated by the increased values of HBI scores recorded at the time of blood sampling.

P0346 TNF-A LEVELS STRONGLY CORRELATED WITH DISEASE ACTIVITY BASED ON HBI AND CDEIS IN PATIENTS WITH CROHN'S DISEASE IN MAINTENANCE TREATMENT WITH ADALIMUMAB

G. Bodini[1,*], V. Savarino[1], P. Dulbecco[1], I. Baldissarro[1], E. Savarino[1]
[1]*IRCCS San Martino DIMI, genova, Italy*
Contact E-mail Address: *bodini.giorgia@gmail.com*

INTRODUCTION: In the last two decades the therapeutic paradigm of Crohn's disease (CD) has changed dramatically thanks to the use of biological drugs. In this scenario, we must consider the pivotal role of tumor necrosis factor-alpha (TNF-α), a pro-inflammatory cytokine, in the pathogenesis and relapse of CD. High levels of TNF-α have been associated with the development of intestinal inflammation in CD and blocking this cytokine with anti-TNF-α molecules may result in mucosal healing. In addition several studies have shown increased TNF-α levels in the serum and in the intestinal mucosa of patients with CD. However, little is known about the course of TNF-α levels and their relationship with disease recurrence in CD patients during maintenance treatment with Adalimumab.
AIMS & METHODS: We assessed TNF-α levels in patients with CD who were in maintenance treatment with ADA and correlated them with clinical and endoscopic disease activity. In this prospective observational cohort study, performed at a single tertiary referral center, 23 [14M/9F; mean age 41 (range 21-66) infliximab-naïve patients with CD in maintenance treatment with ADA were included and followed-up. Blood samples were drawn at standardized time points (i.e. every 6 months and in case of CD relapse) just before ADA injection. Antibodies against ADA (AAA) were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Blood samples were considered positive for AAA presence if $\geq$1.7 U/mL. Disease activity was assessed at the same points by means of the Harvey-Bradshaw Index (HBI, remission <5). Moreover, endoscopic activity was assessed at baseline and at the time of relapse by means of CD endoscopic index (CDEIS; endoscopic remission <9).
RESULTS: We have data from 133 blood samples. AAA were observed in 26/1339 (19.5%) samples, and 10/26 (38.5%) had a value of AAA $\geq$1.7 U/mL. TNF-α levels were present in all samples assessed [mean 4.4, range (0-27.2)]. Patients in clinical remission based on HBI had lower TNF-α levels compared to patients who relapsed [3.7 (0.2-20.2) vs. 5.6 (1.3-27.2); $p=0.0002$]. Similarly, patients in endoscopic remission based on CDEIS had lower TNF-α levels compared to patients who relapsed [3.1 (0.2-20.2) vs. 4.3 (1.3-27.2); $p=0.0034$]. Per-patient median TNF-α levels were strongly correlated with median HBI scores ($r^2=0.702$, $p<0.0001$). Moreover, TNF levels were also correlated with CDEIS ($r^2=0.350$, $p=0.001$).
CONCLUSION: TNF-α levels strongly correlated with disease activity based on HBI and CDEIS indices in patients with CD in maintenance treatment with ADA. Indeed, moderate to severe patients often have high sustained TNF-α levels.
Disclosure of Interest: None declared

P0347 LONG-TERM OUTCOMES OF PATIENTS WITH ULCERATIVE COLITIS TREATED WITH INFLIXIMAB

F.L. Roy[1], L. Siproudhis[1], C. Brochard[1], V. Desfourneaux[2], P.-N. D'Halluin[1], M. Pagenault[1], J.-F. Bretagne[1], **G. Bouguen**[1,3,*]
[1]*Service des Maladies de l'Appareil Digestif,* [2]*Service de Chirurgie Viscérale, CHU Pontchaillou,* [3]*INSERM U991, Université de Rennes 1, Rennes, France*

INTRODUCTION: Data on the long-term efficacy of infliximab for the treatment of ulcerative colitis are scarce. Sustained remission, recurrence and outcomes after infliximab withdrawal beyond one year as well as predictors of long-term outcomes are unknown.
AIMS & METHODS: The medical records of all patients with ulcerative colitis and treated with infliximab in a referral center between 2001 and 2012 were reviewed through September 2013. The cumulative incidence of surgery, remission and recurrence with or without infliximab withdrawal were estimated using the Kaplan-Meier method. Independent predictors of all outcomes were identified using a Cox proportional hazards model.
RESULTS: A total of 100 patients (63 males) with ulcerative colitis and treated with at least one infliximab infusion were included. At infliximab initiation, 17% of patients had severe acute colitis defined by the absence of response following intravenous steroid and 56% of patients had pancolitis. Concomitant treatment at infliximab initiation included steroids and immunosuppressants for 62% and 52% of patients, respectively. After a median follow-up of 55.1 months, the cumulative probabilities of surgery were 27%, 33% and 36% at 1, 3 and 5 years, respectively. A CRP $>$ 6mg/L at week 6 was associated with colectomy (HR = 3.43, 95% CI, 1.17-10.9; $p=.023$). Clinical remission was obtained in 64% of patients but almost half of the patients relapsed (28/64; 44%). Overall the cumulative probabilities for sustained clinical remission were 19%, 31% and 38% at 1, 3 and 5 years, respectively. The absence of infliximab withdrawal was the only factor independently associated with sustained clinical remission (HR = 4.6, 95% IC, 1.66-13.85; $p=0.0029$). Infliximab was withdrawn in 38 of the 64 patients in clinical remission. After a median follow up of 54 months following infliximab withdrawal, 10% (4/38) underwent colectomy, 63.2% (24/38) patients relapsed, and 36.8% (14/38) remained in clinical remission. The cumulative probabilities of relapse after IFX withdrawal at 1, 3 and 5 years were 24%, 61% and 81%, respectively. A young age $<$ 21 years at UC diagnosis (HR = 12, 95% IC, 2.77-58.24; $p=0.001$) and platelets rate $>$ 400000/mm3 at IFX withdrawal (HR = 6.68, 95% IC 1.55-30.82; $p=0.011$) were associated with relapse.
CONCLUSION: After a follow-up of almost 5 years, about one-third of patients experienced sustained clinical remission and one-third of patients underwent surgery. Most of the patients relapsed after infliximab withdrawal. These results suggest early optimization of infliximab treatment to avoid dreaded outcomes and to continue infliximab among responders to sustain remission.

INTRODUCTION: Studies over the past two decades have convincingly demonstrated the role of barrier dysfunction in the pathogenesis of inflammatory bowel disease (IBD). We have previously found that optical biopsy with probe-based confocal laser endomicroscopy (pCLE) could be used to assess mucosal barrier function and predict disease relapse in pediatric IBD patients. The purpose of this pilot study is to evaluate the correlation of pCLE findings between duodenal and terminal ileum in pediatric IBD patients.
AIMS & METHODS: This is a prospective study of pediatric IBD (Crohn's disease - CD and ulcerative colitis-UC) patients undergoing pCLE during both EGD and colonoscopy in a tertiary referral center. The barrier function was assessed with the density of epithelial gaps on pCLE of the duodenum and terminal ileum. Adequate imaging of the duodenum and terminal ileum were defined as at least 3 normal, non-diseased areas sampled; a minimum of 3 villi with the highest number of epithelial gaps were analyzed. The epithelial gap density was calculated based on the total number of epithelial gaps observed normalized per 1000 epithelial cells counted on adequately imaged villi.
RESULTS: A total of 13 IBD patients (9 CD, 4 UC) underwent EGD and colonoscopy with adequate pCLE imaging of the duodenum and terminal ileum in the study. There were 8 F (62%) and 5 M (38%) with a median age of 15 yr (range 10 to 20). The median duration of disease at the time of pCLE was 3 yr (range 0 to 9); for therapy, 4 patients (31%) were on anti-TNF agents, 6 (46%) were on 5-ASA and/or immunomodulators, 1 (7%) were on steroids, 2 (15%) were on no therapy. The disease distributions for CD were: ileo-colitis in 7 patients (78%), ileitis in 1 (11%) and colitis 1 patients (11%). For UC: 1 patients (25%) had pan-colitis, distal colitis in 2 (50%) and proximal colitis in 1 (25%). The gap density (mean ± SE) in the terminal ileum was 5.6 ± 1.7 gaps/1000 cells, while in the duodenum was 1.7 ± 0.5 gaps/1000 cells. There were modest correlation between the gap density in the terminal ileum and duodenum with a spearman correlation coefficient of 0.42 ($p = 0.15$)
CONCLUSION: In this pilot study of pediatric IBD patients, we found pCLE findings of barrier function as measured by epithelial gap density in the terminal ileum and duodenum had modest correlation. Future larger studies are warranted to further investigate the correlation of barrier function in the proximal and distal intestine.

Contact E-mail Address: *caamachado@sapo.pt*

INTRODUCTION: INTRODUCTION: Inflammatory bowel disease (IBD) includes Crohn's disease (CD), ulcerative colitis (UC) and indeterminate IBD (IIBD). Although it primarily affects adults, the diagnosis in patients under 18 is about 25% to 30%, being CD the most frequent. Studies report an increase in the incidence of CD, but a stable incidence of UC. A 2010 study in Minho reports an incidence of 6.4/100000 (CD:66%; UC:34%).
AIMS & METHODS: Our aim was to characterize patients diagnosed with IBD from 2002 to 2013, between the ages of 0 to 17 years and 365 days, residents in Minho (districts of Braga and Viana do Castelo), calculate the incidence and evaluate the health-related quality of life. We conducted a retrospective study, by collecting information from the patient's personal clinical chart. Also performed was a cross-sectional study applying the IMPACT-III© questionnaire that assesses the quality of life of pediatric patients with IBD above 9 years old.
RESULTS: 137 subjects were found. The incidence in 2002-2013 was 5.0/100000 children-years (CD:66%, UC:32%, IIBD:2%), increasing from 2.4/100000 (CD:65%, UC:35%) in the first three years to 8.8/100000 (CD:75%, UC:23%, IIBD:2%) in the last three ($p < 0.0001$). Abdominal pain was the most frequent symptom in CD and hematochezia in UC. In the IMPACT-III©, the average score was 136.5 ± 19.2 ($n = 32$), with a Cronbach's alpha = 0.91.
CONCLUSION: There was a significant increase in the incidence of IBD, mainly due to CD. The symptoms usually indicate the type of IBD, and again in pediatric cases, abdominal pain is more prevalent than diarrhea in the presentation of CD. The quality of life seems to be similar to that found in other studies, still showing good internal consistency of the IMPACT-III©.

INTRODUCTION: Muco-cutaneous manifestations (MCM) are common in adult patients with Crohn's disease (CD), but their frequency in paediatric-onset CD is unknown.
AIMS & METHODS: **The aims of our study** were in a population-based paediatric-onset CD cohort: i) to determine the cumulative incidence of MCM, including aphtous stomatis (AS), erythema nodosum (EN) and pyoderma gangrenosum (PG); and ii) to identify the socio demographic and clinical factors at CD diagnosis associated with a higher risk of developing MCM during the CD course.
Patients and Methods: Clinical data at diagnosis and at maximal follow-up were recorded in a population-based paediatric-onset CD cohort ($n = 537$, < 17 years at CD diagnosis) diagnosed from 1988 to 2004. Data on MCM were reviewed by a dermatologist. Risks of developing MCM were estimated by survival analysis and Cox models.
RESULTS: Median age at CD diagnosis was 14.6 years ($Q1 = 12.2$; $Q3 = 16.1$) and 53.6% of patients were males. At CD diagnosis, 87 patients (16.2%) had MCM including 26 of them (30%) with at least 2 MCM. After a median follow-up of 11 years ($Q1 = 7$; $Q3 = 15$), 148 patients (28%) developed a total of 175 MCM, including 110 (63%) AS, 59 (34%) EN, and 6 (3%) PG. Cumulative incidence of developing MCM was 21% [17.7 -24.6], 25% [21.6-29.0], 27% [23.5-31.2] and 28% [24.3-32.3] at 1, 5, 10 and 15 years, respectively. In multivariate analysis, female gender (HR = 2.6 [1.4-4.6]; $p = 0.002$), patients < 15 years at diagnosis (HR = 2.2 [1.3-3.8]; $p = 0.003$) and L4 location at diagnosis (HR = 2.2 [1.3-3.6]; $p = 0.002$) were significantly associated with a higher risk of developing MCM during the CD course.
CONCLUSION: In this population-based paediatric-onset CD cohort, MCM are frequent both at diagnosis and during CD course, and are associated to female gender, young age and L4 location at CD diagnosis. These results reinforce the need of a close collaboration between dermatologists, paediatric gastroenterologists and gastroenterologists in paediatric-onset CD in order to optimize the therapeutic management of these patients.

P0351 LONG-TERM EFFICACY OF ADALIMUMAB IN PAEDIATRIC PATIENTS WITH CROHN'S DISEASE

W.A. Faubion[1], M. Dubinsky[2], **F. Ruemmele**[3,*], J. Escher[4], J. Rosh[5], A. Lazar[6], S. Eichner[7], Y. Li[7], N. Reilly[7], R.B. Thakkar[7]
[1]*Mayo Clinic, Rochester,* [2]*Cedars-Sinai Medical Center, Los Angeles, United States,* [3]*Universite Sorbonne Paris-Cite, Hospital Necker-Enfants Malades, Paris, France,* [4]*Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands,* [5]*Goryeb Children's Hospital/Atlantic Health, Morristown, United States,* [6]*AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany,* [7]*AbbVie Inc, North Chicago, United States*

INTRODUCTION: The efficacy of adalimumab (ADA) in children with moderately to severely active Crohn's disease enrolled in the IMAgINE 1 trial has been reported up to week (wk) 52[1]. Long-term efficacy of ADA in patients (pts) enrolled in the on-going open-label (OL) extension, IMAgINE 2, is presented.
AIMS & METHODS: Pts who completed IMAgINE 1 through wk 52 were allowed to enroll in IMAgINE 2. Pts entering from blinded therapy received OL ADA according to body weight (≥40 kg: 40 mg ADA every other wk [EOW]; <40 kg, 20 mg ADA EOW). At or after wk 8, pts experiencing flares (increase in PCDAI ≥15 points compared to PCDAI at previous visit) could move to wkly (EW) dosing. Pts entering IMAgINE 2 from OL ADA (40 mg ADA or 20 mg ADA EW) continued to receive the same dose. Remission (PCDAI≤10) and response (PCDAI decrease ≥15 points from IMAgINE 1 baseline) over time were assessed in pts who entered IMAgINE 2. Missing data were handled using non-responder imputation (NRI) and last observation carried forward (LOCF). Endpoints are also reported as observed. A data cut-off of Jun 30, 2013 was used for this analysis.
RESULTS: Of the 188 randomized pts in IMAgINE 1, a total of 100 pts enrolled in IMAgINE 2. As of Jun 30, 2013, a total of 54 pts are ongoing in the study. Approximately 2/3 of pts entered IMAgINE 2 in remission and almost all entered with response (67% and 95%, respectively). Observed remission and response

rates remained stable over time during IMAgINE 2 (Table). Mean PCDAI scores decreased from 40.1 at IMAgINE 1 baseline to 8.6 at wk 192 of IMAgINE 2 (Table). Adverse event rates from IMAgINE 1 baseline up to wk 260 have been previously reported and no new safety signals were observed with prolonged ADA use.[2]

Table. Rates of remission and response and observed mean PCDAI scores during IMAgINE 2

Week	0	24	48	72	96	120	144	168	192
Remission (%)									
NRI	67.0	59.0	55.0	50.0	54.0	51.0	51.0	42.0	26.0
LOCF	67.0	62.2	61.2	57.1	61.2	62.2	63.3	62.2	61.2
Observed	67.0	62.8	66.3	64.1	70.1	73.9	79.7	79.2	81.3
Response (%)									
NRI	95.0	88.0	75.0	74.0	72.0	66.0	64.0	48.0	29.0
LOCF	95.0	91.8	85.7	87.8	85.7	85.7	87.8	82.7	81.6
Observed	95.0	93.6	90.4	94.9	93.5	95.7	100	90.6	90.6
Mean PCDAI	10.2	10.3	9.2	8.9	9.4	7.9	6.1	7.5	8.6

The number of pts declined over time due to discontinuations and not all pts had reached later time points. Results after wk 192 are not shown as few pts had reached longer study durations.

CONCLUSION: Results of the on-going OL study support clinically meaningful efficacy with long-term ADA therapy beyond four years of exposure in children with moderately to severely active CD.

INTRODUCTION: Inflammatory bowel disease (IBD) is increasing in Korea, especially in the pediatric population. Along with the classical treatment of 5-ASA, steroid, and immunomodulators, biologic agents such as infliximab (IFX), adalimumab are used increasingly. However, the safety and efficacy of IFX has not been evaluated much for long-term follow-up.

AIMS & METHODS: This is a single-center retrospective cohort study of 100 pediatric IBD (Crohn disease 90, Ulcerative colitis 10) who used infliximab from 2004 to 2014. The total duration of IFX administration, the dose intensification (DI), the sustainability and efficacy of DI, and immunomodulator use with or without IFX were analyzed. We also analyzed 3 groups to assess the efficacy and durability of IFX into sustained remission, recaptured response, and treatment failure group. Recaptured response meant the patients who recaptured remission by dose intensification.

RESULTS: The total duration of follow-up for patients was 61.7±46.6 months. The mean duration of IFX administration was 31.0±28.0 months. Average age of IFX initiation was 14.1±3.3 years. The interval between IFX initiation and dose intensification was 23.4±23.3 months. Dose intensification was in 53 patients out of 100 for the study period. Sustained remission was in 44 patients out of total and recaptured response was in 42, respectively. Treatment failure was 16 out of 100, who discontinued IFX eventually. We checked for sustained remission rate annually and the rate was declining over time with 46% at 12-24 months, 41% at 24-36 months, and 40% at 36-48 months, respectively.

CONCLUSION: This study shows that almost half of the patients with IFX maintained sustained remission until 2-year follow-up. And recapture rate was 75% for DI, which means high response of treatment efficacy for IFX dose-up. Further study about DI will be needed for the risk factors, for optimal timing of application in clinical course, and for any possible adverse events in long-term follow-up.

INTRODUCTION: Patients with inflammatory bowel disease (IBD) are at increased risk of experiencing complications of influenza infection, thus international guidelines recommend annual influenza vaccination for this population. The vaccine is available at no cost in primary care physician offices, walk-in clinics and pharmacies in Ontario, Canada, yet vaccine uptake remains low.

AIMS & METHODS: We sought to understand barriers to obtaining influenza vaccination in a pediatric IBD cohort, and to determine the impact of educational intervention and vaccine provision in IBD clinic on vaccine uptake. The study was completed over two successive influenza seasons. During the 2012-2013 season (Year 1), we surveyed parents and IBD patients aged ≥14 years regarding influenza vaccination attitudes and practices. The following year (Year 2), an educational module was developed to address concerns about vaccination identified in Year 1. Parents and patients presenting to IBD clinic in the ten weeks prior to the 2013-2014 influenza season were provided with the educational module (Phase 1). When the trivalent inactivated influenza vaccine (TIIV) became available, patients were offered both the educational module and the opportunity for vaccination during their IBD clinic visits (Phase 2). Chi-squared analysis was used to identify significant differences in vaccination rates in each intervention group. Demographic factors were associated with survey responses and vaccination status.

RESULTS: During Year 1, 180 of 183 parents (98%) completed the survey along with all 108 adolescents. Median patient age at time of study was 11 years, 63% were males, and 67% had Crohn's disease. Most patients (74%) were on immunomodulator or biologic medications. In Year 1, 47% of patients obtained the TIIV, and 34% of patients reported obtaining the vaccine annually. Reasons for non-vaccination included a perceived lack of benefit (29%) and concerns about adverse events (20%). Most families (91%) reported they would obtain influenza vaccination if their physician provided evidence of its benefit. Year 2 patients ($n = 228$) did not differ significantly in age, IBD subtype, disease severity or medications from Year 1 patients. 95% of patients and parents who reviewed the educational module reported that it was useful. 71% reported that the module informed their decision to obtain the TIIV, including 19% who had not planned to obtain the TIIV prior to reviewing the module. In Year 2, the vaccination rate in Phase 1 patients who received the educational module alone was 75%, compared to 89% of Phase 2 patients who received both the educational module and the option of obtaining the TIIV in IBD clinic ($p = 0.0043$). Amongst the patients who took part in both Year 1 and Year 2 ($n = 129$), serial determinations of influenza vaccination rates demonstrated an increase from 45% to 82% ($P < 0.0001$).

CONCLUSION: Despite widespread access to the TIIV at no cost, traditional methods of promoting vaccination have yielded low uptake in IBD patients. Providing a focused educational module on efficacy and safety addressed barriers faced by vaccine-hesitant families and improved influenza vaccination rates. Additional vaccine uptake can be achieved by combining educational intervention with provision of influenza vaccination during IBD clinic visits.

INTRODUCTION: Increased visceral adipose tissue (VAT) inflammation is a characteristic hallmark of surgical resections from Crohn's disease (CD) patients. Recent evidence points towards an active immunological role of VAT in CD pathogenesis in addition of VAT being a defense mechanism for bacterial translocation during intestinal inflammation. Magnetic resonance imaging (MRI) studies showed accumulation of intra-abdominal VAT in adults, especially in patients with fistulas and strictures.

AIMS & METHODS: We aimed to quantify the abdominal adipose tissue compartments using MRI (Achieva, Philips Healthcare, Hamburg, Germany) in 29 pediatric CD patients compared with 14 control children (CC) undergoing MRI examination of abdomen for other reason. Total abdominal (TA) adipose tissue, consisting of subcutaneous (SC) and intra-abdominal (IA) adipose tissues were retrospectively measured by a radiologist blinded to the clinical data in transverse slices centered on the umbilicus and expressed as mean ± standard deviation in cm^2. IA/TA and IA/height ratios were assessed and analyzed for association markers. We recorded the mathematically weighted Pediatric Crohn's Disease Activity Index (wPCDAI), disease phenotype, laboratory and anthropometric data at the time of MRI. Mann-Whitney test was applied to analyze differences

between patients and CC. The correlation significance was determined by means of Spearman correlation analysis. $P<0.05$ was considered statistically significant.
RESULTS: CD patients included 20 males and 9 females (mean age 14.8 ± 3.6 years, range 7.7-18.3) with a mean BMI of 18.3 ± 2.7, range 14.0-23.2. Median disease duration from diagnosis to MRI was 21 months (range 0-136). Non-complicated disease behavior (B1) was present in 25/29, 4/29 had stricturing (B2) and 6/29 perianal disease. CC included 4 males and 10 females (mean age 12.8 ± 4.5 years, range 3.0-18.0), BMI (mean 17.6 ± 3.2, range 13.4-23.6). CD patients had higher IA adipose tissue (41.7±20.3 vs. 28.7±11.6, $p<0.05$) but similar SC and TA adipose tissues compared to CC (104.4 ± 70.9 vs. 96.54 ± 50.8 and 146.1 ± 84.7 vs. 125.3 ± 61.5, NS). The IA/TA and IA/height ratios were significantly higher in CD patients compared to CC, respectively (0.31±0.10 vs. 0.24±0.04 and 25.9±12.7 vs. 18.4±7.8, $p<0.05$). Patients with disease duration under 2 years ($n=14$) had lower IA/TA ratio (0.28±0.08 vs. 0.35±0.10, $p<0.05$) compared to longer disease. The IA/TA ratio correlated with disease duration ($p<0.05$, $r=0.425$). No association was found between IA/TA and IA/height ratios and disease phenotype or therapy.
CONCLUSION: Intra-abdominal adipose tissue is increased and accumulates with disease duration in pediatric-onset CD.

INTRODUCTION: Oral formulations of mesalazine (5-aminosalicylic acid; 5-ASA) are recommended first-line therapy for adults with active mild-to-moderate ulcerative colitis (UC). However, little data are available on the use of mesalazine in paediatric UC. This phase 1, multicenter, randomized, open-label study (NCT01130844) evaluated the pharmacokinetic and safety characteristics of 5-ASA and its associated metabolite, acetyl-5-ASA (Ac-5-ASA), after once-daily administration of multimatrix mesalazine to children and adolescents with UC.
AIMS & METHODS: Patients aged 5-17 years with a UC diagnosis of ≥3 months were eligible to enrol. Study participants (stratified by body weight) were administered 30, 60, or 100 mg/kg/day multimatrix mesalazine once-daily for 7 days. In order to attain these doses in children, smaller-sized 300 mg and 600 mg multimatrix mesalazine tablets were developed to supplement the existing approved 1200 mg tablet. Mesalazine was administered to patients at home on Days 1-4 and on-site on Days 5-7, during which pharmacokinetic blood and urine samples were collected and safety evaluations performed. Plasma and urine concentrations of 5-ASA and Ac-5-ASA were determined using a validated LC/MS/MS assay. Derived pharmacokinetic parameters for assessment included maximum concentration ($C_{max,\ ss}$), time of $C_{max,\ ss}$ (t_{max}), area under the curve for one dose interval (AUC_{ss}), renal clearance (CL_R), and percent of dose absorbed.
RESULTS: A total of 52 patients (21 at 30 mg/kg; 22 at 60 mg/kg; and 9 at 100 mg/kg) were treated. Mean (standard deviation) age was 13.3 (3.06) years, and median (range) time since UC diagnosis was of 1.83 (0.2- 9.6) years. By Day 5, steady state plasma concentrations for 5-ASA and Ac-5-ASA were attained for all dose groups. On Day 7, dose-proportional increases in mean AUC_{ss} and $C_{max,\ ss}$ for both 5-ASA and Ac-5-ASA were observed between 30 and 60 mg/kg/day cohorts. For 30, 60, and 100 mg/kg/day doses, the mean percentages of 5-ASA absorbed from multimatrix mesalazine were 29.4%, 27.0%, and 22.1%, respectively. The mean CL_R ranges for 5-ASA and Ac-5-ASA, respectively, were 5.0-6.5 L/h and 10.0-16.2 L/h. Treatment-emergent adverse events were reported by 19.2% of all patients; events were similar among different dose and age groups and no new safety signals were identified.
CONCLUSION: Across all dose groups, children/adolescents with UC receiving multimatrix mesalazine demonstrated pharmacokinetic profiles for 5-ASA and Ac-5-ASA similar to those observed in historical adult data. Multimatrix mesalazine was well tolerated across all dose and age groups, and no novel safety signals were reported.

P0356 DEVELOPMENT OF THE DAILY ULCERATIVE COLITIS SCALE FOR CHILDREN AND CAREGIVERS: FINDINGS FROM COGNITIVE DEBRIEFING INTERVIEWS

E. Flood[1], D.G. Silberg[2], B. Romero[1], K. Beusterien[3], **M.H. Erder**[2,*]
[1]*ICON Commercialisation and Outcomes, Bethesda, MD,* [2]*Shire, Wayne, PA,* [3]*ORS Health, Washington, DC, United States*
Contact E-mail Address: *herder@shire.com*

INTRODUCTION: To test and refine the Daily Ulcerative Colitis Scale (DUCS), an electronic daily sign and symptom diary with a patient-reported outcomes (PRO) version for children 8-17 years and an observer-reported outcomes (ObsRO) version for caregivers of children aged 5-10 years.
AIMS & METHODS: This was a two–visit cognitive debriefing interview study involving children with mild to moderate ulcerative colitis (UC) aged 8-17 years and caregivers of children aged 5-10 years. ''Mild'' to ''Moderate'' UC was defined based on the Pediatric Ulcerative Colitis Activity Index (PUCAI) score at the time of the interview. The interviews involved an initial set of open-ended questions on the signs, symptoms and impacts of UC to confirm findings from a previous concept elicitation study, followed by cognitive debriefing of the DUCS along with items to assess global health, and items to examine device usability and characteristics of the sample. The visit 1 interview was held in person and lasted approximately 1 hour. Visit 2 took place by telephone 3 days after visit 1 and lasted about 25 minutes and was used to explore feasibility. Sample characteristics were analysed using descriptive statistics (mean, SD, median, range for continuous variables and N, % for categorical variables). Interview transcripts were analysed using qualitative analysis software, MAXqda, in which codes were applied to allow focussed review of responses across the sample. Findings were used to refine the DUCS to ensure clarity, relevance and comprehensiveness.
RESULTS: The PRO sample consisted of 38 participants (22 females and 16 males), with 2 participants completing interviews for 2 different diary versions for a total of 40 completed interviews. Age at study enrollment ranged from 8 to 17 years (mean of 12.8; SD 2.4; median of 13). The average PUCAI score, administered at visit 1, was 12.3 (SD 14.2), range 0 to 45. The caregivers of 7 children participated in the cognitive debriefing interviews of the ObsRO version. One caregiver tested two different versions of the eDiary for a total of 8 completed ObsRO interviews. The average age of the 7 caregiver participants was 41.5 years (SD 6.4; median of 42). The caregivers' children were an average age of 8.5 years (SD 1.7; median of 9). Findings from the visit 1 concept elicitation questions were consistent with those of the initial concept elicitation study. Four rounds of revisions were made to the PRO and ObsRO DUCS based on patient/caregiver interview feedback, as well as feedback from the FDA. The FDA suggested changes such as changing response scales, as well as the addition of questions to capture certain symptoms overnight. Patient input influenced changes such as clarification of text and graphics, and the selection of the optimal pain scale. The eDiary's usability was also assessed. Both child and adult participants found the device easy to use and navigate.
CONCLUSION: The DUCS eDiaries are content valid instruments capturing signs and symptoms of pediatric UC and are appropriate for measuring treatment benefit in pediatric UC clinical trials.

P0357 AORTIC INTIMA-MEDIA THICKNESS AS AN EARLY MARKER OF ATHEROSCLEROSIS IN CHILDREN WITH INFLAMMATORY BOWEL DISEASE

M. Aloi[1,*], L. Tromba[2], V. Rizzo[1], G. D'Arcangelo[1], A. Dilillo[1], S. Blasi[2], F. Civitelli[1], F. Viola[1], A. Redled[2], S. Cucchiara[1]

INTRODUCTION: Aims of this study were to determine the presence of endothelial dysfunction by measuring aortic intima-media thickness (aIMT) and carotid intima-media thickness (cIMT) and to evaluate the role of traditional risk factors for premature atherosclerosis in children with inflammatory bowel disease (IBD).
AIMS & METHODS: Thirty-four children with IBD [25 Crohn's disease (CD) and 9 ulcerative colitis (UC); mean age 11.1 years] and 27 healthy subjects matched for sex and age were enrolled. In all patients, demographic characteristics and risk factors for atherosclerosis (age, sex, body mass index, blood pressure, dyslipidemia, active and passive smoking, family history for cardiovascular diseases), CD and UC clinical activity scores and inflammatory markers, were evaluated. Aortic IMT and cIMT were measured by high resolution B-mode ultrasound.
RESULTS: Aortic IMT was significantly higher in patients than controls ($p<0.001$). No significant differences were found for cIMT, although the carotid thickness was higher in IBD patients than healthy subjects. At a univariate analysis, inflammatory markers levels and tobacco smoking exposure were significantly related to higher aIMT values, while at a multivariate analysis the inflammatory status was the only independent variable correlated with high aIMT.
CONCLUSION: Aortic IMT is an earlier marker of preclinical atherosclerosis in young children with active IBD, than cIMT. The inflammatory status and the smoking exposure are significantly correlated with the premature endothelial dysfunction. These data emphasize the importance of controlling the chronic intestinal inflammation and endorsing smoke-free environments for children and adolescents with IBD

P0358 GROWTH IMPROVEMENT IN ADALIMUMAB-TREATED PAEDIATRIC PATIENTS WITH CROHN'S DISEASE: DATA FROM IMAGINE 1

T. Walters[1,*], W.A. Faubion[2], A. Griffiths[1], R. Baldassano[3], J. Escher[4], F. Ruemmele[5], J.S. Hyams[6], A. Lazar[7], S. Eichner[8], Y. Li[8], B. Pappalardo[8], R.B. Thakkar[8]
[1]The Hospital for Sick Children, Toronto, Canada, [2]Mayo Clinic, Rochester, [3]Children's Hospital of Philadelphia, Philadelphia, United States, [4]Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, [5]Universite Sorbonne Paris-Cite, Hospital Necker-Enfants Malades, Paris, France, [6]Connecticut Children's Medical Center, Hartford, United States, [7]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [8]AbbVie Inc, North Chicago, United States

INTRODUCTION: Children with Crohn's disease (CD) often have impaired growth. The IMAgINE 1 trial demonstrated the safety and effectiveness of adalimumab (ADA) on inducing and maintaining remission in children with moderately to severely active CD[1]. The impact of ADA therapy on growth in patients with delayed growth at trial entry is analyzed.
AIMS & METHODS: In IMAGINE 1, patients aged 6-17 years with baseline (BL) PCDAI >30 received open-label induction of ADA at weeks 0/2 according to body weight (≥40kg, 160/80mg; <40kg, 80/40mg). At week 4, patients were randomized to double-blind higher-dose (HD) ADA (≥40kg, 40mg every other week [EOW]; <40kg, 20mg EOW) or lower-dose (LD) ADA (≥40kg, 20mg EOW; <40kg, 10mg EOW) to week 52. Patients were allowed to escalate to blinded weekly therapy for flare or non-response, followed by open-label HD ADA weekly for continued flare or non-response. Change from BL in height velocity z-score was measured at weeks 26 and 52 in patients with and without growth delay at BL (defined as height velocity z-score ≤ -1.0) in all ADA patients regardless of treatment group. Subgroup analyses by BL corticosteroid use, disease severity (based on median BL PCDAI of study population (PCDAI < 40, moderate CD; PCDAI ≥ 40, severe CD), and prior infliximab (IFX) use were performed.
RESULTS: Overall, statistically significant improvement in growth was observed at weeks 26 and 52 with ADA maintenance therapy in patients with growth delay (median height velocity z-score at BL -2.9 and median change from BL at weeks 26 and 52; 2.4 and 3.3, respectively, each $p<0.001$), but not in patients with normal growth (BL median 0.2; median change from BL = 0 at weeks 26 and 52). No statistically significant differences between LD and HD ADA were observed. Growth improvement trended to be larger in patients with BL corticosteroid use, with severe CD, and in IFX naïve patients (Table).
Table. Median BL height velocity z-score values and change from BL at weeks 26 and 52 in patients with growth delay (height velocity z-score ≤ -1.0 at BL)

	BL	ΔWeek 26	ΔWeek 52
LD	-3.0 (N = 47)	2.5* (N = 47)	3.4* (N = 30)
HD	-2.8 (N = 42)	2.3* (N = 42)	3.3* (N = 29)
IFX naïve	-3.1 (N = 54)	2.7* (N = 54)	3.8* (N = 41)
IFX experienced	-2.3 (N = 35)	1.7* (N = 35)	1.4* (N = 18)
Corticosteroid use at BL	-2.8 (N = 38)	2.5* (N = 38)	4.3* (N = 23)
No corticosteroid use at BL	-2.9 (N = 51)	2.3* (N = 51)	2.3* (N = 36)
Moderate CD	-3.2 (N = 26)	2.7* (N = 26)	3.0* (N = 22)
Severe CD	-2.7 (N = 63)	2.3* (N = 63)	3.8* (N = 37)

CONCLUSION: ADA treatment significantly improved growth in children with moderately to severely active CD and growth delay. The pronounced effect of ADA on growth in children with concomitant corticosteroid use or severe disease by PCDAI requires confirmatory studies.

P0359 TREATMENT OF CORTICOSTEROID NAÏVE PAEDIATRIC AND ADOLESCENT PATIENTS WITH ULCERATIVE COLITIS BY THERAPEUTIC DEPLETION OF MYELOID LINEAGE LEUCOCYTES AS MONOTHERAPY OR IN COMBINATION WITH LOW DOSE PREDNISOLONE AFTER FAILURE OF FIRST-LINE MEDICATIONS

INTRODUCTION: Given that patients with active ulcerative colitis (UC) have elevated and activated myeloid lineage leucocytes including the CD14+CD16+ monocyte phenotype known to be a major source of tumour necrosis factor-α, selective depletion of these leucocytes by granulocyte and monocyte adsorption (GMA) should be an effective intervention in UC patients. This thinking is most relevant in paediatric and adolescent patients in whom long-term drug therapy may adversely affect their growth and development.
AIMS & METHODS: This study was to evaluate the efficacy of GMA as a remission induction therapy in children and adolescents with UC in whom first-line medications had failed. In a single centre setting, a total of 27 consecutive children and adolescents, age 11-19 years, bodyweight 31.5-56.5kg were given mesalazine or sulphasalazine as a first-line medication. Twenty patients relapsed while under first-line medication or did not respond to first-line medication and received GMA with the Adacolumn, 2 sessions in the first week, and then weekly, up to 11 sessions. Patients who achieved a decrease of ≥5 in the clinical activity index (CAI) were to continue with GMA, while non-responders were to receive 0.5 to 1.0 mg/kg bodyweight/day prednisolone (PSL) plus additional GMA sessions. However, PSL was to be tapered immediately after CAI started to fall. At entry and week 12, patients' UC severity was clinically and endoscopically evaluated, allowing each patient to serve as her/his own control.
RESULTS: At entry, all 27 patients were corticosteroid naïve and none had extensive loss of the mucosal tissue at the affected sites. Seven patients achieved sustained remission with the first-line medications and did not receive GMA. Eight patients did not respond well to the first 5 GMA sessions and received PSL plus GMA, and in 2 of these with severe UC, the PSL dose was temporarily increased to 2mg/kg bodyweight while 12 patients responded to the first 5 GMA sessions and received additional sessions. At entry, the average CAI was 13.0±2.4, range 8-17, and the average endoscopic index was 8.8±1.6, range 7-11. The corresponding values at week 12 were 2.1±0.2, range 1-4 ($P<0.001$) and 2.4±0.2, range 1-4 ($P<0.001$). PSL was tapered to 0mg within 3 months in the 8 PSL treated patients. Therefore, at week 12, all 27 patients had achieved clinical remission, majority with mucosal healing (complete remission). Except difficulties in achieving blood access causing needle pain in a few cases, no serious GMA related adverse event was observed, and compliance was good, no refusal to receive GMA and no withdrawal from the GMA treatment.
CONCLUSION: In this study, GMA in paediatric and adolescent corticosteroid naïve patients with active UC refractory to first-line medication was associated with clinical remission and mucosal healing, while in non-responders to GMA monotherapy, addition of PSL enhanced the efficacy of GMA and tapering of the PSL dose immediately after the fall in CAI score was not associated with UC relapse. Therefore, with its favourable safety profile, the majority of young steroid naïve patients with active UC refractory to first-line medication should respond well to GMA and be spared from pharmacological interventions.

P0360 PAEDIATRIC IBS IS ASSOCIATED WITH INCREASED SERUM LEVELS OF PROINFLAMMATORY CYTOKINES

L. Öhman[1,2,*], S. Isaksson[1,2], E. Melén[3,4], I. Kull[3,4], M. Wickman[3,4], A. Bergström[3], M. Simrén[1], O. Olén[4,5]

Microbiology and Immunology, Sahlgrenska Academy at University of Gothenburg, Gothenburg, [3]Institute of Environmental Medicine, Karolinska Institutet, [4]Sachs' Children and Youth Hospital, Stockholm South General Hospital, [5]Dept.of Medicine, Clinical Epidemiology Unit, Karolinska Institutet, Stockholm, Sweden
Contact E-mail Address: *lena.ohman@microbio.gu.se*

INTRODUCTION: The pathogenesis of irritable bowel syndrome (IBS) in children is not completely understood, but in adults IBS has been associated with low-grade inflammation. The aim of this study was therefore to evaluate the serum levels of cytokines to determine whether paediatric IBS is associated with increased immune activity.
AIMS & METHODS: In the population based birth cohort BAMSE (n = 4089) adolescents were invited to participate in the 16-year follow up, of which 2547 (62%) agreed to undergo blood testing and clinical examination. Serum samples were obtained from 41 IBS patients (33 (80%) females) and 97 controls with no gastrointestinal (GI) symptoms (63 (65%) females). IBS patients fullfilled the Rome III criteria and were symptomatic at the time of blood sampling. MesoScale Discovery (MSD) multiplex immunoassay analysis was used for the measurement of the following serum cytokines; IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12p70, IL-13, IL-17A, IFN-γ, IL-1β, and TNF. Data shown as median (pg/ml), range 25-75 percentile.
RESULTS: IBS patients had increased serum levels of IL-6 as compared to controls with no GI symptoms (0.39 pg/ml (0.3-0.7) vs. 0.30 pg/ml (0.2-0.4); $p=0.006$). Also levels of TNF (1.65 pg/ml (1.2-2.0) vs. 1.3 pg/ml (1.0-1.8); $p=0.06$) and IL-8 (4.51 pg/ml (3.5-5.6) vs. 3.77 pg/ml (2.9-5.3); $p=0.1$) tended to be increased in serum of IBS patients relative to controls. The levels of IL-6, TNF or IL-8 did not differ between patients with or without constipation or atopic symptoms (asthma, eczema and/or rhinitis). The levels of IL-1β were under the detection limit in more than 80% of the samples and were therefore

not statistically analysed. Remaining serum cytokines, IL-2, IL-4, IL-5, IL-10, IL-12p70, IL-13, IL-17A and INF-γ were similarly expressed in IBS patients and controls.
CONCLUSION: Children with IBS have increased serum levels of proinflammatory cytokines, which mimics previously presented data from adults with IBS. Thus, paediatric IBS, similar to IBS in adults, is associated with increased immune activity.

P0361 3D HIGH-DEFINITION ANORECTAL MANOMETRY IN CHILDREN WITH FUNCTIONAL ANORECTAL DISORDERS

M. Banasiuk[1,*], A. Banaszkiewicz[1], P. Albrecht[1]
[1]*Pediatric Gastroenterology and Nutrition, Medical University of Warsaw, Warsaw, Poland*
Contact E-mail Address: *mbanasiu@tlen.pl*

INTRODUCTION: 3D high-definition anorectal manometry (3D HDARM) is the most precise tool to assess function and 3D topographic picture of pressures along the anal canal. Until now, it has been used only in adult population. The feasibility in paediatric population has not been evaluated so far.
AIMS & METHODS: The aim of the study was 3D manometric evaluation of anorectal function in children with functional anorectal disorders.
Children with functional anorectal disorders diagnosed according to III Rome Criteria were prospectively enrolled in the study. Manometry procedures were performed with ManoScan A300 (Given Imaging Ltd) without premedication. Pressures within the anal canal and 3D picture of sphincters were obtained. If possible, defecation dynamics and thresholds of sensation were evaluated.
RESULTS: 40 children (24 male; age: 9 weeks-15 years, median: 80 months) were studied. All children suffered from functional constipation. 13 out of 40 children presented with fecal incontinence and constipation. Mean resting and squeeze sphincter pressures were 78.98 mmHg and 190.27 mmHg, respectively. The length of the anal canal was 0.9-4.3 cm. Dyssynergic defecation type I was the most common type of abnormal defecation dynamics (9 out of 24 children). Sensation of urge was absent in 6 out of 18 children with the maximum volume of balloon equalled 140 cc. Recto-anal inhibitory reflex was present in all children. There were no lesions of sphincters according to 3D topographic picture of the anal canal.
CONCLUSION: 3D HDARM is a feasible method that can be used in paediatric population.

P0362 RECURRENT ABDOMINAL PAIN IN ADOLESCENTS: COMORBIDITY WITH RECURRENT HEADACHE, BACK PAIN, DIZZINESS, PRESYNCOPE/SYNCOPE, CHRONIC FATIGUE AND ASSOCIATION WITH FERRITIN, SOLUBLE TRANSFERRIN RECEPTOR AND C-REACTIVE PROTEIN LEVELS

M. Shubina[1,*], S. Tereshchenko[1], N. Gorbacheva[1], I. Olkhovskiy[1], M. Stolyar[1], V. Babushkin[1]
[1]*Scientific research institute of medical problems of the North, Krasnoyarsk, Russian Federation*
Contact E-mail Address: *legise@mail.ru*

INTRODUCTION: Many of common complains in routine adolescents medicine practice such as recurrent abdominal pain (RAP) and other recurrent pain syndromes, dizziness, presyncope/syncope and chronic fatigue are significantly associated with anxiety disorders and depression. Data about association of these conditions are limited. Some cases of RAP may be associated with iron deficiency and inflammatory diseases, but association iron deficiency and inflammatory markers with RAP frequency is not studied well.
AIMS & METHODS: 459 adolescents aged 12-18 were screened for RAP (criteria were as follow: (1) More than two episodes of RAP per month in the last 2 months OR (2) Abdominal pain intensity according 7-items Likert-type pain scale $\geq$ 4). Criteria for recurrent headache were as follow: (1) Headache episodes in the last year $>$ 10 OR (2) Headache episodes $>$ 1 per month in the last three months OR (3) Headache intensity according 7-items Likert-type pain scale $\geq$ 4. Criteria for recurrent back pain and dizziness were as follow: (1) More than two episodes per month in the last 2 months OR (2) Intensity according 7-items Likert-type scale $\geq$ 4. Adolescents were asked about history of presence of symptoms presyncope/syncope. Chronic fatigue was estimated with original 10-items questionnaire with assessment of as difficulty or inability initiating activity; reduced capacity maintaining activity; and difficulty with concentration, memory, and emotional stability. Plasma concentrations of ferritin, soluble transferrin receptor (sTfR) and C-reactive Protein (CRP) were estimated with ELISA kits.
RESULTS: We have found positive association between RAP and recurrent headache ($p = 0.002$), recurrent back pain ($p = 0.002$), recurrent dizziness ($p = 0.002$), and chronic fatigue ($p = 0.002$). Results are shown in Table 1.
Table to abstract P0362

Comorbidity symptoms positive adolescents	RAP absence (n = 384)	RAP presence (n = 75)	P (two-tailed exact Fisher test)
Recurrent headache (n = 193)	38.8%	58.7%	0.002
Recurrent back pain (n = 80)	15.1%	29.3%	0.005
Recurrent dizness (n = 42)	6.8%	21.3%	0.003
Presyncope/syncope (n = 88)	17.1%	26.7%	0.079
Chronic fatigue (n = 28)	3.9%	17.3%	<0.001

We have found lower ferritin level ($p = 0.024$), higher sTfR level ($p = 0.043$), and higher sTfR/log ferritin index ($p = 0.037$) in adolescents subgroup with frequent episodes of RAP ($>$ 2 times per month). No differences have been found in CRP levels according assigned RAP criteria and RAP frequency. We have also found no distinctions in ferritin, sTfR, and CPR levels in accordance of presence/absence of headache, back pain, dizziness, presyncope/syncope, and chronic fatigue.
CONCLUSION: RAP in adolescents has comorbidity with broad spectrum of other symptoms (recurrent headache, back pain, dizziness and chronic fatigue). Because of most of these conditions have psychosomatic pathogenic components, we suggest that RAP diagnostics and treatment in adolescents should require estimation and correction their mental health status. We also suggest that adolescents with frequent episodes of RAP should be tested for iron deficiency.

P0363 PSYCHOLOGICAL EFFECTS OF COLORECTAL CANCER SCREENING INVITATIONS: A RANDOMIZED TRIAL

B. Kirkøen[1,*], P. Berstad[1,2], T.de Lange[1], G. Hoff[1,2], T. Bernklev[2]
[1]*Cancer Registry of Norway, Oslo,* [2]*Telemark Hospital, Skien, Norway*
Contact E-mail Address: *benedicte.kirkoen@kreftregisteret.no*

INTRODUCTION: A cancer screening programme with the ability to reduce mortality might be seen as a health service for many with objective benefit for only a few. Screening might cause worries, and has a potential negative influence on the mental health of the population that could outweigh the benefits. The present study therefore aimed to investigate the psychological reactions towards invitations to screening for colorectal cancer, as part of an evaluation of a pilot for a national screening programme in Norway.
AIMS & METHODS: In a prospective, randomized trial participants were invited to either flexible sigmoidoscopy (FS) screening, Faecal Immunochemical test (FIT), or no screening (the control arm). With the invitation, the participants received a Health-related Quality of Life (HRQoL) questionnaire (The ShortForm-12) and an anxiety and depression questionnaire (Hospital Anxiety and Depression Scale), which they were asked to complete and return. Number of invited individuals and questionnaire response rates in the randomization arms were 3804 and 47% in the FS arm, 6780 and 51% in the FIT arm, and 6433 and 33% in the control arm, respectively. Among the responders, mean ages in the trial arms were 63.5, 62.4 and 62.9 years, and 55%, 56% and 57% were women, respectively.
RESULTS: A one-way Analysis of Variance revealed no significant difference between the three arms in four out of the eight HRQoL dimensions (table 1). However, contrast analysis revealed that the FIT arm showed significantly lower physical functioning compared to the control arm. The FS arm showed significantly better social functioning and mental health, compared to both the FIT arm and the control arm, and better role of emotions compared to the control arm. Further, there was a significant difference between the three arms in the anxiety subscale of HADS (table 1). The FS arm had lower anxiety levels compared to the control arm and to the FIT arm. The minimal important difference was operationalized as a difference of at least half a s.d. Thus none of the statistical differences were considered clinically relevant, indicating little effect of being invited for screening on HRQoL and anxiety.
Mean

	FS	FIT	Control	p*	p FS vs control	p FIT vs control	p FS vs FIT
Physical functioning	85.5	84.1	86.3	**.02**	.37	**.01**	.10
Role physical	82.5	80.0	80.6	.11			
Bodily pain	82.4	81.1	81.8	.26			
General health	67.0	67.3	67.9	.63			
Vitality	60.3	58.7	59.3	.19			
Social functioning	89.5	87.3	87.0	**<.01**	**<.01**	.64	**<.01**
Role emotional	87.6	85.6	84.2	**.02**	**.01**	.19	.06
Mental health	81.5	79.7	80.1	**.03**	**.03**	.97	**.01**
Anxiety	3.4	3.8	3.9	**<.01**	**<.01**	.81	**<.01**

Table 1. *One-way ANOVA of differences between the three arms, $p < .05$. Higher scores indicate better HRQoL, and higher levels of anxiety.
CONCLUSION: Our findings indicate no negative psychological reactions to receiving an invitation for colorectal cancer screening with either of the two screening modalities FS or FIT. Thus the burden of participating in a screening programme seems limited at invitation.

P0364 THE COST-EFFECTIVENESS OF "FULL SPECTRUM ENDOSCOPY (FUSE)" COLONOSCOPY FOR COLORECTAL CANCER SCREENING

C. Hassan[1,*], I. Gralnek[2]
[1]*ONRM Hospital, Rome, Italy,* [2]*Department of Gastroenterology, Rambam Health Care Campus, Haifa, Israel*
Contact E-mail Address: *cesareh@hotmail.com*

INTRODUCTION: As compared with Standard Forward Viewing (SFV) colonoscopy, Full Spectrum Endoscopy (Fuse) colonoscopy increases the adenoma detection rate and thereby impacts the recommended post-polypectomy surveillance intervals per current US and European guidelines [1].
AIMS & METHODS: As compared to SFV colonoscopy, we aimed to assess the cost effectiveness of FUSE colonoscopy in a CRC screening and surveillance program. We constructed a Markov model to simulate the occurrence of colorectal neoplasia in a cohort of 100,000 subjects ages 50 to 100 years of age. The cost-effectiveness of FUSE was compared with that of SFV colonoscopy, with each test being assumed to be repeated every 10 years for those 50 to 80 years of age. Sensitivity for adenomatous and hyperplastic polyps $\leq$5 mm, 6-9 mm, and high-risk polyps ($\geq$10 mm; $<$10 mm with unfavourable histology or multiplicity) were derived from the recent RCT tandem Fuse colonoscopy study [1]. Post-polypectomy surveillance was modeled according to polyp histology. Medicare costs were adopted and used in the analysis.
RESULTS: For the modeled cohort, the significantly higher sensitivity of FUSE colonoscopy in detecting additional colonic adenomas resulted in an increase in CRC prevention from 58% to 74%, corresponding to a gain of 9 days per person (2,413 life-years for the entire cohort). This 16% increase led to an absolute reduction in the cost of CRC care from $90 million to $57 million. This $33 million cost savings was only minimally impacted by the higher cost of more frequent post-polypectomy colonoscopy surveillance rates, so that FUSE was associated with a savings of $146 per person. Thus, SFV colonoscopy appeared to be "dominated" by the FUSE colonoscopy strategy, with FUSE colonoscopy being both more effective and less costly. By assuming 68 million of American subjects between 50 and 80 years of age and an annual incidence of 107,483 CRC cases without screening for a discounted annual CRC care cost of $3.7 billion, the additional efficacy of FUSE over SFV would result into the annual prevention of 10,318 CRC and the annual saving of $0.3 billion for CRC related costs.
CONCLUSION: As compared to SFV colonoscopy, FUSE colonoscopy appears to be more cost-effective for CRC screening and surveillance. In particular, the higher associated costs of more frequent post-polypectomy colonoscopy surveillance were compensated by the significant overall reduction in CRC treatment costs.

INTRODUCTION: There are emerging data indicating that Sessile Serrated Adenomas may have different epidemiological characteristics than conventional adenomas.
AIMS & METHODS: This prospective study was aimed to identify any differences in the characteristics of patients with Sessile Serrated Adenomas with and without dysplasia (SSA/Ds) in comparison to patients with conventional Adenomatous Polyps (APs). 85 patients with APs and SSA/Ds were included and data regarding age, sex, smoking, BMI, waist-hip-ratio and medical history (arterial hypertension and diabetes mellitus) were collected. A univariate and a multivariate regression analysis were performed using z test.
RESULTS: 156 APs and 53 SSA/Ds of 85 patients (mean age 66.1±9.8 and 63.1±9.4 years, respectively) with their characteristics and the results from univariate and multivariate regression analysis are presented in the following table.

SSA/D vs AP (univariate)	OR	P-value	95% C. I.
Sex (women/men)	2	0.034	1.05-3.84
BMI	0.92	0.031	0.85-0.99
Waist-hip-ratio	0.01	0.06	0.0002- 1.30
Diabetes Mellitus	0.09	$<$0.001	0.02-0.33
Hypertension	0.24	$<$0.001	0.12- 0.47
SSA/D vs AP (multivariate)	**OR**	**P-value**	**95% C. I.**
Diabetes mellitus	0.1	$<$0.001	0.03-0.36
Hypertension	0.3	0.001	0.14-0.63

There was no statistical significant difference regarding sex, BMI and waist-hip-ratio ($p>0.05$) in the multivariate regression analysis. A peak incidence of SSA/Ds was observed in the ages of 51-60 years compared to a peak incidence in the ages of 61-70 years of APs ($p=0.001$). No significant difference between groups regarding smoking was observed ($p>0.05$).

CONCLUSION: SSA/Ds compared to APs are more common in women, they have a peak incidence 10 years earlier and tend to occur in patients with lower BMI. Waist-hip-ratio, although not statistically significant, had a trend for lower values in patients with SSA/D. The results from both analyses show that SSA/Ds are less common in patients with diabetes mellitus and hypertension in comparison to APs.

INTRODUCTION: Evidence is conflicting regarding the risk factors for development of Sessile Serrated Adenomas.
AIMS & METHODS: This prospective study was performed in order to identify differences in the characteristics of patients with Sessile Serrated Adenomas with and without dysplasia (SSA/D) in comparison to patients with normal colonoscopies. Data from127 patients (100 with normal colonoscopies and 27 with SSA/Ds) regarding age, sex, smoking habits, BMI, waist-hip ratio and medical history (arterial hypertension, diabetes mellitus, past history of polyps) was collected and analyzed by multivariate logistic regression analysis. Four age subgroups: 41-50, 51-60, 61-70 and 71-80 were analyzed with univariate logistic regression analysis. Analyses was performed using Stata 9.0
RESULTS:

SSA/D vs Normal (multivariate)	OR	P-value	95% C. I.
Age	1.04	0.008	1.01-1.08
Current smokers	4.35	0.003	1.63-11.59
Personal medical history of polyps	3.34	0.004	1.48-7.58
Age SSA/Ds vs Normal (univariate)	**OR**	**P-Value**	**95% CI**
41-50	1.33	0.84	0.07-23.5
51-60	9.88	0.032	1.21-80.07
61-70	8.72	0.047	1.02-74.11
71-80	26.18	0.003	3.03-225.9

No statistical significant difference was observed regarding diabetes mellitus, hypertension, BMI and waist-hip-ratio.
CONCLUSION: Smoking and personal past history of polyps increase the risk for SSA/Ds in comparison to normal population. Increasing age also increases the risk for SSA/Ds, especially after the age of 50.

P0367 DRUG ALLERGY AND RISK OF LYMPH NODE METASTASIS IN RECTAL CANCER

C. Gao[1,*], J.-T. Li[1], L. Fang[1], H.-C. Zhao[1]
[1]*Department of Gastroenterology, China-Japan Friendship Hospital, Ministry of Health, Beijing, China*
Contact E-mail Address: *gaochun@bjmu.edu.cn*

INTRODUCTION: Previous epidemiologic studies have reported that a history of allergy is associated with reduced risk of colorectal cancer and other malignancies. However, no information is available for the association between allergy and risk of lymph node metastasis.
AIMS & METHODS: Our study was designed to determine this association in rectal cancer.
Patients who were treated at our hospital in the period from January 2003 to June 2011, and with a pathological hospital discharge diagnosis of rectal adencarcinoma, were included. The clinical, laboratory and pathologic parameters were analyzed. Multivariate logistic regression model was used to determine the association. Moreover, for type of allergic drug, sub-group analysis was performed.
RESULTS: 469 patients were included, including 231 with pathological lymph node metastasis (pLNM) (49.3%) and 238 without pLNM. Univariate analysis showed, compared with patients without pLNM, patients with pLNM had a younger age (60.6±12.8 yr *vs.* 63.6±12.2 yr, $p=0.012$), a lower percentage of drug allergy (8.7% *vs.* 16.0%, $p=0.016$), an increased CEA (median/interquartile-range 5.40/2.40-13.95 *vs.* 3.50/2.08-8.67, $p=0.009$), and a lower serum sodium (141±3.1mmol/L vs. 142±2.9 mmol/L, $p=0.028$). Multivariate analysis showed that drug allergy was associated with a reduced risk of pLNM (OR = 0.553; 95% CI, 0.308-0.994; $p=0.048$). In addition, our results showed that: (1) for tumor classification, patients with drug allergy had a higher percentage of group patients with pT1/ pT2; and (2) for type of allergic drug, this inverse association was found for penicillins, not for other allergic drugs.
CONCLUSION: Drug allergy is associated with a reduced risk of pLNM in rectal cancer.

INTRODUCTION: Anal cancer is an uncommon malignancy but its incidence is increasing worldwide. Chemoradiation is the standard primary treatment for patients with loco-regional limited disease. However, once patients develop metastatic spread, the prognosis is very poor. Human papillomavirus (HPV) is present in around 80% of anal cancers but its prognostic/predictive value is essentially unknown.
AIMS & METHODS: We retrospectively evaluated 50 patients with anal squamous cell carcinoma treated at our Institution with chemoradiotherapy for loco-regional disease. HPV status was evaluated from paraffin-embedded tumor tissues collected at the time of diagnosis by a polymerase chain reaction analysis.
RESULTS: Among 50 patients 42 (84%) were HPV-positive. Thirty-two (64%) patients were positive to genotype 16, two (4%) to genotype 18 and three (6%) to both 16 and 18. Lymph nodal involvement and clinical stage at diagnosis were more advanced for HPV-positive patients. After a median follow-up of 4 years (range 0.4-13.8) 46 (92%) patients were alive. Overall, 8 patients relapsed: 1 loco-regional, 1 regional and 6 distant recurrences were observed. Four patients died from metastatic disease. Five-year disease-free survival (DFS) in HPV-positive and HPV-negative patients was 92.5% and 50.0%, respectively ($p < 0.01$). In multivariate analysis, HPV-positivity was associated with a statistically significant better 5-year DFS. Five-year overall survival in HPV-positive and HPV-negative patients was 93.3% and 66.7%, respectively ($p = 0.12$).
CONCLUSION: In our study HPV-positive anal cancers had a statistically significant improved DFS compared to HPV-negative group.

INTRODUCTION: There has been a growing recognition of metabolic syndrome (MS) as an important risk factor for cardiovascular disease and malignancies. Several investigators from Eastern countries have considered MS as a possible risk factor for colorectal neoplasms.
AIMS & METHODS: The aim of this study was to evaluate the association of MS and colorectal cancer and adenomas in a Western country, where the incidence of MS is over 27%.
Methods: Prospective study between March 2013 and March 2014. MS was diagnosed according to National Cholesterol Education Program-ATP III. Demographic characteristics, anthropometric measurements, metabolic risk factors and colonoscopy pathologic findings were assessed in patients with MS (group 1) who underwent routine colonoscopy at our department. This data was compared with consecutive patients without metabolic syndrome (group 2), with no differences regarding sex and age. Informed consent was obtained and the ethics committee approved this study. Statistical analysis was performed with T-student and χ^2 tests; p-value≤0,05 was considered statistically significant.
RESULTS: We evaluated a total of 258 patients, 129 with MS; 50% males; mean-age 67,1 years (50-87). Among the MS group, 94% had high blood pressure, 91% had increased waist circumference, 60% had diabetes, 55% had low HDL cholesterol level, 50% had increased triglyceride level and 54% had obesity ($BMI \geq 30 kg/m^2$). 51% presented 4 criteria of MS. MS was associated with increased presence of adenomas (43% vs 25%, $p = 0.004$) and colorectal cancer (13% vs 5%; $p = 0.027$), compared with patients without MS. MS was also positively associated with multiple (≥3) adenomas (35% vs 9%, $p = 0.024$) and sessile adenomas (69% vs 53%; $p = 0.05$). No differences existed between location ($p = 0.086$), grade of dysplasia ($p = 0.196$) or size of adenomas ($p = 0.841$). Increased waist circumference was an independent risk factor for the presence of adenomas (85% vs 15%, $p = 0.05$).
CONCLUSION: In our population, MS was associated with colorectal cancer and adenomas. Central obesity was also associated with an increased risk. Recommendations for colorectal cancer screening in patients with MS may need to be different from the average risk population. To our knowledge, no previous study evaluated this association in Portuguese patients.

P0370 THIRD ROUND OF TWO-SAMPLE IMMUNOCHEMICAL FECAL OCCULT BLOOD TEST SCREENING IN THE NETHERLANDS

E.H. Schreuders[1,*], S. Nieuwenburg[1], A. Kapidzic[1], E.J. Grobbee[1], A.J. van Vuuren[1], W. Spijker[2], M.J. Bruno[1], E.J. Kuipers[1], M.C. Spaander[1]
[1]Gastroenterology and Hepatology, Erasmus MC, [2]Stichting Bevolkingsonderzoek Zuid-West Nederland, Rotterdam, Netherlands
Contact E-mail Address: *e.schreuders@erasmusmc.nl*

INTRODUCTION: Screening for colorectal cancer (CRC) by means of immunochemical fecal occult blood test (abbr. iFOBT or FIT) requires successive rounds for an optimal preventative effect. The diagnostic yield of advanced neoplasia may increase with the use of two FITs per round. Therefore, in this study we assessed the diagnostic yield and participation rate of two-sample FIT screening during three successive rounds in a population-based screening pilot in the Netherlands.
AIMS & METHODS: A representative sample of the Dutch population (n = 3197) aged 50-75 years was randomly selected and invited by mail for three rounds of two-sample FIT screening with a 2-year interval. Participants received two identical FIT tests per round to sample on two consecutive bowel movements. Tests were analyzed using the OC Sensor Micro (Eiken Japan) with a positivity cut-off level of 50ng Hb/ml (≥ 10 μg Hb/g feces). Participants with at least one positive test were offered colonoscopy. For each round, we excluded individuals who met exclusion criteria (history of CRC, IBD, colon imaging ≤ 3 years, life expectancy < 5 years, inability to give informed consent) died, moved away or were positive at previous rounds.
RESULTS: The participation rate was 64.4% (95% Confidence Interval (CI) 62.5–66.4%) at the third round, compared to 62.1% (1647/2652; 95% CI: 60.2-63.9%) in the second and 61.3% (1875/3061; 95% CI: 59.6–63.1%) in the first round. One test was positive in 145 (9.8%; 95% CI 8.4–11.4) individuals and in 41 (2.8%; 95% CI 2.0–3.7) both FITs tested positive. Of the 134 (92%) patients who proceeded to colonoscopy, 5 had CRC and 13 had an advanced adenoma (defined as an adenoma ≥10mm, with ≥25% villous component or high-grade dysplasia). The positive predictive value (PPV) for advanced neoplasia was 13.4% (95% CI 8.6-20.3) for at least one positive test and 18.4% (95% CI 9.0-33.9) when both tests were positive. The two-sample methodology detected 61.1% additional participants with advanced neoplasia ($p = 0.28$) who would have been missed with a single FIT test per round; 4 (80%) participants who had CRC and 7 (53.9%) who had an advanced adenoma had only 1 positive test.
Table, 2-sample FIT screening (≥1positive) in multiple rounds

	Eligible invitees	Participation	PR	DR Advanced neoplasia	DR CRC	PPV Advanced neoplasia %
	n	n (%)	n (%)	n (%)	n (%)	(95% CI)
Round 1	3061	1876 (61.3)	239 (12.8)	76 (4.1)	12 (0.6)	34% (28.3 – 40.7)
Round 2	2654	1647 (61.2)	141 (8.6)	26 (1.6)	4 (0.2)	19.0% (13.3 - 26.4)
Round 3	2297	1480 (64.4)	145 (9.8)	18 (0.8)	5 (0.2)	13.4% (8.6 - 20.3)

CONCLUSION: Two-sample FIT screening is associated with a stable and high participation rate of more than 60% after three rounds. Positivity rates and detection rates with two-sample FIT screening, are higher compared to historical data of screening with one-sample FIT per round (van Roon Gut 2012). This implies that FIT screening with two samples has an added benefit to detect a maximum number of individuals with advanced neoplasia.

INTRODUCTION: Recommendations for colorectal cancer (CRC) screening are based on patients' age and family history of cancer, although men are at higher risk for adenomas and CRC and develop the lesions earlier than women. Several risk factors such as BMI, gamma GT levels, presence of diabetes and physical activity are known to increase the incidence of adenomas and CRC but less is known about the impact of those risk factors on prevalence of colorectal neoplasia in men and women.
AIMS & METHODS: To investigate the impact of risk factors on sex specific adenoma detection rates (ADR) and advanced adenoma detection rates (AADR). We included patients who attended preventive health check up examinations and screening colonoscopy at the same time point (within six months) in Austria between November 2007 and December 2012.
RESULTS: The investigated risk factors had greater impact on male patients than on female patients. High BMI influenced ADR ($p < 0.0001$) and AADR ($p < 0.0001$) in male patients and ADR ($p = 0.0229$), but not AADR ($p = 0.2720$) in female patients. High gamma GT levels also increased ADR ($p < 0.0001$, OR = 1.11, CI = 1.05-1.16) and AADR ($p = 0.0045$, OR = 1.12, CI = 1.04-1.21) in male, but not in in female patients ($p = 0.5237$, OR = 1.02, CI 0.96-1.09 for ADR and $p = 0.3804$, OR = 0.95, CI 0.85-1.07 for AADR). Presence of diabetes has an impact on ADR ($p = 0.0049$, OR = 1.2) and AADR ($p < 0.0001$, OR = 1.6) in male, but not in female patients ($p = 0.276$, OR = 1.1 and $p = 0.234$, OR = 1.3). Physical activity impacts ADR ($p = 0.0018$, OR = 0.8) and AADR ($p < 0.001$, OR = 0.6) in male as well as AADR in female patients ($p = 0.0150$, OR = 0.7) but not the ADR in female patients (0.0792, OR = 0.8).
CONCLUSION: Our results show that acknowledged risk factors for colorectal neoplasias seem to affect particularly male patients which raises the need of implementation of gender specific prevention recommendations for CRC, especially for men with risk factors.

INTRODUCTION: HER2/*neu* is reported as an overexpressed target on the cell surface in variety of solid cancers such as gastric cancer and breast cancer. Here, we (1) validated that HER2 is a tumor-treated target in colorectal cancer, and (2) designed an anti-HER2/neu peptide (AHNP)-labeled Tc-99m to detect the expression of HER2 in HER2-postive HCT-15-induced tumors.
AIMS & METHODS: The aim of this study was to create a HER2-binding peptide, AHNP, labeled with Tc-99m to detect HER2-positive tumors. First, the colorectal cancer cells, HCT-15, were used to investigate the binding specificity of AHNP. The AHNP was conjugated with HYNIC and PEG at N and C-terminus, respectively. The designed AHNP was chelated with Tc-99m through HYNIC and the isotope-labeled rate was analyzed by iTLC. Then, a nanoSPECT/CT was used for tumor detection.
RESULTS: We found that HER2 was overexpressed in colorectal HCT-15 tumor cells and the tumors of HCT-15-induced xenograft mice using Western blots. AHNP labeled with fluorescent FITC was performed to detect the binding efficacy of AHNP to HCT-15 in vitro using flow cytometry. The results revealed that AHNP specifically bound to HER2-positive HCT-15 cells compared to HER2-negative gastric MKN45 tumor cells, indicating that AHNP can be applied to diagnose HER2-positive tumors. Therefore, we labeled nuclear isotope, Tc-99m, with AHNP coupled with PEG to prolong the half-life of peptide in animals. The labeled rate of Tc-99m with AHNP through HYNIC chelating was measured $> 90\%$ using iTLC analysis. However we did not observe apparent difference in nuclear imaging for detecting tumors in HCT-15-induced xenografts, suggesting that peptide was unstable or rapidly metabolized in animals.
CONCLUSION: Our results showed that HER2 overexpressed in colorectal HCT-15 cells as a tumor target. HER2 specific binding peptide, AHNP, can be used to detect HER2-positive tumors as a good candidate tool in vitro, however, it was rapidly metabolized in animals.

Contact E-mail Address: *alexandra.kalmar@gmail.com*

INTRODUCTION: Surgically removed formalin-fixed, paraffin-embedded (FFPE) specimens are routinely used for morphological and molecular diagnostics, although application of these samples in molecular biology analyses can be challenging. Methylation-sensitive high-resolution melting analysis (MS-HRM) is a cost-effective tool for the assessment of DNA methylation level alterations during several types of tumor formation including colorectal cancer (CRC).
AIMS & METHODS: We aimed to compare the applicability of recent and archive FFPE tissue samples for gene-specific MS-HRM using two different commercially available DNA isolation kits. Genomic DNA isolation was performed from two groups of FFPE blocks; archive samples older than 5 years ($n = 10$; 5 CRC, 5 normal adjacent tissue (NAT)), recent samples younger than 6 months ($n = 10$; 5 CRC, 5 NAT) using FFPE DNA Isolation Kits from Roche and Qiagen. The yield and purity of DNA samples were evaluated by spectrophotometry and by fluorometry. The integrity and applicability of DNA for PCR was examined by qPCR and a multiplex PCR experiment that contains primers producing four amplicons with different lengths. DNA samples were bisulfite converted and gene-specific DNA methylation analyses were performed for *MAL, SFRP1* and *SFRP2* genes by using MS-HRM analysis and GS Junior sequencing
RESULTS: Based on OD260 measurements the Qiagen method resulted in a slightly higher recovery in archive and a significantly higher recovery in fresh FFPE samples compared to the Roche method. More selective detection of RNA and DNA by fluorometric dyes revealed that Qiagen samples contain high amounts of RNA, more than the Roche isolated samples, which was also supported by the higher OD260/280 and OD260/230 ratios of Qiagen samples. The two isolation methods did not differ significantly in their DNA yield in case of archive samples, but Qiagen yielded about two times more DNA in average from fresh FFPE samples. The DNA integrity and amplificability of fresh FFPE samples were higher than the archive ones. Despite the equal DNA yield of Qiagen and Roche samples in the archive sample group, the integrity of Roche samples was higher, and their qPCR amplification was also significantly more effective. Identical DNA methylation pattern was detected by MS-HRM for Qiagen and Roche samples in the fresh FFPE group. However, in case of archive samples, more reproducible methylation results were obtained from Roche samples. The differences in the methylation level of selected tumor samples could be confirmed also by sequencing the PCR products of MS-HRM examinations.
CONCLUSION: Sufficiently reproducible MS-HRM results can be obtained from recently fixed, fresh FFPE samples, but less reliable results can be expected for archive ones. In case of archive samples more parallel reactions, and usage of highly effective primer assays is recommended.

INTRODUCTION: A broad range of biological samples are being analysed with increasing number in the routine pathology; automated DNA isolation can be a promising solution to decrease the hands-on time.
AIMS & METHODS: Our aim was to analyse the performance of MagNA Pure 96 nucleic acid isolation system in DNA isolation from fresh frozen, biopsy and formalin-fixed, paraffin-embedded (FFPE) tissue specimens. Furthermore, we aimed to test the applicability of the isolated DNA in downstream DNA methylation analyses, and to compare results after automated and manual isolation. Fresh frozen ($n = 20$; 10 CRC, 10 normal adjacent tissue (NAT)) tissue specimens, biopsies ($n = 20$; CRC = 10, healthy colonic tissue = 10), FFPE blocks ($n = 20$; 10 CRC, 10 NAT) were collected. DNA isolation was performed from the fresh frozen and biopsy samples with QIAamp DNA Mini Kit (Qiagen) and with automated method with MagNA Pure DNA and Viral NA Small Volume kit (Roche Applied Science) on the MagNA Pure 96 system Kit in parallel, the FFPE samples were isolated with manual QIAamp DNA FFPET kit (Qiagen) and with automated MagNA Pure DNA and Viral NA Small Volume kit (Roche Applied Science). After DNA quantity and quality measurements, DNA methylation levels for MAL, SFRP1 and SFRP2 were analysed with methylation-specific high resolution melting analysis (HRM).
RESULTS: Yield of manually isolated samples were found to be equal in fresh frozen tissue samples and significantly higher compared to the automated method in the case of biopsy and FFPE samples. OD260/280 ratio was found to be similar in fresh frozen and biopsy samples, while manual isolation resulted in higher purity in FFPE samples. OD260/230 ratio was similar in fresh frozen tissue samples after both isolation methods, the automated method was superior in biopsy samples and the manual protocol in FFPE samples. DNA integrity was found to be the highest in fresh frozen samples, and half of the analyzed FFPE samples showed higher integrity after manual extraction, while the rest of samples had similar integrity after both methods. In biopsy and fresh frozen samples DNA methylation estimations were found to be highly similar after two isolation methods. In the FFPE samples the linearity of the assays lower even in FFPE samples SFRP1 and SFRP2 assays showed good correlation in the methylation percent data after the two different isolation methods.
CONCLUSION: Similar DNA methylation results were found after automated and manual DNA isolation, thus automation can be a suitable alternative in CRC diagnosis workflow beside manual protocols especially for laboratories with high sample throughput.

INTRODUCTION: The post-polypectomy surveillance colonoscopy is recommended because of the risk of synchronous and recurrent lesions. There are several factors used to stratify the probability of polyp recurrence. However, there are no studies correlating the location of the initial polyp and that of the recurrent one.
AIMS & METHODS: The aim of this study is to verify if the polyp location at the surveillance colonoscopy is correlated with the location of the previously excised polyps at the baseline colonoscopy.
We included all patients submitted to two total colonoscopies, with at least one-year interval and complete excision of the polyps detected in the baseline colonoscopy. We evaluated 346 patients, of whom 78 were excluded for not having polyps at the surveillance colonoscopy. We divided the intestine into cecum, ascending, transverse, descending, sigmoid and rectum and also evaluated the characteristics of polyps. We used the Kolmogorov-Smirnov test to determine the normality, Kappa for agreement and Chi-square, t-Test or Mann-Whitney as necessary.
RESULTS: We found a male predominance (64.9%) and a mean age of 64 ± 10 years. The number and size of the polyps at the initial and surveillance colonoscopy was 3 ± 1 *vs* 2 ± 1 polyps and 11 ± 9 *vs* 7 ± 5mm, respectively. The mean interval between the two colonoscopies was 37 ± 20 months. The overall agreement rate of polyp location between colonoscopies was 44%. Probability of recurrence in the several segments: cecum 50.0% [OR 6.4-62.4], ascending 57.0% [OR 2.3-7.2], transverse 46.4% [OR 1.9-6.9], descending 34.6% [OR 1.3-4.4], sigmoid 57.6% [OR 2.3-6.9], rectum 40.4% [OR 1.6-5.1], $p < 0.001$. No statistically significant difference was found between the rates of recurrence at the same location, taking into consideration: polyp morphology (sessile 59.8%; pedunculated 51.6%), size (11mm), polypectomy technique (biopsy forceps 64.3%; snare 54.0%; mucosectomy 70.4%), histology (low-grade dysplasia 54.7%, high-grade dysplasia 41.7%; hyperplastic 64.9%), resection (complete 48.6%; fragmented 58.3%). There was also no difference after stratification in

advanced adenoma (50.5%), non-advanced adenoma (56.8%) and hyperplastic (64.9%).
CONCLUSION: There seems to be a significant correlation between the initial location of polyps and the recurrence site in the surveillance colonoscopy. This may have future implications in terms of technical execution and accuracy of the procedure, including alerting for better scrutiny of the segment with previous polypectomy.

P0376 COMPARISON THE EFFICIENCY OF HIGH RESOLUTION MELTING ANALYSIS AND PYROSEQUENCING IN COLON CANCER DNA METHYLATION STUDIES

B. Péterfia[1,*], P. Hollósi[2], B. Wichmann[1], Z. Tulassay[1], B. Molnár[1]

INTRODUCTION: Identification of differentially methylated regions (DMRs) in the genome of cancer samples by comparing them with normal samples is a basic process in the course of epigenetic investigations. Methylation-sensitive high-resolution melting analysis (MS-HRM) and pyrosequencing of bisulphite modified DNA are two of the most popular technologies among single locus DNA methylation studies. Both techniques involve PCR amplification of bisulphite converted DNA, although they differ in their cost, hands-on time and in the output information they provide.
AIMS & METHODS: In order to test MS-HRM and pyrosequencing on colon cancer samples, fresh frozen tissue specimens were collected (20 CRC, 15 adenoma and 20 normal adjacent tissue (NAT)). After DNA isolation and bisulphite conversion, 12 different CpG rich regions of 9 genes were amplified by PCR (COL1A2, ENTPD5, PRIMA1, PTGDR, SFRP2, SOCS3, SULF1, SULT1A1 and THBS2). PCR amplification was carried out with primers designed to amplify both methylated and unmethylated templates. After amplification MS-HRM was carried out, and PCR amplicons were subsequently pyrosequenced.
RESULTS: In general, MS-HRM provided less accurate estimation, thus it is not suitable to detect very slight methylation level alterations. However, results of MS-HRM and pyrosequencing were in harmony with each other in 89% of cases. The number of hypermethylated tumours found by MS-HRM versus pyrosequencing was as follows: COL1A2: 5 vs. 7; PRIMA1: 5 vs. 7; PTGDR: 3 vs. 0; SFRP2: 13 vs. 13; SOCS3: 10 vs. 12; THBS2: 4 vs. 5, respectively. A promoter of an alternative variant of THBS2 was found to be hypomethylated in 4 vs. 5 tumour samples. The total number of DMRs found in the 20 CRC samples investigated was 44 by MS-HRM and 49 by pyrosequencing, which means that the efficiency of MS-HRM is 82% of the pyrosequencing. In contrast to pyrosequencing, MS-HRM was able to detect sample heterogeneity, especially in case of adenomas and tumour samples. Further experiments with laser captured microdissected cells from these samples revealed that epithelial cells were hypermethylated in tumours, while no DNA methylation level alteration could be detected in stromal cells.
CONCLUSION: Taken together, MS-HRM is cost-effective and needs less manual work than pyrosequencing, which makes it a suitable tool for DNA methylation screening study. The efficiency of MS-HRM is close to that of the pyrosequencing in DMR detection. Moreover, it gives information about sample heterogeneity. The major advantage of pyrosequencing is its higher sensitivity and the single CpG site information it provides.

INTRODUCTION: Mutation analysis of certain genes is an essential procedure for an individualized therapy. The number of important target genes is gradually rising, pressing a requirement for continuous expansion of analytic methods. Fulfilling this goal in a time-efficient manner is a big challenge for diagnostic laboratories, using conventional sequencing procedures.
AIMS & METHODS: Creating a mutation sequencing panel helped us to reach the aim to investigate the potential of Next Generation Sequencing (NGS) in colon cancer genotyping. A multiplex PCR panel was designed to amplify mutation hot spots of 12 selected genes. Those genes were selected that are frequently mutated in colon cancer or that are investigated in routine oncodiagnostics (APC, BRAF, CTNNB1, EGFR, FBXW7, KRAS, MSH6, NRAS, PIK3CA, SMAD2, SMAD4, TP53). Amplicons were sequenced by a GS Junior Instrument (Roche) using ligated and barcoded adaptors. Eight samples could be sequenced in one single run. Altogether, control cell lines with known mutation profiles and 60 DNA samples were investigated by the panel (8 normal colon mucose; 33 adenomas and 17 adenocarcinomas).
RESULTS: In control cell lines (HT29 and Caco-2), 4 mutations were anticipated to be found by our panel; and three of them were successfully detected. Only one adenine insertion, which was located in an adenine homopolymer region, was not detected. We found one mutated normal of eight investigated samples (12.5%). This rate was much higher in adenomas and carcinomas (78% and 76%, respectively), indicating high sensitivity. The average number of mutations found in mutated samples was 1 in low grade adenomas; 1.8 in high grade adenomas; 1.9 in carcinomas and 2.3 in serrated adenomas. The only mutation found in normal samples was a germ line APC mutation. This typical gatekeeper suppressor gene was mutated in adenomas more frequently than in carcinomas (36% vs. 24%), in contrast with other caretaker or proto-oncogenes. The most frequently mutated genes were APC, TP53 and KRAS with 36%, 18% and 26% frequencies in adenomas and 24%, 47% and 45% frequencies in carcinomas, respectively. Interestingly, there was no sample found having APC and TP53 mutations together.
CONCLUSION: Our NGS based screening panel can be a useful and affordable tool to study the mutation profile of colon cancer. Additionally, not only can it detect sporadic, but many of frequent germ line mutations as well. Its application in diagnostic practice to predict therapeutic response is worth to consider.

P0378 REPORTED DELAY IN THE DIAGNOSIS OF COLORECTAL CANCER: ANALYSIS OF GP REPORTS OF AVOIDABLE DELAY FROM THE RCGP NATIONAL AUDIT OF CANCER

C.M. Dobson[1], E. Titova[2], **G. Rubin**[1,*]
[1]*School of Medicine, Pharmacy & Health, Durham University, Durham,* [2]*Lincolnshire Partnership NHS Foundation Trust, UK, Lincolnshire, United Kingdom*
Contact E-mail Address: *c.m.dobson@durham.ac.uk*

INTRODUCTION: The UK has significantly poorer cancer survival rates than comparable countries(1) and diagnostic delay is perceived to be a significant contributory factor to this (2). In 2009/10 The RCGP undertook a National Audit of Cancer Diagnosis in Primary Care, obtaining data on 18,889 cancer patients, from 1120 practices (3). GPs also provided free text comments on any perceived avoidable delays within the patient's diagnostic pathway.
AIMS & METHODS: The aim of this study was to analyse the principal causes of delay, as reported by GPs.
The audit contained data on 2737 patients with colorectal cancer and avoidable delay was reported for 36%. Free text reports of the nature of the delay were available for 753 (28%) patients. These were transformed into quantitative data, utilising an extended version of The Model of Pathways to Treatment (4) as an analytical framework. Comments were independently categorised by CD and GR, with disagreements in categorisation reconciled through discussion. A proportion (10%) of cases were also coded by ET, as a data quality measure. In order to validate GP perceptions of diagnostic delay we compared categorised primary care and referral intervals for patients with and without perceived delay, using a chi-squared test.
RESULTS: GP reports of avoidable diagnostic delay were significantly associated with longer primary care and referral intervals ($p = < 0.0001$). The commonest reasons for delay were GP (mis)appraisal (29%), referral delays (e.g. routine rather than urgent) (13%) and investigation delays (28%). For colorectal cancer patients, help seeking delay was also a prominent factor (8%). Because these causes of delay were reported by GPs there was a potential reporting bias, with delays occurring prior to first consultation or in secondary care possibly being under-reported.
CONCLUSION: The causes of diagnostic delay for patients with colorectal cancer are complex. GP appraisal and type of referral appeared to be substantial contributors to cases of avoidable diagnostic delay. Interventions aimed at reducing the time to diagnosis should consider the specific causes of delay for colorectal cancer patients.

P0379 CONFOCAL LASER ENDOMICROSCOPY FOR THE DETECTION OF EARLY MUCOSAL CHANGES IN RECTAL STUMPS OF PATIENTS WITH FAMILIAR ADENOMATOUS POLYPOSIS

C. Bucci[1,2,*], V. D'Angelo[1], G.B. Rossi[1], V. Passananti[3], M. De Bellis[1], A. Tempesta[1]
[1]*Istituto Nazionale Tumori, Fondazione G. Pascale, Naples,* [2]*University of Salerno, Salerno,* [3]*University Federico II, Naples, Italy*

INTRODUCTION: Familial adenomatous polyposis (FAP) is an inherited, autosomal-dominant disease caused by a germline mutation of the adenomatous polyposis coli gene (APC). This condition inevitably leads to colorectal cancer. Prophylactic colectomy, or proctocolectomy with ileal pouch-anal anastomosis (IPAA) is recommended. Since any remaining rectal mucosa might still be at risk for malignancy, endoscopic surveillance of both the residual rectal stump and the ileal pouch is mandatory. Confocal laser endomicroscopy (CLE) is a novel technique that performs virtual histology of gastrointestinal mucosa with high accuracy, detecting in vivo early mucosal changes.
AIMS & METHODS: ***Aims:*** To assess the appropriateness of CLE for *in vivo* diagnosis of abnormal mucosal changes in rectal stumps of patients with FAP. ***Methods:*** Both white light endoscopy (WLE) and CLE were utilized in the examination of rectal stumps in 12 patients who had undergone proctocolectomy with IPAA. During WLE normal mucosa and polyps were classified according to both

Paris and Kudo classifications. CLE images were scored according to the MIAMI classification. Targeted biopsies were taken from normal mucosa and polyps were removed with biopsy forceps or polypectomy snares. CLE and histological findings of both background mucosa and polyps were compared.
RESULTS: WLE revealed that all but one patient had diminutive polyps (table 1) and the background mucosa always appeared normal. CLE confirmed that background mucosa was normal in all cases, whereas the diminutive polyps were classified adenomas in 9/11 patients and hyperplastic in 2/11 cases. After pathological examination, biopsies of the background mucosa always revealed normal colonic mucosa, while the diminutive polyps resulted to be 6/11 adenomas with low grade dysplasia (LGD), 3/11 adenomas with high grade dysplasia and 2/11 LGD adenomas with serrated features.

Patient	Polyp size (mm)	White light Endoscopy	Paris/Kudo Classification	MIAMI Classification	Histology
1	3	adenoma	Is-IIIL	adenoma	Low grade adenoma
2	4	adenoma	Is-IIIL	adenoma	Low grade adenoma
3	4	adenoma	Is-IIIL	adenoma	High grade adenoma
4	6	adenoma	Is-IIIL	adenoma	High grade adenoma
5	4	adenoma	Is-IIIL	adenoma	Low grade adenoma
6	7	adenoma	IIa-IIIL	adenoma	Low grade adenoma with serrated features
7	5	adenoma	Is-IIIL	adenoma	Low grade adenoma with serrated features
8	3	adenoma	Is-II	hyperplastic	High grade adenoma
9	5	hyperplastic	Is-IIIL	adenoma	Low grade adenoma
10	3	hyperplastic	Is-II	adenoma	Low grade adenoma
11	3	hyperplastic	Is-II	hyperplastic	Low grade adenoma

Table 1. Summary of findings in operated FAP patients undergoing surveillance with WLE and CLE
CONCLUSION: CLE showed good correlation with pathology in diagnosing diminutive polyps of rectal stumps in patients with FAP. Possibly, CLE could be useful for tailoring the surveillance in these patients. However, further studies are needed to confirm this hypothesis.

INTRODUCTION: According to the guidelines for TNM staging of colorectal cancer, occult nodal tumour cells are categorised as micrometastasis (MMs) and isolated tumour cells (ITCs). A recent meta-analysis demonstrated that MMs, but not ITCs, are prognostic for disease recurrence in patients with stage I/II colon cancer.
AIMS & METHODS: The objective of this retrospective multicentre study was to analyse the incidence of MMs in the sentinel node of patients with stage I/II colon cancer, to analyse the correlation between MMs, tumour differentiation and vaso-invasive growth, and to analyse the prognostic value of MMs for disease recurrence. Patients with elective surgery for stage I/II colon cancer were identified from databases about ex vivo sentinel lymph node mapping and ultrastaging, from three Dutch hospitals (2005-2012 Gelre Hospital (GH), 2011-2013 Leiden University Medical Center (LUMC) and 2010-2012 Jeroen Bosch Hospital (JBH)). Immunohistochemical staining was performed with antibody against pan-cytokeratin (LUMC, JBH) or cytokeratin-18 (GH) and findings were classified according to the 6th AJCC staging manual. Univariable analysis was applied for the correlation between MMs, tumour differentiation and vaso-invasive growth. Two year disease-free-survival (2yDFS) of patients with MMs, ITCs and patients without occult nodal tumour cells was compared with a Kaplan-Meier analysis.
RESULTS: A total of 214 patients were pooled in a multicentre database (GH n = 128; LUMC n = 19; JBH n = 67). MMs were found in twelve patients (5.6%), ITCs in 39 patients (18.2%) and occult tumour cells were absent in 163 patients (76.2%). Between these three groups, there were no significant differences in baseline characteristics or type of surgery. Tumour differentiation and vaso-invasive growth were comparable as well. Four patients with MMs received adjuvant therapy (33.3%) which was significantly more than patients with ITCs (n = 1; 2.6%) or patients without occult tumour cells (n = 7; 4.3%)(p = 0.004). After a median follow up of 20 months (IQR 20-47) recurrence of cancer was diagnosed in 12 patients (5.1%). Three recurrences were diagnosed in patients with MMs; one locoregional recurrence despite adjuvant treatment, and two distant metastases in patients who did not receive adjuvant treatment. Survival analysis showed a significantly reduced 2yDFS in patients with MMs compared to patients with ITCs or patients without occult tumour cells (p = 0.013).
CONCLUSION: In this study, the incidence of MMs in patients with stage I/II colon cancer was 5.6%, and was not correlated to tumour differentiation or vaso-invasive growth. Despite a relative large proportion of patients with adjuvant treatment, MMs were prognostic for disease recurrence.

P0381 PLASMA MICRORNAS AS SCREENING BIOMARKERS FOR COLORECTAL ADENOMAS

A.M. Verma[1,2], **M. Patel**[1,2,*], M. I. Aslam[1,2], P. Wurm[2], J. Jameson[2], J.H. Pringle[1], B. Singh[2]

Contact E-mail Address: *ajaymarkverma@gmail.com*

INTRODUCTION: The identification and resection of colorectal adenomas during screening colonoscopy is the cornerstone of colorectal cancer prevention within bowel cancer screening programmes (BCSP).
Biennial faecal occult blood testing (FOBt) of patients aged 60-75 is the screening tool within the United Kingdom BCSP with a positive test identifying patients requiring colonoscopy. At screening colonoscopy, the yield for adenomas is 46.5% and for adenocarcinomas in 6%. [1] Whilst effective, FOBt lacks high sensitivity, specificity and accuracy. As a result, half of screening colonoscopies are normal or reveal other gastrointestinal disorders such as haemorrhoids and diverticular disease (that have lead to false positive FOBt results). This is a concern as colonoscopy is an invasive test which can cause patient harm. Another concern is the uptake of FOBt within screened populations is less than 60%. [1]
A biomarker screening test based on blood sampling may increase uptake – especially for individuals not keen to undertake faecal testing. If a biomarker had a high sensitivity, specificity and accuracy, the proportion of patients undergoing screening colonoscopy and having a non adenoma/ adenocarcinoma diagnosis would fall.
AIMS & METHODS: We plan to investigate microRNAs (miRs – short (18-24 nucleotides) evolutionary conserved non-coding RNA molecules) as potential biomarkers. 220 FOBt positive patients undergoing BCSP colonoscopy were recruited and samples of whole blood were taken (100+ patients with adenomas, 90+ controls – normal or non adenoma/ adenocarcinoma diagnosis). RNA was extracted from plasma and converted to complementary DNA. Pooled groups of patients with adenomas and controls were analysed using array cards. MiRs 19a, 98, 146b, 186, 331-5p, 452 and 625 were identified as candidate biomarkers. All cases were analysed for these candidates using quantative polymerase chain reaction.
RESULTS: All 7 candidate MiRs showed significant differences in expression in patients with colorectal adenomas when compared to controls.
MiRs 19a, 331-5p, 452 $p = <0.05$, miRs 98, 146b $p = <0.01$, miRs 186, 625 $p = <0.001$.
When ROC curve analysis was performed area under the curve was higher in patients with diverticular disease/ haemorrhoids than those without (0.866 vs 0.788).
CONCLUSION: This study suggest plasma miRs are potential screening biomarkers for patients with colorectal adenomas and also may help to identify patients with adenomas in the cohort of patients with background diverticular disease/ haemorrhoids. Further study and analysis is needed to validate these exciting findings.

P0383 ACUTE TREATMENT OF MALIGNANT COLORECTAL OCCLUSION: SELF-EXPANDABLE METALLIC STENTS AS BRIDGE-TO-SURGERY OR PALLIATIVE TREATMENT VERSUS EMERGENCY SURGERY

D. Fernandes[1,*], S. Domingues[1], B.M. Gonçalves[1], J.-B. Soares[1], P. Bastos[1], A. Ferreira[1], R. Gonçalves[1], A. Mesquita Rodrigues[2], L. Lopes[3], C. Rolanda[1]

Contact E-mail Address: *daliafernandes09@gmail.com*

INTRODUCTION: Colorectal cancer presents as acute bowel occlusion in 10-40% of the patients. There are two main therapeutic approaches for decompression: emergency surgery and the endoluminal placement of self-expandable metallic stents (SEMS). Due to high mortality and morbidity rates associated to emergency surgery, SEMS placement as bridge-to-surgery or as palliation is being increasingly used with controversial results.
AIMS & METHODS: This study aimed to clarify the risk/benefit of the mentioned approaches. We conducted a retrospective longitudinal multicenter study, including 189 patients with acute malignant colorectal occlusion, diagnosed between January 2005 and March 2013. Demographic, clinical characteristics of the patients, tumor features and procedure details were analyzed.
RESULTS: Globally (85 patients – 35 bridge-to-surgery and 50 palliative) SEMS's technical success was 94.4%. Palliative SEMS had a limited clinical success (60.0%) and were associated to 40.0% of complications. SEMS occlusion (18.8%) was the more frequent, followed by migration (9.4%) and bowel perforation (7.1%). Elective surgery after stenting was associated to a higher frequency of primary anastomosis (93.8% *vs* 76.4%; $p = 0.038$), and a lower of colostomy (25.7% *vs* 54.9%; $p = 0.004$) and overall mortality (31.3% *vs* 56.7%; $p = 0.020$). However, no significant differences were identified concerning to postoperative complications. In palliative treatment, there was no difference in complications rate and overall mortality between SEMS and decompressive

colostomy. In this SEMS subgroup, we found a higher rate of reinterventions (40.4% vs 5.0%; $p=0.004$) and a longer hospital stay (14,9 *vs* 7,3 days; $p=0.004$).
CONCLUSION: SEMS placement as bridge-to-surgery should be considered in acute treatment of colorectal malignant occlusion, since it has advantages regarding to primary anastomosis, colostomy rate and overall mortality. However, the longer the SEMS stayed in place the higher the risk for complications. Therefore in palliative SEMS, despite the possible psychological effect of not having a colostomy, it does not seem to present significant advantages comparing to the decompressive colostomy.

Contact E-mail Address: *biophyz@gmail.com*

INTRODUCTION: Today new approaches for colorectal cancer treatment appear through traditional chemotherapy failure. The specificity of potential therapeutics, impact on malignant cells and/or their restraint within the tumor nodes, as well as the mininization of therapy and carcinogenesis side effects, are at the top of interests. Proteine kinase inhibitors are the most specific anticancer agents due to malignant cell peculiarities, whereas stem cells are the most specific anticancer drug vehicles due to tumor node metabolism. But the effects of the first and the last often are evaluated on xenograft models characterized by the immune deficient status of the host. So it is impossible to assess the state of the organism experiencing cancer adequately.
AIMS & METHODS: The investigation of the effects of new protein kinase inhibitors pyrrol derivates (PD) 5-amyno-4-(1,3-benzothyazol-2-yl)-1-(3-methoxyphenyl)-1,2-dihydro-3H- pyrrol-3-one and 1-(4-Cl-benzyl)-3-Cl-4-(CF_3- fenylamino)-1H-pyrrol-2,5-dione compared with therapeutic 5-fluorouracil (5FU) and the effect of allogenic trophoblast stem cells (TSC) on the tumor formation and growth and on the state of apparently healthy colon mucosa was undertaken. The 1,2-dimethylhydrazine (DMH) induced rat colon cancer model, which has histopathological and biochemical features similar to human colorectal cancer, was used. Carcinogenesis was initiated by 20 weekly injections of DMH (20 mg/kg) (up to tumor formation equal $T_{1\text{-}2}N_{0\text{-}1}M_0$ stage of human colorectal cancer) and followed by PD daily or 5FU weekly treatments for 7 weeks, or with TSC intravenous transplantation at 22nd week with no treatment for further 5 weeks. At 27th week of experiment the animals were euthanized, the colorectal tumors were counted and measured, the samples of colon walls with and without tumors were processed and examined under the light microscopy.
RESULTS: PD reduces the tumor number (N_t) and total tumor lesions area (S_t) at 27th week by preventing of new tumor formation and by regress of existing ones, as well as 5FU does (N_t and S_t at 27th week are less than these ones at 20th week). PD also diminishes the DMH-induced inflammation of the apparently healthy colon mucosa, whereas 5FU escalates this process. The data obtained suggest cell death predominantly by necrosis was caused by 5FU and by apoptosis one caused by PD. TSC transplanted at 22nd week at high dose ($1.5*10^6$ cells/kg) stops tumor growth compared to nontreated rats, as well as reduces mucosa inflammation, but does not cause regression of existing tumors (N_t and S_t at 27th week are the same at 22nd week). TSC transplanted at the same time at low dose ($0.5*10^6$ cells/kg) attenuates the inflammation features but doesn't affect tumor growth. We suppose TSC signals dominate the cancer stem cells ones and therefore contribute to normalization of cancer stem cells microenvironment and thus prevent further carcinogenesis.
CONCLUSION: Targeted therapy is suitable for non-metastatic stage of colorectal cancer, whereas the administration of stem cells could stop further carcinogenesis only but couldn't reduce the existing tumor nodes.

P0385 THE INDICATION FOR ADDITIONAL SURGICAL COLECTOMY WITH NODAL DISSECTION IN T1 COLORECTAL CARCINOMAS

H. Miyachi[1,*], S.-E. Kudo[1], K. Ichimasa[1], Y. Kouyama[1], T. Hisayuki[1], H. Oikawa[1], Y. Mori[1], M. Misawa[1], T. Kudo[1], K. Kodama[1], T. Hayashi[1], K. Wakamura[1], A. Katagiri [1], M. Kaga[1], E. Hidaka[1], F. Ishida[1], S. Hamatani[1]
[1]*Digestive Disease Center, SHOWA UNIVERSITY NORTHERN YOKOHAMA HOSPITAL, Yokohama, Japan*

INTRODUCTION: With the introduction of screening programs for colorectal cancer and the recent advancement in EMR and ESD technology, a lot of T1 colorectal carcinomas are resected endoscopically with negative margins, and the percentage of early carcinomas amenable to endoscopic resection has increased. But, around 10% of the patients of T1 colorectal carcinoma have lymph node metastasis (LNM). Then, additional surgical colectomy with nodal dissection should be considered after endoscopic treatment. Therefore, it is critical to determine the criteria for curative endoscopic resection.
AIMS & METHODS: The aim is to clarify clinicopathological risk factors for LNM of T1 colorectal carcinomas and to establish the indication for additional surgical colectomy with nodal dissection.
A total of 19882 colorectal neoplasms excluding advanced cancers have been resected endoscopically or surgically at our unit from April 2001 to October 2013. Of these, 907 T1 carcinomas were included. Initial or additional surgical colectomy with nodal dissection was performed in 568 cases, and of which LNM was found in 55 cases (9.7%). We analyzed the clinicopathological risk factors as follows: age, gender, size, location, morphology, vessel permeation, tumor budding, poorly-differentiated or mucinous carcinoma (POR/MUC) component, desmoplastic reaction (DR) on the superficial layer, degree of SM invasion, and state of muscularis mucosae (MM grade). MM grade was evaluated into two conditions using the desmin immunostaining: MM grade 1 (complete or almost maintenance) and MM grade 2 (fragmentation or disappearance). Finally, based on significant factors, we stratified these T1 cancers into 3 groups at ultralow, low and high risk of LNM.
RESULTS: The existence of vessel permeation, tumor budding, POR/MUC component, MM grade 2 or the gender of female was significant. In contrast with MM grade 2, no lesions corresponding to MM grade 1 had LNM. Among T1 carcinomas with MM grade 2, male patients without vessel permeation, tumor budding or POR/MUC component showed low incidence (1/93: 1.1%) of LNM, while 54 (12.7%) of 433 patients with at least one factor had LNM.
CONCLUSION: The indication for additional surgical colectomy after endoscopic resection has been more clarified and simplified: MM grade 1 was suggested to be an anti-risk factor for nodal metastasis (Ultralow-risk group). T1 carcinomas with MM grade 2 and without female gender, vessel permeation, tumor budding or POR/MUC component may be acceptable for only monitoring (Low-risk group). For T1 carcinomas with MM grade 2 and with at least one factor, additional surgical colectomy with lymph node dissection should be recommended (High-risk group).

P0386 DOES THE TYPE OF COLECTOMY MODIFY THE RISK OF DESMOID TUMOR DEVELOPMENT IN FAMILIAL ADENOMATOUS POLYPOSIS PATIENTS?

Z. Wang[1], T. Walter[2], O. Guillaud[2], A. Pasquier[3], E. Cotte[3], O. Vinet[2], G. Poncet[4], T. Ponchon[5], **J.-C. Saurin**[5,*]

INTRODUCTION: Desmoid tumors represent one major complication of the disease in patients with familial adenomatous polyposis (FAP). Our aim was i) to study factors associated with the development of desmoid tumors in a large cohort of FAP patients and ii) to review the different treatment proposed with corresponding results.
AIMS & METHODS: We reviewed retrospectively 190 cases of patients with FAP, with complete medical records, followed at our institution between 1965 and 2013. There were 10 patients with biallelic MUTYH mutation (mean age 56,5 years) and 180 patients with either identified APC gene mutation, either a personal and family history suggesting APC-related polyposis (mean age 44,1 years, 22-85).
Treatment of desmoid tumor was proposed in those patients with progressive disease at radiological evaluation on a 4 to 6 month observational period. The response was evaluated retrospectively from the reports, according to RECIST criteria.
RESULTS: The median follow-up since the diagnosis of FAP was of 25 years. No patients (0/10) with MUTYH mutation ever developed desmoid tumor. In contrast, 31/180 (17.2%) patients with a mutation/phenotype of APC related polyposis (11 H, 20 F) developed 58 DT, at a mean age of 44,1 yrs (range 22-78 yrs). The localization of DT was: mesenteric 25, abdominal wall 25, extra-abdominal 3 (breast 2, gluteal muscle 1). From these 180 patients, a colectomy with ileo-rectal anastomosis had been performed in 104 (12 with DT, 11%) and proctocolectomy in 76 (19 with DT, 25%, $p=0.027$). There was no other factor associated with the development of DT, including the modality of surgery (laparotomy versus laparoscopy). As regards the treatment of DT: no treatment was proposed in 3 patients (mean FU 7,17 years); 12 patients (with 28 DT) had 29 medical therapeutic sessions with a mean duration of 12,8 months (range 3-24 months). Following RECIST criteria, a response was observed in 3 tumors (10.3%), a stabilisation in 17 cases (58.7%) and a progressive disease in 9 cases (31%). Medical treatment was: celecoxib (6 sessions), sulindac (9), tamoxifen (4), imatinib (8), sorafenib (1), bevacizumab (2). Surgical treatment of the DT was attempted for 32 tumors from 16 patients: 12 mesenteric (5 recurrences, 41.6%) et 21 extra mesenteric (6 recurrences, 28.5%).
CONCLUSION: This study suggests that the type of colorectal surgery (colectomy versus proctocolectomy) is a major determinant of the risk of developping desmoid tumors in APC type FAP patients. If confirmed, this may impact profoundly our surgical choices in these patients. On the other hand, we confirm the low efficacy of available medical treatments for desmoid tumors of FAP patients, and the high prevalence of post-surgical recurrences.

INTRODUCTION: A mainstay in the treatment of prostate and some gynecological cancers is the use of external beam radiation therapy. Radiation proctitis is a well-recognized complication of pelvic radiation and Argon Plasma Coagulation (APC) is a very effective means of treatment. The literature supporting the use of APC is small.

AIMS & METHODS: The current study is a prospective analysis of patients with radiation proctitis referred from the Newfoundland and Labrador Bliss Murphy Cancer Centre. There were 81 patients referred to one gastroenterologist and 55 were treated with APC (Jan. 2010 to Dec. 2013). We studied the complete resolution of symptoms which was defined as the absence of rectal bleeding. A partial resolution was defined as a reduction in rectal bleeding.
RESULTS: This prospective cohort study was performed on all adults who underwent colonoscopy for radiation proctitis. In total, 81 patients were seen, 90.1% men and mean age = 68.4 (range: 48-87 years). The average time between the last dose of radiation and the development of symptoms of proctocolitis was 21.8 months (range: 0-132 months). Complete resolution of symptoms was reported in 75.9% of cases, partial resolution in 22.2% and only one patient (1.85%) showed no improvement. The mean sessions of treatment with APC was 1.86, (range 1-4). Furthermore, 61.5% of those with incomplete response had other potential sources of rectal bleeding identified such as hemorrhoids or an anal fissure. The rate of complications was 3.6% with 2 patients developing a rectal ulcer. Colonic adenomas were detected in 60.5% of individuals and colorectal cancer is 6.2%. Hemoglobin values before and after APC were available in ten patients and the mean increase was 9.6 g/L (range: -3 to 25 g/L).
CONCLUSION: APC is a safe and effective therapeutic modality for the treatment of radiation-induced proctitis. Pelvic radiation exposure can be associated with the development of symptoms of radiation proctitis. It is also associated with the development of adenomas and colorectal cancer. This is the largest reported case series to date regarding the utilization and efficacy of APC.

P0388 INHIBITION OF HUMAN AND MOUSE INTESTINAL AFFERENT MECHANOSENSITIVITY BY ACTIVATION OF GUANYLATE CYCLASE C

A. Broadhead[1,*], C. McGuire[1], D. Reed[1], M. Peiris[1], C. Knowles[1], C. Kurtz[2], A. Silos-Santiago[2], D. Bulmer[1], L.A. Blackshaw[1]

INTRODUCTION: The guanylate cyclase C (GCC) agonist linaclotide reduces abdominal pain in constipation-predominant IBS (IBS-C). Its mechanism of action is via production and release of cyclic guanosine monophosphate (cGMP) by intestinal epithelial cells, which subsequently acts on high-threshold colonic afferent endings to reduce generation of pain signals in response to mechanical stimuli[1].
AIMS & METHODS: To determine 1. if inhibition of afferents by GCC agonism and by cGMP is seen also in a tubular preparation of mouse colon; 2. if this translates to inhibition of responses to the same stimulus in human appendix. Electrophysiological responses were recorded from human-extrinsic nerve bundles innervating tubular preparations of appendix[2]. A similar preparation was used in mice to record responses of lumbar splanchnic afferents innervating the distal colon.
RESULTS: Distension of mouse colon caused reproducible, stimulus-dependent excitation of splanchnic afferents up to 60mmHg. Administration of cGMP (500uM) or GCC agonist (linaclotide 1uM) significantly reduced the response to medium-level (40mmHg; N = 7, p = 0.01) and high-level distension (60mmHg; N = 7, p = 0.02). No effect was seen on response to low-level distension (20mmHg; N = 7, p = 0.9). In recordings of human appendix afferent responses to ramp distension (0-60mmHg), we attempted to release endogenous cGMP by activating GCC maximally with intraluminal enterotoxin ST (100nM). This had a similar pattern of effect as activation of GCC on mice on responses to distension, inhibiting only at high levels of distension (25% reduction, N = 5, p = 0.008).
CONCLUSION: GCC agonists inhibit mechanosensory responses to distension in intact *in vitro* preparations of both human and mice large intestine, but only at high intensities that correspond to those that would evoke pain *in vivo*. This provides important validation of the mechanism of action of linaclotide in relieving pain in IBS-C via peripheral inhibition of nociceptors in human intestine.

INTRODUCTION: We recently demonstrated that a combined nutrient and lactulose challenge test allows symptom-based clustering of patients with irritable bowel syndrome (IBS) unrelated to exhaled gas and Rome III subtype (Le Nevé *et al* Am J Gastro 2013; oral communication UEGW 2013).
AIMS & METHODS: The aim was to further characterize the two IBS clusters previously identified. We included 100 patients with IBS (Rome III) and 38 healthy controls. The fasted subjects were served a test meal consisting of a 400ml liquid breakfast (Nutridrink®, 1.5 kcal/ml) containing 25g lactulose. The severity of gastrointestinal (GI) symptoms, fatigue, somatization, anxiety and depression were evaluated by questionnaires before the test (IBS-SSS, GSRS, VSI, FIS, PHQ-15, HAD), as well as visceral sensitivity (barostat) and fecal microbiota composition (16S rRNA pyrosequencing). The intensity of eight GI symptoms, the overall level of digestive comfort and the amount of exhaled H_2/CH_4 were assessed every 15min during 4h after meal intake. A mapping of the eight GI symptoms was done using a Principal Components Analysis (4h mean score). Independently, a hierarchical cluster analysis was performed on the same parameters to identify GI symptom-based IBS clusters.
RESULTS: The combined nutrient and lactulose challenge test discriminated IBS from healthy controls. The challenge also allowed clustering of IBS patients in two subgroups i.e "High GI symptom" (HGS) and "Low GI symptom" (LGS) based on intensity of GI symptoms, in line with our previous study. Patients in the HGS group (n = 39; mean 4h pain = 9.3, bloating = 10.3, distension = 11.2, discomfort = 11.8) displayed higher IBS-SSS score (353.7 vs. 236.8; $p < 0.0001$) and higher levels of anxiety (9.0 vs. 7.0; $p < 0.05$), fatigue (71.3 vs. 42.2; $p < 0.001$) and somatization (14.7 vs. 11.8; $p < 0.01$) as well as lower overall digestive comfort (8.0 vs. 12.8; $p < 0.001$) than patients in the LGS group (n = 61; mean 4h pain = 2.4, bloating = 3.0, distension = 3.4, discomfort = 4.8; $p < 0.001$). Patients in the HGS group displayed significantly higher rectal sensitivity compared to both LGS patients and healthy controls ($p < 0.001$ for pain intensity at 12 and 24mm Hg). No significant difference was seen between IBS clusters for fecal microbiota composition.
CONCLUSION: A test meal containing 25 g of lactulose allows clustering of IBS patients according to their GI symptom response, which reflects visceral sensitivity, IBS severity and psychological co-morbidity. This clustering cannot be predicted by fecal microbiota composition. The lactulose challenge test appears to be a promising tool to better define postprandial symptoms and the pathophysiology of IBS, and to non-invasively assess visceral sensitivity.

INTRODUCTION: Altered intestinal barrier function has been suggested to play an important role in the pathophysiology of IBS, but the properties of one of the most important components of the intestinal barrier, the intestinal mucus layer, have not been studied in IBS. The colonic mucosa is covered by a thick mucus layer consisting of an inner adherent layer and an outer loose layer. The inner layer is normally devoid of bacteria. We tested the hypothesis that the penetrability of colonic mucus in situ to fluorescent beads the size of bacteria is increased in patients with irritable bowel syndrome (IBS).
AIMS & METHODS: Sigmoid biopsies were taken from unprepared colon in 12 healthy controls (mean age 28 years, 5 males and 7 females) and 14 IBS patients (2 males and 12 females), 2 IBS-C, 2 IBS-D and 10 IBS-M). 21 patients who underwent colonoscopy for other reasons (e.g. bleeding of unknown origin), with prepared colon, and 27 patients with ulcerative colitis (UC) in remission served as positive controls. The biopsies were mounted horizontally in an oxygenized perfusion chamber. After 20 minutes, a standardized amount of fluorescent beads with a size similar to that of bacteria (2 and 1 and 0.5 um) were added on the mucosal side. 40 minutes later, bead distribution was assessed by confocal laser microscopy at three laser frequencies, 488, 555 and 639 nm. The confocal images were transferred into Matlab and were processed by customized software. Mean bead intensity per 10 μm slice was calculated as a function of distance from end of crypt openings and the distance of this slice from end of tissue was used as a marker for bead penetrability. Mucus thickness was also measured repeatedly over time in a horizontal perfusion chamber using a micropipette after addition of charcoal particles to the apical side of the biopsy.
RESULTS: When measured repeatedly over time using carbon powder and a micropipette ruler, mucus thickness after 60 min was 540±65 μm in the controls and 610±50 in the IBS patients (p = 0.19). When studied with fluorescent microbeads, the distance of the slice with maximal bead intensity from the mucosa at 60 minutes was 400±60 μm in the controls and 470±80 μm in the IBS patients (p = 0.50). In the control patients, with prepared colon, the corresponding value was 500±60 μm (n.s.). In contrast, in prepared colon from UC patients in remission the distance was 280±60 μm ($p < 0.01$ versus other groups). Three different bead sizes were used to test the occurrence of size-dependent

permeability. However, no significant differences in impermeable layer thickness were found between the three bead sizes in any of the groups.
CONCLUSION: The values for mucus thickness in unprepared colon obtained with the micropipette ruler + carbon powder and the data obtained with the fluorescent microbeads agree closely, with slightly lower values obtained with the microbeads. In this small sample, sigmoid mucus from patients with IBS symptoms tended to have a mucus layer slightly thicker than in healthy controls (n.s. with both techniques), while the UC patients in remission had a markedly reduced thickness of the bead-impenetrable mucus layer.

INTRODUCTION: Intestinal immune activation and mast cell intestinal infiltration play a pathophysiological role in the irritable bowel syndrome (IBS). Palmithoylethanolamide (PEA), the saturated fatty acid ethanolamide of palmitic acid, structurally related to the endocannabinoid anandamide, exerts anti-inflammatory and anti-nociceptive actions and inhibits mast cell activation. Polydatin (PD) acts synergistically with PEA in reducing mast cell release of cytokines and related T cell activation.
AIMS & METHODS: We designed a pilot, phase 2, randomized, double-blind, placebo-controlled, multicenter study evaluating the efficacy and safety of PEA/PD in patients with IBS. Patients with Rome III confirmed IBS and healthy age- and gender-matched subjects (HC) were recruited from 5 European study centers (Bologna, Nantes, Barcelona, Tuzla, and Zagreb). After a 2-week run-in, the patients were randomly assigned to oral tablets micronized PEA/PD 200 mg/20 mg or placebo, b.i.d for 12 weeks. The efficacy evaluation included the assessment of: 1) mast cell infiltration and endocannabinoid system in patients with IBS *vs.* HC. 2) the effect of active treatment *vs.* placebo on mast cell infiltration, endocannabinoid system, and symptoms in patients with IBS. Colonic mucosal biopsies were obtained during at screening visit and at the end of the study. Biopsies were processed for quantitative immunohistochemistry for mast cells, and for biomolecular analysis of the endocannabinoid system (by liquid chromatography and western blot).
RESULTS: A total of 54 patients with IBS (29 allocated to PEA/PD and 25 to placebo) and 12 HC were recruited in the study. Mast cell counts were significantly increased in patients with IBS in comparison with HC (5.3%±2.7% vs. 3.2±1.3; $p = 0.013$). Compared to HC, expression of the peripheral cannabinoid receptor CB_2 in the tissue was higher in IBS ($p = 0.012$) while the fatty acid amide oleoylethanolamide was significantly reduced ($p = 0.007$). The logistic model for repeated measures did not reveal statistically significant effects of PEA/PD on mast cells and endocannabinoid system. Nonetheless, compared with placebo, PEA/PD improved abdominal pain severity (repeated measure ANOVA test; $P < 0.05$).
CONCLUSION: Our study suggests that PEA/PD is a promising effective treatment in the management of pain in patients with IBS. Whether the PEA/PD effect is secondary to mast cell stabilising or to modulation of the endocannabinoid system remains to be further investigated. ClinicalTrials.gov Identifier: NCT01370720.

INTRODUCTION: At present the role of changes of the intestinal microbiota in pathogenesis of irritable bowel syndrome (IBS) is widely discussed. Impact of microbiome on the gastrointestinal motility and visceral hypersensitivity is assumed. However the relevant data have been investigated insufficiently.
AIMS & METHODS: To estimate correlation between changes of the composition of intestinal microbiota, anorectal motility disorders and visceral hypersensitivity in patients with diarrhea-predominant IBS (IBS-D).
31 patients with IBS-D (clinical type was determined according to the ROME III criteria) and 15 healthy volunteers were studied. All subjects were analysed by examining sequencing data of the 16s rRNA from fecal samples, the hydrogen breath test with lactulose to determine small intestinal bacterial overgrowth (SIBO), high-resolution anorectal manometry (HRAM) using 20 channel water-perfused catheter with a polyethylene balloon (Solar GI, MMS, the Netherlands).
RESULTS: By sequencing of the 16s rRNA differences were found in the composition of intestinal microbiota between the IBS-D patients and healthy volunteers. In patients with IBS *Bacteroides* (18.9%), *Coprococcus* (7.2%) and *Blautia* (5.4%) were detected more often, the control group showed prevalence of *Blautia* (17.1%), *Prevotella* (8.3%) and *Faecalibacterium* (6.9%) ($p < 0.05$). A positive result of breath test (the presence of SIBO) was found in 20 patients with IBS-D (62.5%) and was not detected in the control group. A negative correlation was revealed between positive result of the breath test and the following parameters of rectal sensitivity and function of the anal sphincter: average pressure of the anal sphincter, average maximum compression pressure of the anal sphincter, the threshold for strong urge to defecate and maximum tolerable volume ($p < 0.05$).
CONCLUSION: Disruptions in the qualitative and quantitative composition of intestinal microbiota are found in patients with IBS-D; these changes are correlated with the parameters of anorectal motility and rectal sensitivity.

P0393 INSULAR HTR1A-NR2B PATHWAY MEDIATE THE VISCERAL HYPERSENSITIVITY INDUCED BY CHRONIC STRESS IN RATS

H. Sun[1,*], L. Yi[1], L. Zhou[1], Y. Chen[1], Y. Jiang[1], P. Wu[2], S. Xu[1]

INTRODUCTION: In many clinical studies, 5-HT1A receptor (HTR1A) of the central nervous system (CNS) was thought to be important in the pathogenesis of chronic stress related functional gastrointestinal disorders (FGIDs), but its potential mechanism is still not clear. Some studies thought the abnormality of HTR1A in CNS, through changing neuron activities of visceral sensory area such as insular cortex, mediated visceral hypersensitivity which was an important pathophysiological mechanism of stress-related FGIDs. NR2B was perhaps one key downstream signaling molecule of HTR1A. Insular HTR1A-NR2B pathway is inferred to be important in modulating the visceral hypersensitivity induced by chronic stress.
AIMS & METHODS: This study aimed to determine if insular HTR1A-NR2B pathway influences the activity of insula and mediates the visceral hypersensitivity induced by chronic stress in rats. Chronic water avoidance stress (WAS) was used to establish visceral hypersensitivity rat models. Visceral sensitivity was determined by measuring the visceromotor response (VMR) amplitude to 60mmHg colorectal distention (CRD). The HTR1A agonist 8-OH-DPAT and the HTR1A antagonist WAY100635 were microinjected into the left or right insular cortex. The expression levels of 5-HT, HTR1A, NR2B and c-fos were observed by RT-PCR, Western Blot or immunohistochemical staining.
RESULTS: Compared with sham WAS and normal rats, the expression levels of 5-HT and HTR1A in the bilateral insular cortex of WAS rats were significantly lower ($p < 0.05$), but the expression levels of c-fos and NR2B were significantly higher in the bilateral insular cortex of WAS rats ($p < 0.05$). After 8-OH-DPAT intervention of left or right insular cortex, the VMR amplitudes to 60mmHg CRD could be significantly reduced in WAS rats ($p < 0.01$). After WAY100635 intervention of left or right insular cortex, the VMR amplitudes have no significant changes in WAS rats ($p > 0.05$). The expression levels of bilateral insular NR2B and c-fos in 8-OH-DPAT intervention group were significantly lower than that in WAY100635 intervention group ($p < 0.05$).
CONCLUSION: Through regulating the activity of insular neuron, HTR1A-NR2B pathway has a critical role in mediating the visceral hypersensitivity induced by chronic stress in rats.

INTRODUCTION: A positive self-image is one of the key components for good health and wellbeing. Irritable Bowel Syndrome has been reported to be associated with altered psychological and cognitive functioning such as mood disturbances somatization, catastrophizing or altered visceral interoception by negative emotions and stress (1,2).
AIMS & METHODS: Aims to investigate the psychosocial constructs of self-esteem and sense of coherence among IBS patients compared to non-IBS patients. A case-control study in primary care setting among IBS patients meeting the ROME III criteria ($n = 140$) compared to controls i.e non-IBS patients ($n = 213$) in primary care without any present or previous gastrointestinal complaints. The data were collected through self-reported questionnaires of psychosocial factors.
RESULTS: IBS patients reported significantly higher frequency of more negative self-esteem than controls ($p < 0.0001$), had lower scores on the positive self-esteem measurement ($p < 0.0001$), and lower sense of coherence ($p < 0.0001$) than the controls. The IBS cases were also less likely to report 'good' health

status ($p<0.0001$) and less likely to report a positive belief in the future ($p<0.0001$). After controlling for relevant confounding factors in multiple regressions, the more negative self-esteem for IBS patients remained statistically significant ($p=0.02$), as were the lower scores for sense of coherence for IBS cases ($p=0.04$).

CONCLUSION: The more frequently reported negative self-esteem and inferior coping strategies among IBS patients found in this study suggest the possibility that psychological therapies such as cognitive behavior therapy might be helpful for these patients. However these data do not indicate the causal direction of the observed associations. More research is therefore warranted to determine whether these psychosocial constructs are more frequent personality traits in IBS patients or if the disease itself lowers self-esteem and leads to inferior coping strategies.

P0395 LABOUR PRODUCTIVITY LOSS BECAUSE OF IRRITABLE BOWEL SYNDROME COMPLAINTS

C. Flik[1,*], W. Laan[1], A. Smout[2], N.de Wit[1]
[1]*Julius Center, Health Sciences and Primary Care, University Medical Centre, Utrecht,* [2]*Gastroenterology and Hepatology, Academic Medical Centre, Amsterdam, Netherlands*
Contact E-mail Address: *c.e.flik@umcutrecht.nl*

INTRODUCTION: Irritable Bowel Syndrome (IBS) is the most prevalent chronic functional bowel disease. IBS often results in a substantial disease burden for the patient and leads to considerable medical costs. Systematic reviews reporting economic consequences of IBS focus on direct medical costs and indirect societal costs, such as loss of productivity. When calculating indirect costs for IBS most researchers only take the costs for loss of labour days into account. In our view disease-related loss of labour productivity should also consider the IBS-related impact on work productivity on the days that the IBS patient is present at work.

AIMS & METHODS: We report the overall impact of IBS on labour productivity, i.e. the combined number of sick leave days and the loss of efficiency during the days IBS patients did work with active IBS complaints.

207 adult patients (18-65 years of age) with IBS, meeting Rome III criteria, who were recruited for a randomized controlled trial on hypnotherapy were selected. The impact of IBS on work was measured with four questions of the Trimbos/iMTA questionnaire for Costs associated with Psychiatric Illness (Tic-P): question 1 is about absenteeism from work because of IBS in the past two weeks (yes/no), Q2 about absenteeism for more than two weeks (yes/no),Q3 assessed if one was hindered by IBS complaints when working in the past two weeks (no, not at all; yes, somewhat; yes considerably) and Q4 assessed how efficient one has worked with the IBS complaints (from zero, indicating maximally inefficient up to 10: as efficiently as normal).

RESULTS: Of the 140 patients who had a job, 104 (74.3%) were women and 36 (25.7%) men. Of these female IBS patients 19 (18.2%) were absent from work because of IBS complaints, 10 (9.6%) less than two weeks, 9 (8.7%) more than two weeks. Eleven of these patients had moderate and 8 patients had severe IBS. Five of the male IBS patients (13.9%) were absent from work because of IBS complaints, 3 (8.3%) less than two weeks, 2 (5.6%) more than two weeks; one had moderate and four severe IBS. IBS subtype was known of 131 working IBS patients, 21 (16%) had IBS-Constipation, 33 (25.2%) had IBS-Diarrhea and 77 (58.8%) had IBS-Mixed type. Of the patients with IBS-C 2 (9.5%) were absent less than two weeks, 0% more than two weeks; of the patients with IBS-D 3 (9.1%) were absent less than two weeks and 2 (6.1%) more than two weeks; of the patients with IBS-M 8 (10.4%) were absent for less than two weeks and 8 (10.4%) for more than two weeks. In 20% of the female and 7% of the male working IBS patients IBS complaints had no impact on their labour productivity, 64% of women and 23% of men were hindered to some extent and 16% of women and 23% of men were hindered very much by their IBS complaints in performing their job; 33.3% of women and 52.8% of men indicated that they worked less efficiently than normal (score ≤ 6) because of their IBS complaints.

CONCLUSION: IBS complaints do not only result in substantial absenteeism from work, but also in severe loss of efficiency among those IBS patients who do not report sick, but continue working. When quantifying disease-related loss of labour productivity both aspects should be taken into account.

P0396 EXTENSIVE OVERLAP AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME WITH CONSTIPATION, CHRONIC IDIOPATHIC CONSTIPATION, FUNCTIONAL DYSPEPSIA, AND GASTROESOPHAGEAL REFLUX DISEASE: A CROSS-SECTIONAL, POPULATION-BASED SURVEY

N. Vakil[1], **J.M. Johnston**[2,*], M. Stelwagon[2], E. Shea[2], S. Miller[3]
[1]*University of Wisconsin School of Medicine and Public Health, Madison,* [2]*Ironwood Pharmaceuticals, Cambridge,* [3]*Lieberman Inc., Great Neck, United States*

INTRODUCTION: Individuals with functional gastrointestinal disorders (FGIDs) may report symptoms of more than one FGID as well as symptoms of gastroesophageal reflux disease (GERD). This US cross-sectional Internet-based survey assessed overlap of these disorders and sufferers' symptom experience.

AIMS & METHODS: A random sample of 10,030 US citizens completed an online screening questionnaire to identify those meeting Rome III criteria for irritable bowel syndrome with constipation (IBS-C), chronic idiopathic constipation (CIC), and/or functional dyspepsia (FD), and/or who reported GERD (defined as heartburn or regurgitation $\geq$twice/week in the absence of treatment). Survey responses were weighted for age and gender to be representative of the US census. Respondents who met criteria for $\geq$1 condition completed a detailed questionnaire including a symptom checklist and questions about bothersomeness, severity and frequency of symptoms and healthcare-seeking behaviour. Respondents reported symptoms experienced in the past 12 months, rating them on a scale from "less than 5 days a year" to "everyday." Overall and individual gastrointestinal (GI) symptom bothersomeness was reported on a 5-point scale from "not at all" to "extremely" bothersome.

RESULTS: A total of 2641 respondents met criteria for $\geq$1 condition. Including those with overlapping conditions, 328 met criteria for IBS-C, 552 for CIC, 1690 for FD and 1337 for GERD; 56.5%, 39.9%, 44.7% and 44.2%, respectively, reported very/extremely bothersome GI symptoms. Overall, 1592 (60.3%) met criteria for a single condition, 832 (31.5%) met criteria for 2 conditions and 217 (8.2%) met criteria for 3. Of the 4 conditions, respondents with IBS-C were the most likely to have overlapping conditions. Overall bothersomeness of symptoms increased with condition overlap: 22.5-30.4% of respondents with 1 condition had very/extremely bothersome symptoms, compared to 37.1-65.7% of those with 2 conditions, and 65.1-73.5% of those with 3 conditions. With the exception of heartburn/acid reflux, the frequency and bothersomeness of individual symptoms—including abdominal pain, bloating, diarrhea, and constipation—also increased with condition overlap.

TABLE 1. Condition Overlap

N (total = 2641)	IBS-C (n = 328)	CIC (n = 552)	FD (n = 1690)	GERD (n = 1337)
One Condition Only	57 (17%)	207 (38%)	721 (43%)	607 (45%)
and IBS-C[1]			247 (15%)	137 (10%)
and CIC[1]			289 (17%)	160 (12%)
and FD[1]	247 (75%)	289 (52%)		650 (49%)
and GERD[1]	137 (42%)	160 (29%)	650 (38%)	
3 conditions	113 (34%)	104 (19%)	217 (13%)	217 (16%)

CONCLUSION: Functional GI disorders frequently overlap with each other and with GERD. Patients with overlapping FGIDs have more frequent and bothersome symptoms and greater symptom burden. Results of clinical trials in FGIDs may be modified by overlapping FGIDs; baseline symptom severity may be affected by FGID overlap and global response measures may mask therapeutic response in one or the other FGID. P0397 THE PATH FROM GI SYMPTOMS TO DEPRESSED MOOD AND ELEVATED STRESS: IS IT SPECIFIC TO IBS?

M. Jones[1,*], S. Walter[2], E. Grodzinsky[3], L. Viktorsson[3], N.J. Talley[4], Å. Faresjö[5]
[1]*Psychology Department, Macquarie University, North Ryde, Australia,* [2]*Institution of Clinical and Experimental Medicine,* [3]*Department of Medical and Health Sciences, Linköping University, Linköping, Sweden,* [4]*Faculty of Health & Medicine, University of Newcastle, Callaghan, Australia,* [5]*Dept of Medicine and Health Sciences, Linköping University, Linköping, Sweden*
Contact E-mail Address: *mike.jones@mq.edu.au*

INTRODUCTION: The irritable bowel syndrome (IBS) has been associated with depressed mood[1] and elevated levels of perceived life stress[2], presumably via the adverse effects of the gastrointestinal (GI) symptoms associated with the disorder. However some degree of GI symptoms are also present in non-IBS individuals, including healthy community members.

AIMS & METHODS: We aimed to determine whether the path from GI symptoms to disordered mood leading to elevated perceived stress was different in IBS and non-IBS or undifferentiated between these groups.

Subjects (n = 192, 16% IBS, 84% controls) were all patients at primary health care clinics in one of three Swedish cities as part of the "Twin Cities" study based at Linköping University. Rome II criteria were assessed by the standard Rome Foundation questionnaire. GI symptom burden was assessed by 14 day diary and measures included percent of days with record of nausea, bloating, any abdominal pain (AP), moderate AP and intense AP. Maximum recorded pain intensity was also noted. Mood was assessed via questions addressing depression symptoms and the EuroQol 5 questionnaire. Stress was measured via the Perceived Stress Scale (PSS). A Structural equation model (SEM) was used to model latent variables for GI symptom burden predicting mood, which then predicted stress. Standardized path coefficients are reported along with measures of model fit.

RESULTS: In the combined sample GI symptom burden was found to predict mood ($b=0.184$, $SE=0.076$) and mood was found to predict stress ($b=0.591$, $SE=0.080$). When stratified, the model path coefficients were not different in any significant respect between IBS and non-IBS patients. GI symptoms

predicting mood yielded: IBS (b = 0.163, SE = 0.176) and control (b = 0.219, SE = 0.090) while for mood predicting stress: IBS (b = 0.708, SE = 0.141) and control (b = 0.582, SE = 0.089). Model fit did not differ significantly between the combined and stratified models, indicating that the subtle observed differences in path coefficients were consistent with random chance. The latent variables representing GI symptoms and mood provided an adequate representation of the GI and mood constructs (c^2/df = 1.73, CFI = 0.99, RMSEA = 0.06). This was equally true in the IBS and control groups.

CONCLUSION: Our data support the general hypothesis that symptom experience is associated with elevated mood disturbance which is associated with elevated levels of psychological stress. However while it has been assumed that there is something special about IBS symptomatology that induces mood disorder, our data suggests that while IBS is associated with higher levels of symptoms, the association between GI symptoms and mood, thence perceived stress exists equally in IBS and non-IBS individuals.

INTRODUCTION: Previous studies have found discrepancies between recall and diary reports of symptoms[1]. While questionnaires are commonly used and convenient they can also be prone to recall bias [2]. Since the standard Rome criteria are symptom recall based, if the source of symptom information tangibly changes the clinical picture it calls into question diagnostic criteria.

AIMS & METHODS: We investigated the concordance between the IBS-supportive criteria ''pain relieved by defecation'' and ''onset of stools associated with a change in stool consistency'' between questionnaire recall and prospective diary reports. The present study population consists of 272 participants of a random population based colonoscopy study. Pain relieved by defecation (PRBD) was identified in 7 day diary records by selecting all hours when defecation was reported then checking whether pain was reported in a two-hour window prior to the hour in which defecation was reported but was absent in the two hour window after defecation was reported. The Rome II IBS criterion of stool consistency altered by pain was assessed by comparing the distribution of Bristol stool scores (Bristol) on days when pain was reported to the distribution on days when no pain was reported. Statistical contrasts, based on unconditional logistic regression, are adjusted for repeated measurements on individuals using the linearization method to yield correct standard errors and p-values.

RESULTS: *Pain relieved by defecation*: The PRBD pattern was ever identified in 3.4% of participants compared with the corresponding questionnaire item asking whether pain was ever relieved by defecation in a 3-month recall period where the prevalence was 55.3%. However concordance between diary and questionnaire was only 66.1% and kappa was close to zero (0.07). The PRBD diary pattern was seen significantly more often in persons who reported pain relieved by defecation on the questionnaire (7.2%) than persons who did not (1.3%) indicating that diary and questionnaire are not completely disconnected. *Change in stool form with pain*: Among all participants, hard stools were more often reported on pain days (OR: 4.06, 95% CI: 2.14-7.71, $p < 0.001$ for Bristol score 1 and OR: 2.67, 95% CI: 1.61-4.42, $p < 0.001$ for Bristol score 2). However this was true for all participants, regardless of whether they reported onset of pain or discomfort associated with hard stools on the questionnaire. No difference in the occurrence of loose stools on pain versus non-pain days was observed, not even in participants who reported onset of pain associated with loose stools.

CONCLUSION: The poor concordance between prospective diary and retrospective questionnaire might be due to any of: 1) poor recall when completing questionnaires, 2) symptoms fluctuate over short time scales or 3) a 7 day diary is too short to accurately capture low prevalence conditions. Given the apparent central importance of measurement methodology to prevalence of disease the reasons for this poor concordance needs to be elucidated.

P0399 EFFECT OF THE FODMAP-RESTRICTED DIET ON COLONIC GAS PRODUCTION CAPACITY IN PATIENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS

M.L. Ones[1,*], I. Thun[1], F.Van Megen[1], M.H. Morken[1], G.E. Kahrs[1], G.M. Olderøy[1], T. Hausken[1], J.G. Hatlebakk[1]
[1]*Department of Clinical Nutrition and Section of Gastroenterology, Department of Medicine, Clinical Institute 1 (K1), University of Bergen, Haukeland University Hospital, Bergen, Norway*
Contact E-mail Address: *mon083@student.uib.no*

INTRODUCTION: The FODMAP-(fermentable oligo-, di-, and monosaccharides and polyols) restricted diet is used as a treatment for functional gastrointestinal disorders such as irritable bowel syndrome (IBS) [1], with the goal of reducing fermentation and gas related symptoms. We wanted to investigate whether the capacity for gas production changed over time when consuming a FODMAP-restricted diet among patients with IBS or functional dyspepsia (FD).

AIMS & METHODS: 29 patients with IBS (n = 19) or FD (n = 10), were diagnosed according to ROME III criteria for IBS and FD (24F/5M, age 34±11y). Participants were instructed thoroughly about the diet from a clinical dietician and followed closely for 6 ± 1 weeks. Repeated 4 days prospective food records (baseline and 6 weeks) were used to measure diet changes and adherence to the diet. Lactulose breath test was performed before, and during the last week of the diet. Participants were adviced to not drink/eat/smoke 10 hours before the test (usually at 8:30). After baseline breath test they consumed 10 g of lactulose dissolved in 120 ml water and breath samples were collected every 15 min for 180 min. Hydrogen and methane gas was analysed in a Model SC Quintron Gas Chromatograph. The area under the curve (AUC) was used as a measurement for gas production, and breath samples before lactulose intake were used to study adherence with the diet. Statistical test used were paired t-test, Wilcoxon signed rank and Spearman and Pearson correlation test.

RESULTS: The FODMAP intake significantly decreased from median 8 g/d to 0.25 g/d ($p < 0.0001$), and good adherence was also verified by baseline breath samples for hydrogen which decreased from median 6 to 2 ppm ($p = 0.0124$), and methane from median 25 to 18 ppm (n.s. $p = 0.6797$). 28 (18 IBS/10 FD) had hydrogen production and there was a significant reduction from median 4418 to 1710 ppmxmin ($p = 0.0035$) during the diet intervention. 9 (7 IBS/2FD) participants had methane production, with a reduction from median 9495 to 6750 ppmxmin (n.s. $p = 0.5415$). Correlation between the change in FODMAP intake and the change in hydrogen ($r = -1609$, $p = 0.4045$) or methane production was not significant ($r = -0.1019$, $p = 0.7943$).

CONCLUSION: The FODMAP-restricted diet was associated with a reduction in the capacity for hydrogen gas production in patients with IBS or FD, which might indicate a shift in colonic microbiome

P0400 WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT IN IBS: A MULTIFACETED PROBLEM

Å. Frändemark[1,*], G. Ringström[1], H. Törnblom[1], M. Simrén[1]
[1]*Deparment of Internal Medicine & Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Göteborg, Sweden*
Contact E-mail Address: *asa.frandemark@gmail.com*

INTRODUCTION: IBS is one of the most prevalent functional gastrointestinal disorders. Earlier studies have shown that IBS patients are more likely to be impaired at work and during daily activities compared to non-IBS patients. However, factors of importance for this impairment have not yet been fully examined.

AIMS & METHODS: Our aim was to investigate the relationship between work impairment and other factors related to IBS. We included 533 patients with IBS (median age 34 (17-80) years, 420 females). The patients completed the Work Productivity and Activity Impairment Questionnaire:IBS (WPAI:IBS), as well as questionnaires to assess IBS symptom severity (IBS-SSS), GI-specific anxiety (VSI), somatic symptoms (PHQ-15), depression and anxiety (HAD), and fatigue (MFI). Uni- and bivariate analyses were performed, as well as linear regression analyses to determine factors independently associated with the work productivity and activity impairment measures.

RESULTS: The IBS patients reported 7±19% (mean±SD) absenteeism (actual work time missed), 33±25% presenteeism (impairment while at work), 36±27% overall work productivity loss and 46±27% activity impairment. Female IBS patients reported greater activity impairment than males (47±27 vs. 41±27%; $p < 0.05$), but no other gender differences were found. A weak, but statistically significant negative association was noted between age and activity impairment ($rho = -0.11$; $p < 0.05$), but otherwise age was not associated with the work productivity and activity impairment. No differences between IBS-subtypes were found. With increasing severity of IBS symptoms, somatic symptoms and GI-specific anxiety, higher degrees of absenteeism, presenteeism, overall work productivity loss and activity impairment were seen ($p < 0.0001$ for all). Among the fatigue measures, physical fatigue, general fatigue and reduced activity demonstrated the strongest associations with the work productivity and activity impairment ($rho = 0.28$-0.47; $p < 0.01$). Weaker, but still statistically significant associations were seen between general anxiety and depression and presenteesim, overall productivity loss and activity impairment ($rho = 0.19$-0.30; $p < 0.05$). Using linear regression analysis, IBS symptom severity, GI-specific anxiety and general fatigue were independently associated with presenteeism ($R^2 = 0.36$; $p < 0.05$) and overall productivity loss ($R^2 = 0.42$; $p < 0.05$), while activity impairment was independently associated with IBS symptom severity and general fatigue ($R^2 = 0.40$; $p < 0.05$).

CONCLUSION: Work productivity and activity impairment is a substantial problem in patients with IBS. A combination of IBS and somatic symptom severity, fatigue and psychological factors seem to impact the IBS patients' ability to be active and productive at work. Based on this, a multidimensional treatment approach for IBS patients seems logical.

P0401 THE SEVERITY OF SYMPTOMS RELATED TO IRRITABLE BOWEL SYNDROME IS A RISK FACTOR FOR THE MISCLASSIFICATION OF SIGNIFICANT ORGANIC DISEASE

D. Carter[1,2,*], E. Bardan[1,2], E. Derazne [1], B. novis[1,2], M. Beer-Gabel[1,2]
[1]*Sackler Faculty of Medicine, Tel Aviv,* [2]*Gastroenterology, Chaim Sheba Medical Center, Ramat Gan, Israel*
Contact E-mail Address: *dr.dancarter@gmail.com*

INTRODUCTION: The diagnosis of Irritable Bowel Syndrome (IBS) is based mainly of clinical evaluation. The reported incidence of misclassification of significant organic diseases in previously diagnosed IBS patients differs between studies.
AIMS & METHODS: We examined the incidence and risk factors for the diagnosis of significant organic diseases (inflammatory bowel disease (IBD), Celiac disease, gastrointestinal malignancy and thyroid dysfunction) in a cohort of 2645 IBS.
RESULTS: During follow-up, organic disease was diagnosed in 27 subjects (1.03%): IBD in 23, Celiac disease in 2, IBD and Celiac disease in one and hypothyroidism in one. The mean interval from the diagnosis of IBS to the diagnosis of an organic disorder was 13.08±8.51 months. Increased symptom severity was the only significant risk factor for the misclassification of an organic disease (HR 2.26, 95%CI 1.01-5.05 $p = 0.047$). The risk ratio for misclassification of organic diseases in moderate to severe IBS was increased by 2.575 (95%CI 1.10-6.51, $p = 0.027$) in relation to mild IBS.
CONCLUSION: The incidence of misclassification of major organic disease in IBS patients was low. Increased symptoms severity was the only significant risk factor for the misclassification of organic disorders. Further gastrointestinal evaluation should be considered when symptoms are moderate to severe.

P0402 BILE ACID DIARRHOEA MASQUERADES AS DIARRHOEA-PREDOMINANT IRRITABLE BOWEL SYNDROME: RESULTS FROM A DUAL CENTRE PROSPECTIVE STUDY

I. Aziz[1,*], S. Mumtaz[2], H. Bholah[2], F.U. Chowdhury[3], D.S. Sanders[1], A.C. Ford[2]
[1]*Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield,* [2]*Leeds Gastroenterology Institute,* [3]*Nuclear Medicine Department, St James's University Hospital, Leeds, United Kingdom*

INTRODUCTION: Several studies have suggested that bile acid diarrhoea (BAD) can present with symptoms that are compatible with diarrhoea-predominant irritable bowel syndrome (IBS-D). However, uncertainty exists as these have often been retrospective, have not defined IBS-D according to accepted diagnostic criteria, or have included patients with chronic diarrhoea in the analysis. We have examined this issue in a well-characterised cohort of patients with rigorously defined IBS-D.
AIMS & METHODS: This was a prospective cross-sectional survey conducted among consecutive patients with IBS-D attending Gastroenterology clinics in two hospitals in Sheffield and Leeds, UK. All patients underwent 23-seleno 25-homo-tauro-cholic acid (SeHCAT) scanning according to local protocol, with a retention of $<15\%$ at day 7 used to confirm BAD. The degree of BAD was classed as severe if retention $<5\%$, moderate if $5.0\% > 9.9\%$, and mild if $10.0\% > 14.9\%$. Presence of IBS-D was defined according to the Rome III criteria. Patients with other known risk factors for BAD, including previous cholecystectomy, terminal ileal Crohn's disease, terminal ileal resection, pelvic or abdominal radiotherapy, coeliac disease, or microscopic colitis, were excluded. Participants completed the patient health questionnaire-15, a validated somatisation score, and the hospital anxiety and depression score. Demographic data, including age, gender, lifestyle, and body mass index (BMI) were collected. The effect of all these factors on presence or absence of BAD was examined by multivariate logistic regression analysis, with results expressed as odds ratios (ORs) with 99% confidence intervals.
RESULTS: This is an interim analysis of an ongoing study. In total, 51 patients with IBS-D according to the Rome III criteria have been recruited to date (37 (72.5%) female, mean age 47.0 years). In total, 14 (27.5%) were found to have BAD following SeHCAT scanning. Of these, nine (17.6%) had severe BAD, four moderate, and one mild. Mean age, BMI, anxiety, depression, and somatisation scores were not significantly different among those with, compared with those without, BAD. No predictors of presence of BAD were identified following multivariate logistic regression.
CONCLUSION: Our data suggest that more than one-in-four IBS-D patients, if investigated, have definite evidence of BAD. In the majority, this is severe. Failure to investigate patients to exclude BAD as an underlying cause of symptoms compatible with IBS-D results in misdiagnosis and a failure to institute effective therapy, in the form of bile acid sequestrants. This suggests that future IBS management guidelines should advocate diagnostic testing to exclude BAD before a diagnosis of IBS-D is made.

Contact E-mail Address: *hans.tornblom@gu.se*

INTRODUCTION: Irritable bowel syndrome (IBS) is a diagnosis based on symptom criteria. In order to perform epidemiologic studies based on national health-care registers there is a need to assess the accuracy of the diagnostic code in clinical practice at different time points.
AIMS & METHODS: The aim of this study was to evaluate the positive predictive value of the ICD-10 (International Classification of Diseases, version 10) code for IBS in Sweden in hospital based outpatient care during 2005 (using the Rome II criteria) and 2010 (Rome III criteria). We identified all Swedish adults that had received the ICD-10 code for IBS as the main diagnosis during hospital-based outpatient care in 2005 and 2010 by use of the Swedish National Patient Register. We excluded individuals from the IBS cohort if they had been diagnosed with predefined diagnoses, incompatible with IBS, during a time span of 6 months before or after the IBS diagnosis. The National Board of Health and Welfare generated a random sample of 300 identities. Each medical record was retrieved and read by two of the authors (N. J. and H. T.) who noted if symptoms compatible with IBS according to Rome II criteria (2005 cohort) or Rome III criteria (2010 cohort) could be identified.
RESULTS: We received a total of 248 medical records (2005, $n = 127$; 2010, $n = 121$). In 173 patients (70%), the diagnosis fulfilled diagnostic criteria with a high certainty and in 75 patients (30%) it did not. The proportions of valid diagnoses were similar in 2005 (Rome II criteria, 68%) and 2010 (Rome III criteria, 72%) ($\chi_2 = 0.67$, $df = 1$, $p = .41$). Out of the 75 cases that did not fulfill diagnostic criteria, 24 were labeled "probable IBS" because of insufficient medical data. There was no difference when comparing tertiary (72% correct) and secondary care (69% correct) ($p = .62$), but a significant difference in accuracy was noted comparing departments of internal medicine (155/210, 74%) and non internal medicine departments (18/38, 47%) ($p = .001$). The most common reasons for a diagnosis being judged as not valid were: insufficient patient data available in 33 patients (13%), symptoms only including abdominal pain/discomfort *or* abnormal bowel habit in 19 patients (8%), an obvious misuse of the diagnosis in 12 patients (5%) and too short duration of symptoms in 11 cases (4%).
CONCLUSION: The use of the ICD-10 diagnostic code for IBS in Swedish secondary and tertiary care has a high validity in departments of internal medicine but less so in other departments. This finding needs to be addressed when planning and interpreting epidemiologic studies of IBS.

P0404 ALTERATIONS IN ENTERIC GLIA CELL PHENOTYPE AND FUNCTIONS IN IRRITABLE BOWEL SYNDROME

N.L. Lilli[1,*], Q. Lucille[1], A. Philippe[1], R.-D. Malvyne[1], D. Tony[1], K. Elise[2], B. Giovanni[3], D.G. Roberto[3], B.D. V. Stanislas[2], C. Emmanuel[2], N. Michel[1]

INTRODUCTION: Irritable bowel syndrome (IBS) is a complex disease characterized by symptoms including chronic abdominal pain or discomfort and alteration of bowel habit. Increasing evidence demonstrates a central role of intestinal epithelial barrier (IEB) dysfunction, and especially increased paracellular permeability, in the pathophysiology of IBS. The enteric nervous system (ENS), and in particular enteric glial cells (EGC) play a pivotal role in the maintenance of IEB.
AIMS & METHODS: The purpose of this study was to characterize the lesions of the EGC in IBS patients and the putative causative role of soluble factors produced by the colonic IEB microenvironment in these lesions. ***Methods*****:** Eighteen IBS patients (6 constipation-predominant IBS (IBS-C), 6 diarrhea-predominant IBS (IBS-D) and 6 mixed bowel habits IBS (IBS-M) patients) and 9 healthy controls (HC) were included. For each patient gastrointestinal symptoms were assessed using the Rome III questionnaire and colonoscopy was performed with 12 biopsies of left colon. Paracellular and transcellular permeability was measured on 3 biopsies using the Ussing chambers. Supernatant was obtained by incubation of 4 biopsies in Krebs-Hepes solution during 25 minutes at 37°C. At the end of the incubation time, biopsies were processed for Western blot analysis. Both total Glial fibrillary acidic protein (GFAP) expression and the 55-kDa band as well as S100b were analysed. The mRNA expression levels of glial markers (Sox-10; S100b) and inflammatory cytokine TNF-a were measured using real-time PCR. Intracellular calcium flux in response to adenosine triphosphate (ATP) stimulation was measured using Fluo-4 probe in culture of rat EGC after 48h incubation with patients and HC supernatants or protease-activated receptor agonists (SLIGRL and Thrombin), serotonin or histamine.
RESULTS: Paracellular and transcellular permeability of biopsies from all subtypes of IBS patients was similar as compared to HC, except in the IBS-C subtype for which transcellular permeability was significantly increased. No difference in S100b, total GFAP and the specific 55-kDa band expression was observed for any subtype. Sox-10 and S100b mRNA expression was similar in biopsies of all IBS subtypes as compared to HC. Interestingly, we observed a

significant increase in TNF-a mRNA expression in IBS-M but not C or D subtype as compared to control. Intracellular calcium responses (maximal amplitude and half max duration) to ATP were significantly decreased in rat EGC cultures incubated with supernatants of IBS-D and M but not C subtypes as compared to control. No difference in calcic response to ATP was observed in EGC cultures after incubation with different SLIGRL, thrombin, serotonin and histamine concentrations.

CONCLUSION: Our study demonstrates that enteric glial phenotype and functions are altered in IBS in a subtype dependent fashion. The mediators responsible for these changes as well as the functional consequences of these changes remain to be identified.

P0405 ABDOMINAL PAIN VERSUS ABDOMINAL DISCOMFORT: IMPLICATIONS FOR DIAGNOSTIC ASSESSMENT OF IRRITABLE BOWEL SYNDROME (IBS)

O. Palsson[1,*], S. Heymen[1], W.E. Whitehead[1]
[1]*Department of Medicine, Division of Gastroenterology and Hepatology, University of North Carolina, Chapel Hill, United States*
Contact E-mail Address: *opalsson@med.unc.edu*

INTRODUCTION: Diagnostic questions in the current Rome criteria for IBS inquire about frequency of abdominal "discomfort or pain", whereas the U. S. Food and Drug Administration guidelines for IBS clinical trials only reference abdominal pain frequency. It is unknown to what extent people perceive abdominal pain and discomfort differently or whether both are needed in GI diagnosis questions.

AIMS & METHODS: We compared abdominal pain and discomfort ratings in a U. S. nationwide internet community survey of 328 adults, containing the Rome III diagnostic questions for IBS in the new response formats planned for Rome IV diagnoses (Gastroenterology 2013;144(5) Suppl.1:S-916), including the standard "in the past 3 months, how often did you have discomfort or pain anywhere in your abdomen?" and alternative forms of that question replacing "abdominal discomfort or pain" with only "pain" or only "discomfort". Also included was a multiple-choice question about the extent to which abdominal pain and discomfort are experienced as separate sensations, and demographic questions. To avoid over-estimating agreement between alternative question forms, responses from people who reported having neither pain nor discomfort in the abdomen in the past 3 months were excluded from analysis, as well as those inconsistent on either of two repeated quality-check questions, leaving 218 for analysis. Analysis calculated percent agreement between alternate question forms, and also Cohen's Kappa (K-values) for diagnostic performance as this controls for rate of chance agreement (K > 0.8 = excellent agreement).

RESULTS: The subjects (52.8% females; mean age = 45.8, range 19-85 years) varied widely in their perception of the relationship between abdominal pain and discomfort: 33.9% stated they were entirely or mostly independent sensations, 27.1% that they were mostly or entirely the same sensation, and 39.0% that both were equally true – i.e., they could be either separate sensations or discomfort a mild version of pain. Only about half of subjects rated frequency of pain alone (52.8%) and discomfort alone (55.5%) as identical in intensity (i.e., same response option chosen on the 9-point frequency scale) to ratings on the standard "pain or discomfort" question. However, when the diagnostic frequency threshold for IBS (>3 days a month in the past 3 months) was compared, the agreement with "pain or discomfort" on that threshold being met (when met by either version) was 72.4% (K = 0.63) for the pain alone and 76.8% (K = 0.66) for discomfort alone, and 81.3% between the latter two (K = 0.74). When full IBS criteria were examined using the 3 different question versions, the agreement with the standard question version when at least one method qualified subjects as IBS was 80.8% (K = 0.85) for the pain-only version and 87.7% (K = 0.90) for discomfort-only, with the latter two also showing 87.7% agreement (K = 0.90). IBS diagnosis with discomfort alone diagnosed a slightly higher rate of IBS (71 cases) compared to the other 2 versions (66 cases each).

CONCLUSION: The use of abdominal "discomfort or pain" as a criterion for IBS diagnosis is ambiguous because there is no agreement among U. S. adults regarding whether these are qualitatively different sensations. However, in 4 out of every 5 cases the same individuals would be diagnosed IBS regardless of which descriptor is used. P0406 PREVALENCE OF ORGANIC GASTROINTESTINAL DISEASE IN SUSPECTED IRRITABLE BOWEL SYNDROME (IBS) VARIES ACCORDING TO SUBTYPE

P. Patel[1,*], P. Moayyedi[2], P. Bercik[2], M.-I. Pintos-Sanchez[2], C. Bolino[2], D. Morgan[3], A. Ford[4]
[1]*School Of Medicine, University of Leeds, Leeds, United Kingdom,* [2]*Farncombe Family Digestive Health Research Institute, Gastroenterology Division, McMaster University, Health Sciences Center,* [3]*Gastroenterology Department, St. Joseph's Healthcare, Hamilton, Canada,* [4]*Leeds Gastroenterology Institute, St. James's University Hospital, Leeds, United Kingdom*
Contact E-mail Address: *um10pp@leeds.ac.uk*

INTRODUCTION: In patients who report symptoms compatible with IBS in the absence of alarm symptoms, guidelines suggest the diagnosis can be made without investigations. However, there are few validation studies of the current gold-standard, the Rome III criteria, and the prevalence of organic gastrointestinal (GI) disease in people with suspected IBS is unclear.

AIMS & METHODS: We evaluated consecutive patients with Rome III-defined IBS, and examined whether prevalence of organic GI disease varied according to IBS subtype, or the presence or absence of alarm symptoms. Demographic and symptom data were collected from 4224 patients with GI symptoms attending outpatient clinics at two hospitals in Hamilton, Ontario. Participants completed the Rome III diagnostic questionnaire for the functional GI disorders, which was used to categorise IBS subtype. Individuals underwent colonoscopy, with assessors blinded to symptom status. Patients with normal colonoscopy and no evidence of coeliac disease were classed as having no organic GI disease. Prevalence of organic GI disease was compared according to IBS subtype, and in patients who did, compared with those who did not, report alarm symptoms (weight loss, rectal bleeding, anaemia, or family history of colorectal cancer) using a χ^2 test.

RESULTS: 537 patients met Rome III criteria for IBS (mean age 42yrs, 404 (75.2%) females). Organic GI disease was present in 138 (25.7%), with the commonest finding Crohn's disease (n = 46 (8.6%)). 63 patients had IBS-C, 209 IBS-D, and 265 IBS-M. Prevalence of organic GI disease was significantly lower in IBS-C (n = 8 (12.7%)) versus IBS-D (n = 67 (32.1%)) or IBS-M (n = 63 (23.8%)) (p = 0.005) (Table). In the 410 patients who reported ≥1 alarm symptom, prevalence of organic GI disease was significantly higher (n = 116 (28.3%)) compared with 127 patients who did not report any alarm symptom (n = 22 (17.3%)) (p = 0.013). In IBS-D, there was a significantly higher prevalence of organic GI disease in those with alarm symptoms (36.0%) compared with those without (17.85%) (p = 0.02). However, IBS-C and IBS-M prevalence of organic GI disease in patients with alarm symptoms versus those without was not significantly higher (IBS-C 11.6% versus 15.0%, p = 0.708; IBS-M 25.6% versus 17.7%, p = 0.202

	Total IBS (n = 537)	IBS-D (n = 209)	IBS-C (n = 63)	IBS-M (n = 265)
No organic GI disease (%)	399 (74.3)	142 (67.9)	55 (87.3)	202 (76.2)
Ulcerative colitis (%)	34 (6.3)	19 (9.1)	1 (1.6)	14 (5.3)
Crohn's disease (%)	46 (8.6)	21 (10.0)	2 (3.2)	23 (8.7)
Colorectal cancer (%)	14 (2.6)	5 (2.4)	2 (3.2)	7 (2.6)
IBD unclassifiable (%)	24 (4.5)	11 (5.3)	2 (3.2)	11 (4.2)
Microscopic colitis (%)	12 (2.2)	8 (3.8)	0 (0)	4 (1.5)
Coeliac disease (%)	8 (1.5)	2 (1.0)	2 (3.2)	4 (1.5)

CONCLUSION: Patients with suspected IBS-C are unlikely to have underlying organic GI disease, compared with IBS-D or IBS-M. Although the incorporation of the absence of alarm symptoms into the diagnostic criteria for IBS reduced the likelihood of organic GI disease, this was only for IBS-D and, because alarm symptoms are so common, ≥60% of patients still have normal investigations. Better ways of diagnosing IBS are needed.

P0407 SOMATISATION LEVEL VARIES ACCORDING TO IRRITABLE BOWEL SYNDROME (IBS) SUBTYPE AND DRIVES BLOATING SEVERITY

P. Patel[1,*], P. Moayyedi[2], P. Bercik[2], M.-I. Pintos-Sanchez[2], C. Bolino[2], D. Morgan[3], A. Ford[4]
[1]*School Of Medicine, University of Leeds, Leeds, United Kingdom,* [2]*Farncombe Family Digestive Health Research Institute, Gastroenterology Division, McMaster University, Health Sciences Center,* [3]*Gastroenterology Department, St. Joseph's Healthcare, Hamilton, Canada,* [4]*Leeds Gastroenterology Institute, St. James's University Hospital, Leeds, United Kingdom*
Contact E-mail Address: *um10pp@leeds.ac.uk*

INTRODUCTION: Literature suggests that somatisation is strongly associated with IBS. However, it remains unclear whether the degree of somatisation varies according to IBS subtype. Furthermore, whether there is an association between higher levels of somatisation and more severe IBS symptoms is unknown.

AIMS & METHODS: Demographic and symptom data were collected from 4224 adult patients attending gastrointestinal (GI) outpatient clinics at two hospitals in Hamilton, Ontario. Participants completed the Rome III diagnostic questionnaire for the functional GI disorders. Somatisation data were collected via the Patient Health Questionnaire-15 (PHQ-15), comprising 15 somatic symptom items. To avoid overestimation of the severity of somatisation we excluded the 3 GI items from the original PHQ-15 questionnaire to form the PHQ-12. Somatisation severity was categorised according to total PHQ-12 (minimal ≤3, low 4-7, medium 8-12 and high ≥13) with a maximum somatisation score of 24. Mean somatisation score and total number of somatic symptoms reported were compared between IBS subtypes (diarrhoea-predominant (IBS-D), constipation-predominant (IBS-C), and mixed stool pattern (IBS-M)) using analysis of variance. The effect of level of somatisation on the severity of individual IBS symptoms, including lower abdominal pain or discomfort, stool frequency, stool consistency, bloating or abdominal distension, tenesmus, and urgency was compared according to IBS subtype using a χ^2 test with P values of <0.01 denoting statistical significance.

RESULTS: 840 patients met the Rome III criteria for IBS and provided complete somatisation data (mean age 38.3 years, 702 female (83.6%)). Of these, 289 patients had IBS-D, 138 IBS-C, and 413 had IBS-M. Mean PHQ-12 scores were significantly higher in those with IBS-M (n = 10.35), compared with IBS-C (n = 8.94) or IBS-D (n = 9.24) respectively (P < 0.001). Mean number of PHQ-12 symptoms reported was also significantly higher in IBS-M patients (7.2) compared with patients with IBS-C (n = 6.2) or IBS-D (n = 6.4) respectively (P < 0.001). High level of somatisation was present in 222 patients (26.4%).

The prevalence of a high level of somatisation was significantly greater in patients with IBS-M (131 patients (31.7%)) compared with IBS-C (31 (22.5%)) or IBS-D (60 (20.8%)) respectively ($p = 0.003$). For all subtypes of IBS, high levels of somatisation were associated with a greater severity of bloating or abdominal distension ($P < 0.001$ for IBS-M and IBS-D, and $p = 0.004$ for IBS-C respectively). For patients with IBS-M, high levels of somatisation were also associated with a significantly greater prevalence of likelihood of reporting < 3 stool per week ($p = 0.001$). No other significant associations between somatisation severity and symptom severity were observed.

CONCLUSION: IBS-M is strongly associated with higher levels of somatisation. The number of reported somatic symptoms reported is higher in IBS-M compared with other IBS subtypes. Severity of bloating or abdominal distension reported by all patients with IBS is strongly associated with high levels of somatisation. This suggests psychological stress may drive the severity of this commonly reported symptom in IBS, and may partly explain why it can be difficult to treat.

INTRODUCTION: Immune activation (low grade inflammation) and an altered intestinal microbiota are postulated to be involved in the multi-factorial pathophysiology of Irritable Bowel Syndrome (IBS), especially in the diarrhea predominant subtype. Fecal calprotectin and plasma cytokines, as markers of intestinal inflammation and systemic immune activation, respectively, and the antimicrobial protein human beta defesin-2 (HBD-2), have previously been assessed in IBS patients, but results were inconsistent and numbers were too small for subtype analyses.

AIMS & METHODS: The aim of our study was to compare fecal calprotectin, HBD-2 and plasma cytokines levels of a large well characterized IBS cohort to healthy controls (HC), and to assess differences between subtypes.

Fecal and blood samples were obtained from IBS patients (Rome III) and age- and gender-matched HC. Calprotectin and HBD-2 levels in fecal samples were analyzed by ELISA, while non-stimulated levels of IL-1β, IL-6, IL-8, IL-10, IL-12P70 and TNF-α were assessed by Luminex assay. Kruskal Wallis test was used for multi-group comparison and Mann-Whitney U test for 2-group comparisons, with post-hoc Bonferroni correction (for multiple testing).

RESULTS: We included 164 HC and 264 IBS patients (IBS < SUB > TOTAL < / SUB >): 92 diarrhea predominant (IBS-D), 48 constipation predominant (IBS-C), 105 with mixed stools (IBS-M) and 19 with undefined subtype (IBS-U). IBS-U was not analyzed separately due to small numbers. Calprotectin was higher in IBS < SUB > TOTAL < /SUB > compared to HC (median [IQR]: 40.3 [19;81] vs. 20.4 [5-48] ug/g, $p < 0.001$, resp), and in all IBS-subtypes compared to HC. HBD-2 levels were lower in IBS < SUB > TOTAL < /SUB > compared to HC (31.0 [18;48] vs. 37.5 [27;60] ng/g, $p < 0.01$), which was also true for IBS-D vs. HC. The cytokines IL-1β (0.11 [0.11;1.12] vs. 0.11 [0.11;1.46] ug/l, $p < 0.01$) and IL-6 (0.19 [0.19;0.19] vs. 0.52 [0.19;3.13] ug/l, $p < 0.01$) were lower in IBS < SUB > TOTAL < /SUB > vs. HC, while IL-12p70 (0.08 [0.08;3.52] vs. 0.08 [0.08;1.53] ug/l, $p < 0.01$) and TNF-α (0.45 [0.26;0.69] vs. 0.67 [0.38;8.32] ug/l, $p < 0.01$) were higher IBS < SUB > TOTAL < /SUB > compared to HC. The IL10/12 ratio was also lower in IBS_{TOTAL} compared to HC (0.45 [0.26;0.69] vs. 0.67 [0.38;8.32], $p < 0.01$). The findings were consistent for all subtypes, apart for TNF-α being only increased in IBS-D and no differences found between all subtypes and HC for IL-1β. No significant differences were found for IL-8 and -10.

CONCLUSION: Calprotectin levels were significantly higher, but mildly elevated, in IBS patients and all subtypes compared to HC, pointing to low grade mucosal inflammation in IBS. The overall cytokine levels were low, but combined systemic cytokine data point to a pro-inflammatory state in the total group of IBS patients as well as in all subtypes. Interestingly, HBD-2 levels were lower in IBS patients compared to HC, especially in IBS-D, suggesting an altered host-microbe interaction.

In conclusion, our data point to a low-grade mucosal and systemic inflammatory state with reduced intestinal defensin levels in IBS patients when compared to healthy controls. The findings did not depend on dominant bowel habits, indicating that immune activation may plays a role in the pathophysiology of all IBS subtypes.

INTRODUCTION: Ischemic colitis (IC) is the most common vascular disorder of the intestinal tract and the second most common cause of lower digestive bleeding. The clinical disease course of ischemic colitis may vary from self-limiting to life-threatening and has a wide spectrum of endoscopic findings.

AIMS & METHODS: In this study, we made a retrospective analysis of endoscopy findings and clinicopathologic characteristics of IC in the endoscopy center of our hospital during the last 10 years (2002 to 2012) and try to identify the predictors of endoscopic severity of IC. The data collected included demographic (age, gender), clinical (symptoms, comorbidities and medication), laboratory (hemoglobin, leucocytes, C-reactive protein, lactate dehydrogenase), and endoscopic findings (localization, extension, severity of the lesions) and outcomes (length of hospitalization stay, treatment and death).

RESULTS: The study included 194 patients (92 women; 62 men), with mean age of 75 years. The most common comorbid disease was hypertension (56.5%), followed by cardiovascular disease (21.5%), arrhythmias (14.8%) and cerebrovascular disease (6.6%). The majority of patients had a history of drug use (89.6%), 23.4% of them nonsteroidal anti-inflammatory agents and 13.6% digitalis preparations. Hematochezias (79.2%) and abdominal pain (73.3%) were the most common presentation symptoms. The average elapsed time between the beginning of the symptoms and the diagnosis was 2,1 days. Ischemic lesions were located mainly in the left colon (77.3%) and were found in more than 2 colonic segments in 42.9%. The endoscopic lesions were grade I in 57.1%, grade II in 39.6% and grade III in 3.2% of patients. The involvement of more than 2 colonic segments ($\rho < 0.0001$), the involvement of sigmoid and descendent colon ($\rho < 0.0001$), anemia ($\rho < 0.04$), and mortality ($\rho < 0.0001$) were significantly higher in patients with severe endoscopic lesions. Death occurred in 4 patients (2.6%) and surgery was performed in only 1 patient. The mean length of hospital stay was 7.5 days. The involvement of more than 2 colonic segments ($p > 0.0001$), longer elapsing time between the beginning of symptoms and the diagnosis ($p > 0.0001$), antibiotics use ($p > 0.009$) and age higher than 80 years ($p < 0.001$) were related to longer hospitalization.

CONCLUSION: In our study, the majority of patients were female, over 50 years of age and with several risk factors. The clinical disease course was self-limiting and was associated a low mortality. The involvement of more than 2 colonic segments, the involvement of sigmoid and descending colon and anemia may be predictive factors of endoscopic severity in IC. An intimate knowledge of endoscopic findings and pathologic characteristics of ischemic colitis plays a pivotal role in decreasing the misdiagnosis rate of ischemic colitis.

P0410 THE CLINICAL CHARACTERISTICS OF PATIENTS WITH PNEUMATOSIS CYSTOIDES INTESTINALIS IN JAPAN

M. Miura[1,*], D. Saito[1], M. Hayashida[1], A. Sakuraba[1], Y. Yamada[1], G. Koyama[1], S. Takahashi[1]
[1]*The Third Department of Internal Medicine, Kyorin University School of Medicine, Tokyo, Japan*

INTRODUCTION: Pneumatosis cystoides intestinalis (PCI) is a relatively rare disease, in which multilocular or linear pneumatic cysts developed under the mucosa or serosa of the intestinal wall. In recent years, with the advances in imaging technologies, the number of reported cases of PCI has been increasing. Here, we investigated the clinical characteristics of patients with PCI.

AIMS & METHODS: 55 patients were diagnosed as PCI at Kyorin University Hospital during the 6-year period from September 2007 to August 2013. We conducted a retrospective analysis of the clinical characteristics of these patients, including sex, age, the site of lesion, symptoms and treatments.

RESULTS: The male to female ratio was 29:26 and the median age was 64.7 years. The diagnosis was made by CT(47 cases), or colonoscopy (8 cases). In regard to the site of lesion, the stomach was 2 patients, small intestine was 18 patients, ascending colon was 26 patients, transverse colon was 4 patients, descending colon was 2 patients and the sigmoid colon was 2 patients. 31 patients complained of symptoms of abdominal pain (18), abdominal distension (9), fever (2), diarrhea (2), and melena (1). There were 20 patients whose condition was idiopathic and 35 patients whose condition was secondary to other underlying diseases including diabetes (12), malignant tumors (9), intestinal tract necrosis (9), collagenosis (7), constipation (1), chronic obstructive pulmonary disease (1) and ileus (1). Eleven patients had a history of steroid use, and 12 patients had a history of treatment with α-glucosidase inhibitors. Thirty-four patients received in hospital treatment including conservative treatments such as nil by mouth, treatment with prokinetic agents, supplemental oxygen in 24 patients—and abdominal operation in 11 patients. Portal venous gas (HPVG) was observed in 9 patients, and 8 of these had underlying intestinal tract necrosis.

CONCLUSION: In most patients, PCI is mild, asymptomatic and resolves spontaneously. The principally used treatment strategy for PCI is conservative treatment. Appropriate consideration of the indications for operation is important for avoiding unnecessary invasive treatment. However, especially in cases of PCI complicated by HPVG, underlying intestinal tract necrosis should be borne in mind and it seems to be important to promptly determine whether emergency surgery is needed. There are numerous unresolved issues in respect of the pathological characteristics of PCI, therefore, further accumulation and examination

of cases are necessary. Further elucidation of the pathological characteristics and establishment of suitable treatments are expected.

P0411 PROFILE AND OUTCOME OF PATIENTS WITH ISCHEMIC COLITIS

R. Oprita[1,*], F. Musat[1], A. Ragea[1]
[1]*Gastroenterology, Bucharest Clinical Emergency Hospital, bucharest, Romania*
Contact E-mail Address: *ruxandraa@netscape.net*

INTRODUCTION: - Ischemic colitis incidence is most likely underestimated because the mild form often is of transient nature and misdiagnosed when patients suffer from other diseases such as inflammatory bowel disease or infectious colitis.
AIMS & METHODS: We prospectively studied patients referrd for colonoscopy for lower gastro-intestinal bleeding from January 2013 until January 2014.
There were enrolled 74 patients (27 females and 47 males), aged between 20 to 75 years old, with a median age of 51 years old.
The findings at colonoscopy will depend on the stage and severity of ischemia. In the early stages of ischemia, petechial hemorrhages are interspersed with areas of pale, edematous mucosa. Later, segmental erythema, with or without ulcerations and bleeding, may be observed. The colon single-stripe sign, a single longitudinal ulcerated or inflamed colon strip, may characterize milder disease. With more severe ischemia, the mucosa appears cyanotic, dusky, gray, or black. Pseudopolyps and pseudomembranes may be appreciated, as well. A chronic stage of ischemia characterized by stricture, decreased haustrations, and mucosal granularity may occur several weeks or months later.
There are no endoscopic findings that are specific for ischemia, thus the clinical setting must be considered.
RESULTS: Conditions mandating anticoagulation, such as atrial fibrillation or dilated cardiomyopathy, were identified in 32% of case patients. Conditions requiring antiarrhythmic therapy were identified in 25% of case patients; in 4 of the patients, cocaine was identified as the leading cause.
Of 74 patients, 5 required immediate surgery and 3 of them were positive for clostridium difficile.
CONCLUSION: Ischemic colitis occurs as the result of a compromise in intestinal blood flow that can produce a spectrum of injury from transient self-limited ischemia to fulminant ischemia or transmural infarction. Its diagnosis requires a high index of suspicion, and the clinician should consider the diagnosis in patients with acute abdominal pain and bloody stools.

P0412 CHRONIC KIDNEY DISEASE AND HIGH ECOG PERFORMANCE STATUS ARE RISK FACTORS FOR SEVERE ISCHEMIC COLITIS

S.R. Jee[1,*], S.R. Choi[2], G.A. Song[3], S.J. Park[4], C.S. Song[5], H.U. Park[6]
[1]*gastroenterology, INJE UNIVERSITY COLLEGE OF MEDICINE,* [2]*Dong-A University,* [3]*gastroenterology, Busan national University,* [4]*gastroenterology, Kosin University,* [5]*gastroenterology, Good Samsun hospital,* [6]*gastroenterology, Maryknoll Hospital, Busan, Korea, Republic Of*
Contact E-mail Address: *tokimom@nate.com*

INTRODUCTION: Ischemic colitis is most frequent form of intestinal ischemic disease. However, there have been debates about prognostic factors of ischemic colitis
AIMS & METHODS: The aim of this study was to identify risk factors of severe ischemic colitis. From January 2000 to December 2011, a retrospective study was undertaken of patients with ischemic colitis hospitalized at 4 university hospitals and 2 secondary hospitals at Busan, Korea. Patients with colon ischemia were divided into two groups: those with mild disease and those with severe disease. Data collected included age, sex, symptoms (abdominal pain, hematochezia and abdominal angina), cormobidity (hypertension, diabetes mellitus, ischemic heart disease, stroke, arrhythmia, congestive heart failure, peripheral vascular disease, chronic obstructive lung disease, chronic kidney disease, hemodialysis, peritoneal dialysis, hyperthyroidism, hypothyroidism and irritable bowel syndrome), laboratory findings (total cholesterol, TG, LDL, HDL, total protein, albumin, Hg, WBC count, Platelet count, ESR and CRP), endoscopic fidings (location of lesions), and ECOG performance status.
RESULTS: A total of 292 patients were enrolled (mild group: 259, severe group: 33). In univariate analysis, location (involving Rt. Colon), chronic kidney disease (stage V), ECOG, Platelet count, CRP were significant risk factors for severe ischemic colitis. In multivariate analysis, chronic kidney disease (stage V) (OR, 5.289; 95% CI 1.308-21.378; $p = 0.019$), ECOG (OR, 1.690; 95% CI 1.108-2.579; $p = 0.015$) were significant risk factors for severe ischemic colitis.
CONCLUSION: Chronic kidney disease (stage V) and high ECOG performance status were independent risk factors for severe ischemic colitis. More caution would be necessary when treatment of patients with ischemic colitis having these factors.

INTRODUCTION: The current practice of routinely resecting all diminutive (1-5mm) and small (6-9mm) colonic polyps and submitting them for histopathologic assessment has several disadvantage in terms of cost-effectiveness and risks from repeated colonoscopies. The resect-and-discard (RD) strategy has been proposed to reduce retrieval of diminutive polyps (1-5mm) for histology which has been deemed not to have advanced histologic features. RD strategy for small polyps (6-9mm) are still controversial. The prevalence of advanced histologic features in the diminutive and small polyp category remains small but not clearly defined.
AIMS & METHODS: In this cross-sectional study, we aim to find the prevalence of small & diminutive polyps resected that shows advanced histologic features such as high grade dysplasia (HGD) or carcinoma to determine if RD policy is feasible in the local Asian tertiary setting. Data was retrieved from Jan-Dec 2009 with assistance from the Pathology Department to identify all submitted colonic polyp specimens. Each patient also had their colonoscopy report (s) and detailed histology report reviewed by 2 separate colleagues within the team to ensure data consistency. The variables captured include demographics, total polyp number, polyp distribution in the colon, histology, polyp size and respective number in each histology subtype and concurrent colorectal carcinoma (CRC).
RESULTS: There were a total 1482 polypectomy specimens retrieved for histology from 871 patients. The colonic distribution of the polyps was 45.4% right sided, 46.1% left sided and 8.5% rectal.
Please refer to Table 1 for summary of polyp distribution and dysplasia.

Colonic polyp histology	Tubular Adenoma (TA)	Tubulovillous Adenoma (TVA)	Villous Adenoma (VA)	Serrated Adenoma (SA)	Hyperplastic
Low grade dysplasia (LGD)	79.2%	26.7%	0.0%	83.9%	NA
High grade dysplasia (HGD)	20.8%	73.3%	100.0%		
No dysplasia	NA	NA	NA	16.1%	100.0%
Total number (1482)	1067(72%)	150(10.1%)	3(0.2%)	118(8.0%)	144(9.7%)

There were 844 diminutive polyps (1-5mm), 447 small polyps (6-9mm) and 191 large polyps (≥10mm). The proportion of HGD seen in each of these groups were 18.7%, 37.6% and 56.5% respectively. The percentage of HGD present in diminutive and small polyps was relatively high and significant. There were no concurrent carcinomatous features seen in all the polyps.
CONCLUSION: These findings showed that a significant proportion of diminutive polyps (18.7%) and small polyps (37.6%) harboured features of HGD, which is significantly higher than previous findings of 1% for diminutive polyps in some literatures. Based on size alone without the aid of narrow band imaging (NBI) or other forms of image enhanced endoscopy (IEE), we find that RD strategy for diminutive or small polyps may miss a significant group of patients with advanced neoplastic histology who needs earlier colonoscopic surveillance. There may be merits in the RD approach but this would require incorporation of other real-time endoscopic modalities such as IEE and more robust evaluation

P0414 THE STRAY PATIENT DEMOGRAPHIC LABEL: IMPLICATIONS FOR PATIENT SAFETY AND QUALITY IN THE ENDOSCOPY UNIT

D.C. Sadowski[1,*], G. Lutzak[1]
[1]*Division of Gastroenterology, Royal Alexandra Hospital, Edmonton, Canada*

INTRODUCTION: Over a 6-month period, 3 separate incidents occurred in our unit where the wrong patient demographic labels were affixed to the endoscopy biopsy requisition form (EBRF), the biopsy specimen container (BSC) or both. This type of incident can have a significant impact on patient safety and is an indicator of poor quality in the specimen control process.
AIMS & METHODS: The purpose of this study was to identify factors contributing to this medical error and to develop a process to prevent future occurrences. A Quality Assurance Review (QAR) was conducted to determine the systems issues that contributed to the incidents. This review was carried out at the Royal Alexandra Hospital in Edmonton, Canada. The endoscopy unit at this hospital performs about 18,000 procedures per year. A QAR using Systems Analysis Method of Review (SAM) was conducted to identify issues that contributed to the patient-specimen mismatches. SAM identified the following system issues: a) variation in the set-up of nursing workspaces, b) variation in where and when the EBRF was completed, and c) the occurrence of stray patient demographic labels. The QAR identified several recommendations to prevent future mislabeling: a) standardize how nursing workspaces are set up, b) develop a checklist to ensure proper patient identification prior to procedure initiation, proper labeling of EBRF and BSC, completion of EBRF, and c) remove all patient demographic labels from the theatre immediately after the conclusion of the procedure.

RESULTS: Since EBRF and BSC mislabeling incidents are rare events; we utilized indicators of EBRF information quality as surrogate markers for effectiveness of the QAR recommendations. We deemed the following factors as key quality indicators of EBRF information: a) completion of clinical history by physician, b) correct identification of specimen anatomic site, c) avoidance of ambiguous terminology, and d) correct patient label on EBRF and BSC. We tracked these indicators daily. We reported the data weekly to physician leaders and other healthcare providers in order to engage them in this initiative. We used the Reporting and Learning System (RLS) for patient safety to monitor reporting of similar incidents prior to implementation of the QAR recommendations, the average number of EBRF containing deficient information was 16.6/month. Subsequent to the implementation of QAR recommendations, this number decreased to 6.4/month ($p = 0.02$). However, in the 7 months subsequent to the QAR recommendation implementation, we had 4 further incident of mislabeling with the wrong patient label and 3 episodes of unlabeled specimen containers.
CONCLUSION: Stray patient data labels are a significant contributing factor to EBRF and BSC mislabeling. QARs can reduce the incidence of this medical error and improve quality of EBRF completion; however, without health care provider engagement, serious incidents may still occur.

P0415 A NOVEL SAMPLING DEVICE FOR COLLECTING MUCOCELLULAR MATERIAL FROM THE UNPREPARED RECTUM

J. Booth[1,*], J. Lacy-Colson[2], M. Norwood[3], C. Murray[1]
[1]*Origin Sciences Ltd, Cambridge,* [2]*Surgery, Royal Shrewsbury Hospital, Shrewsbury,* [3]*Surgery, Leicester Royal Infirmary, Leicester, United Kingdom*
Contact E-mail Address: *jodie.booth@originsciences.com*

INTRODUCTION: Earlier detection of colorectal and other gastrointestinal malignancies is an urgent objective. Currently much effort is directed at the development of in vitro diagnostic tests that evaluate informative protein or DNA biomarkers in blood or stool samples. Stool samples are relatively inconvenient to collect, require special handling facilities, and additionally suffer from contamination that may interfere with molecular assays. Blood samples, while more convenient, may not be as informative early in the disease process. Several studies have shown that significant numbers of exfoliated cells and their products are retained in a muco-cellular layer overlying the colonic mucosa but distinct from the stool itself, and that this material flows toward the rectum, where it can be captured for analysis
AIMS & METHODS: Origin Sciences has developed a novel sampling device, which incorporates an inflatable nitrile membrane. Following insertion into the unprepared rectum via a standard proctoscope, the membrane is inflated to make contact with the rectal mucosa for 10 seconds. The membrane is then deflated and retracted into the device prior to removal from the patient. Upon retraction the material sampled from the rectal mucosa is retained on the inverted membrane, which acts as a receptacle for the addition of buffer to preserve the material for subsequent analysis.
RESULTS: The sampler has now been tested in over 2000 patients and healthy volunteers, and has shown excellent patient acceptability. Tests and in vitro experiments with monolayers of cultured human cells indicate that the membrane captures intact cells, which are easily washed off the membrane for further investigation. Detailed evaluation of the mucous-associated soluble material captured by the device in both normal and diseased states, shows it to be rich in protein and nucleic acids. Levels of soluble protein material present in the buffer vary between 90 and 3000 μg/mL, with a mean of 710 μg/mL. As part of a programme to identify novel cancer biomarkers, Origin Sciences has evaluated the presence of auto-antibodies in the proteinaceous component of the preparation, and has detected informative auto-antibody isotypes IgA, IgG and IgM by ELISA. The preparation is also rich in nucleic acids. DNA is found in amounts ranging from 0.5 to 21.9 ug/mL. Laboratory experiments have shown that this DNA retains a high degree of integrity and is suitable for PCR amplification, and subsequent sequencing, since we have been able to detect a number of genes by quantitative PCR.
CONCLUSION: The sampling device represents a novel and minimally invasive means of capturing biomarker-rich material from the unprepared rectum. Since there is minimal contamination by stool, the material collected is readily analysable, in principle lending itself to Point of Care tests for a wide range of indications, including infectious and inflammatory diseases of the GI tract in addition to malignancy. The device can be used as a robust means of collecting material for later analysis by a wide range of technologies.

P0416 SYMPTOM-SPECIFIC REFERRAL CONTENT: WHAT DOES THE GASTROENTEROLOGIST NEED?

S.L. Eskeland[1,*], L. Aabakken[2], T.de Lange[1]
[1]*Department of Medical Research, Bærum Hospital, Vestre Viken Hospital Trust,* [2]*Department of Gastroenterology, Oslo University Hospital, Rikshospitalet, Oslo, Norway*
Contact E-mail Address: *s.l.eskeland@medisin.uio.no*

INTRODUCTION: Low quality referrals are a challenge for gastroenterologists when assessing and prioritizing the patients. However, it is not known which information the gastroenterologists rely on for this task. We wanted to identify what gastroenterologists considered the most important variables to include in the referral letters for 9 common indications.
AIMS & METHODS: 25 Norwegian gastroenterologists completed a web-based survey where they were asked to select the 15 most important variables out of a list of 29-36 potential variables.
RESULTS: For all 9 indications, information about duration, current medical treatment and weight loss were selected. The remaining selected variables were for:
Dyspepsia: Medical history, nausea/vomiting, reflux, hematemesis, dysphagia, abdominal pain, effect of anti-acid treatment, general condition, abdominal palpation (AP), previous gastroscopies and lab-analyses for anaemia and faecal occult blood (FOBT).
Dysphagia: Progression (intermittent, stable, progressive), texture provoking dysphagia, subjective localization of obstruction, hematemesis, regurgitation of undigested foods, presence of reflux, stimulantia, ulcerogenic medication, general condition, previous endoscopies and radiology and lab-analyses for anaemia.
Diarrhoea: Hematochezia, nocturnal diarrhoea, recent antibiotic treatment, general condition, digital rectal exploration (DRE), previous endoscopies and lab-analyses for anaemia, FOBT, celiac disease, infection/inflammation, inflammatory bowel disease (IBD) and faecal bacteria/parasites.
Bowel changes: Type of change, hematochezia, abdominal pain, B symptoms (fever, night sweat, weight loss), AP, DRE, general condition, previous endoscopies and lab-analyses for anaemia, celiac disease, IBD and FOBT.
Hematochezia: Blood colour, location of blood (on paper/on faeces/in faeces), percentage of bowel movements with observed blood, bowel changes, symptoms from upper or lower GI-tractus, hematemesis, AP, DRE, previous endoscopies and lab-analyses for anaemia, IBD and FOBT.
Chronic abdominal pain: Medical history, characterization and location of pain, nocturnal pain, relation to meals, presence of bowel changes, AP, general condition, previous radiology/endoscopies and lab-analyses for anaemia, liver/pancreatic function, IBD and FOBT.
Constipation: Main complaint (hard/ rare/slow etc), frequency and consistency of bowel movements, hematochezia, abdominal pain, effect of treatment-attempts, predisposing factors, AP, DRE, previous endoscopies and lab-analyses for anaemia, thyroid disease and FOBT.
Jaundice: Medical history, exposure liver-toxic substances, stimulantia, colour changes urine/faeces, abdominal pain, AP, liver stigmata, previous radiology and lab-analyses for liver/pancreatic function, hepatitis serology, specific liver diseases and infection/inflammation.
Weight loss: Presence of any abdominal symptoms, B symptoms, abdominal pain, appetite, food intake, general condition, AP, symptoms/findings from other organ-systems, previous radiology and lab-analyses for anaemia, celiac disease and FOBT.
CONCLUSION: We identified 15 variables considered essential by gastroenterologists for each of the 9 most common reasons for referrals. Validation of the relation between the findings and the quality of referrals remains unknown, and need further assessments.

P0417 PREVIOUS SCREENING EPISODE PREDICTORS OF REPEAT PARTICIPATION IN THE NHS BOWEL CANCER SCREENING PROGRAMME

S.H. Lo[1], **S.P. Halloran**[2,3,*], J. Snowball[2], H.E. Seaman[2,3], J. Wardle[1], C.von Wagner[1]
[1]*Department of Epidemiology and Public Health, Health Behaviour Research Centre, University College London, London,* [2]*NHS Bowel Cancer Screening Southern Programme Hub,* [3]*University of Surrey, Guildford, United Kingdom*
Contact E-mail Address: *s.halloran@nhs.net*

INTRODUCTION: Effective colorectal cancer (CRC) screening using faecal occult blood (FOB) tests requires adherence to a programme of repeat participation. This study investigated previous screening episode predictors of screening uptake among previous responders.
AIMS & METHODS: The NHS Bowel Cancer Screening Programme (BCSP) in England offers biennial screening using a guaiac FOB test. Uptake data for the second (R2) and third (R3) biennial invitation round were studied among 62,099 individuals (aged 60-64) in the Southern Hub of the BCSP. R3 invitees comprised three subgroups: 'Consistent Screeners' (screened in R1 and R2), 'Dropouts' (screened in R1, not screened in R2) and 'Late Entrants' (not screened in R1, screened in R2). Predictors of uptake derived from previous screening episodes included late return of the test kit (after more than 28 days), test results and compliance with follow-up investigations (usually colonoscopy). Age, gender, area-level socioeconomic deprivation and screening history were included in multivariable logistic regression analyses.
RESULTS: Overall uptake among previous responders was 86.6% in R2 and 88.6% in R3. In R3, repeat uptake was 94.5% among 'Consistent Screeners', 59.8% among 'Dropouts' and 78.0% among 'Late Entrants' (differences between groups, $p < 0.001$). Returning the test kit after more than 28 days in a previous episode was associated with a reduced likelihood of repeat uptake in R2 (82.3% vs. 88.7%, $p < 0.001$) and R3 (84.5% vs 90.5%, $p < 0.001$). Receiving an abnormal test result was also strongly associated with reduced repeat uptake in R2 (61.4% vs. 86.8%, $p < 0.001$) and R3 (65.7% vs. 88.8%, $p < 0.001$). Furthermore, repeat uptake in R2 and R3 was particularly low among subjects who had not attended their follow-up test (R2: 24.3% vs. 67.1%, $p < 0.001$; R3: 43.2% vs. 69.9%, $p < 0.001$).
CONCLUSION: Previous screening episode factors related to various stages of the screening process have been implicated in subsequent uptake. These previous screening episode predictors could be used to identify individuals at risk of dropping out of screening and provide an opportunity to tailor invitation and reminder letters to elicit increased uptake by selected sub-populations.

P0418 CAN WE EXPLAIN THE APPARENT DECLINE IN UPTAKE OF INVITATIONS FOR COLORECTAL CANCER SCREENING IN ENGLAND?

J. Snowball[1], H.E. Seaman[1,2], **S.P. Halloran**[1,2,*]
[1]*NHS Bowel Cancer Screening Southern Programme Hub,* [2]*University of Surrey, Guildford, United Kingdom*
Contact E-mail Address: *s.halloran@nhs.net*

INTRODUCTION: The NHS Bowel Cancer Screening Programme (BCSP) provides biennial guaiac-based faecal occult blood test (gFOBT) screening for colorectal cancer (CRC) to individuals aged 60-74 years (inclusive). Uptake of screening invitations in England, which averages about 55%, is affected by individual factors that include screening history, sex and level of social deprivation. Data for 2013 indicate a marked decline in uptake in England during the second half of 2013. The BCSP in England is co-ordinated by five regional Hubs; each works with local screening centres that provide follow-up investigations (usually colonoscopy) for individuals with a positive gFOBT result. The Southern Hub provides the screening service to about 26% of the population in England (14.6 million); it sends over one million invitations for screening and analyses about ¾ million test kits every year. Uptake in the Southern Hub averages 61% (2012/2013) but demonstrates the decline since June 2013 reported across the rest of the country, an observation investigated by the Southern Hub research team.
AIMS & METHODS: All BCSP screening activity is recorded on the Bowel Cancer Screening System (BCSS). Data for the period 2009-2013 were analysed to investigate patterns of uptake according to age, sex, screening episode, index of multiple deprivation (IMD) and screening centre.
RESULTS: Amongst individuals aged 60-74 years, although subject to marked fluctuations throughout each year, the overall trend was towards increased uptake until June 2013, after which uptake declined sharply. Uptake amongst first-time invitees aged 60 years was the most consistent (55%) between 2009 and 2012, although a marked fall in uptake was evident from mid-2013. The most deprived showed the greatest fall in the first invitation episode (60-year-olds) and there was no change in uptake by the least deprived individuals. Different patterns observed across screening centres may reflect different start dates resulting in a different mix of episodes, with the population with the longest screening history possibly subject to 'screening fatigue'.
CONCLUSION: We have not explained the decline in uptake of CRC cancer screening invitations during 2013. A decline in CRC screening uptake has been observed by the other BCSP Hubs and by the NHS screening programmes for the breast and cervix (personal communication), although the decline in uptake of breast and cervix screening has been more gradual. It may be that the public is reacting to adverse publicity about the benefits of screening surrounding breast screening, in particular, although data from the Scottish programme do not demonstrate the decline observed in England (personal communication). The benefits of CRC screening are well-recognised and efforts to improve uptake of screening invitations and close monitoring of uptake should continue.

P0419 PATIENT PREFERENCES FOR TERMINOLOGY USED TO IDENTIFY FECAL INCONTINENCE

S. Heymen[1,*], O. Palsson[1], S.M. Kim[1], S. Twist[1], W.E. Whitehead[1]
[1]*Medicine, University of North Carolina, Chapel Hill, United States*
Contact E-mail Address: *steve_heymen@med.unc.edu*

INTRODUCTION: Fecal incontinence (FI) affects 9% of non-institutionalized U. S. adults, but fewer than 30% have discussed this problem with their physician. This is unfortunate because effective treatments are available. Two factors that may contribute to low consulting rates are embarrassment about this taboo topic and unfamiliarity with the terms used by physicians.
AIMS & METHODS: Our goal was to identify terms that are the most acceptable and understandable to FI patients to make it easier for clinicians to inquire about and discuss FI with patients, and easier for patients to disclose the problem. Thirty patients with FI (29 women) recruited by advertisement participated in internet chat rooms of 1-5 persons. They were asked: "What words do you use to describe your FI when you are talking to doctors, family members, or friends?" with requests to rate 3 domains on a 0-10 scale: 1) the understandability of these terms, 2) their appropriateness for discussions with others, and 3) the patient's level of discomfort (embarrassment) in using the term. Based on focus group input, 29 terms were selected for participants to evaluate for a national survey. Thirty-one terms were not included because the investigators deemed them to be offensive (e.g., squirts, shits, taco butt) or because they were adjectives describing emotional reactions to FI or characteristics of FI (e.g. Embarrassing, Disgusting). This sample was stratified by FI status, age, sex, and race/ethnicity.
RESULTS: The national survey recruited 560 participants (42% with FI). Sixty-four participants were excluded for answering identical questions inconsistently. The remaining 496 participants had a mean age of 47.5 (range 18-91) years, 48% of participants were males, and race/ethnicity was 69.6% Caucasian, 15.7% Hispanic, and 14.7% African American. Participants were also divided into three age groups for analysis: 35 and younger (n = 146), 36-64 (n = 243) and 65 and older (n = 106). Appropriateness ratings are reported here. When we compared the ratings from participants with FI and without FI, four of the top five rated terms were the same for both groups (Bowel Incontinence, Bowel Control Issues, Accidental Bowel Leakage, and Diarrhea). Women rated all of these terms as significantly more Appropriate than men did. A consistent race/ethnicity pattern showed highest Appropriateness ratings for Caucasians, then Hispanics, and lowest by African Americans on all of these terms. Ratings also differed significantly by age group, increasing with age across the three groups for all of these terms. Ratings differed on only one of these terms due to Education level (Bowel Control Issues) or Income (Bowel Incontinence).
CONCLUSION: We recommend excluding the term Diarrhea as it is not specific to leakage of diarrhea. The remaining top three terms were ranked identically for participants with and without FI: 1) Bowel Incontinence, 2) Bowel Control Issues, 3) Accidental Bowel leakage. All three terms scored below the median on the Uncomfortableness domain. The term used most often by providers, fecal incontinence, did not score in the top 10 on any of the 3 domains. Accidental Bowel leakage, recently described as patients' preferred term, ranked 3rd. This information may help improve communication between patients and providers and enable more patients to receive treatment. Supported by Salix Pharmaceuticals.

INTRODUCTION: Colorectal adenomas are cancer precursor lesions of the large bowel. A multitude of genomic and epigenomic changes have been documented in these preinvasive lesions, but their impact on the protein effectors of biological function has not been comprehensively explored.
AIMS & METHODS: Using shotgun quantitative MS, we exhaustively investigated the proteome of 30 colorectal adenomas and paired samples of normal mucosa. Total protein extracts were prepared from these tissues (prospectively collected during colonoscopy) and from normal (HCEC) and cancerous (SW480, SW620, CACO2, HT29, CX1) colon epithelial cell lines. Peptides were labeled with isobaric tags (iTRAQ 8-plex), separated by OFFGEL electrophoresis, and analyzed by LC-coupled tandem MS. Non-redundant protein families (4325 in tissues, 2017 in cell lines) were identified and quantified. Principal component analysis of the results clearly distinguished adenomas from normal mucosal samples, and cancer cell lines from HCEC cells.
RESULTS: Two hundred twelve proteins displayed significant adenoma-related expression changes (q-value < 0.02, mean fold change vs. normal mucosa +/- 1.4), which correlated (r = 0.74) with similar changes previously identified by our group at the transcriptome level. Fifty-one (~25%) proteins displayed directionally similar expression changes in colorectal cancer cells (vs. HCEC cells) and were therefore attributed to the epithelial component of adenomas. Although benign, adenomas already exhibited cancer-associated proteomic changes: 69 (91%) of the 76 protein upregulations identified in these lesions have already been reported in cancers. One of the most striking changes involved sorbitol dehydrogenase (SORD), a key enzyme in the polyol pathway.
CONCLUSION: Validation studies revealed dramatically increased SORD concentrations and activity in adenomas and cancer cell lines, along with important changes in the expression of other enzymes in the same (AKR1B1) and related (KHK) pathways. Dysregulated polyol metabolism may represent a novel facet of the metabolome remodeling associated with tumorigenesis.

P0421 KNOWLEDGE AND PERCEPTION OF DOCTORS ON RISK FACTORS AND SCREENING OF COLORECTAL CANCER (CRC)

Y.J. Wong[1,*], Z. Poh[1], M.L. Ong[1], K.L. Shum[1], V. Namasivayam[1], K.L. Ling[1]
[1]*Gastroenterology, Singapore General Hospital, Singapore, Singapore*
Contact E-mail Address: *eugene.wong@mohh.com.sg*

INTRODUCTION: CRC has claimed 214,675 lives Europe and is expected to rise by 12% by 2020[1]. Knowledge and perception of doctors is important to future success of CRC screening program as early detection of CRC improve survival. However, little is known about doctors' knowledge and perception towards CRC. We aim to determine current knowledge and perception of colorectal cancer screening amongst junior doctors.
AIMS & METHODS: 169 junior doctors practicing across 7 specialties at a local academic institution were recruited from July -September 2013. Standardized questionnaires consisting of 44 questions were administered during structured resident teaching sessions that were unrelated to CRC. Individual responses were collected. Absent doctors were contacted via email. Standard statistical techniques were employed.
RESULTS: 74% (125/169) of junior doctors responded. Respondents' mean age was 27.7 years (23-35). Mean duration of practice locally was 3.2 years (1-8). Majority (97.6%) were aware that CRC is curable if treated early, and 85.6% recognized that CRC screening reduces mortality. Only 78.4% recognized CRC as the commonest cancer locally. Most CRC risk factors (CRC-RFs) such as age, family history, smoking, inflammatory bowel disease and colonic polyps were correctly identified (84.8-100%). However, knowledge of modifiable CRC-RFs was poor. Few recognized diabetes mellitus (5.6%), sedentary lifestyle (39.2%) and obesity (43.2%) as CRC-RFs. In addition, 10.4% wrongly identified traditional medicine as a CRC-RF, and only 45.7% correctly identified the recommended age for CRC screening according to local guidelines. More fresh graduates (PGY1) correctly identified ≥80% of CRC-RFs compared to the rest (40% vs 21.9%; p = 0.044). Only 90.4% and 88% identified colonoscopy and fecal occult blood test (FOBT) as acceptable CRC screening methods. 94.2% felt FOBT had poor test performance. Physician's concerns for colonoscopy included cost (76.9%), risk of perforation (61.5%), bleeding (46.2%), and inconvenient bowel preparation (66.7%). In spite of this, 80.8% will offer colonoscopy while only 68% will offer FOBT for CRC screening to their patients. There was

no difference in attitudes and practice patterns between doctors of different postgraduate years.
CONCLUSION: Majority of junior doctors correctly identified CRC as a significant healthcare burden, and that CRC screening and early detection reduces mortality. However, knowledge on modifiable CRC-RFs is still lacking. Many had concern about FOBT test performance, and more will offer screening colonoscopy. Continual medical education for junior doctors on modifiable CRC-RF and importance of CRC screening should be emphasized for continual success of CRC screening.

INTRODUCTION: In idiopathic parkinsonism (IP), flexor rigidity is greater the higher the circulating natural-killer cell count, an effect modulated by CD4+ count.[1] These counts are higher with hydrogen-breath-test positivity for small-intestinal-bacterial-overgrowth. Two-thirds of IP-patients are positive at presentation.
AIMS & METHODS: Improving intestinal transit with laxatives might reduce rigidity by reducing overgrowth.
Relationships of interventions for constipation to rigidity and overgrowth were explored using generalised linear mixed models. Surveillance yielded 1378 objective measures of arm rigidity in 74 IP-patients over 343 person years, with 437 2-h lactulose-hydrogen-breath-tests in 48. Maintenance osmotic laxative (macrogols) was exhibited in 50 (176 person years); bulk-forming laxative (ispaghula husk/methylcellulose/sterculia) in 52 (196); enterokinetic agent (prucalopride) in 25 (45); and guanylate cylase-C receptor agonist (linaclotide) in 8 (12).
RESULTS: Osmotic laxative was the only intervention associated with a change in rigidity. Flexor rigidity increased (by 6.8 (4.3, 9.4) % per year, $p = 0.001$) where not exhibited, stabilised where exhibited (1.4 (95% CI -0.9, 3.8) % per year, $p = 0.2$). Bulk-forming laxative had no additional effect on rigidity ($p = 0.5$). Similarly, the ratio, flexor to extensor rigidity, indicating tendency to simian posture, increased (3.2 (0.7, 5.7) % per year, $p = 0.01$) where osmotic laxative was not exhibited, stabilised where exhibited (-1.6 (-3.9, 0.8) % per year, $p = 0.2$). Bulk-forming laxative had no additional effect on the ratio ($p = 0.6$).
Only bulk-forming laxative was associated with change in breath-hydrogen. Peak hydrogen was lower by 11 (1. 20) ppm ($p = 0.03$) where exhibited, with no differential effect of time ($p = 0.9$). (Odds ratio for a positive breath-test where exhibited compared with where not: 0.55). Osmotic laxative had no additional effect on peak hydrogen ($p = 0.3$).
CONCLUSION: Osmotic laxative may reduce rigidity by reducing inflammation, directly, or by removing an inhibitory effect on anti-parkinsonian medication. Any effect of overgrowth on rigidity may relate to organisms not flagged by hydrogen-breath-test.

P0423 DOES BODY POSITION MODIFY ANORECTAL PRESSURE VALUES RECORDED BY THREE-DIMENSIONAL HIGH-RESOLUTION ANORECTAL MANOMETRY?

A. Benezech[1,2,*], M. Bouvier[1,2], J.-C. Grimaud[1,2], N. Lesavre[3], K. Baumstarck[4], V. Vitton[1,2]
[1]*Centre d'Exploration Fonctionnelle Digestive, Service de Gastroentérologie, Hôpital Nord,* [2]*Interface de Recherche Translationnelle en Neurogastroentérologie, CRN2M, UMR 7286, Aix-Marseille Université,* [3]*Centre d'Investigation Clinique 9502, Hôpital Nord,* [4]*Unité d'Aide Méthodologique à la Recherche Clinique, EA3279, Laboratoire de Santé Publique, Aix-Marseille Université, Marseille, France*

INTRODUCTION: Anorectal manometry is the gold standard in the physiological exploration of anorectal disorders. In recent years, three-dimensional high-resolution anorectal manometry (3DHRAM) was developed. However, exams (conventional manometry or 3DHRAM) are traditionally made in the left lateral decubitus position while anorectal symptoms (dyschezia and anal incontinence) occur in the standing or sitting position.
AIMS & METHODS: The aim of our prospective study was to compare the pressure values obtained by 3DHRAM in the lying position (left lateral decubitus position) and in the standing position.
All patients referred to our center to explore anal incontinence or dyschesia by 3DHRAM and EUS were eligible. Patients with a history of anorectal surgery or suffering from anal pain were excluded. The 3DHRAM was performed by the same operator successively in the left lateral decubitus position and in the standing position. The EUS was perfomed the same day. KESS and Wexner scores were routinely rated, as well as size and weight of the patients. The calculated number of patients required for this study was 40.
RESULTS: These are preliminary results (20 patients included in the 40 to be included). 17 females and 3 males, with a median age of 41 years (20-73) and a median body mass index of 23 kg/m^2 (17-36) were included. The indication of examinations was anal incontinence in 8 patients and constipation in 12 cases, with a median KESS score of 20 (9-32) and a median Wexner score of 9 (7-20). No manometric measured parameters was significantly different in the supine or standing position, whatsoever in the subgroup of incontinent patients or in the subgroup of constipated patients.
CONCLUSION: These preliminary results showed no significant difference between the pressure values measured by 3DHRAM in the supine and standing position. At this stage of study, two hypotheses can be advanced: 1) the lack of power related to the low effective since we have included only half of the patients required; 2) no difference whatever the position of the patient when the measurements are made with 3DHRAM. Analysis of the results when all patients will be included will provide the answer to this question.

INTRODUCTION: Treatment with gonadotropin-releasing hormone (GnRH) analogs have led to severe dysmotility, which implicates roles for the reproductive peptide/hormones in the gastrointestinal tract. Administration of the GnRH analog buserelin to rats leads to neurodegeneration and ganglioneuritis. During these experiments, we have observed that the treated rats have exhibited a more stressed behavior than controls. Stress has been shown to increase secretion of corticotropin-releasing factor (CRF) and to increase intestinal permeability in humans, and to increase locomotion, rearing, pellet excretion, and altered colonic microbiota in rodents. CRF is highly expressed in the enteric nervous system in humans and rodents, and has been shown to abolish the vasoactive intestinal peptide (VIP)-induced neuronal survival.
AIMS & METHODS: The aim of the present study in rat was to evaluate the effect of the GnRH analog buserelin on enteric neurons immunoreactive to CRF and the intestinal microbiota.
Forty rats were given either buserelin (B) (20 μg, 1 mg/ml) or saline (C) subcutaneously, once daily for five days, followed by three weeks of recovery, representing one session of treatment. Two weeks after the fourth session, the animals were euthanized. Gastrointestinal tissue were collected and analyzed for neuronal survival and CRF immunoreactivity. Microbial DNA (16S rRNA genes) was extracted from the colonic mucosa and analyzed with molecular genetic methods. The Terminal Restriction Fragment Length Polymorphism (T-RFLP) method was used to analyze microbial diversity. Bacterial abundance of the bacterial groups *Clostridium leptum* and *Enterobacteriaceae* was estimated using separate quantitative PCR assays.
RESULTS: Body weight transiently increased by buserelin treatment at week 5 and 9 ($p < 0.001$). Enteric neurons were reduced in number by approximately 40% in both submucous and myenteric ganglia of ileum and colon. Enteric neurons in colon immunoreactive to CRF increased in submucous ganglia (C = 10 (6-16)%, B = 21 (14-25)%, $p < 0.05$) and in myenteric ganglia (C = 7 (5-9)%, B = 19 (18-23)%, $p < 0.01$) due to buserelin treatment. In submucous ganglia, the number of neurons immunoreactive to both nitric oxide synthase (NOS) and CRF increased due to buserelin treatment ($p < 0.05$). In the myenteric ganglia, the number of neurons immunoreactive to NOS or VIP, in addition to CRF, tended to increase after buserelin treatment ($p < 0.14$ and $p < 0.08$, respectively). The CRF fiber density was unaffected by buserelin treatment throughout all the different layers of the bowel wall. The total amount of bacteria and diversity in colon did not differ between groups. The number of bacteria in the group of *Enterobacteriaceae* was significantly lower in buserelin-treated rats compared to saline-treated rats ($p < 0.05$), whereas the total amount of bacteria in the groups of *Clostridium leptum* did not differ between broups.
CONCLUSION: The relative number of enteric neurons expressing CRF was increased after induction of enteric neuropathy. The enteric nervous system shows proof of plasticity, since NOS-immunoreactive neurons starts to express CRF after buserelin treatment. Despite a marked enteric neuropathy, no signs of bacterial overgrowth or diminished diversity are at hand in colon.

INTRODUCTION: Women treated with gonadotropin-releasing hormone (GnRH) analogs develop in some cases enteric neuropathy with ensuing severe

dysmotility. Administration of GnRH analog to rats leads to similar degenerative changes and ganglioneuritis.
AIMS & METHODS: The aim of the present study in rat was to evaluate the enteric neuropathy, in terms of affected neuronal subpopulations and gastrointestinal function, and to investigate levels of zonulin and titers of GnRH and luteinizing hormone (LH) and their receptors in plasma.
Forty rats were given either the GnRH analog buserelin (B) (20 μg, 1 mg/ml) or saline (C) subcutaneously, once daily for five days, followed by three weeks of recovery, representing one session of treatment. Two weeks after the fourth session, the animals were euthanized. Prior to sacrifice, feces were analyzed for weight and fat, and GI transit time and galactose absorption were studied. Neuronal subpopulations and survival were analyzed in GI tissue. Blood samples were analyzed for zonulin, GnRH and LH and their receptors.
RESULTS: Body weight transiently increased by buserelin treatment at week 5 and 9 ($p < 0.001$). Buserelin increased estradiol in plasma and uterine muscle layers were thickened, implicating high estrogen activity. Enteric neurons were reduced in number by approximately 40% in both submucous and myenteric ganglia of ileum and colon. Feces weight decreased in buserelin-treated rats (C = 4.3 (3.4- 5.9) g; B = 3.2 (2.4-3.6) g, $p < 0.01$) whereas fat content in feces increased (C = 2.8 (2.9-3.9)%; B = 3.6 (2.6-3.2)%, $p < 0.01$), compared to saline-treated rats. Total GI transit time and galactose absorption were not affected by buserelin treatment. Studies on the various neuronal subpopulations in colon showed increased relative number of somatostatin immunoreactive neurons in submucous, but not myenteric, ganglia while the numbers of cocaine-amphetamine-related transcript (CART), calcitonin gene-related peptide (CGRP), galanin, gastrin-releasing peptide (GRP), neuropeptide Y (NPY), nitric oxide synthase (NOS), serotonin, substance P (SP) and vasoactive intestinal peptide (VIP) were unchanged. The levels of zonulin in plasma and the titers of antibodies against GnRH, LH or their receptors were unaffected by buserelin treatment.
CONCLUSION: A marked enteric neuropathy is at place with only modest effects on gastrointestinal function after buserelin treatment. Altered feces weight and fat content is suggested as early signs of dysfunction.

INTRODUCTION: Various treatment modalities for GI motility disorders have been developed so far including medications and electrical stimulation. But little is known about biomechanical properties of gastrointestinal smooth muscle, in contrast to vascular or respiratory smooth muscle. In this study, we made a novel actuator model for characterization of biomechanical property of small intestinal smooth muscle.
AIMS & METHODS: In the order to characterize active and passive properties of intestinal smooth muscle, we performed tensile test and isometric, isotonic experiments using viable small intestines of 3 month old pig. In the tensile testing, we connected excised intestinal samples to the universal testing machine developed by our own group only for soft tissue measurement. In isometric and isotonic experiments, porcine small intestine was bathed in HTK-solution for preservation of energy source. After connection of the sample to sensor, muscle contraction was induced by acetylcholine chloride. Contractile force and velocity were measured by isometric force transducer and isotonic transducer.
RESULTS: In tensile experiment, tensile stress was maximum at the 1.67 times its original length and 0.702N at break point. In isometric experiment, maximum contractile force was observed at the resting length which was 12.35±0.5 mN after 50min of acetylcholine stimulation. Intestinal smooth muscle contraction was sustained for 55min. In isotonic experiment, intestinal smooth muscle was 10 to 100 times slower than skeletal muscle contraction. We calculated contractile velocity for various loads and acquired load free contractile velocity by curve fitting method (0.4952 mm/min). Finally, we combined previously acquired passive and active parameters of intestinal smooth muscle to make a comprehensive intestinal smooth muscle model.
CONCLUSION: In this study, we characterized active and passive parameters and applied them to modified Hill type muscle model for making a novel actuator of intestinal smooth muscle. This study would provide basic tool for understanding biomechanical properties of intestinal smooth muscle, and we can utilize this as basic data for development of a more efficient GI electrical stimulator.

P0427 5HT SELECTIVE RECEPTOR AGONISTS AND GALLBLADDER MOTILITY IN PATIENTS WITH MIGRAINE

D. Georgescu[1,*], **C. Georgescu**[2], R. Buzas[1]
[1]Internal medicine, University of Medicine, [2]Neurology, County Hospital, Timisoara, Romania
Contact E-mail Address: *dgeorgescu@hotmail.com*

INTRODUCTION: Some 5HT selective receptor agonists (triptans) are reported to have gastric motor effects but less is known about their role on gallbladder (GB) motility.
AIMS & METHODS: Assessment of GB motility in patients treated with orodispersable triptans .30 patients diagnosed with mild to moderate migraine: 15 with with aura (3 men, 12 women, mean age = 43.13±17.72 years) and 15 without aura ((1 man, 14 women, mean age = 47.73±18.50 years), with an ejection fraction (EF) of GB < 60%, previously measured by elipsoid ultrasound Dodds method, without prokinetic treatments, collagen or thyroid disease, diabetes mellitus, cardiac, liver or kidney failure, undertook this study. The same measurements were made while having a migraine attack, before and every 15 minutes till 90 minutes after receiving 5 mg of orodispersable zolmitriptan.
RESULTS: There was no statistical significant difference between initially EF of the two groups ($p = 0.8190$). Patients with migraine with aura showed before therapy a mean EF = 42.53±4.31%; after therapy the mean EF improved significantly: 48.80±3.23% ($p = 0.0001$). Patients with migraine without aura displayed an initially mean EF = 42.53±3.27% and had a very statistically significant response to therapy with increasing of EF to 61.47±7.07% ($p < 0.0001$). There was also a statistically significant difference of respose to therapy in patients with migraine without aura (61.47±7.07% vs 48.80±3.23%; $p < 0.0001$).
CONCLUSION: 5HT selective receptor agonists increased GB motility in migraine attacks with a better response in patients without aura.

INTRODUCTION: Chronic constipation (CC) represents one of the most common gastrointestinal (GI) complaints in Parkinson's disease (PD), being diagnosed in about 80% of patients. Furthermore, CC often precedes the somatic motor impairment in PD. The enteric nervous system (ENS), controlling gut functions, can be a target of the PD although the precise neurochemical ENS abnormalities underlying CC/PD patients remain largely unknown.
AIMS & METHODS: In CC/PD patients we aimed to: 1) characterize constipation by assessing colonic transit time (TT) and anorectal manometry (AM); 2) analyze colonic submucosal neurons of PD patients *vs* controls, particularly assessing the secretomotor neuron component.
GI symptoms were evaluated by the Rome III questionnaire, while PD was established by a Unified Parkinson's Disease Rating Scale (part III). CC was studied in 25 PD patients (7F, 18M; age range: 64-85 yrs) by TT, AM and colonoscopy; 14 control subjects (4F, 10M; age range: 33-77 yrs) undergoing screening colonoscopy were also enrolled in the study. Using routine biopsies during colonoscopy, we obtained submucosal specimens with related neural network in 10 CC/PD patients and 10 controls. The submucosal plexus was studied by immunohistochemistry on whole mount preparations using a mouse monoclonal anti-HuC/D as pan-neuronal marker (Invitrogen, 1:50) and two rabbit polyclonal anti-VIP (vasoactive intestinal peptide-7913; CURE/DDRC, UCLA, 1:2500) and anti-pChAT (peripheral choline acetyl transferase, Justus-Liebig-University Giessen, Germany; 1:100) antibodies.
RESULTS: Four groups of CC/PD patients were characterized: a) 55% with a delayed TT and altered AM; b) 15% with a delayed TT; c) 20% with an altered AM; d) the remaining 10% with no evident functional impairment. There were no significant differences in the number of HuC/D immunoreactive (-IR) neurons/ganglion between CC/PD (4.7±0.8) and controls (5.5±1.5); however, a reduced number of HuC/D/VIP-IR neurons was found in CC/PD (73.3±17.1) *vs* controls (86.0±10.9) ($P < 0.05$). No significant changes were detected for HuC/D/ChAT neurons in both groups (85.6±11.1 *vs*. 91.2±10.1).
CONCLUSION: Most (90%) of CC/PD patients has a marked impairment of colonic motor and rectal sensory functions. Neurochemical changes in a subset of VIP containing secretomotor neurons suggest that altered secretory mechanisms may accompany sensorymotor dysfunction in PD-related CC pathophysiology.

P0429 EHLERS-DANLOS SYNDROME AND IBS - SAME GI SYMPTOMS, DIFFERENT DISEASES

G. Mohammadian[1,2,*], J. Lunding[3], G. Lindberg[2,3]
[1]*Center of Digestive Diseases, Karolinska Universtity Hospital,* [2]*Institution of Medicine, Huddinge, KAROLINSKA INSTITUTET,* [3]*Center of digestive diseases, Karolinska University Hospital, Stockholm, Sweden*
Contact E-mail Address: *ghazaleh.mohammadian.kermani@ki.se*

INTRODUCTION: Ehlers-Danlos syndrome (EDS) is usually an autosomal derived disease with defects in the collagen synthesis. It is divided into six subgroups according to the Brighton criteria. The most common subtype gives hypermobility of the joints, frequent luxations and fractures. It is also connected with gastrointestinal symptoms, most commonly abdominal pain and other symptoms that are included in the functional symptom spectrum. Patients with EDS fulfil the Rome III criteria for functional gastrointestinal disorders in 84%. So far there are no systematic studies of GI physiology and treatment for GI-disorders in these patients.
AIMS & METHODS: To evaluate symptoms, gastrointestinal work up, opioid therapy, treatment response to octreotide, and findings on 24h ambulatory small bowel manometry in patients with EDS.
Information obtained from patient database and retrospectively acquired information from the medical record system in the out- and inpatient clinic in Center of Digestive Diseases, Karolinska University Hospital, Stockholm, Sweden.
RESULTS: The search found 24 patients from 2001 to 2014, all but one were female. Abdominal pain was present in 100%, change of bowel habits in 19/24. Ten had done small bowel manometry, 3 of them were classified as enteric dysmotility and 5 patients had some changes of MMC phase III. Ten of the patients had tried octreotide and seven of them had clinical response and continued the octreotide treatment. Eleven patients were unable to do small bowel manometry due to use of opioids and three are on the waiting list for the manometry.
CONCLUSION: We show that patients with EDS have a high frequency of changes in small bowel manometry and high prevalence of enteric dysmotility. Treatment with octreotide is effective, even without having enteric dysmotility. Abdominal pain in patients with EDS should not be considered as IBS but EDS should be considered in patients with joint hypermobility and abdominal pain. Further studies are needed for evaluation of gastrointestinal physiology of patients with EDS.

INTRODUCTION: Functional dyspepsia (FD) is one of the most common GI disorders. Because of the chronic relapsing nature & lack of effective treatment options, FD is associated with significantly impaired quality of life and considerable health care costs.
Based on the central role stress seems to be playing in functional GI diseases, available animal models for FD rely on exposing animals to various types of stress either in the neonatal period or in adulthood.
However, clinical studies have shown that adverse physiological or psychological experiences in early life are associated with the development of FD symptoms, as well as acute stressful conditions in adulthood. Hence, childhood traumatic experiences followed by later exposure to acute stress may play key roles in the development & in modulation/ maintenance of FD.
AIMS & METHODS: In the present study, we tried to mimic this situation by combining early life stress (neonatal maternal separation, NMS) and acute stress in adulthood (restraint stress, RS) in rats, in the hope of developing a multidimensional experimental model of FD with closer resemblance to the clinical situation.
To explore the validity of this sequential stress model in trying to develop new drugs for FD, we tested the effects of STW5, a multicomponent herbal preparation widely used to treat FD with strong clinical evidence, as a standard drug.
RESULTS: Fundus strips from rats subjected to the combined stress showed significantly reduced responses to adrenaline, carbachol, KCl and 5HT as compared to those from normal rats or animals subjected to either stressor. Animals treated with STW5 showed normalized response to adrenaline, carbachol and 5HT. Combined stress also markedly increased plasma levels of CRF to twice as much as either stressor alone. The elevation of CRF was associated with a corresponding increase in plasma corticosterone. Pretreatment with STW5 protected against the increase in both CRF and corticosterone. None of the treatments significantly affected active plasma Ghrellin.
CONCLUSION: These data indicate that combined early life stress and acute stress effectively induce stomach motility disorders as well as hormonal derangements that might be more representative of the complex clinical situation and might represent a model for the screening of new FD drugs.

P0431 RECIPROCAL MODULATION OF INTESTINAL SMOOTH MUSCLE CELL CONTRACTILITY BY TH17 AND TH1 CYTOKINES

H. Akiho[1,*], K. Ohbuchi[2], K. Tsuchiya[2], E. Ihara[3], K. Nakamura[3], M. Yamamoto[2]
[1]*Gastroenterology, Kitakyushu Municipal Medical Center, Kitakyushu,* [2]*Tsumura Research Laboratories, Tsumura & Co., Ibaraki,* [3]*Medicine and Bioregulatory Science, Kyushu University, Fukuoka, Japan*

INTRODUCTION: Gastrointestinal motility disorders, such as infection, IBD, ileus, achalasia and functional gastrointestinal disease, have been associated with immune activation. We have previously reported that the hypercontractility of small intestinal (SI) smooth muscle cells (SMC) is mediated by IL-17A-induced NFkB/IkBz-RGS4 signaling resulting in down regulation of RGS4 activity. RGS4 is known to suppress Gaq/11 signaling triggered by stimulation of the acetylcholine (muscarinic 3) receptor. On the contrary, IL-1β, which is known to induce hypomotility of SMC, upregulates RGS4 expression and function. However, these opposite effects by IL-17A and IL-1β both have been found to be mediated by NFkB/IkBz activation. In the present study, we have investigated the mechanism by which IL-17A- and IL-1β-induced NFkB/IkBz activation produces the different outcomes.
AIMS & METHODS: Murine SMCs were isolated, cultured, and treated with various chemical probes, IL-17A, IL-1β, and IL-4 (10–50 ng/ml). Contraction was assessed using a cell imaging analyzer on a temperature-responsive UpCell 96-well plate. Activation of NFκB was evaluated by the strength of the nuclear NFκB p65 immunosignal. Activation of RGS4, myosin light chain (MLC) and MAPKs were determined by immunoblotting.
RESULTS: IL-17A significantly enhanced carbachol-induced contractile responses, concomitant with increased phosphorylated MLC (p-MLC) and decreased RGS4 activity. IL-1β significantly decreased p-MLC and increased RGS4 activity. These effects of IL-17A and IL-1β were both abrogated by an NFκB inhibitor and IκBζ siRNA. Screening of activated MAPK using a proteome profiler revealed that IL-1β activated p38MAPK and JNK but IL-17A activated p38MAPK only. The effect of IL-17A was abrogated by p38MAPK inhibitors but not by JNK inhibitors. The effect of IL-1β was abrogated by JNK inhibitors but enhanced by p38MAPK inhibitors. Anisomycin, a p38MAPK activator induced hypercontractility.
CONCLUSION: These data suggest that the balance of relative activity levels of JNK and p38MAPK is critical for determining the direction of contractile response and that NFκB/ IκBζ signaling fuels the movement of MAPK-triggered molecular events toward/against hypercontractility of SI SMC. The relatively stronger activation of p38MAPK may result in hypercontractility, induced by IL-17A, and that of JNK may result in hypocontractility, induced by IL-1β. Our findings may lead to the development of new pharmacotherapeutic strategies for gastrointestinal motor dysfunctions.

INTRODUCTION: IBS may be responsible for an impaired quality of life (QoL) and represents an economic burden for society. Efficacy of treatments is poor and patients often feel isolated and dissatisfied with medical care[1]. This work aims to describe the characteristics of IBS in members of the French organization of IBS patients (APSSII, www.apssii.org) and to compare their expectations to their past experiences with health care providers.
AIMS & METHODS: From January to June 2013 all members of APSSII were asked (once, by mail or online) to answer a questionnaire with a description of: IBS, treatments, impact on QoL, expectations and experiences in relation to the disease and health care system.
RESULTS: 222 out of 330 members (67%) responded (women 68.5%, age 46.5±17.7 years, disease duration 8.8±0.7 years, IBS-D 33.6%, IBS-C 26.7%, IBS-A 38.2%). A colonoscopy was performed in 87%, and diagnosis was made by a physician in 88%. Patients were followed up by a doctor in 65% (specialist 57% or GP 38%), and 82% had consulted for IBS in the last 12 months. Past or current treatments were antispasmodics (46%), laxatives (25%), antidepressants (25%), probiotics (38%), homeopathy (34%), hypnosis (15%), relaxation (31%), osteopathy (28%), acupuncture (25%) and 46% were on a diet. IBS was severe (IBS-SSS $>$ 300) in 53% and major depression was present in 45% (HAD score $>$ 19). QoL was impaired (FDDQL score 41±14), more frequently in women (44.9±14 vs. 40.2±14.4 ($p = 0.039$), with no difference according to IBS subtype, and was correlated with disease severity and HAD score ($r = -0.707$ and $r = -0.484$, $p < 0.001$; respectively). Patients' expectations about IBS were "improved health", "information on the causes and treatments" for 94%, and "better disease recognition" for 86%. Expectations vs. experiences (%) in relation to the medical providers were: "sufficient information" (94% vs. 16%), "listening with empathy" (97% vs. 36%), "providing hope" (85% vs. 9%), "improved health"

(95% vs 15%). Patients thought that their doctors had ''good knowledge on IBS'' in 18%, ''believed in their symptoms'' in 47% and suggested to them that "it was in their head" in 65%. Only 16% were satisfied with the health care system for IBS management and 68% considered that an improvement in the management of symptoms would have an impact on overall IBS cost. There was a discrepancy between the desired information sources on IBS (more information via the doctor) and the reality: internet 84%, specialist 47.9% and GP 32%.
CONCLUSION: These French data on expectations of IBS patients from a survey conducted among members of a patients' organization show 1) a severe disease with frequent psychological impact and impaired QoL, 2) many unsatisfied expectations with respect to the disease and health care professionals, and 3) a need for improving the quality of patient-physician relationship.

P0433 PROTECTIVE EFFECTS OF SACRAL NERVE STIMULATION AGAINST TNBS-INDUCED ACUTE INTESTINAL INFLAMMATION

J. Bregeon[1,*], A.C. Cordeiro[1], P. Aubert[1], J. Jaulin[1], J. Chevalier[1], J. Hervouet[2], D. Minault[2], E. Coron[1], M. Neunlist[1], G. Meurette[1]
[1]*Inserm U913, Digestive Diseases Institute, Nantes University Hospital,* [2]*Inserm U1064, Laboratoire des grands animaux, Nantes University Hospital, NANTES, France*

INTRODUCTION: Inflammatory Bowel Diseases (IBD) dramatically alter the quality of life for the young adult and have a high societal cost. Treatments of IBD have made recent progress but their adverse side effects are numerous and relapse prevention remains a problem. Enhancing intestinal epithelial barrier (IEB) functions emerges as a promising new therapeutic approach. The enteric nervous system (ENS), a key regulator of gut homoeostasis, exhibits major barrier protective effects. Sacral nerve stimulation (SNS), probably via activation of the ENS, has been reported to enhance IEB resistance (1) but its putative protective effects in response to inflammatory challenge remain unknown.
AIMS & METHODS: Therefore, the aim of this study was to determine whether SNS protects barrier dysfunction as well as modulates intestinal inflammation induced by an acute inflammatory stress induced by TNBS. Twelve pigs were implanted for percutaneous bilateral SNS (S3 stimulation) (Medtronic 041828-004, Minneapolis, USA; 14 Hz, 210ms). Six pigs were stimulated 3 hours prior and 3 hours after administration of rectal enemas of TNBS (15 mg/ml). Control animals (CT) were implanted but not stimulated and also received TNBS enema. Rectal panparietal biopsies were performed before (T0) and 1h, 3h, 24h after enema. Intestinal para- and transcellular permeability was assessed in Ussing chambers. *In vivo,* intestinal inflammation was evaluated by endoscopy and confocal endomicroscopy (CEM) scores. Impact of SNS upon the mucosal changes induced by TNBS was evaluated by combining histological and transcriptomic approaches.
RESULTS: In CT, a significant and transient increase in rectal para- and transcellular permeability was measured as early as 3h following TNBS enema. 24h after enemas permeability was still increased in CT as compared to its T0 value. In SNS pig, a significant and transient increase in para- and transcellular permeability occurred as early as 1h following TNBS enema. However, 24h after enemas permeability was similar to its T0 value. At 24h, similar results were observed at the rectosigmoidal hinge level. Consistently, the SNS pigs exhibited a trend toward a lower UCEIS score ($p = 0.07$, $n = 5$) as compared to CT. At 24h, CEM scores revealed that TNBS induced alterations in crypt circularity, tortuosity and brightness were significantly reduced by SNS as compared to control ($p = 0.05$, $n = 6$; $p = 0.008$, $n = 6$, respectively). Furthermore, epithelial desquamation and edema formation was significantly larger in CT as compared to SNS pigs ($p = 0.03$, $n = 6$, both measures). Finally, mRNA expression of key tight junction proteins such as Claudin-1 ($p = 0.04$, $n = 6$) and ZO-1 ($p = 0.03$, $n = 6$) were significantly increased in SNS ($p = 0.04$, $n = 6$; $p = 0.03$, $n = 6$, respectively) as compared to CT pigs. Western blot analysis of ZO-1 also showed that ZO-1 protein expression was increased in SNS as compared to CT animals ($p = 0.018$, $n = 6$).
CONCLUSION: Altogether these results show that SNS exhibit major reparative properties on mucosal lesions induced by acute inflammatory stress. These identify SNS as a putative alternative or complementary therapy targeting diseases such as IBD.

P0434 FAECAL INCONTINENCE IN TYPE 2 DIABETICS: COMPARISON WITH NON DIABETIC HEALTHY INDIVIDUALS AND ANALYSIS OF RELATED FACTORS

J.X. Jorge[1,2,*], L.S. Fernandes[3], C.C. Almeida[2], F.J. Delgado[4], E.A. Panão[5], M.A. Simões[2]
[1]*Faculty of Medicine, Agostinho Neto University, Luanda, Angola,* [2]*Faculty of Medicine, University of Coimbra, Coimbra,* [3]*Medicine Urgency, Hospital Fernando Fonseca, Lisboa,* [4]*Medicine, Hospital de Alcobaça, Alcobaça,* [5]*Gastroenterology, Hospital dos Covões, Coimbra, Portugal*
Contact E-mail Address: *cambombo@hotmail.com*

INTRODUCTION: Faecal incontinence is a complaint that some type 2 diabetic patients frequently refer[1]. The factors involved with are not well known.
AIMS & METHODS: The aim of this study was to compare the frequency of faecal incontinence between type 2 diabetic patients and non diabetic healthy individuals and to analyse some factors involved in this perturbation in diabetics. A questionnaire of Gastrointestinal Symptoms Rating Scale[2] was completed by to 140 type 2 diabetics and 132 non diabetic healthy individuals, matched by age and gender.
RESULTS: The frequency of faecal incontinence in diabetics vs. non diabetics was 14.3% vs. 3.1%, $p < 0.01$. According to the severity, the frequency of faecal incontinence between diabetics vs. non diabetics was as follows: minor symptoms, 3.6% vs. 2.3%; moderate symptoms, 7.9% vs. 0.8%; severe symptoms, 2.1% vs. 0.0%; very severe symptoms, 0.7% vs. 0.0%, $p = 0.03$.
When analysing the frequency of faecal incontinence in diabetics according to the disease duration, $</= 10$ years vs. > 10 years the results was 9.5% vs. 24%, $p < 0.01$. The symptoms for severity was also significantly higher in diabetics with more than 10 years of disease, $p = 0.01$. In diabetic patients, age, gender and glycaemia control did not influence the frequency and severity of faecal incontinence.
CONCLUSION: 1- Faecal Incontinence is more frequent and severe in type 2 diabetics than non diabetic healthy individuals. 2- Diabetes duration influences the frequency and the severity of faecal incontinence. 3- Age, gender and glycaemia control did not influence the frequency and the severity of faecal incontinence in type 2 diabetic patients.

INTRODUCTION: To date it is known that in spite of different points of view on etiology and variety of cellular and molecular pathogenetic components of pulmonary manifestations in gastroesophageal reflux disease (GERD) and combination of GERD and asthma there is a key feature of inflammation and the immune response disorder in the form of Th1/Th2 imbalance in the pathogenesis of the disease. Th1 or Th2 direction of immune response is mainly predetermined by innate and adaptive immune response cells - macrophages. Considering the concept of M1/M2 programming in changing microenvironment, macrophages can obtain either pro-inflammatory M1 phenotype, or alternatively anti-inflammatory M2 phenotype and change their phenotype in the disease formation. So we can suppose that Th1/Th2 imbalance is mainly due to impairment ability of macrophages to adequate change their phenotype, i.e. with impaired phenotypic plasticity of macrophages.
AIMS & METHODS: Assessment of alveolar macrophages (AM) phenotypic plasticity in GERD and its combination with asthma and healthy volunteers under the influence of different serum (FBS) concentrations. **Methods:** In vitro experiments were carried out on AM, isolated from BALF of patients with GERD ($n = 15$, 46.41 ± 4.18 y.o.), combination of GERD and asthma ($n = 16$, 49.30 ± 3.64 y.o.) and healthy volunteers (HV) ($n = 10$, 51.83 ± 3.52 y.o.). AM phenotype was assessed by flow cytometry (Beckman Coulter, FC500) by cytokine production of proinflammatory M1, anti-inflammatory M2 and bivalent M1/M2 cytokines in culture medium (CM) of AM (BenderMedSystems, BMS810FF). Phenotypic plasticity of AM was measured as percentage change of markers during 36 hours of AM reprogramming in the presence of 0%, 10%, 40% standard fetal bovine serum, containing endogenous reprogramming factor – surfactant protein D.
RESULTS: Pooled analysis of M1 and M2 phenotypic plasticity in GERD and its combination with asthma against HV showed maximum of M1 phenotypic plasticity in GERD – M1/M2 index of the macrophages ability to change their phenotype towards M1 was 5.33 and this was 8.5 times increased vs combination of GERD and asthma ($p < 0.05$). Maximum macrophage phenotypic plasticity towards M2 phenotype was observed in combination of GERD and asthma and M1/M2 index of phenotypic plasticity was 5.45 times higher than in GERD.
CONCLUSION: The ability of AM to change their phenotype under the influence of the microenvironment in GERD and its combination with asthma was changed as compared to healthy volunteers. In GERD macrophages possess more possibilities to obtain M1 phenotype than M2, but the in combination of GERD and asthma macrophages are more predisposed to obtain M2 phenotype. So the studied ability of macrophages to adapt their phenotype to the microenvironment and to reprogram the phenotype of the cells can be thought of as the base for new therapy approach in personalized medicine influencing the initial links of inflammatory response and Th1/Th2 imbalance even in initial stages of pathological process.

P0436 INCREASED LEPTIN SIGNALING IN ESOPHAGEAL ADENOCARCINOMA CELL LINE TREATED WITH PERITUMORAL ADIPOSE TISSUE-DERIVED CONDITIONED MEDIUM

E. Trevellin[1], **M. Scarpa**[2,*], A. Carraro[3], L. Saadeh[2], M. Cagol[2], R. Alfieri[2], U. Tedeschi[3], C. Castoro[2], R. Vettor[1]

INTRODUCTION: Obesity is associated with an increased risk of cancer and it has been hypothesized that the action of adipokines (e.g. leptin and adiponectin) may influence tumor invasiveness.
AIMS & METHODS: Our aim is to investigate if peritumoral adipose tissue may play a direct role by altering the expression of genes involved in migratory/mesenchymal transition processes in human esophageal adenocarcinoma cells.
Human esophageal adenocarcinoma cells (OE33) were cultured with conditioned medium (CM) derived from adipose tissue fragments of peritumoral and distal (omental) depots of 15 patients with esophageal adenocarcinoma, undergoing surgical resection. After 48h we measured mRNA levels of leptin receptor (ObR), adiponectin receptor (AdipoqR), alpha-smooth muscle actin (α-SMA) and E-cadherin (CDH1) in OE33 cells using Real Time quantitative PCR.
RESULTS: Gene expression of ObR, AdipoqR, α-SMA and CDH1 were dramatically increased in OE33 cells cultured with CM, compared to control cells. Moreover, expression of ObR, AdipoqR α-SMA and CDH1 was significantly higher in OE33 cells cultured with CM of peritumoral depot, compared to cells cultured with CM of omental depot. Interestingly, ObR and α-SMA expression was significantly increased in OE33 cells cultured with CM of peritumoral depot derived from patients with lymph node involvement (N+), compared to peritumoral CM of patients with no positive lymph node (N-).
CONCLUSION: Our results suggest that peritumoral adipose tissue may influence esophageal adenocarcinoma cells, through the action of secreted factors. In particular, leptin signaling may be involved in the induction of α-SMA expression in esophageal adenocarcinoma cells, possibly promoting a more aggressive behaviour of tumor.

INTRODUCTION: Actual pathogenesis studies of pulmonary manifestations in gastroesophageal reflux disease (GERD) and its combination with asthma showed that respiratory system inflammation and imbalance between Th1 and Th2 immune responses are the main pathologic components of the process. Considering the present-day concept of Th1/Th2 Paradigm and M1/M2 macrophages programming, immune response disorders depend largely on the balance of functional phenotypes of alveolar macrophages (AM). One of significant bivalent regulatory components of AM activity is surfactant protein D (SP-D). So we suppose that pooled analysis of AM phenotype with quantitative and qualitative analysis of SP-D composition in broncho-alveolar lavage fluid (BALF) will add to research in pathogenesis of pulmonary manifestations in GERD and can be used as additional biomarker in GERD and its combination with asthma.
AIMS & METHODS: This study evaluated pooled data of AM phenotype and quantitative/qualitative composition of SP-D in BALF in patients with pulmonary GERD manifestations and its combination with asthma in comparison with healthy volunteers. **Methods:** Pooled analysis of AM phenotype in patients with GERD ($n=15$, 46.41 ± 4.18 y.o.), combination of GERD and asthma ($n=16$, 49.30 ± 3.64 y.o.) and healthy volunteers (HV) ($n=10$, 51.83 ± 3.52 y.o.) was performed by flow cytometry (Beckman Coulter FC500) by expression of M1 and M2 AM phenotypes CD markers (CD25, CD80 and CD163, CD206, respectively) and cytokine production of proinflammatory M1, anti-inflammatory M2 and bivalent M1/M2 cytokines in culture medium (CM) of AM (BenderMedSystems, BMS810FF). Quantitative analysis of SP-D in BALF was performed by ELISA. Qualitative assessment of SP-D oligomeric forms in BALF was performed by western blot analysis using tris-acetate gels (Invitrogen, NuPAGE, # EA03752BOX).
RESULTS: Analysis of AM phenotype in patients with GERD, its combination with asthma vs. HV showed that pooled M1/M2 ratio of AM CD markers and cytokine production was 2.16 and 2.52, 0.91 and 0.84 vs. HV, respectively. The results indicates shift of AM towards M1 phenotype vs HV in GERD and towards M2 phenotype vs HV – in combination of GERD and asthma. SP-D level in BALF in patients with GERD was 2.66 times decreased vs patients with combination of GERD and asthma (155.83 ± 18.13 ng/ml vs 414.72 ± 50.22 ng/ml, $p<0.05$) and 3.42 times decreased vs. HV (155.83 ± 18.13 ng/ml vs 533.20 ± 21.12, $p<0.05$). Qualitative analysis of SP-D oligomeric forms in GERD and its combination with asthma showed predominance of monomeric forms vs HV with monomeric and multimeric SP-D oligomers.
CONCLUSION: In GERD with pulmonary manifestations and combination of GERD and asthma AM phenotype and quantitative and qualitative composition of SP-D in BALF vary against healthy volunteers and each other. Shift of AM phenotype towards M1 vs healthy and significant maximum decreased SP-D level in BALF are typical for GERD with pulmonary manifestations, whereas shift of AM phenotype towards M2 and less decreasing SP-D level in BALF are specific for combination of GERD and asthma. There were no significant differences in qualitative oligomeric composition of SP-D in BALF in GERD and its combination with asthma.

P0438 INITIAL EXPERIENCE WITH HEMOSPRAY IN THE TREATMENT OF ACUTE UPPER GASTROINTESTINAL BLEEDING

B. Disney[1,*], A.K. Kurup[1], S. Ishaq[1], S. Shetty[1], H. Muhammad[1]
[1]*Gastroenterology, Russells Hall Hospital, Dudley, United Kingdom, Dudley, United Kingdom*

INTRODUCTION: Upper gastrointestinal bleeding remains a medical emergency. Endoscopic therapies such as adrenaline injection, heater probe and clips are used to achieve haemostasis. However, accurate delivery of these endotherapies can be challenging. Hemospray (Cook Medical, Winston-Salem, North Carolina, USA), an inorganic haemostatic powder, is licensed for use in non-variceal acute upper GI bleeding. The delivery system allows a wide area of coverage, negating the need for accuracy, and has promising results.
AIMS & METHODS: Retrospective analysis of all upper GI bleeds utilising Hemospray following its introduction to Russells Hall Hospital in July 2013. Patients were identified using the Unisoft endoscopy database and endoscopy unit logbooks. Data on the use of Hemospray, bleeding lesion identified and use of other therapeutic modalities were collected. Outcomes including mortality, primary haemostasis and rebleeding were obtained. The aim of this study was to assess the effectiveness of Hemospray in the real-life setting.
RESULTS: Hemospray was used 17 times in 13 patients with acute upper GI bleeding (mean age 69 years, range 37-96 years; 69% male). The patients had a median Blatchford score of 10 (range 5-13) and Rockall score of 7 (range 3-8). Three patients had Hemospray used on more than one occasion.
The cause of bleeding was peptic ulcer in 10/17 patients (58.8%), upper GI malignancy in 6/17 patients (35.3%) and unknown source in 1/17 patients (5.9%). Hemospray was used as primary endotherapy in 11/17 patients (65%) achieving initial haemostasis in 16/17 cases (94%). Technical failure occurred in one patient with the cartridge failing to operate and deliver Hemospray. Rebleeding within 30 days occurred with 6/17 uses (35%); 5 of these in the context of peptic ulcer disease and 1 in upper GI malignancy. When Hemospray was used as primary therapy rebleeding occurred on 4 occasions compared to 2 when used as second line therapy ($p=0.57$). Blatchford scores were higher in those patients suffering from rebleeding (12 versus 10, $p=0.21$). No significant differences in rebleeding was noted between malignant and non-malignant causes of acute upper GI bleeding. 30-day mortality in this patient cohort was 2/13 (15.4%). There were no documented complications of Hemospray therapy.
CONCLUSION: Hemospray is a safe, and easy to use, endoscopic therapy with excellent initial haemostasis as both a primary or second line treatment. In the context of bleeding as a result of upper GI malignancy Hemospray provided good palliation. Although there appeared to be a higher rebleeding rate seen when Hemospray was used as primary therapy this was not significant and may reflect the low numbers in the study.

P0439 CORRECT USE OF PROTON-PUMP INHIBITORS FOR STRESS ULCER PROPHYLAXIS IN INTENSIVE CARE UNIT: NO GI BLEEDING AND NO CL. DIFFICILE?

S. Segato[1,1], L. Bardelli[1], **C.C. Cortelezzi**[1,*], M. Parravicini[1], M. Montanari[1], S. Piana[1], S. Bonecco[1], S. Segato[1], G. Bisso[1], G. Minoja[2]
[1]*Gastroenterology,* [2]*Intensive Care Unit, Azienda Ospedaliero Universitaria Macchi Varese, Varese, Italy*
Contact E-mail Address: *sergio.segato@ospedale.varese.it*

INTRODUCTION: Despite limited data about their use in critically ill patients, proton pump inhibitors (PPIs) have become the first line therapy in stress ulcer prophylaxis (SUP). PPIs may increase the risk of hospital-acquired pneumonia and enteric infections, especially *Clostridium difficile* related diarrhoea. Many studies showed an overuse of acid suppressive therapy in Intensive Care Unit (ICU), with unintended consequences of therapy.
AIMS & METHODS: The aim of the study was to evaluate the current practice of SUP, the correlation with the evidence-based American Society of Health-System Pharmacist (ASHP) guidelines and the occurrence of GI hemorrhage, pneumonia, and CDI in critical care setting.

The study was made on 300 consecutive patients (186 men, 114 women, medium age 63.9 yrs, range 23-99 yrs, median ICU stay 11.42 days range 3-45 days) admitted to ICU of the teaching hospital Macchi Varese between January 1st and June 30th 2012 and January 1st and June 30th 2013; patients admitted to neurocritical care unit and children under 18 yrs were excluded. Data about clinical indications, drug assumption and outcomes (gastrointestinal haemorrhage, pneumonia and enteric infections) were collected during ICU stay.

RESULTS: Mechanical ventilation for more than 48h was the reason for initiating prophylaxis in 294 patients (98%); 6 pts. had a platelet count under 50.000/mm3.

281 pts (93.6%) used PPIs (omeprazole 40mg daily i.v.), 19 pts (6.3%) H2RAs (ranitidine 150 mg every 8 hours i.v.), 296 pts (98.6%) antibiotics, 166 pts (55.3%) vasoactive drugs.

32 patients (10.6%) developed nosocomial pneumonia; 26 of them had other risk factors (1 asthma, 14 chronic obstructive lung disease, 1 AIDS, 10 were older than 75 years). One pt had *Clostridium difficile* related dyarrhea. One pt with a history of active duodenal ulcer had ulcer bleeding.

CONCLUSION: All SUP were classified as appropriate according to the ASPH guidelines. PPIs represent the first line therapy. Bleeding from stress ulceration is extremely uncommon; *Clostridium difficile* related dyarrhea is unexpectedly rare too. Patients who developed hospital-acquired pneumonia during acid-suppressive therapy, usually had other risk factors linked to this kind of infection. In this prospective observational study, the occurrence of GI bleeding and symptomatic CDI in critically ill patients, treated following ASHP guidelines, is lower than reported in other studies. More data from well-designed randomized clinical trials are needed before any change in practice.

Contact E-mail Address: *andrew.palmer1@nhs.net*

INTRODUCTION: The early use of risk stratification scores is recommended by the International Consensus Upper Gastrointestinal (GI) Bleeding Group for patients presenting with acute non-variceal upper GI bleeds (ANVUGIB) [1]. Such models permit identification of patients who are suitable for early hospital discharge or even outpatient care. The most widely used is the Glasgow-Blatchford Score (GBS) [2]. The score ranges from 0 to 23 and the risk of requiring clinical intervention and death has been shown to increase with increasing score [3]. More recently a simpler scoring system known as AIMS65 was devised, which is based on serum **A**lbumin (<30g/dl), **I**NR >1.5, altered **M**ental status (GCS<14), **S**ystolic BP (<90) and age >**65**. One point is scored for the presence of each variable and it has been shown to accurately predict mortality, length of stay, and be superior to the GBS in predicting mortality [4,5]. However, its ability predict the need for clinical intervention has yet to be established.

AIMS & METHODS: The aim of this study was to examine the ability of the AIMS65 score in predicting the need for clinical intervention and mortality in comparison to the GBS. To do this we performed a retrospective analysis of 150 adults who presented to a single district general hospital in Scotland with a primary diagnosis of ANVUGIB and who underwent upper GI endoscopy between March 2008 & April 2013. GBS and AIMS65 scores were calculated and requirement for clinical intervention, defined as the need for endoscopic treatment, blood transfusion and/ or surgery was recorded. The area under the receiving-operator characteristic curve (AUROC) was calculated for each score.

RESULTS: Of the 150 patients 62% were male and 38% female. The mean age was 68 years (SD 16), GBS 7.9 (SD 4.6) and AIMS65 score 1.0 (SD 1.0). The overall mortality was 6%. The GBS had a high predictive accuracy and was superior to AIMS65 in predicting requirement for any clinical intervention (AROC 0.81 vs. 0.70), blood transfusion (AROC 0.85 vs. 0.67) and endoscopic therapy (AROC 0.67 vs. 0.58). With respect to mortality, AIMS65 was superior to the GBS (AROC 0.79 vs. 0.68). Patients with a GBS <4 experienced no mortality, GBS ≥4 <8 2.6% and for those with GBS ≥8 10.1%. For the GBS these cut off values maximised the sensitivity and specificity for inpatient mortality. Patients with low risk AIMS65 scores (0 or 1) experienced mortality (4%) questioning its use as a risk stratification tool for safe, early, hospital discharge.

CONCLUSION: In our population the GBS was superior to the AIMS65 score in terms of predicting the need for any clinical intervention, blood transfusion or endoscopic therapy. We identified potential cut off values for the GBS that allow stratification of patients into low, medium and high risk groups on the basis of predicted mortality. This warrants further investigation.

P0441 OUTCOMES AND PREDICTIVE FACTORS OF TRANSCATHETER ARTERIAL EMBOLIZATION FOR NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING

H.H. Lee[1,*], J.M. Park[1], C.-H. Lim[1], J.S. Kim[1], Y.K. Cho[1], B. **I. Lee**[1], **I.S. Lee**[1], S.W. Kim[1], M.-G. Choi[1]

INTRODUCTION: Transcatheter arterial embolization (TAE) has been considered a therapeutic option for upper gastrointestinal (GI) bleeding when endoscopic treatment fails.

AIMS & METHODS: We aimed to assess the efficacy and clinical outcomes of TAE for acute nonvariceal upper GI bleeding and to identify predictors of recurrent bleeding within 30 days.

Transcatheter angiography was performed in 66 patients (42 men, 24 women; mean age, 60.3 ± 12.7 years) who experienced acute nonvariceal upper GI bleeding during a 7-year period. Clinical information was reviewed retrospectively. Outcomes included technical success rates, complications, and 30-day rebleeding and mortality rates.

RESULTS: TAE was feasible in 59 patients. The technical success rate was 98.3%. Rebleeding within 30 days was observed in 46.6% and was managed with reembolization in 8 patients, endoscopic intervention in 5, surgery in 2, and conservative care in 12. The 30-day overall mortality rate was 42.4%. Of the 34 patients whose initial endoscopic hemostasis failed, 31 (91.2%) underwent angiographic embolization, which was successful in 30. Rebleeding occurred in 15 patients (50.0%), mainly because of malignancy. Two factors were independent predictors of rebleeding within 30 days by multivariate analysis: coagulopathy (OR, 4.37; CI, 1.25–15.29; $P=0.021$) and embolization in $^{3}2$ territories (OR, 4.93; CI, 1.43–17.04; $P=0.012$). Catheterization-related complications included hepatic artery dissection and splenic embolization.

CONCLUSION: TAE controlled acute nonvariceal upper GI bleeding effectively. TAE may be considered when endoscopic therapy is unavailable or unsuccessful. Coagulopathy and embolization of $^{3}2$ territories were significant predictors of angiographic failure. Correction of coagulopathy before TAE is recommended.

INTRODUCTION: Many patients with gastrointestinal bleeding show anemia and usually need red blood cell transfusion. Several studies suggested that restrictive transfusion strategy and low hemoglobin threshold for transfusion showed acceptable outcomes in patients with acute upper gastrointestinal bleeding [1,2]. But clinicians are concerned about low hemoglobin affects prognosis and clinical outcome after discharge. This study aimed to assess whether discharge hemoglobin influences on outcomes, or not, in patients with acute non-variceal gastrointestinal bleeding.

AIMS & METHODS: Retrospective analysis was carried out on patients who had upper gastrointestinal bleeding between January 2011 and December 2012. We analyzed the patients who had lowest hemoglobin below 10 g/dL during admission. Patients with variceal bleeding, stroke, or cardiovascular disease were excluded. We divided the patients into two groups by discharge hemoglobin (Low discharge hemoglobin group; 8 g/dL ≤ hemoglobin <10 g/dL, High discharge hemoglobin group; 10 g/dL ≤ hemoglobin <12 g/dL) and compared clinical outcomes and hemoglobin level changes.

RESULTS: A total of 212 patients with upper gastrointestinal bleeding had undergone the endoscopic hemostasis during study periods. One hundred two patients had satisfied the inclusion criteria. Fifty patients discharged with hemoglobin level under 10 g/dL and fifty two patients discharged with hemoglobin level over 10 g/dL. There was no significant difference of endoscopic findings between two groups. Patients in low discharge hemoglobin group showed a lower consumption of pRBC(Low discharge Hb group; 3.2 ± 1.4 pint, High discharge Hb group; 4.1 ± 1.8 pint, P Value = 0.01) and shorter hospital days (Low discharge Hb group; 4.3 ± 2.5 days, High discharge Hb group; 5.6 ± 4.2 days). Hemoglobin levels were not fully recovered at out-patient department until 7 days after discharge. But, most patients showed hemoglobin recovery at 45 days after discharge (Low discharge Hb group; Hb 12.2 ± 2.0 g/dL at OPD 45, High discharge Hb group;; Hb 11.9 ± 2.0 g/dL at OPD 45). Clinical symptoms after discharge were presented no significant difference between two groups.

CONCLUSION: In patients with acute gastrointestinal bleeding, discharge hemoglobin between 8 to 10 g/dL was showed favorable outcomes during outpatient department follow-up. It seems to be tolerable level without additional pRBC transfusion. Despite of high hemoglobin over 10 g/dL at discharge, there was no significant advantage in clinical outcome. Our result can increase the evidence available to support restrictive transfusion strategies in patients with acute non-variceal upper gastrointestinal bleeding.

P0443 EVALUATION OF THE PREDICTIVE VALUE OF REBLEEDING RATE OF FORREST SIMPLIFIED CLASSIFICATION

J. Moleiro[1,*], A. Ferreira[2], J. Torres[3], E. Barjas[3], M. Cravo[3]
[1]*Gastroenterology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E. P. E., Lisboa,* [2]*Gastroenterology, Centro Hospitalar do Algarve, Portimão,* [3]*Gastroenterology, Hospital Beatriz Ângelo, Loures, Portugal*

INTRODUCTION: A simplification of the Forrest classification (FC) into three levels (high risk: Ia; increased risk: Ib to IIc; low risk: III) has recently been proposed [(1)].

AIMS & METHODS: Our aim was to evaluate the prognostic value of this new simplified classification (SC) in predicting re-bleeding of peptic ulcer (PU) and to compare it with the traditional FC. We retrospectively identified patients admitted to our unit between 07/2012 to 02/2014 with upper gastrointestinal bleeding due to PU. Demographic, clinical, laboratorial and endoscopic data were collected. Therapeutic interventions and cases of re-bleeding and mortality within a 30 days period were registered. The predictive value of the FC and SC were compared using logistic regression and ROC curves.

RESULTS: 81 patients underwent upper gastrointestinal endoscopy due to bleeding PU; the mean age was 70 ± 16 years; 61 (75%) were men. Clinical presentation of PU bleeding was melena in 33 cases (41%), hematemesis in 29 (36%), symptomatic anemia in 8 (10%), hematochezias in 7 (9%) and hemodynamic instability in 4 (5%). The mean hemoglobin at admission and heart rate were 8.75 g/dL and 94 bpm, respectively. Forty-eight percent of the ulcers were located in the stomach and 52% in the duodenum. Endoscopic therapy was performed in 39 patients (49%), and was effective in 38. One patient (1.2%) required surgery. At the 30th day, re-bleeding occurred in 15 patients (19%) and the mortality rate was 6%. Re-bleeding occurred in 1 of 2 patients with Forrest Ia ulcer (high risk) and 8 (38%) with Forrest IIa (increased risk). The odds ratio for re-bleeding of high risk and increased risk ulcers was 33.00 and 14.30 ($p = 0.013$), respectively. The AUROC (for re-bleeding) was 0.733 for SC and 0.723 for FC.

CONCLUSION: FC maintains its predictive value in determining re-bleeding in PU. The proposed SC maintains the prognostic value of the FC, and therefore is an alternative to assess the risk of re-bleeding.

P0444 SURVIVAL OUTCOMES AFTER IMPLEMENTATION OF THE UK IMPROVING OUTCOMES GUIDANCE' (IOG) FOR OESOPHAGEAL AND GASTRIC CANCERS

R.K. Fofaria[1,*], J. Deacon[1], A.Z. Al-Bahrani[2], A. Polychronis[3], I.R. Sargeant[1], D. Morris[1]
[1]*Gastroenterology, Lister and QEII Hospitals, Stevenage,* [2]*General Surgery, Watford Hospital, Watford,* [3]*Medical Oncology, Mount Vernon Cancer Centre, Northwood, United Kingdom*
Contact E-mail Address: *rishi.fofaria@nhs.net*

INTRODUCTION: Oesophago-gastric (OG) cancer is the 3rd most common cause of cancer-related death in the UK. Historically, it has been suggested that the UK may have lagged behind European OG survival outcomes because of fragmentation of service provision, suboptimal access to leading specialist centres and delayed presentation and referral of patients from primary care. The 'Improving Outcomes Guidance' (IOG) for Upper GI Cancers (2001) and Manual for Cancer Services (2004, 2011) recommended centralising curative therapies, reconfiguring access to diagnostic/staging services and formalising the role of the 'Cancer Network' and peer-reviewed 'Network Site Specific Groups'. Lister and QE2 District Hospitals (part of the Mount Vernon Cancer Network) cover a catchment population of 600,000 people and reconfigured their upper GI cancer services in mid-2009.

AIMS & METHODS: Aims: To assess survival outcomes in patients with OG cancer over a 9-year period before and after the reconfiguration of a local upper GI cancer network.

Methods: The medical, endoscopic and computerised notes of multi-disciplinary team meetings of all patients diagnosed with OG cancer between 1 January 2004 - 31 March 2013 were retrospectively analysed. Age, sex, histology, tumour site, treatment intent and number of patients surviving at 6, 12, 24 and 42 months and at 1 April 2014 were noted. The χ^2 (Chi-Square) test was used to analyse the significance of survival outcomes.

RESULTS: From January 2004 - December 2008 there were: 139 gastric cancers (27% curative therapeutic intent) and 234 oesophageal cancers (23% therapeutic intent; 63.6% adenocarcinoma), with overall 12-month survival of 30% and 42% and 42-month mortality of 12% and 15%, respectively. From January 2009 – March 2013 there were: 111 gastric cancers (18% curative therapeutic intent; 68.5% male; average age 75) and 230 oesophageal cancers (26.5% therapeutic curative intent; 65.2% male; average age 72; 69.1% adenocarcinoma) with overall 12-month survival of 40% and 36% and 42-month mortality of 16% and 8%, respectively ($p > 0.05$ for all corresponding follow-up intervals). Sub-group analysis shows increased survival in the 2009-2013 gastric cancer cohort treated with curative intent at 6 months ($p < 0.05$) and palliative therapy at 12 months ($p < 0.05$). There was no significant decrease in survival outcome at any stage of follow up in both cancer groups and cohorts.

CONCLUSION: These findings are in keeping with national outcomes and show that the institution of recommendations from the IOG, including centralisation of curative therapies and access to specialist services, show no significant decrease in survival outcome for OG cancer. Indeed, there is a modest increase in short-term gastric cancer survival. The lower percentage of patients treated with curative intent, compared to national data, may reflect the late presentation of OG cancers and partially explain survival outcomes in this population.

P0445 THE FLAME MODEL: SUPPORTING ENDOSCOPY TRAINING IN LOW RESOURCE SETTINGS

S. Goddard[1,*], J. Ansell[1], N. Hawkes[2]
[1]*School of Postgraduate Medical and Dental Education, Cardiff University,* [2]*Gastroenterology Department, Royal Glamorgan Hospital, Cardiff, United Kingdom*
Contact E-mail Address: *goddardsg@cardiff.ac.uk*

INTRODUCTION: Simulation permits selective breakdown of key motor skills for a clinical procedure into basic steps, which is better for acquisition, teaching and assessing. (1, 2) Environment doesn't significantly affect skills transfer, implying endoscopy can be learnt outside the clinical setting. Basic endoscopic competencies can be taught with ex-vivo animal models. (3) The British Society of Gastroenterology supported an excursion to Kurdistan whose remit to 'train-the-trainers' required provision of a suitable model.

AIMS & METHODS: Develop and Validate: Flexible Lightweight Animal Model for gi Endoscopy (FLAME), to support hands-on endoscopy training in a low-resource setting, specifically, to facilitate training in GI haemostasis, variceal banding and polypectomy. Pilot prototyping indicated use of a lightweight, mouldable, plastic frame with selected ports for the attachment of premade animal tissue patches with bespoke defects. Potential port sites were analysed to optimise access and offer different technical challenges. A foil plate and cling film wrap-around supported use of diathermy and prevented fluid leakage. The model was housed in foam and enclosed in a lightweight box. External Velcro straps provided further anchorage. The model was validated during a hands-on training course conducted in Erbil, Iraq in February 2014. Attendees completed 11-point realism (visual, anatomical and mechanical) surveys based on a 7 point Likert scale,(4) separately for GI haemostasis, variceal banding and polypectomy. Analysis using Wlicoxon signed rank test (PASW Statistics 18) for non-parametric data reported scores against a hypothetical mean of 4.0 for statistical significance ($n = 17$ gave >90% power to detect a difference of 1 point).

RESULTS: 20 delegates (6 consultants, 14 trainees) completed the surveys. For polypectomy all scores were greater than 1 point above the 4.0 hypothethical mean, range 5.26-5.76 (score of 7 indicates strong agreement with realism). Mean overall score was 5.59 [$p < 0.05$; CI 4.96-6.22]. For both variceal banding and GI haemostasis, all mean scores were above 4.0 though the overall reality scores did not reach significant difference; variceal banding - range 4.62-5.31, overall score 4.62; GI haemostasis – range 4.5-5.83, overall score 4.56. Separate evaluation of the overall training course revealed high levels of delegate satisfaction, principally the hands-on model training elements.

CONCLUSION: The FLAME's initial evaluation in a course setting demonstrates face and content validity for polypectomy. Whilst banding and GI haemostasis values didn't achieve statistical significance ratings for all parameters, all were higher than the hypothetical mean. The model is cost-effective, easy to transport, robust in practice and was highly valued by delegates in course evaluation. We plan further adaptations with follow-up validation studies.

P0446 THE FIRST REPORT ON THE GASTROPROTECTIVE EFFECT OF TRIPEPTIDE T-34 UNDER CONDITIONS OF WATER-IMMOBILISATION STRESS IN RATS

C. Nasadyuk[1,*], A. Sklyarov[1]
[1]*Biochemistry, DANYLO HALYTSKY LVIV NATIONAL MEDICAL UNIVERSITY, Lviv, Ukraine*
Contact E-mail Address: *nasadyukch@gmail.com*

INTRODUCTION: There is accumulating evidence that a number of short peptides are envolved in the regulation of the function of gut and may be considered as new pharmacological drugs for the prevention and treatment of gastric ulceration.
AIMS & METHODS: Objective of our research was to explore the effect of tripeptide T-34 (H-Glu-Asp-Gly-OH) on the area of water-immobilisation stress (WIS)-induced gastric lesions in rats and activities of NO-synthases (NOS) and lipid peroxidation processes in gastric mucosa (GM).
The studies were conducted on white male rats. 30 min before the exposure to WIS rats were pretreated with T-34 introduced intragastrically (IG) in dose 10μg ($n = 5$) or intraperitoneally (IP) - 2μg ($n = 5$). Control rats were injected 0.5 ml of saline ($n = 5$). After 5 hours of WIS, rats were sacrificed, gross inspection of GM was conducted and NOS activity, NO and MDA content in GM were determined. In blood plasma L-arginine concentration was measured.
RESULTS: WIS caused the formation of gastric lesions (18±1.9 mm), accompanied by acute rise of NO-synthase activity ($p < 0.05$), in particular its inducible isoform – iNOS ($p < 0.01$), increased production of NO and MDA ($p < 0.05$) in GM compared to intact rats. The concentration of L-arginine, NO precursor, in blood plasma decreased ($p < 0.05$). Pretreatment with T-34 IG caused 27% ($p < 0.05$) decrease of ulceration area, at that NOS activity decreased for 45% ($p < 0.05$), iNOS activity diminished for 60% ($p < 0.01$) in GM compared to control rats. Decrease of NO ($p < 0.05$) and tendency to decrease of MDA content in GM were also noted, whereas L-arginine concentration in plasma increased ($p < 0.05$). Pretreatment with T-34 IP also resulted in the decrease of iNOS activity in GM ($p < 0.05$) but no statistically significant difference of the area of GM damage was evaluated compared to saline-treated rats exposed to WIS.
CONCLUSION: T-34 decreased the indices of nitrooxidative stress in GM under the conditions of WIS-induced gastric lesions in rats. IG administration of T-34 was superior to IP injection of this compound towards reduction of gastric mucosa damage. Deeper studies on the elucidation of the cytoprotective effect of tripeptide T-34, optimization of dosage and route of application are required.

INTRODUCTION: Though the symptoms of functional dyspepsia (FD) are not considered to correlate with mucosa changes the histopathological evaluation seems to be fundamental not to miss the early onset of atrophic-metaplastic transformation.
AIMS & METHODS: Our aim was to assess the frequency and type of histological changes in patients with functional dyspepsia. This work was a part of a randomized superiority trial in which combined treatment using eradication therapy (ET) plus antidepressant by comparison with ET for patients with FD was assessed. Adult patients (18 - 65 years) with confirmed diagnosis of FD by the Rome III criteria (2006) were eligible to participate. Exclusion criteria: the presence of "red flag" signs and other comorbidities that could explain the symptoms. Biopsy specimens were taken from stomach following the Houston-updated gastric biopsy sampling protocol for the next histological examination. One expert gastrointestinal pathologist, blinded to all patient clinical but not endoscopic information, assessed all tissue samples. The degree of inflammatory changes was scored by the 4-grade Visual Analogue Scale, atrophy - following Operative Link for Gastritis Assessment (OLGA) and metaplasia - following Operative Link on Gastric Intestinal Metaplasia (OLGIM) staging systems. All patients were tested for *H. pylori* using two methods (rapid urease test and by morphological examination).
RESULTS: 75 patients fulfilled all criteria and were included into the study. Mean age was 40.3±3.9; males – 26 (34.7%). *H. pylori* was detected in all 75 patients. The main location of *H. pylori* infection was antral part. Patients had mainly a mild degree of mucosal inflammation (84%) which in most cases was limited to antral part. Atrophy was statistically significant more frequently diagnosed in antrum (64.0%) than in corpus (12.0%) ($p < 0.0001$) and in all cases didn't exceed OLGA stage I. Metaplasia of intestinal type was found in 26 (34.7%) patients in antral part and was not detected in corpus ($p < 0.0001$). No case of dysplasia was detected. We also tried to collate the degree of gastritis and the stage according to OLGA (2008) in antrum and corpus with the presence of such clinical syndromes of FD as postprandial distress and epigastric pain. No statistically significant correlation was found ($p > 0.05$).
CONCLUSION: As in most studies, we also didn't find the correlation between stage and degree of gastritis and clinical symptoms of FD. But we shouldn't forget about possible microscopic changes of mucosa when dealing with "functional" patients, thus conducting a primary prophylaxis of gastric cancer.

Contact E-mail Address: *tomas.douda@fnhk.cz*

INTRODUCTION: Surface electrogastrography (EGG) is a non-invasive method for the assessment of gastric myoelectrical activity. Erythromycin, as a potent prokinetic drug, increases the dominant frequency of EGG both in humans and experimental pigs. The aim of this study was to evaluate the effect of erythromycin on the porcine EGG power (assessed by areas of amplitudes) and power ratio (simple fraction ratio of the areas of amplitudes after and before erythromycin administration).
AIMS & METHODS: Six mature female pigs (3 months old, mean weight 23.2±2.1, median 23 kg) were included in the study. All EGG recordings were performed under general anaesthesia in the morning after 24 hours of fasting (by means of the MMS EGG System, Enschede, the Netherlands). The baseline EGG recording lasted 15 min., erythromycin ethylsuccinate (1,500 mg) was subsequently administered by gastric tube into the stomach. The EGG trial recording lasted 150 min. (ten 15-minute intervals: P1 to P10) after erythromycin administration. Running spectral analysis (based on Fourier transform) was used for initial evaluation of the EGG. The gastric myoelectric activity was estimated by EGG power analysis and by power ratio assessment.
RESULTS: Erythromycin increased the EGG power significantly after 15 to 30 min. from the baseline mean value 828±633 (μV^2) to 1583±4238 (at P1) and 1102±2077 (P2 interval), $p = 0.003$. Afterwards, the EGG power decreased to its minimum at P4 (237±200), $p < 0.001$; and increased to 709±1213 μV^2 after 150 min. (at P10), $p < 0.001$. The EGG power ratio reached the highest values at P1 (1.64±3.98) and P2 (1.91±4.27), decreased significantly at P4 (0.29±0.27; $p < 0.001$) and balanced out after 150 min. at P10 interval (1.15±2.48; NS: $p = 0.668$).
CONCLUSION: A medium single dose of erythromycin caused a significant increase in the EGG power and power ratio after 15 to 30 min. after intragastric administration. Both myoelectrical markers decreased after 60 min. and returned close to the initial values after 150 min.

P0449 FUNCTIONAL MOTOR-SECRETORY LIGAMENTS OF DIGESTIVE ORGANS

Y. **I. Reshetilov**[1,*], S.N. Dmitrieva[1], H.Y. Vasilchenko[1], N.N. Protsenko[1]
[1]*Family Medicine and Gastroenterology Department, State Institution Zaporizhzhya Medical Academy of Postgraduate Education, Ukraine, Zaporozhye, Ukraine*

INTRODUCTION: Definition of motor stomach and duodenum disorders role in gastroduodenal zone development process is interesting for peculiarities of digestive system disorder clinical realization. Phase structure of interdigestive motility reflects changes of digestive system activity and inactivity periods; influences interdigestive cycle duration and essentially changes during gastric and duodenum diseases.
AIMS & METHODS: Patients with functional diseases (65), chronic gastritis/gastroduodenitis (184) and duodenal peptic ulcer (55) took part in study of stomach and duodenum motility (GDM). Also 30 healthy men took part in this testing. GDM was studied by the special bougie. Electrodes were based in duodenum, antrum and in body of stomach. External probe ends were connected with polygraph strain gauge, which registered GDM and defined interdigestive cycle periods of inactivity (I phase) and activity (II phase – intermittent motility, III phase – rhythmic phase).
RESULTS: Correct alternation of GDM was diagnosed among healthy men: I phase 22.4±2.0; II phase – 42.6±2.6; III phase – 5.6±1.7 min, in case of interdigestive cycle total time is 69.7±2.3 min. Amplitude and frequency characteristics of stomach and GDM were lowest during I phase (1-4 low-amplitude contractions per min), but they became higher during II phase (3-8 contractions of different height per min) and during III phase (9-15 rhythmic amplitude signals per min). Phase research of intragastric pH in basal conditions showed, that stomach pH decreases till 1.0±0.10 during II phase and it increases till 1.7±0.12 during the third one, as maximal realization of acidogenesis stomach function at the beginning of working period. Patients were separated in 3 observation groups: with heightened, preserved and reduced acidogenesis stomach function. The I group endurance period of inactivity (1 phase) lasted for 15.6±1.0 min, working period of II and III phase was increased till 50.6±1.0 and 6.2±0.9 min, properly ($P < 0.05$). Patients of the II group had phase indexes, which essentially did not differ from control group results (20.6±1.6-42.3±2.3-5.2±1.3; $P > 0.05$). In the group motor indexes and interdigestive total time did not statistically differ from check ones ($P > 0.05$). Patients from the III group had these results: I phase lasted for 27.3±0.9 min, II phase – 38.5±0.7 and III phase was shortened to 4.1±1.1 min; the inactive period increase was determined by means of working period, which was equivalent to gastroduodenodyskinesia.
CONCLUSION: In case of inflammatory gastroduodenum pathology, GDM structure changes according to the picularities of stomach acidogenesis during intagastral cycle. This fact can be explained by secretory and motor function of digestive system functional correlation.

INTRODUCTION: Gastric electrical stimulation (GES) with the Enterra system is a therapeutic alternative for patients with therapy refractory nausea and vomiting secondary to diabetic or idiopathic gastroparesis (GP). Some patients with normal gastric emptying also benefit from GES (Andersson et al, 2011) after selection with a temporary percutaneous stimulation (TPGES) test.
AIMS & METHODS: The aim of this study was to assess response rate and quality of life after one year of treatment with GES in patients selected by a TPGES test period. We used the TPGES technique described by us previously in a randomized double blind crossover design with 2 weeks stimulation ON (5-7 mA range) followed by stimulation OFF, or the opposite order. Treatment response was defined as a symptom reduction $\geq$50% during the ON period compared to the OFF period for one or both of weekly nausea hours (WNH) and weekly vomiting frequency (WVF). Non-responders to blinded TPGES were offered an open treatment period with increased stimulation (5-10 mA as tolerated). The response to permanent GES was judged by the same response definition but comparing one-year data with baseline symptom registration. Quality of life was evaluated by use of the SF36 questionnaire at baseline and after 12 months of GES therapy.
RESULTS: Twenty-eight patients (22 female (78.6%), median age 43.5 years (range 20-70)) with therapy refractory nausea and vomiting were included. Gastric emptying was normal in 17 patients (61%) and delayed in 11 (39%). Ten patients (36%) were responders after blinded TPGES and 18 were not. Six accepted an open stimulation period during which two more were responders and two were judged as responders by patient preference, both of whom had diabetes mellitus. Thus, a total of 14 patients (50%) were offered and accepted a permanent device (Table 1). After one year of GES treatment, 11 patients (79%) were still responders. Response to treatment could not be predicted by gastric emptying status, neither after TPGES ($p = .70$) nor after GES ($p = .61$). Responders to GES had a significant improvement in quality of life after one year comparing with baseline in terms of bodily pain ($p = .017$), vitality ($p = .035$), social functioning ($p = .026$), role emotional ($p = .038$), mental health ($p = .024$) and general health ($p = .017$).
Table 1. Clinical diagnosis, gastric emptying status, TPGES response and one-year response number in patients selected for permanent GES.

Diagnosis (n)	Gastroparesis	Responders TPGES (open stim)	Responders 1 year GES
Diabetes mellitus (5)	0	3 (2)	3
Idiopathic gastroparesis (3)	3	1	1
Postsurgical nausea or vomiting (7)	5	3 (1)	2
Functional dyspepsia (9)	0	5 (1)	3
Enteric dysmotility (4)	3	2	2

CONCLUSION: TPGES is a good selection tool for patients with non-established indications for GES treatment and results in a high one-year response rate. A significant improvement in quality of life after 1 year of GES therapy was also shown in the responder group.

P0451 EFFICACY OF PNEUMODILATION IN ACHALASIA AFTER FAILED HELLER MYOTOMY

C. Saleh[1,*], F. Ponds[1], M. Schijven[1], A. Smout[1], A. Bredenoord[1]

INTRODUCTION: Heller myotomy is an effective treatment for the majority of achalasia patients. However, a small proportion of patients suffers from persistent or recurrent symptoms after surgery and they are usually subsequently treated with pneumodilation (PD).
AIMS & METHODS: The efficacy of PD as secondary treatment for achalasia has scarcely been studied. This study therefore aimed to investigate the efficacy of PD as treatment for achalasia patients suffering from persistent or recurrent symptoms after Heller myotomy. 20 patients with recurrent or persistent symptoms (Eckardt score >3) after Heller myotomy were selected. Patients were treated with PD, using a graded distension protocol with balloon sizes ranging from 30 to 40 mm. After each dilation symptoms were assessed to evaluate whether a subsequent dilation with a larger balloon size was required. Patients with recurrent or persistent symptoms (Eckardt score >3) after treatment with a 40-mm balloon were identified as failures.
RESULTS: 12 patients presented with achalasia type I, 6 with achalasia type II and 2 with achalasia type III (Chicago classification). Median relapse time was 4 years after Heller myotomy (IQR: 7 years and 9 months). 3 patients were not suitable for PD; 1 patient was morbidly obese and 2 had a mega-oesophagus. 5 patients were successfully treated with one 30-mm balloon dilation (median follow-up time: 2 years; IQR: 7 years). 8 patients required dilations with 30- and 35-mm balloons (median follow-up time: 6 years; IQR: 6.5 years). 4 patients underwent 3 dilations with balloon sizes up to 40 mm, and all failed on the 40-mm balloon as well. Thus, PD was successful for 13 out of the 17 patients who could be treated, resulting in a success rate of 76% for treatable patients or 65% for all patients. Patients successfully treated with a 30-mm balloon all suffered from achalasia type I. Baseline LOS pressure (before dilation) was not different between successfully treated patients (Median: 15.0 mmHg; IQR: 11.5 mmHg) and those that failed (median: 12.5 mmHg; IQR: 6.5 mmHg) treatment ($p > 0.05$). Furthermore, baseline Eckardt scores were not predictors of successful treatment; there was no difference between successful (median: 6; IQR: 2) and failed (median: 5.5; IQR: 3.25) treatment. Baseline symptom pattern was not a predictor of successful treatment either.
CONCLUSION: Pneumodilation for recurrent symptoms after previous Heller myotomy has a success rate of 76%, using 30- and 35-mm balloons. Patients with recurrent symptoms after pneumodilation with 35-mm balloon are likely to also fail after dilation with a 40-mm balloon.

INTRODUCTION: Oesophageal high resolution manometry (HRM) is a useful tool for the detection of hiatus hernia (HH) as two high pressures zones, lower oesophageal sphincter (LOS) and crural diaphragm (CD) can be clearly identified. Two types of HH have been described in HRM, type IIIa, associated with a further decrease in LOS pressure during inspiration, and IIIb associated with an increase in LOS pressure during inspiration.
AIMS & METHODS: The aim of this study is to determine if these HRM classifications for hiatus hernia are useful in clinical practice.
39 consecutive patients with HH detected by HRM were included. HRM (Manoscan; Given) was performed in supine and analyzed according to 2012 Chicago classification criteria. HH was defined as a separation $>$ 2 cm between LOS and CD at inspiration. Upper endoscopy was performed on all patients and 24 hours pH-monitoring on 30 (76.9%) of them. Statistical analysis: U Mann Whitney; Chi-Square.
RESULTS: Clinical data, HRM and pH-monitoring results are expressed in the table. Hypotensive LOS (resting pressure $<$ 10 mmHg) was found in 42.8% HH IIIa and in 27.8% HH IIIb; oesophagogastric junction (OGJ) obstruction (IRP-4 $>$15 mmHg) at the level of the CD was found in 19.1% HH IIIa and in 16.7% IIIb ($p = 0.591$). There were no significant differences in oesophageal body motility (normal 76.2% in HH IIIa and 61.1% in HH IIIb; $p = 0.457$). Multiple water swallow test was normal in 47.4% in HH IIIa and in 75% in HH IIIb ($p = 0.055$).

	HH IIIa (n = 21)	HH III b (n = 18)	p-value
Clinical data			
Age	63.8 [57.4-70.1]	58.6 [51.8-65.3]	0.234
Sex (F)	13 (58.9%)	9 (50%)	0.455
BMI (kg/m2)	30.7 [27.9-33.5]	27.2 [25.2-29.2]	**0.037**
Abdominal perimeter (cm)	105.7 [100.8-110.6]	97.4 [91.2-103.5]	0.078
Co-morbidity	1 (4.8%)	2 (11.1)	0.873
No	20 (95.2%)	16 (88.9%)	0.424
Yes	19 (90.5%)	15 (83.3%)	0.311
Previous PPI treatment	10 (47.6)	12 (66.8%)	
Upper endoscopy	2 (9.5%)	1(5.5%)	
Normal	4 (19.1%)	4 (22.2%)	
Peptic esophagitis	2 (9.5%)	1 (5.5%)	
Barrett	1 (4.8%)		
Ring/Stenosis	2 (9.5%)		
Diverticulum			
Other (gastritis, ulcer)			
	HRM parameters		
Resting pressure (mmHg)	12.6 [8.7-16.5]	12.5 [9-12,3]	0.945
IRP-4s	8.9 [6.1-11.8]	6.7 [3.7-9.8]	0.112
OGJ total length (cm)	7.3 [6.3-8.3]	7.7[6.3-9.1]	0.791
Oesophageal length (cm)	20.5[19.4-21.7]	20.8[19-22.7]	0.813
Sac length	3.3 [2.5-4]	3.1 [2.1-4.2]	0.646
DCI (mmHg.cm.s)	1474.4 [1027.5-1921.2]	2070 [868.7-3272.7]	1
VFC (cm/s)	3.8 [2.8-4.8]	4.2[2.9-5.4]	0.626
IBP (mmHg)	18.6 [14.4-22.8]	23.1[14.9-31.3]	0.967
Distal Latency (s)	5.4 [4.8-6.1]	5.9[5.6-6.3]	0.119
	pH-monitoring result		
Abnormal	7 (43.8%)	7 (50%)	0.509
Positive symptom index	3 (18.7%)	3 (21.4%)	0.558

CONCLUSION: There were no significant differences between the two HH types in the clinical data, in upper endoscopy, HRM and pH-monitoring results although patients with HH IIIa are more obese and tend to have a more hypotensive LOS. The differentiation between both subtypes is therefore not useful for routine clinical practice.

P0453 MULTIPLE RAPID SWALLOWING IS A USEFUL COMPLEMENTARY TEST TO CORRELATE SYMPTOMS TO ESOPHAGEAL MOTILITY ABNORMALITIES

E. Savarino[1,1,*], C.de Cassan[1], F. Galeazzi[1], R. Salvador[1], E. Marabotto[2], M. Furnari[2], P. Zentilin[2], N.de Bortoli[3], S. Marchi[3], R. Bardini[1], G.C. Sturniolo[1], **V. Savarino**[2]

INTRODUCTION: Although esophageal motor disorders (EMD) are associated with non-cardiac chest pain (NCCP) and dysphagia, minimal data support a direct relationship between abnormal motor function and symptoms. Indeed, a recent study failed to observe a correlation between high-resolution manometry (HRM) metrics and symptoms during the manometric protocol. On the other hand, multiple rapid swallowing (MRS) has been recently suggested as a complementary test during HRM in order to observe abnormalities in inhibitory or excitatory esophageal mechanisms that could potentially underlie esophageal symptoms. Limited data are available on the role of MRS in eliciting NCCP or dysphagia during HRM testing.
AIMS & METHODS: We aimed to evaluate the yield of MRS to provoke esophageal symptoms in patients with normal or abnormal standard manometry. Consecutive patients with NCCP or dysphagia without previous surgery were enrolled. All patients underwent HRM as follows: after a 5-min baseline recording to locate and assess the esophago-gastric junction, the subjects took 10 single water swallows (5 mL) at 30-s intervals (standard assessment) and two MRS (one swallow every 2–3s) while 10mL of water was injected steadily into their mouths through a syringe. Symptoms reported were recorded and graded based on a 5-point Likert scale (0-4) and a 10-cm visual analogue scale (VAS). The tracings were analyzed based on Chicago Classification (CC) criteria for EMD and, further, MRS were analyzed for completeness of esophageal body inhibition and for augmentation of contraction after the last MRS swallow. Also the last swallow during MRS was classified according to the CC criteria.
RESULTS: We enrolled 31 [18M/13F; mean age 55 (35-78)] patients complaining of NCCP (n = 14) and dysphagia (n = 17) as major symptom. Fourteen (45%) patients had incomplete esophageal body inhibition, whereas 13 (42%) patients failed to increase wave amplitudes after MRS. Overall, 18 (58%) patients had abnormal MRS, with 5 (16%) of them having normal peristalsis. No patient complained of NCCP or dysphagia during standard assessment. In contrast, 9 (29%) patients reported either NCCP [n = 5; mean Likert scale 3.0 (range 2.0-4.0) and VAS scale of 7.7 (6.6-9.2)] or dysphagia [n = 4; mean Likert scale 2.8 (range 2.0-3.0) and VAS scale of 7.6 (5.2-8.8)] during at least one MRS (p = 0.0020). Among them, at standard manometric assessment, we found normal peristalsis (n = 2), Jackhammer Esophagus (n = 3), distal esophageal spam (n = 2), outflow obstruction (n = 1), and absent peristalsis (n = 1), whereas MRS resulted to be abnormal in 8 cases. Interestingly, when symptoms were reported, they were always associated with an abnormal last MRS swallow according to CC criteria (premature swallow, n = 4; rapid contraction, n = 3; hypercontractile swallow, n = 1; failed, n = 1). This was observed also in the only case with normal MRS.
CONCLUSION: MRS was a useful complementary test during HRM in order to detect esophageal motility abnormalities in patients with either normal or abnormal standard manometry. Moreover, MRS was superior to standard assessment in provoking esophageal symptoms in patients with NCCP or dysphagia and permitted to correlate them to abnormal motor function.

P0454 VALIDATION OF THE CHICAGO CLASSIFICATION FOR THE DIAGNOSES OF PRIMARY ESOPHAGEAL MOTILITY DISORDERS BASED ON OUTCOME DATA

G. Capovilla[1], R. Salvador[1], M. Costantini[1], L. Nicoletti[1], G. Zaninotto[2], **E. Savarino**[1,*]
[1]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, Italy,* [2]*Imperial College, London, United Kingdom*

INTRODUCTION: Early comparisons between 8-channel water-perfused (WP) conventional manometry and 36 pressure transducers solid-state (36-SS) high-resolution manometry (HRM) showed that high spatial resolution increases the diagnostic yield and accuracy for clinically relevant esophageal motility disorders (EMD). Thus, a new classification of EMD based on HRM findings, the Chicago Classification (CC), has been proposed. Limited data are available on the clinical impact of this classification in terms of patients' outcome.
AIMS & METHODS: We aimed to prospectively assess the clinical value of the CC comparing the diagnoses of EMD obtained by using the 36-SS and the 24-channel WP system in a group of patients with esophageal symptoms and evaluating their clinical outcome at 1-year after treating them based on 36-SS HRM findings. Diagnoses of EMD have been collected from a prospective, randomized, double blind, crossover study aimed to measure and compare normal values of conventional and high-resolution manometry metrics as well as to assess the inter-rater and inter-device agreement for the diagnoses of EMD between the 36-SS (Given Imaging, US) and the 24-WP system (EB Neuro, Italy). Twenty patients [11M/9F; 48 (43-55)] underwent both procedures blinded and in random order. Two expert reviewers (RS, ES) performed a blind analysis of the patients plots. Diagnoses based on CC were obtained. Inter-rater and inter-device agreement for each reviewer were evaluated. Then, according to CC-based diagnoses at 36-SS HRM plus impedance-pH features in case of suspected reflux disease, patients were empirically treated and followed-up for 1 year. Outcome was evaluated as positive (≥50% of symptomatic relief) or negative (<50%) based on validated disease-related questionnaires.
RESULTS: Diagnostic inter-device agreement was moderate for both reviewers [k (RS) = 0.5; k(ES) = 0.4], whereas diagnostic inter-rater agreement was higher for the 36-SS ($k = 1$) than for the 24-WP ($k = 0.68$) system. As to the outcome evaluation at 1-year, we found that 17/20 (85%) patients had a positive outcome. Among them, 7 patients had dysphagia with achalasia (type II, n = 5; type III, n = 1; type I, n = 1) and were surgically (n = 4) or endoscopically (n = 3) treated, 7 patients had reflux symptoms with normal peristalsis (NP; n = 4) or frequent failed peristalsis (FFP; n = 2) or weak peristalsis (WP; n = 1) and were surgically (n = 2, Nissen Fundoplication) or medically (n = 5, PPI plus alginate) treated, 1 patient had chest-pain with WP and was treated with PPI plus prokinetic and, finally, 2 patients had dysphagia with FFP and outflow obstruction (OO) and were treated with prokinetic and endoscopic dilatation, respectively. Out of 3/20 (15%) patients with a negative outcome, 1 had dysphagia with NP (also at 24-WP HRM) and was treated with PPI plus prokinetic, 1 had regurgitation with OO (normal peristalsis at 24-WP HRM) and was treated with PPI plus prokinetic, and 1 had chest-pain with distal esophageal spasm (FFP at 24-WP HRM) and was treated with endoscopic dilatation.
CONCLUSION: The 36-SS HRM was more accurate and reproducible than the 24-WP system for diagnosing clinically relevant EMD based on the CC. Moreover, the Chicago classification has been found greatly useful as diagnostic tool in order to obtain good outcome in patients reporting esophageal symptoms.

P0455 CLINICAL AND ENDOSCOPIC CHARACTERISTICS CAN HELP DISTINGUISH PSEUDOACHALASIA FROM ACHALASIA

F.A. Ponds[1,*], I.M. van Raath[1], A.J. Smout[1], A.J. Bredenoord[1]
[1]*Department of Gastroenterology and Hepatology, Academic Medical Centre Amsterdam, Amsterdam, Netherlands*
Contact E-mail Address: *f.a.ponds@amc.uva.nl*

INTRODUCTION: Pseudoachalasia is a condition in which clinical and manometric signs of idiopathic achalasia are mimicked by another abnormality, most often a malignancy. An underlying malignancy should be recognized early to prevent inappropriate therapeutic intervention and delay in appropriate treatment. However, clinical identification of pseudoachalasia can be challenging.
AIMS & METHODS: The aim of our study was to identify characteristics that suggest potential pseudoachalasia caused by malignancy. Patients diagnosed with achalasia by manometry were retrospectively included between 2000 - March 2014 in a single centre. Manometric criteria for achalasia were defined as aperistalsis and dysrelaxation of the lower oesophageal sphincter (LOS). Pseudoachalasia was diagnosed in patients with clinical and manometric signs of achalasia that were found to have an underlying malignancy. Clinical (Eckardt symptom score), manometric, endoscopic and radiological findings were reviewed and compared between patients with pseudoachalasia versus achalasia.
RESULTS: In total 205 patients with achalasia were included (116 male, median age 52 (39-64) (median (IQR)). Pseudoachalasia was diagnosed in 10 patients (4.9%, 8 male) and caused by oesophageal adenocarcinoma (n = 3), oesophageal

squamous cell carcinoma (n = 3), adenocarcinoma of the cardia (n = 3) or pancreatic adenocarcinoma (n = 1). The underlying malignancy was found at EUS (30%), at a second or third endoscopy with biopsies (20%) or during a treatment session (30%; 2x Heller myotomy, 1x pneumodilation). In 20% of the patients a CT-scan after achalasia treatment, performed because of quick recurrence of symptoms, eventually showed the malignancy. Patients with pseudoachalasia were older at time of diagnosis compared to achalasia patients (68 (50-72) vs 51 (38-63), $p < .05$)), had a shorter clinical history (6 (5-12) months vs 24 (11-68) months, $p < .01$) and lost more weight (12 (10-20) kg vs 6 (0-10) kg, $p < .01$). The Eckardt symptom score was higher in the group with pseudoachalasia (9 (8-10) vs 7 (6-9), $p < .05$). However when the score was corrected for weight loss no difference was seen (6 (6-7) vs 5 (5-7), $p > .05$). Manometries in both groups showed aperistalsis and dysrelaxation of the LOS, with no difference in LOS pressure (33 (19-35) mmHg vs 23 (18-32) mmHg, $p > .05$). In 80% of patients with pseudoachalasia a barium oesophagography was performed and in 75% it was suggestive of achalasia showing an enlarged diameter, narrowing of the LOS and stasis of contrast compared to 91% in idiopathic achalasia. All patients with pseudoachalasia underwent 1 or more endoscopies and in 80% the LOS was difficult or even impossible to pass. In achalasia patients the LOS was difficult to pass during endoscopy in only 22%.

CONCLUSION: Advanced age, short clinical history, considerable weight loss and difficulty in passing the LOS during endoscopy are characteristics that should arouse a higher suspicion of pseudoachalasia and warrant additional investigations. It is not possible to distinguish pseudoachalasia from achalasia with the conventional diagnostics used for achalasia such as manometry and barium oesophagography.

INTRODUCTION: A validated instrument to assess severity of eosinophilic esophagitis (EoE) in clinical trials and observational studies is urgently needed. The international Eosinophilic Esophagitis Activity Index (EEsAI) study group is currently developing an activity index for adult EoE patients. Three instruments have been developed to assess endoscopic, histologic, and clinical EoE activity.

AIMS & METHODS: We aimed to develop instruments that assess endoscopic and histologic findings and the corresponding score based on the items that best explain the variability in the physician global assessment (PGA) of EoE severity. To assess whether items of the patient-reported outcomes (PRO) instrument, which is designed to assess symptom severity, also help to explain the variability of the PGA. We sought input from the experts and patients to generate the item list to be included into 3 different instruments. Physicians provided PGA that took into account symptoms, endoscopy, and histology and was assessed on a Likert scale from 0 to 10. Using the physician instrument, severity of EoE-associated endoscopic features including white exudates, rings, edema, furrows, and strictures was graded. Severity of EoE-associated histologic findings including peak eosinophil counts, eosinophil abscesses, basal layer enlargement, and subepithelial fibrosis was assessed by the means of histopathology instrument. The dysphagia characteristics and behavioral adaptations associated with consumption of foods of different consistencies, among others, were assessed using the PRO instrument. Linear regression and analysis of variance (ANOVA) was used to evaluate the extent to which variations in the severity of EoE-associated endoscopic and histologic features explain the variability in PGA. ANOVA was used to examine the extent to which variations in symptom severity help to explain the variability in PGA over and above variations in severity of endoscopic and histologic features.

RESULTS: The physician, histopathology, and PRO instruments were evaluated in 153 adult EoE patients (72.5 % males, median age 38 years) recruited in Switzerland and in the United States. Variations in severity of endoscopic features including white exudates, rings, edema, furrows, and strictures explained 52 % of the PGA variability. Variations in severity of histologic features including the peak esophageal eosinophil numbers and eosinophilic microabscesses explained additional 9 % of the variability in PGA. Variations in symptom severity (7 items of the PRO module recalled over the last 7 days) explained an additional 10 % of the variability in PGA.

CONCLUSION: The variations in severity of EoE-associated endoscopic and histologic features explained most variability in physician global assessment of EoE severity (total of 61 %).

P0457 DIETARY TREATMENTS FOR INDUCING REMISSION OF EOSINOPHILIC ESOPHAGITIS. A SYSTEMATIC REVIEW AND META-ANALYSIS

A.J. Lucendo[1,*], Á. Arias[2], J. González-Cervera[3], J.M. Tenias[2]

[1]Gastroenterology, Hospital General de Tomelloso, Tomelloso, [2]Research Support Unit, Hospital General La Mancha Centro, Alcázar de San Juan, [3]Allergy, Hospital General de Tomelloso, Tomelloso, Spain

Contact E-mail Address: *alucendo@vodafone.es*

INTRODUCTION: Eosinophilic esophagitis (EoE) is a chronic esophageal immune/allergy-mediated disorder, which represents a distinctive form of food-allergy. Various dietary interventions have been used to treat patients with EoE, yielding varied results.

AIMS & METHODS: This systematic review assesses the efficacy of different dietary therapies in inducing disease remission of EoE in adult and pediatric patients with the disease.

A systematic search was performed in MEDLINE, EMBASE, and SCOPUS for studies investigating the efficacy of various dietary interventions in inducing remission (< 15 eosinophils/hpf) of inflammatory infiltration as observed in esophageal biopsies from both pediatric and adult EoE patients. Summary estimates, including 95% confidence intervals (95% CI), were calculated for exclusive feeding with amino acid-based elemental formulas, allergy testing-directed food elimination diets, and six-food elimination diets (SFED). A fixed or random effects model was used depending on heterogeneity (I^2); publication bias risks were assessed by means of funnel plot analysis.

RESULTS: The search yielded 578 references, of which 30 were included in the quantitative summary. All told, the studies described 1,285 EoE patients (1,124 children and 161 adults) undergoing different dietary treatments. Elemental diets were effective in 90.4% of cases (95% IC: 84.7–95.5%, I^2: 2.3%), SFED in 73% (66.6–78.9%; I^2: 0%), and allergy testing-directed food elimination induced remission in 46.3% of cases (35.6–57.1%; I^2: 7 6.4%). Additional dietary therapy strategies (elimination of cow's milk and gluten-free diets) were also evaluated. Overall, no significant differences in remission rates were documented between children and adults (67.4% *vs.* 71.5%).

CONCLUSION: Dietary treatment is effective in achieving histological remission in patients with EoE. Elemental diets and SFEDs were the most consistent alternatives, achieving < 15 eosinophils/hpf in 90.4 and 73% of treated patients, respectively.

INTRODUCTION: Eosinophilic esophagitis (EoE) is a rare disorder and is reported to be associated with concurrent allergic disorders. In this study, we aimed to evaluate the prevalance EoE in patients with allergic rhinitis and to assess clinical features in those patients having EoE.

AIMS & METHODS: Patients with allergic rhinitis were questioned with respect to esophageal and gastric symptoms (i.e., epigastric pain, gastroesophageal reflux (GER), dysphagia), and underwent upper gastrointestinal (GI) endoscopy and serum IgE level measurement. Multiple tissue samples were taken from the upper, middle and lower esophagus, gastric corpus and antrum, and duodenum during upper GI endoscopy. EoE was defined as the presence of eosinophilic

P0457

Dietary Treatment		Overall effect	N	Children	N	Adult	N
All		67.9% (57.9% – 77.1%)	42	67.4% (55.9% - 78%)	34	71.5% (53.3% - 86.7%)	6
Elemental diets		90.8% (84.7% - 95.5%)	13	90.4% (83.5% - 95.5%)	12	94.4% (17/18)	1
Allergy testing-direct elimination diets		46.3% (35.6% - 57.1%)	13	47.9% (36.8% - 59.1%)	12	26.6 (4/15)	1
SFED		73% (66.6% - 78.9%)	6	72.8% (62.5% - 82%)	4	73.1% (64.8% - 80.7%)	2
Gluten-free diet		52.2% (15.3% - 87.8%)	6	45.5% (2.6% - 93.8%)	4	100% (1/1)	1
Milk elimination diet		68.2% (47.8% - 85.6%)	3	66.6% (44.7% - 84.8%)	2	100% (1/1)	1
Subgroups according to quality	**Medium/High - High**	69.8% (58.4% - 80.1%)	32	70.3% (56.5% - 82.4%)	26	70.6% (51.1% - 86.8%)	5
	Low – Medium/Low	60.6% (35.3% - 83.1%)	10	58.5% (32.2% - 82.3%)	9	100% (1/1)	1

infiltration in the squamous epithelium of the esophagus (eosinophil number ≥15/HPF for patients using PPI and ≥20/HPF for patients not using PPI) and the absence of eosinophilic infiltration in corpus, antrum and duodenum. Reexamination with upper GI endoscopy was performed after a 2-month proton pump inhibitor (PPI) therapy. Allergy test results were recorded. Symptoms, serum IgE levels, allergy test positivity, *Helicobacter pylori* positivity, endoscopic findings and histologic findings were compared between patients with EoE and those without EoE.
RESULTS: Sixty seven patients were included in the study. Of them, 15 were male. Mean age of male and female patients were similar (p = 0.129). Histopathological diagnosis of EoE was made in 7 patients (10.4%) and none of them had a history of PPI usage prior to diagnosis. Symptoms of GER and dysphagia were present in 71.4% and 28.57% of patients with EoE, while they were present in 28.30% and 1.67% of those without EoE. In patients with histologically proven EoE (n = 7), 4 had endoscopic findings compatible with EoE (57%), 2 had grade A reflux esophagitis (28.6%) and 1 had normal endoscopic findings. In patients without EoE (n = 60), 1 had endoscopic findings compatible with EoE and 3 had grade A reflux esophagitis. All patients with EoE had eosinophil number ≥20/HPF in tissue samples from upper and middle portion of the esophagus. Serum IgE levels were significantly higher in patients with EoE than in those without EoE (281.59±204.12 vs 105.75±161.6) (p = 0.013). *H. pylori* positivity were similar (p = 0.816). Allergy test positivity was 85.7% in patients with EoE and 50% in those without EoE.
CONCLUSION: GER is the most common symptom in patients with EoE.
EoE may be present even in patients with normal endoscopic findings
Serum IgE levels are higher and allergy test positivity are more common in patients with allergic rhinitis and EoE.
EoE is common in patients with allergic rhinitis.
It is important to question patients with respect to EoE symptoms in patients with allergic rhinitis and high serum IgE levels, especially when corticosteroid therapy is considered.

P0459 CLINICAL AND HIGH RESOLUTION MANOMETRY DATA SUPPORT THE HYPOTHESIS THAT PROTON PUMP INHIBITOR-RESPONSIVE ESOPHAGEAL EOSINOPHILIA REPRESENT A GERD-RELATED PHENOMENON

O. Bartolo[1], C.de Cassan[1], R. Caccaro[1], F. Galeazzi[1], T. Morbin[1], S. Tolone[1], R. Salvador[1], G.C. Sturniolo[1], M. Costantini[1], **E. Savarino**[1,*]
[1]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, Italy*

INTRODUCTION: Eosinophilic esophagitis (EoE) and Proton Pump Inhibitor-response esophageal eosinophilia (PPI-REE) present similar phenotypic appearance, similar histopathology but different response to antisecretory therapy. Thus, it is unclear if PPI-REE is a gastro-esophageal reflux disease (GERD)-related phenomenon, a subtype of EoE, or a completely unique entity. High resolution manometry (HRM) is a novel technique that has been recently shown to provide new insights on GERD pathogenesis. In particular, esophago-gastric junction (EGJ) morphology different from type I and weak peristalsis have been strongly associated with GERD.
AIMS & METHODS: We aimed to compare HRM features of patients with EoE and PPI-REE. Consecutive patients with symptoms suggestive of EoE underwent upper endoscopy in order to assess the presence of at least 15 eos/hpf on oesophageal biopsies at mid/proximal esophagus and, then, were treated with twice-daily PPI for at least 8 weeks. Thereafter, patients repeated upper endoscopy and were stratified into two groups: EoE, in case of persistence of at least 15 eos/hpf on oesophageal biopsies, and PPI-REE, in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients underwent also HRM with a 5-min baseline recording to assess the EGJ and 10 single water swallows (5 mL) at 30-s intervals to evaluate the esophageal peristalsis. Tracings were analyzed based on Chicago Classification and each EGJ was classified as: Type I, no separation between the Lower Esophageal Sphincter and the Crural Diaphragm; Type II, minimal separation (>1 and <2 cm); Type III, >2 cm of separation.
RESULTS: Thirty-one patients were identified as having EoE [24M/7F; mean age 28 (18-75)], whereas 10 patients were diagnosed with PPI-REE [9M/1F; mean age 38 (20-64)]. The two cohorts had similar dysphagia for solids (EoE 71% vs. PPI-REE 66%, p = 0.6979), bolus impaction (65% vs. 60%, p = 1.000) and chest-pain (23% vs. 20%, p = 1.000), but different heartburn (26% vs. 60%, p = 0.0485) and regurgitation (16% vs. 50%, p = 0.0446). Endoscopic features had the same frequency between EoE and PPI-REE: rings (45% vs. 50%, p = 1.000), furrows (26% vs. 10%, p = 0.4101) and plaques (23% vs. 40%, p = 0.4132). Esophageal strictures tended to be more frequent in EoE (52% vs. 10%, p = 0.0592). At HRM testing, EoE patients had higher mean integrated relaxation pressure [9 (2-16) vs. 6 (2-16), p = 0.0616] and LES basal pressure [26 (10-54) vs. 17 (1-34), p = 0.0388], but similar mean distal contraction integral [1094 (522-2653) vs. 1763 (483-5281), p = 0.5613] compared to patients with PPI-REE. Type II and III EGJs were less common in EoE than in PPI-REE patients (9% vs. 50%, p = 0.0129). Manometric diagnoses were similar between EoE and PPI-REE: weak peristalsis including large or small breaks and frequent failed peristalsis (16% vs. 40%, p = 0.2221), absent peristalsis (3% vs. 10%, p = 1.0000) and distal esophageal spasm (3% vs. 0%, p = 1.0000).
CONCLUSION: Typical reflux symptoms and HRM features GERD-related are more common in patients with PPI-REE than in patients with EoE. These data support the hypothesis that PPI-REE may represent a GERD-related phenomenon rather than a subtype of EoE or a separate entity. Further larger studies are needed to confirm these findings.

Contact E-mail Address: *xavi_molina@hotmail.com*

INTRODUCTION: Proton pump inhibitor-responsive esophageal eosinophilia (PPI-REE) is diagnosed in at least a third of patients with a phenotype suggestive of eosinophilic esophagitis (EoE). However, neither long-term response to PPI therapy in PPI-REE patients nor influencing factors have been evaluated yet.
AIMS & METHODS: We aimed to determine the long-term efficacy of PPI therapy in PPI-REE and its association to *CYP2C19* genotype status. Retrospective multicenter study in PPI-REE adult patients, defined by consensus guidelines. After a diagnosis of PPI-REE, PPI therapy was tapered and maintained at the lowest dose with the target endpoint of clinical remission. Histological remission was defined by < 15 eos/HPF. Follow-up endoscopy was performed at 12 months or longer on PPI maintenance dose. *CYP2C19*2* and *CYP2C19*17* were determined from blood samples in Spanish patients.
RESULTS: 46 PPI-REE patients were included (mean follow-up time: 27 months (12-79)). While on clinical remission on low-dose PPI therapy, 34/46 (74%) had sustained histologic remission (19 double-dose PPI, 21 single-dose PPI). In 8/12 relapsers (66%) on maintenance PPIs, esophageal eosinophilia recurred exclusively at the distal esophagus. Compared to patients with sustained PPI-response (n = 13), this subset of distal relapsers showed borderline significant higher rates of *CYP2C19*2* rapid metabolizer genotype (100% *vs.* 53%, P 0.07) and reflux esophagitis at baseline (50% vs. 0%, P 0.08). All distal relapsers re-achieved histological remission after PPI-dose intensification (omeprazole 40 mg bid).
CONCLUSION: 74% of adult PPI-REE patients had persistent clinico-histological remission on low-dose maintenance PPI therapy. While on clinical remission, two thirds of relapsers showed eosinophilic inflammation limited to the distal esophagus. Baseline reflux esophagitis and a CYP2C19 rapid metabolizer genotype were associated to this relapsing pattern and histological remission was re-achieved after PPI-dose intensification in all patients.

INTRODUCTION: Esophagoscopy with biopsy is considered the only method for diagnosis and monitoring EoE. Therefore it is important to find out less invasive diagnostic methods. Regarding this issue, obtaining oesophageal cytology is a way to explore to design in the future devices that allow to obtain samples without endoscopy and biopsy. The aim of the study was to analyze the accuracy of liquid-based cytology (LC) of the esophagus in the diagnosis and monitoring EoE histological activity.
AIMS & METHODS: LC specimens were obtained in patients with active EoE (AEoE) (≥15 eo/hpf) and EoE in remission (EoER) (<15 eo/hpf) by oesophageal aspirate samples collected after instillation of 50 cc of saline solution suctioned by bronchioalveolar lavage system adapted to the gastroscope. The samples were collected in Cytolyt solution (Hologic), obtaining Papanicolaou and May-Grünwald/Giemsa that were assessed by two independent pathologists. EoE specimens were compared with LC obtained from patients with GERD.
RESULTS: Specimens of 36 patients (69.4% male, mean age 30.88 years) were included. AEoE (17, 47.2%), EoER (11, 30.5%) and GERD (8, 22.2%). Eo / hpf proximal oesophageal biopsies (AEoE 28.58 vs EoER 2.09 vs GERD 1.25, p < 0.001) and distal (AEoE 23.33 vs EoER 2.36 vs GERD 2.50, p = 0.002). LC Eo/hpf (AEoE 9.23 vs EoER 1.54 vs GERD 2, p = 0.01). Linear correlation between Eo/hpf average biopsy and LC Eo/hpf: r = 0.57, p < 0.001. For diagnosis of EoE, ≥ 3 Eo/hpf in LC obtained a Sensitivity 70%, specificity 81%, PPV 86% and NPV 60% (AUC = 0.81, p = 0.01). For detection of AEoE, ≥ 3 Eo/hpf in LC obtained a sensitivity 70%, specificity 82%, PPV 81% and NPV 66% (AUC = 0.87, p = 0.001).
CONCLUSION: LC in oesophageal aspirate obtained by a cutoff in 3 eo/hpf seems to be effective for the diagnosis and monitoring activity in EoE. These results open the door to the development of non endoscopic devices that allow us the diagnosis and monitoring of disease noninvasively.

INTRODUCTION: Esophagoscopy with biopsies is considered the gold standard for diagnosis and monitoring EoE. This is due to lack of correlation between histology, endoscopy and clinical manifestations of the disease. A novel endoscopic classification for assessment of eosinophilic esophagitis (EoE) activity has been recently proposed (EREFs). We aimed to address the correlation of clinical and endoscopic EoE activity scores with histological response after different therapeutic interventions.
AIMS & METHODS: Spanish multicenter prospective study in consecutive patients with EoE, according to consensus guidelines. Clinical (Dysphagia Symptom Score (DSS) Scale) and endoscopic (EREFS) disease activity, along with eosinophil peak count, were assesed at baseline and after topical steroids or elimination diet, including food reintroductions. Histological remission was defined by < 10 eos/HPF at both distal and proximal esophagus. Patients were subclassified: Group A (Baseline), Group B (No histological remission after therapy/food reintroduction) and Group C (Histological remission after therapy/food reintroduction).
RESULTS: 79 patients undergoing 128 upper endoscopies have been included so far (77.2% male, age 34.7 years-old, dysphagia 100%). Group A: 47 (36.7%), Group B: 61 (47.7%) and Group C: 20 (15.6%). DSS score was significantly higher in Group A (A = 7.16, B = 5.15, C = 3.70; p = 0.006), but no differences were observed between groups B and C (p = 0.12). Regarding endoscopic findings, inflammatory features were significantly decreased after histological remission (furrows: A = 63.8%, B = 72.1%, C = 40%; p = 0.034 / exudates (grade 2): A = 10.6%, B = 18%, C = 5%;p = 0.002), but not fibrostenotic features (pseudorings: A = 68.1%, B = 55.4%, C = 55%;p = 0.44/stricture: A = 10.6%, B = 9.8%, C = 5%;p = 0.75). Mucosal edema was common at baseline and persistent regardless of histological remission (A = 61.7%, B = 78.7%, C = 60%; p = 0.09).
CONCLUSION: EoE clinical activity significantly decreased after different therapeutic interventions, with no differences between patients showing eosinophilia remission or persistence after therapy. Histological remission was correlated with significant decrease of inflammatory endoscopic features, but not of fibrostenotic findings. Mucosal edema was mostly persistent regardless of histological remission, suggesting it might belong to the fibrotic remodelling spectrum.

P0463 IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE, GLOBUS IS ASSOCIATED WITH ABNORMAL OROPHARYNGEAL ACID EXPOSURE

M. Di Stefano[1], **C. Mengoli**[1,*], M. Bergonzi[1], E. Pagani[1], E. Miceli[1], G.R. Corazza[1]
[1]*1st Department of Internal Medicine, IRCCC Policlinico S. Matteo, University of Pavia, Pavia, Italy*

INTRODUCTION: Globus, a persistent or intermittent non-painful sensation of a lump or foreign body in the throat, is frequently associated with gastroesophageal reflux disease (GERD): it is estimated that up to 68% of GERD patients suffer from globus. However, previous esophageal pH and pH-impedance studies failed to define a causative role of acid or non-acid reflux in globus pathophysiology.
AIMS & METHODS: The aim of this study was to investigate both distal and proximal, oropharyngeal acid exposure, with a new device, in patients with non-erosive reflux disease (NERD) with and without globus.
A group of 37 patients affected by NERD was enrolled. The presence of reflux symptoms was evaluated and severity was graduated by VAS. In eight patients, globus was the main symptom; in the other 29, globus was not present and they were thus considered the control group. Patients underwent standard stationary esophageal manometry (6 channels+sleeve) and 24-hr pH-impedance esophageal monitoring (Sleuth, Sandhill Scientific) combined with 24-hr oropharyngeal pH monitoring (Restech Dx-pH Measurement System).
RESULTS: Distal esophageal acid exposure (pH <4), number of acidic and weakly acidic reflux episodes and proximal extension of refluxate were similar between patients with and without globus. On the contrary, patients with globus showed a significantly longer oropharyngeal exposure to pH < 5.5 (total duration of acid exposure: 222 min ± 230 min vs 47 min ± 88 min, p < 0.05; and percent of recording: 16.07±16.2% vs 3.56±6.84%, p < 0.05), compared to patients without globus; the longest episode of oropharyngeal acid exposure was significantly longer in patients with globus than in patients without globus (110 min ± 115 min vs 15 min ± 25 min; p < 0.05). A higher score for heartburn was evident in the group of patients without globus (3.45±3.31 vs 1.31±1.44, p < 0.05); no difference was found in regurgitation, cough, sore throat, or thoracic pain score. Finally, the prevalence of esophageal motor disorders was similar in the two groups.
CONCLUSION: Oropharyngeal acid exposure could have an important pathophysiological role in globus onset. Oropharyngeal pH monitoring seems a more accurate diagnostic tool than the standard 24-hr pH-impedance study to define the role of acid exposure in this subgroup of patients.

INTRODUCTION: Non-response to proton pump inhibitor (PPI) therapy in patients with reflux symptoms and a normal gastroscopy remains a challenge. Impedance-pH (MII-pH) monitoring clarifies the symptom profile and evaluates patients objectively for acid reflux (AR) and non-acid reflux (NAR).
AIMS & METHODS: To study MII-pH characteristics in patients referred for GERD evaluation who remain symptomatic despite PPIs, and study mechanisms related to persistent symptoms. Methods: Between January 2009-December 2013, consecutive patients with typical symptoms (group 1); atypical symptoms (group 2) and non-cardiac chest pain (NCCP, group 3) underwent 24 hour MII-pH after PPI washout. Prevalence of (i) oesophageal acid exposure time (AET) > 4.2%; (ii) bolus exposure (BE > 1.4%), (iii) high reflux numbers (> 73) and/or (iv) positive symptom marker based symptom index (SI ≥50%) and/or symptom association probability (SAP ≥95%) for AR or NAR events was compared between groups by chi-square and student t-testing.
RESULTS: 208 patients (80M, mean age 45.9 ± 12.5) were studied (Table 1). Elevated AET occurred in 24 (11.5%). 120 (57.7%) recorded a positive study on MII-pH evaluation despite a normal overall AET. Group 1 and 3 patients had significantly more symptomatic AR events (p < 0.05) compared to group 2. Symptomatic NAR related events did not differ significantly different between groups. Patients with a positive symptom association for AR events were more likely to have abnormal BE (p = 0.01) and abnormal reflux numbers (p < 0.05). Table 1.
CONCLUSION: Use of MII-pH in PPI non-responders identifies AR and NAR events and serves as an important diagnostic modality to evaluate the symptom profile and guide appropriate therapy, which may extend beyond PPIs.

INTRODUCTION: Esophageal baseline impedance (BI) may be considered as an indirect way to express macroscopic and/or microscopic mucosal integrity since recent evidence has shown that patients with both erosive or non erosive esophagitis have lower level of BI than healthy subjects.
AIMS & METHODS: The aim of our study was to evaluate how BI is transiently influenced by the nature of reflux events.
We studied 60 patients (28 M - mean age 45.8 ± 16.1) with typical GERD-symptoms (heartburn and regurgitation) and negative endoscopy, who performed a 24h-pH impedance monitoring from January to March 2014. Among these, 33 exams were performed on therapy with proton pump inhibitor, while 27 were off-therapy. For each patient, 24 hours esophageal BI was calculated during the first period of 60 seconds without an impedance event (swallow or reflux) every four hours. Then, we calculated BI immediately before and 1 minute after the end of the same reflux event. Pre and post-reflux BI for acid and non acid were calculated in off and on-therapy patients, respectively. Moreover, for each reflux episode, the minimum pH reached was also registered.
RESULTS: 24 hours BI and pre-reflux BI were similar for both acid and non acid events (2422±641 vs 2424±758mΩ and 2386±497 vs 2384±639 mΩ, respectively, all p = NS). On the contrary, a significant reduction between pre and post-reflux BI for acid and a significant increase was registered for non acid reflux (2424±758 vs 2130±721 mΩ, p = 0.001 and 2384±640 vs 2767±489 mΩ, p = 0.004, respectively). The same results were observed in the subgroups of subjects off and on therapy (Off-therapy: 2330±766 vs 2083±684 mΩ, $p < 0.01$; On therapy: 2187±478 mΩ vs 2713±503 mΩ, $p < 0.01$, respectively).
Most interestingly differences between pre and post-reflux BI of all patients were positively correlated to the pH nadir of each reflux event ($p < 0.0001$, $r^2 = 0.42$).
CONCLUSION: Baseline impedance may be transiently influenced by the nature of reflux episodes, being acid and non-acid refluxes respectively associated with a decrease and an increase of baseline impedance. Our data indicate that nature of refluxes is able to differently affect BI, likely, if this phenomenon underlies changes in mucosal integrity or it is associate with abnormal perception deserves further investigation.

INTRODUCTION: Patients with untreated celiac disease (CD) often complain of reflux symptoms, which in 30% of cases are considered moderate to severe (CGH 2011; 9: 214-9). The gluten-free diet leads to a rapid and persistent improvement in reflux symptoms and most cases do not require the use of proton pump inhibitors. The mechanisms involved in the expression of reflux symptoms in CD patients are unknown.
AIMS & METHODS: Objective: We explored symptomatic and mucosal markers of permeability of the lower esophagus in patients with newly diagnosed CD at the time of diagnostic endoscopy, patients with symptoms of GERD but no CD (GERD controls) and healthy controls without symptoms (healthy controls: HC).
Methods: A cohort of 23 consecutive patients with active CD at the time of diagnosis, 5 GERD control patients, and 11 HC subjects, were enrolled in the study. Nine out of 23 CD patients had GERD symptoms considered as moderate or severe (>2 points in the GSRS questionnaire). Endoscopic biopsies from the distal esophagus were obtained 2 cm above the z-line. Samples were assessed for histological damage, dilated intercellular space (DIS) scores by optical microscopy (OM) and electron microscopy (EM), and tight junction (TJ) mRNA expression for zonnula occludens-1 (ZO-1) and claudin-2 and -3 (CL-2; CL-3) using Real Time qRT-PCR.
RESULTS: Patients with active CD had increased DIS scores compared to HC subjects (OM: 8.0±3.1 vs. 2.2±2.5; $p < 0.003$ and EM: 31.7±9.5 vs. 15.0±5.1; $p < 0.04$) but similar to GERD controls. CD patients without GERD symptoms also had higher DIS scores compared to HC (OM: $p < 0.006$; EM: $p < 0.03$) but similar to those in CD patients with GERD symptoms. Overall CD patients had lower expression of ZO-1 than HC (CD patients with and without GERD symptoms: $p < 0.003$ and $p > 0.05$; respectively). A non-statistical trend for higher CL-2 and CL-3 expression was observed in CD patients compared with GERD controls and no differences were detected between CD subgroups with or without GERD symptoms. CD patients had similar expression of CL-2 and CL-3 compared to HC.
CONCLUSION: Our study suggests an impairment of mucosal permeability in the distal esophagus of patients with active CD irrespective of the presence of GERD symptoms. The altered expression of ZO-1, and CL-2 and CL-3 may underlie loss of TJ integrity in the esophageal mucosa, an expression pattern that is reminiscent of intestinal permeability abnormalities observed in CD, and that may contribute to reflux symptom expression and its reversion by the gluten-free diet.

P0467 RECEPTOR MODULATION AND MAP-KINASE SIGNALING INDUCED BY STW5 AND BY THE PROTON-PUMP INHIBITOR OMEPRAZOL IN A RAT MODEL FOR GASTROESOPHAGEAL REFLUX DISEASE AND IN HET1A-CELLS

INTRODUCTION: We had earlier demonstrated that STW5 affects multiple chemokine families on genome and proteome level reducing inflammation in the esophageal tissue in our rat model for gastroesophageal reflux disease (GERD)[1].
AIMS & METHODS: Here we investigated selected receptors and which signaling cascades are activated during the anti-inflammatory processes by STW5 and by the proton-pump inhibitor Omeprazole (O). **Methods:** Rats were pretreated with either STW5 (0.5 or 2ml/kg) or O (30mg/kg). Esophagitis was induced surgically followed by a further 10d treatment. On day 10 animals were sacrificed and whole cell lysates of the esophagi were evaluated by Western Blot analysis for the receptors GPR 84 and LOX-1 (lectin-like oxidized low density lipoprotein receptor 1) and the stress induced mitogen activated kinase (MAPK) p38. Further investigations were undertaken with the human esophageal squamous cell line HET-1A. Inflammation was induced with Capsaicin (50µM, 18hrs) and cells were treated with either STW5 (0.17; 0.5; 1.7; 5µl/ml) or O (10µg/ml; 30µg/ml). MAPKs p38, ERK1 and 2 were determined. Data were normalized either with the respected unphosphorylated protein or with ß-Actin.
RESULTS: The LOX-1 receptor was only detected in the esophagi of rats with esophagitis, but not in the esophagi of sham operated or treated rats. The GPR 84 receptor was increased in the esophagitis group compared to the sham group and down regulated by STW5 and O. In the sham group neither total p38 MAPK nor the phosphorylation of p38 was increased. The treatment of STW5 inhibited the phosphorylation of p38 MAPK in the tissue, but did not influence the increase in the total amount of p38 of the esophagitis group. In HET1A cells capsaicin slightly increased the expression of GPR84 which was reduced by the high concentration of STW5. Capsaicin induced an increase in the phosphorylation of ERK1/2 compared to the control. This increase was inhibited in the presence of STW5 as well as in the presence of O.
CONCLUSION: The LOX-1 and the GPR 84 receptor activation contribute to experimental GERD. They are targeted like P38, which is known to be acid sensitive in GERD[2], by STW5. Data further substantiate differential MAPKinase signaling in GERD. They support the classification of GPR84 as proinflammatory receptor with a link to the immune response in oesophageal tissue.

INTRODUCTION: Up to 70% of patients with gastro-esophageal reflux disease do not have erosions visible in conventional endoscopy. They are classified as non-erosive reflux disease (NERD). Studies on endoscopy with optical magnification described a variety of minimal changes in NERD patients, also concerning vessels. Until now it is not clear why some patient develop erosions and others do not. Differences in self-defense mechanisms may matter. Vascular endothelial growth factor (VEGF) is a signal protein working through its receptor (VEGFR) promoting angiogenesis and wound healing.
AIMS & METHODS: We evaluated squamous epithelium above Z line in magnification up to 105 times in 20 patients with NERD, 12 patients with erosive esophagitis (EE) and 5 controls (patients without reflux disease). The magnified images were analyzed with respect to: visibility of palisade blood vessels, appearance of intrapapillary capillary loops (IPCLs) and white points seen as whitish pinpoint spots encirculating IPCLs or independent from IPCLs. Biopsy specimens for the histopathologic examination were taken 1-2 cm above Z line. In histology presence of inflammation was evaluated in a scale from 0 (absent) to 3 (severe). Expression of VEGF and VEGFR in squamous epithelium was

evaluated by immunohistochemistry method. The reaction of VEGF and VEGFR proteins was defined as low if positive in less than 33% of vessels, moderate if positive in 33-66% of vessels and high if positive in over 66% of vessels. Statistics was executed with Fisher exact test.
RESULTS: Expression of VEGF and VEGFR was significantly higher in EE than NERD group ($p < 0.05$). Control group had comparatively low expression of VEGF and VEGFR.

Number of patients	VEGF expression			VEGFR expression		
	Low *	Moderate	High *	Low **	Moderate	High **
EE	0 (0%)	5 (42%)	7 (58%)	1(8.3%)	4 (33.3%)	7(58.3%)
NERD	8 (40%)	8 (40%)	4 (20%)	11 (55%)	5 (25%)	4 (20%)
Controls	2 (40%)	3 (60%)	0 (0%)	3 (60%)	1 (20%)	1 (20%)

Enlarged IPCLs, white points or diminished visibility of palisade vessels seen in magnification endoscopy did not correlate with expression of VEGF and VEGFR, neither did the grade of esophagitis evaluated in plain histology.
CONCLUSION: VEGF and VEGFR expression is higher in EE than NERD patients. This phenomenon may be the part of esophageal mucosa healing in EE.

INTRODUCTION: Epidermal growth factor (EGF) and its receptor (EGFR), a tyrosine kinases receptors (TKs), are associated with epithelial proliferation and restitution, the two key mechanisms involved in oesophageal epithelial defense against reflux. It has been shown that EGFR expression increases with the progression from gastro-oesophageal reflux disease (GORD) to Barrett's oesophagus/adenocarcinoma. Systemic sclerosis (SSc) is characterized by deposition of collagen and other extracellular matrix proteins in the connective tissues, imbalance of the immune system, and microvasculature abnormalities. Besides TKs physiological roles, they are key players in various diseases, including SSc. Indeed, their pathological activation may drive carcinogenesis, vascular remodelling, and fibrogenesis. No studies investigated the EGFR expression on oesophageal mucosa of SSc patients.
AIMS & METHODS: We aimed to assess and compare the presence of EGFR expression on oesophageal mucosa of GORD and SSc patients. We studied 24 SSc (22F, median age 56yrs) and 22 GORD (9F, median age 64yrs) patients. They underwent upper endoscopy and multiple specimens ($n = 4$) were taken from the distal oesophagus (at the Z-line and 2 cm above it). Biopsies were fixed in formalin and embedded in paraffin. After preparation, anti-human EGFR monoclonal antibody, clone H11 (anti-EGFR) (Dako), was applied to the slides and EGFR expression was considered positive when staining was detected on the membrane. Patients were endoscopically classified as having erosive oesophagitis (EO), non-erosive reflux disease (NERD, in case of no mucosal breaks and GORD symptoms) or negative endoscopy (NE, in case of no mucosal breaks and absence of GORD symptoms). Microscopic oesophagitis (MO) was diagnosed by using a previously validated score.
RESULTS: At endoscopic evaluation, 3/24 (13%) SSc patients had EO, 11/24 (46%) had NERD and 10/24 (42%) had NE, whereas at microscopic evaluation 3 had evidence of erosive oesophagitis, 11 of MO and 10 of normal mucosa, respectively. Among GORD patients, we found at endoscopic and microscopic evaluation that 3/22 (14%) had EO with histological reply of 2 erosive oesophagitis and 1 MO, 12/22 (55%) had NERD with evidence of MO and 7/22 (31%) had normal findings at both measurements. Overall comparison of EGFR expression between SSc and GORD patients was not significant, whereas comparison of EGFR expression between the 10/24 SSc and 7/22 GORD patients without endoscopic and histological alterations was statistically significant ($p = 0.0068$). EGFR expression between the 14/24 SSc patients with erosive and microscopic oesophagitis was higher than in the 10/24 with normal mucosa ($p = 0.0177$) as well as in GORD patients with and without oesophagitis ($p = 0.0004$). In GORD patients EGFR expression decreases proximally, while in SSc patients it seems overexpressed.
CONCLUSION: In GORD patients, EGFR expression correlates with histological findings and seems to play a major role in maintaining epithelial integrity. In SSc patients, it is overexpressed and this can act as an inflammatory reactive stimulus, even in the absence of microscopic lesions.

P0470 ACID INFUSION INTO THE STOMACH DOES NOT AFFECT THE NUMBER OF MEAL-INDUCED TRANSIENT LOWER ESOPHAGEAL SPHINCTER RELAXATIONS (TLESR)

P. Banovcin[1,*], J. Halicka[1], M. Halickova[1], J. Androvic[1], M. Duricek[1], R. Hyrdel[1], M. Tatar[1], M. Kollarik[1,2]

INTRODUCTION: TLESRs are considered to be the most important mechanism of gastroesophageal reflux (GER). However, the regulation of TLESRs by acid is incompletely understood. We have recently reported that acid in the esophagus enhanced TLESR (Abstract Tu1868, Digestive Diseases Week, Gastroenterology Vol. 146[2014] suppl.). Specifically, we found that the acid infusion into the esophagus increased the number of meal-induced TLESRs by 60% compared to control infusion.
AIMS & METHODS: In the present study we evaluated the effect of acid infusion into the stomach on the meal-induced TLESRs. The study was carried out in healthy subjects (age 23 ± 0.3 years) None of the subjects had any esophageal motility abnormality as defined by Chicago criteria. TLESRs were evaluated by using high resolution manometry (HRM). The study was performed in sitting position. For infusions a tube (O. D. 1mm) was attached to the HRM catheter with the opening positioned in the stomach at least 5 cm below the manometrically identified lower esophageal sphincter. Each subject was studied at two occasions (control or acid infusion) separated by at least 7 days. Following a standard meal (chicken sandwich and soda drink), acid (0.15 M HCl) or water was infused into the stomach (8ml/min, 20 min) by using a perfusion pump. TLESRs were counted during 2h following the completion of the infusion. In some subjects TLESRs were also counted during 20 min of acid infusion. The study conformed to Declaration of Helsinki. All subjects gave informed consent.
RESULTS: 10 subjects (7M/3F) completed the study. We found that acid infusion into the stomach did not affect the number of meal-induced TLESRs. The number of TLESRs (median[interquartile range]) during 2h following the control vs. acid infusion was 17[12-18.75] vs. 15.5[12.25-20.25], $n = 10$, $p = NS$, Wilcoxon Signed-Rank Test). The average duration of TLESRs was not changed (16.3s±0.4s, $n = 153$ vs. 17.2s±0.7s, $n = 151$, $P > 0.2$, unpaired T-test). The number of TLESRs during the acid infusion was also not affected (quantified in 6 subjects, 4M/2F). The number of TLESRs during the 20 min of control vs. acid infusion was 5.5[2.75-6] vs. 4[3.25-4.75], $n = 6$, $p = NS$, Wilcoxon Signed-Rank Test).
CONCLUSION: We conclude that the acid infusion into the stomach does not affect the meal-induced TLESR. These results are consistent with the notion that the direct effects of acid in the stomach has limited role in the regulation of TLESR. Our results also indicate that the substantial enhancement of TLESR by acid infusion into the esophagus observed in our previous study was not due to acid effect in the stomach.

P0471 EFFECT OF GHRELIN ON EXPERIMENTAL ESOPHAGITIS IN RATS

P. Konturek[1,*], K. Celinski[2], G. Burnat[1], S. Kwiecien[3], M. Raithel[4], **S. Konturek**[3], **T. Brzozowski**[3]
[1]*Department of Medicine II, Thuringia Clinic, Saalfeld, Germany,* [2]*Department of Gastroenterology, Medical Academy Lublin, Lublin,* [3]*Institute of Physiology, University School of Medicine, Cracow, Poland,* [4]*Department of Medicine I, University Erlangen-Nuremberg, Erlangen, Germany*

INTRODUCTION: Both ghrelin and leptin are involved in the regulation of food intake but their effect on the development of experimental reflux esophagitis (RE) is unknown.
AIMS & METHODS: The present study was designed to assess; 1) the effects of pre-treatment with ghrelin and leptin on lesion score and esophageal blood flow in rats with RE; 2) the influence of ghrelin and leptin on mucosal gene expression and release of proinflammatory cytokines (IL-1b, TNF-a and IL-6) and 3) the influence of ghrelin and leptin on the expression of COX-2 and HSP70 in esophageal mucosa during development of RE. RE was induced in rats ($n = 6$/group) according to technique proposed by Nakamura et al (Jpn J Pharmacol 1982, 32:445) by two ligation of 1) the duodenum at the pyloric sphincter and 2) at the region between the forestomach and gastric corpus. Following treatment groups were used: A) intact rats; B) rats with RE pretreated 1h before with saline (control); C) rats pretreated with ghrelin (40 μg/kg i.p.) and D) leptin (40 μg/kg i.p.) 1 h before exposure to RE. The lesion score (scale 0-5) and esophageal blood flow using H2 gas clearance was measured. In addition, gene expression of IL-1b, TNF-a, IL-6 and release of these cytokines was analyzed by quantitative RT-PCR and ELISA. Furthermore, gene expression of COX-2 and HSP70 was measured by RT-PCR.
RESULTS: Both ghrelin and leptin significantly attenuated (by ~50%) the lesion score induced by RE and this effect was accompanied by a significant increase in esophageal blood flow. The expression of mRNA for COX-2 TNF-a, IL-1b and IL-6 was negligible in the intact esophageal mucosa but was upregulated in esophageal mucosa of rats with RE. The pretreatment with ghrelin and leptin decreased the expression of mRNA for COX-2, TNF-a, IL-1b and IL-6. In contrast, HSP70 was significantly downregulated in esophageal mucosa of rats with RE and this effect was reversed in rats pretreated with ghrelin or leptin. Ghrelin receptor (GHS-R) was detected both in intact and RE-inflamed esophageal mucosa.
CONCLUSION: Appetite hormones, such as leptin and ghrelin, significantly attenuate the inflammatory reaction in esophageal mucosa caused by pathologic reflux of gastric acid. The anti-inflammatory effect of ghrelin and leptin is may be attributed to their inhibitory effect on expression and release of proinflammatory cytokines, COX-2 and the restoration of protective Hsp70 inhibited due to RE.

P0472 ROLE OF ACID AND NON-ACID REFLUX IN ESOPHAGEAL MUCOSAL DAMAGE (EROSIVE ESOPHAGITIS AND BARRETT'S ESOPHAGUS)

V. Kaibysheva[1,*], A. Trukhmanov[1], A. Ponomarev[1], O. Storonova[1], M. Konkov[1], V. Ivashkin[1]
[1]*FIRST MOSCOW STATE MEDICAL UNIVERSITY, Moscow, Russian Federation*

INTRODUCTION: The effect of acid reflux is commonly accepted nowadays. Substantial experimental and clinical evidence strongly supports the importance of acid and pepsin in causing esophageal mucosal injury. The role of weakly-acid and duodenogastroesophageal reflux as an etiological factor of esophageal mucosal injury is not clarified until recently. With introduction of combined esophageal pH-impedance monitoring, a precise diagnostic test for non-acid reflux is now available.
AIMS & METHODS: The aim of this study was to assess the role of acid and non-acid reflux in esophageal mucosal injury. 127 patients (75(59.1%) women and 52(40.9%) men, averaging 48.6 ± 14.9 years), off acid-suppressive therapy underwent diagnostic work-up including upper-GI endoscopy with biopsy and combined esophageal pH-impedance monitoring. According to data from pH-impedance study patients were subdivided into three groups by predominant characteristic of reflux: GERD with acid reflux (n = 65; AR); GERD with weakly-acid reflux (n = 36, WR), and GERD with duodenogastroesophageal reflux (n = 26, DGR).
RESULTS: The absence of endoscopically visible lesions or catarrhal esophagitis (NERD) was found during endoscopy in 55.4%, 86.1%, and 76.9% for AR, WR, DGR, respectively (p (AR-WR) <0.05). Erosive esophagitis (ERD) was found in 40%, 13.9% and 23.1% for AR, WR, DGR, respectively (p (AR-WR) <0.05). Esophageal ulcers were found only in AR group in 4.6%. Moreover, AR and DGR patients had significantly higher activity and degree of mucosal inflammation than patients in WR group ($p<0.05$). Endoscopic changes indicating Barrett's esophagus with histologic presence of esophageal intestinal metaplasia was found in 16%, 5.8%, and 42.9% for AR, WR, DGR, respectively (pAR-DGR <0.05; pWR-DGR <0.05).
CONCLUSION: Higher frequency of esophageal mucosal injury in AR group in comparison with patients in WR group suggests that acid is the key factor in causing esophageal injury. While weakly acidic reflux does not contribute significantly to esophageal mucosal damage. Similarly, the DGR patients had significantly higher rate of intestinal metaplasia which indicates the important role of duodenal content (bile or alkaline pancreatic secretions) in developing Barrett's esophagus.

P0473 IMPEDANCE-PH REFLUX PATTERNS IN PATIENTS WITH NON-EROSIVE REFLUX DISEASE AND EROSIVE REFLUX DISEASE

V. Kaibysheva[1,*], A. Trukhmanov[1], V. Ivashkin[1]
[1]*FIRST MOSCOW STATE MEDICAL UNIVERSITY, Moscow, Russian Federation*

INTRODUCTION: Non-erosive reflux disease (NERD) and erosive reflux disease (ERD) are the most common phenotypic presentations of gastroesophageal reflux disease.
AIMS & METHODS: To assess acid and non-acid reflux patterns in patients with NERD and ERD using combined esophageal pH-impedance monitoring. 133 patients (off acid-suppressive medication) complaining of reflux symptoms were underwent diagnostic work-up including upper gastrointestinal endoscopy and ambulatory 24-h esophageal pH-impedance monitoring. According to data of endoscopy patients were graded to NERD (90 patients (67.6%)) and ERD (43 patients, (32.3%)).
RESULTS: When compared to NERD, ERD patients showed a higher incidence of acid reflux episodes in 24 h (72 (43;103) vs. 47 (21; 68), $p<0.05$) and higher duration of total esophageal acid exposure (10.8% (6.6; 19.4) vs. 4.5% (1.4;7.1), $p<0.05$). Reflux-related acid exposure (pH drops associated with reflux detected by impedance) in ERD patients was twofold higher than in NERD patients (2.2% (1.6; 2.9) vs. 1.08% (0.5;1.9), $p<0.05$). Similarly, reflux-related alkaline exposure (pH elevation (pH > 7) [1] associated with reflux detected by impedance) was also higher in ERD patients (1.3% (0.8; 1.7) vs. 0.13% (0; 0.49), $p<0.05$). In contrast to ERD patients, NERD patients had significantly higher (1.08% (0.46; 1.86) vs. 0.04% (0; 0.2), $p<0.05$) reflux-related weakly – acid exposure (pH drops (pH < 7) [1] associated with reflux detected by impedance). When compared with accepted normal values [1] NERD patients had significantly higher mean number of weakly-acid refluxes (41(28;55)). Episodes of weakly-acid reflux in NERD patients happened mainly at postprandial period. Median acid (chemical) clearance time was twice higher in ERD patients (120 (76; 166) s.) in comparison to NERD's (60 (49; 116) s.) group. Meanwhile, there was no significant difference in median volume clearance time between ERD and NERD patients (23.3 (20.3; 27.6) vs. 19.1 (16.2; 23.6) s, $p>0.05$). In both GERD groups median volume clearance was significantly faster than median chemical clearance ($p<0.05$). Meanwhile, esophageal mucosa's exposure to reflux volume during 24 hour period, as assessed by impedance monitoring, was similar in both ERD and NERD patients (3.8% vs.3.1%, $p>0.05$).
CONCLUSION: While ERD and NERD patients have similar total esophageal bolus exposure, ERD patients have an increased level of esophageal acid exposure and reflux-related esophageal acid and alkaline exposure due to excessive number of acid and alkaline reflux as well as long duration of chemical clearance. Similarly, NERD patients have excessive number of postprandial weakly-acid reflux and increased level of reflux-related esophageal weakly-acid exposure. Consequently, this observation tends to support a notion that weakly-acid reflux is less damaging to esophageal mucosa than acid reflux. Significant differences between acid and bolus clearances' time may be caused by two different mechanisms of clearance. Volume clearance is achieved by peristalsis while chemical clearance requires neutralization by saliva.

INTRODUCTION: Nighttime reflux is strongly associated with sleep disturbances; however, the detailed characteristics of nighttime reflux occurring during sleep have not been elucidated.
AIMS & METHODS: The present study aimed to analyze nighttime reflux by using multi-channel intraluminal impedance pH (MII-pH) monitoring and a portable electroencephalograph (EEG) in patients with gastroesophageal reflux disease. Seventeen patients with heartburn and/or regurgitation were examined by using MII-pH and a portable EEG simultaneously. Nighttime reflux was divided based on reflux type, acidity, and extent. Phases of nighttime at bed were divided as follows: (1) recumbent-awake before falling asleep; (2) nonrapid eye movement (NREM); (3) rapid eye movement (REM); (4) awakening from sleep; and (5) post-awakening in the morning.
RESULTS: A total of 184 nighttime refluxes were analyzed. Forty-three (23%) refluxes occurred during recumbent-awake before falling asleep; 28 (15%) during NREM; 14 (8%) during REM; 86 (46%) during awakening from sleep, with 50 (27%) during long awakening (≥ 5 min), and 13 (7%) during post-awakening in the morning. Liquid reflux was common during awakening from sleep, NREM, and REM. Prevalence of proximal migration was significantly lower in NREM and REM than in the other phases. There was no difference in acidity and bolus clearance time among the sleep phases. Nighttime reflux was highly prevalent during long awakening (19/24, 79%). Among them, eight (42%) refluxes occurred during the first epoch of long awakening.
CONCLUSION: Different reflux pattern at each phase during nighttime might explain the pathogenesis of GERD and its related sleep disturbances.

INTRODUCTION: Gastroesophageal reflux disease (GERD) is one of the most common diseases and, according to recent epidemiological studies, clinical and endoscopic GERD symptoms can be detected in 8-25% of the population depending on country, race and gender. In the Russian Federation, the prevalence of GERD reaches 11-15%. Despite improvements in diagnosis and treatment of GERD, there are still many unresolved issues. GERD is characterized by disorders in immune response presented by misbalanced cellular (Th1) and humoral (Th2) parts of immune response which depend on expression of cytokines.
AIMS & METHODS: To determinate the circulating level of cytokines in patients with different forms of gastroesophageal reflux disease (GERD): non-erosive reflux disease (NERD), erosive esophagitis and Barrett's esophagus. In prospective cohort study were included 55 patients and randomized in 4 groups: group 1 - 20 patients with NERD (11 men, 9 women; average age 37.75± 12.04), group 2 – 20 patients with erosive esophagitis (13 men, 7 women; average age 38.33±12.55), 3 group – 5 patients with Barrett's esophagus (5 men; average age 34.25±9.88) and group 4 (control group) – 10 healthy volunteers (5 men, 5 women; average age 33.37±9.39). In all enrolled patients were performed the upper gastrointestinal endoscopy and the determination of plasma cytokines (IL-4, IL-8, IL-10, IFN-γ, TNF-α) by flow cytometry. Statistical analyses were performed using SPSS 17.0 statistical package.
RESULTS: In patients with erosive esophagitis the median rate of IL-8 was 17.54 pg/mL (95% CI, 15.83 to 19.24), IFN-γ 72.97 pg/mL (95% CI, 15.24 to 130.7), TNF-α 16.31 pg/mL (95% CI, 14.03 to 18.58). The expression of IL-8 in patients with erosive esophagitis was 2,3 times higher than in patients with NERD ($p=0.02$) and 5,04 times higher than in patients with Barrett's esophagus ($p=0.02$). The expression of IFN-γ in patients with erosive esophagitis was 2,58 times higher than in patients with NERD ($p=0.03$) and 27,03 times higher than in patients with Barrett's esophagus ($p=0.03$). The expression of TNF-α in patients with erosive esophagitis was 2,22 times higher than in patients with NERD ($p=0.04$) and 2,26 times higher than in patients with Barrett's esophagus ($p=0.05$). In patients with Barrett's esophagus the median rate of IL-4 was 14.95 pg/mL (95% CI, 12.75 to 17.15), IL-10 9.2 pg/mL (95% CI, 8.75 to 9.68). The expression of IL-4 in patients with Barrett's esophagus was 2.36 times higher than in patients with erosive esophagitis ($p=0.03$) and 3.33 times higher than in patients with NERD ($p=0.05$). The expression of IL-10 in patients with Barrett's esophagus was 1.59 times higher than in patients with

erosive esophagitis ($p = 0.03$) and 2.53 times higher than in patients with NERD ($p = 0.03$).
CONCLUSION: In patients with erosive esophagitis in comparison with NERD and Barrett's esophagus we found overexpression of pro-inflammatory cytokines (IL-8, IFN-γ, TNF-α), that reflects their role in the Th1 immune response. In patients with Barrett's esophagus in comparison with NERD and erosive esophagitis was the overexpression of anti-inflammatory cytokines (IL-4, IL-10), that reflects their role in the Th2 immune response.

P0476 THE CIRCULATING LEVEL OF CYTOKINES IN PATIENTS WITH REFRACTORY TO PROTON PUMP INHIBITORS GASTROESOPHAGEAL REFLUX DISEASE

Y. Evsyutina[1,*], A. Trukhmanov[1], S. Lyamina[2], I. Malyshev[2], V. Ivashkin[1]
[1]*Sechenov First Moscow State Medical University,* [2]*Moscow State University of Medicine and Dentistry, Moscow, Russian Federation*
Contact E-mail Address: *uselina@mail.ru*

INTRODUCTION: Gastroesophageal reflux disease (GERD) is one of the most common diseases and, according to recent epidemiological studies, clinical and endoscopic GERD symptoms can be detected in 8-25% of the population depending on country, race and gender. In the Russian Federation, the prevalence of GERD reaches 11-15%. 50-60% of patients suffernig from refractory GERD who despite the received therapy do not have improved clinical and endoscopic picture, than can be explained with misbalance of Th1 and Th2 parts of immune response which depend on expression of cytokines.
AIMS & METHODS: To determinate the circulating level of cytokines in patients with GERD depending on the response to standard proton pump inhibitors (PPI) therapy. In prospective cohort study were included 50 patients randomized in 3 groups: group 1 - 20 patients with non- refractory GERD (the complete response to standard PPI therapy during 8 weeks which was defined on disappearance of complaints) - 11 men, 9 women; average age 37.66±10.02, group 2 - 20 patients with refractory GERD (the partial response or absence of response to standard PPI therapy during 8 weeks which was defined on maintenance of complaints) - 12 men, 8 women; average age 38.25±9.42, and group 3 (control group) – 10 healthy volunteers (5 men, 5 women; average age 34.25±9.88). In all enrolled patients were performed the upper gastrointestinal endoscopy and the determination of plasma cytokines (IL-4, IL-8, IL-10, IFN-γ, TNF-α) by flow cytometry. Statistical analyses were performed using SPSS 17.0 statistical package.
RESULTS: In patients with refractory to PPI gastroesophageal reflux disease in comparison with patients with non- refractory GERD were higher levels of IL-8 (18.10 pg/mL vs. 6.66 pg/mL; $p = 0.02$), IFN-γ (61.7 pg/mL vs. 24.10 pg/mL; $p = 0.022$), TNF-α (14.77 pg/mL vs. 7.97 pg/mL; $p = 0.03$). The high level of IL-8 is associated with relapse of erosive esophagitis within 2 years ($p \leq 0.01$).
CONCLUSION: In patients with refractory to PPI gastroesophageal reflux disease in comparison with non- refractory GERD was overexpressed IL-8, IFN-γ, TNF-α. Thus the high level of IL-8 was correlated with recurrent erosive esophagitis within 2 years, and this cytokine can be used as the marker defining the prediction of a course of a disease.

INTRODUCTION: A prolonged acid inhibition may be associated with the important consequences like nutritional defects, increased risk of fractures or infections and development of gastric polyps. The majority of data originate from retrospective epidemiological studies only.
AIMS & METHODS: The aim of the study was to prospectively evaluate the incidence of the possible risk events among patients during the long term acid suppressive treatment.
A prospective observational study in gastroesophageal reflux disease (GERD) patients requiring a long term treatment with proton pump inhibitors (PPI) was performed. The development of fractures, pulmonary and enteric infection and gastric polyps were recorded. The results were compared with control group recruited from endoscopy outpatients without any history of the proton pump inhibitor intake.
RESULTS: The cohort of 230 patients on maintenance GERD treatment (44% female, age 53.8 ±14.4) was followed-up for 7.1 years (1631 patient-years). Results were matched with 209 controls. The users of PPI were equally likely to develop fractures 3.5% (OR 0.53; 95% CI 0.21-1.32) and bronchopneumonia 0.4% (OR 0.29; 95% CI 0.03-2.87) as the controls. The development of infectious diarrhea was less frequent in PPI users than in controls (OR 0.11; 95% CI 0.01-0.09). No case of hypomagnesemia was diagnosed in PPI users. Only a development of fundic gland polyps was associated with PPI use in 12.6% of exposed patients (OR 2.7; 95% CI 1.07-6.63).
CONCLUSION: A long term acid suppressing treatment of gastroesophageal reflux disease did not increase the likelihood of fractures, infectious diarrhea, bronchopneumonia and hypomagnesemia. Our results could encourage the importance of prospective evaluation of risk events in subgroups according to the indication of PPI use.

P0478 30° MAY BE MORE APPROPRIATE THAN 45° FOR THE CRITICALLY ILL PATIENTS RECEIVING MECHANICAL VENTILATION AND ENTERAL NUTRITION

Y. Leng[1,*], Y. Liiu[1]
[1]*Intensive care unit, Peking University Third Hospital, Beijing, China, Beijing, China*
Contact E-mail Address: *lengyuxin1980@126.com*

INTRODUCTION: Semi-recumbent position plays a pivotal role in prophylaxis for the development of ventilator-associated pneumonia in the critically ills. In the present study, we aimed to find a more appropriate semi-recumbent position between 30° and 45° for the critically ill patients receiving mechanical ventilation and enteral nutrition on balancing their advantages in ventilator-associated pneumonia (VAP) prophylaxis and disadvantages in organ protection.
AIMS & METHODS: A prospective, randomized clinical study to investigate the effect of different HOB (30° or 45°) on all extent gastroesophageal reflux, proximal gastroesophageal reflux and development of VAP; intra-abdominal pressure (IAP), hemodynamic parameters [mean arterial pressure (MAP), abdominal perfusion pressure (APP), filtration gradient (FG)] and development of organ failure was conducted on 86 consecutive patients admitted to a comprehensive intensive care unit (ICU).
RESULTS: No significant differences in the incidence of VAP and number of all extent reflux were found between 30° group and 45° group. However, the number and percentage of proximal reflux in 45° group were unexpectedly higher than 30° group (Number: acid: $p = 0.022$; weakly acidic: $p = 0.257$; non acid: $p = 0.168$; Percentage: acid: $p = 0.000$; weakly acidic: $p = 0.000$; non acid: $p = 0.000$). Patients in 45° group had a trendency to develop new onset organ failure more easily (45° vs. 30°: 11/42 vs. 5/44, $p = 0.077$), accompanied with higher IAPs measurement (17.64±5.32 mmHg vs.14.98±5.34 mmHg, $p = 0.023$) and lower MAP, APP, and FG (MAP, $p = 0.001$; APP, $p = 0.000$; FG, $p = 0.000$).
CONCLUSION: For mechanically ventilated patients with enteral nutrition, keeping the HOB at 45° doesn't show superiority over 30°. Elevating the HOB from 30° to 45° can't reduce the incidence of VAP effectively but brings new onset organ failure more easily.

P0479 DETECTION OF BURIED BARRETT'S GLANDS AFTER RADIOFREQUENCY ABLATION (RFA) WITH VOLUMETRIC LASER ENDOMICROSCOPY (VLE)

A.-F. Swager[1,*], D.F. Boerwinkel[1], D.M. de Bruin[2], D.J. Faber[2], T.G. van Leeuwen[2], B.L. Weusten[1], S.L. Meijer[3], J.J. Bergman[1], W.L. Curvers[1]

INTRODUCTION: The prevalence and clinical relevance of Buried Barrett's (BB) epithelium after radiofrequency ablation (RFA) in Barrett's oesophagus (BO) is questioned. Recent studies using small optical coherence tomography (OCT) catheters for scanning underneath the neosquamous epithelium demonstrated a high prevalence of tissue structures that might correspond to BB. Histological correlation, however, is lacking. Volumetric Laser Endomicroscopy (VLE) is a novel balloon-based OCT imaging technique that provides a 6-cm long circumferential volumetric scan of the oesophageal wall layers to a depth of 3 mm with a resolution comparable to low-power microscopy.
AIMS & METHODS: To evaluate if post-RFA subsquamous structures, detected with VLE, actually correspond to BB and to pursue direct histological correlation of VLE images.
In-vivo VLE was performed to detect subsquamous structures suspicious for BB in patients with 100% endoscopic regression of dysplastic Barrett's epithelium after RFA. Areas with suspicious subsquamous VLE structures were marked with electrocoagulation after which in-vivo VLE was repeated to confirm that the correct area was demarcated. These areas were subsequently resected endoscopically, followed by immediate ex-vivo VLE scanning to reconfirm the presence of the subsquamous VLE structures. Extensive histological sectioning was then performed and all histopathology slides were evaluated by an expert BO pathologist (blinded for VLE images).
RESULTS: In 17 patients, 13 areas with suspicious subsquamous structures were seen on in-vivo VLE and resected. Ex-vivo VLE of these 13 ER specimens reconfirmed the presence of these subsquamous structures in 12 ER specimens. Extensive histological sectioning of these areas showed BB in one area. The other subsquamous VLE structures corresponded to dilated (ducts of) (sub)mucosal glands or blood vessels.
CONCLUSION: VLE may potentially detect BB under endoscopically normal appearing neosquamous epithelium. However, most post-RFA subsquamous structures identified by in-vivo VLE did not correspond to BB. Further studies

are required to identify VLE features that allow for differentiation of BB from normal subsquamous structures.

Contact E-mail Address: *a.swager@amc.uva.nl*

INTRODUCTION: Volumetric laser endomicroscopy (VLE) is a novel balloon-based optical coherence tomography (OCT) imaging technique. It provides a 6-cm long circumferential volumetric scan of the oesophageal wall layers to a depth of 3 mm with a resolution that is comparable to low-power microscopy. VLE has the potential for detection and delineation of early neoplastic lesions in Barrett's oesophagus (BO). In order to investigate this, it is important that structures identified on VLE can be correlated with histology and -vice versa- that of areas containing early neoplasia on histology the corresponding VLE features can be studied. Most previous OCT studies lack such a direct correlation between histology and OCT images.
AIMS & METHODS: To investigate the optimal approach for one-to-one correlation of VLE images with histology.
BO patients with and without early neoplasia underwent endoscopic resection (ER) of areas marked in-vivo with electrocoagulation markers (ECM). Subsequently ER specimens underwent additional ex-vivo marking with several different markers (ink, pin, ECM) followed by ex-vivo VLE scanning. Tissue blocks were carefully sectioned guided by the placed markers. After further histological processing a histopathology slide was sectioned from each block. When necessary, extensive sectioning of tissue blocks was performed in order to visualize all markers that were included in the tissue block on histology. All histopathology and VLE slides were evaluated by 2 researchers and considered a match if a) ≥ 2 markers were visible on both modalities and b) mucosal patterns aside from these markers matched on both histology and VLE. All slides were evaluated by an expert BO pathologist.
RESULTS: From 16 ER specimens (overall diagnosis: 7 non-dysplastic BO, 9 dysplastic BO (1 LGD, 4 HGD, 4 EAC)) 120 tissue blocks were sectioned of which 57 contained multiple markers and thus could potentially be matched with VLE. Based on several combinations of these markers in total 14 histology-VLE matches could ultimately be constructed. Markers that achieved the best yield of matches respectively were: in-vivo placed ECMs (8 matches with 12 markers), pins (7 with 11), and ink (4 with 5). Histopathological evaluation was not hindered by marker use. In this pilot study the last 6 ER specimens yielded 9/14 matches demonstrating a clear learning curve due to methodological improvements in marker placement and tissue block sectioning.
CONCLUSION: One-to-one correlation of VLE and histology is complex but feasible. The groundwork laid in this study will provide high-quality histology-VLE correlations that will allow further research on VLE structures and VLE features of early neoplasia in BO.

Contact E-mail Address: *chlo@rn.dk*

INTRODUCTION: Oesophageal sensitivity to mechanical and acid stimulation in Barrett's oesophagus has previously been shown to be decreased.
AIMS & METHODS: The aim was to investigate the oesophageal sensitivity in Barrett's oesophagus using a multimodal (mechanical, thermal, electrical, acid) pain model.
Twenty-two patients with Barrett's oesophagus (mean age: 64.6 years) were compared to twelve healthy controls (mean age: 54.3 years) using oesophageal multimodal pain stimulation following upper endoscopy. A probe with a polyurethane bag was placed in the lower oesophagus. The probe was then used to apply mechanical, thermal, and electrical stimulation as well as a modified Bernstein test with infusion of 0.1 N HCl. All stimulations were stopped when the subject felt moderate pain, defined as 7 out of 10 on a visual analogue scale (VAS = 7).
RESULTS: Five of the Barrett's oesophagus patients had oesophagitis (Los Angeles grade A or B) on endoscopy.
For mechanical stimulation, the bag distension volume evoking VAS = 7 was significantly higher in the Barrett's group (mean volume 42 vs 28 mL, $P = 0.006$). For thermal stimulation, there was a non-significant tendency in the Barrett's group towards a higher "area under the curve" to reach VAS = 7 (949 vs. 677 s*°C, $P = 0.14$). The stimulus required to reach VAS = 7 during electrical stimulation was significantly higher in the Barrett's group (32.7 mA vs. 21.9 mA, $p = 0.03$. During the modified Bernstein test, the acid volume required to reach VAS = 7 or a maximum infusion volume of 200 mL was lower in the Barrett's group (mean 77 vs. 127 mL, $P = 0.03$). The time passed before feeling the first burning sensation during acid infusion was shorter in the Barrett's group, but just failed to be significant (181 vs. 329 seconds, $P = 0.056$).
The referred pain area defined by the subject immediately after sensing VAS = 7 was insignificant between groups ($P > 0.05$) for all 4 stimulation modalities.
CONCLUSION: Barrett's oesophagus patients showed *hypo*sensitivity to mechanical, thermal and electrical stimulation, but *hyper*sensitivity to acid stimulation. This is to some degree different from earlier findings, but the latter finding could indicate a sensitisation to acid because of oesophagitis underlying the disease.

INTRODUCTION: Surveillance is recommended for Barrett's esophagus (BE) to detect esophageal adenocarcinoma (EAC) at an early stage.
AIMS & METHODS: The aim of this study was to evaluate the cost-effectiveness of surveillance intervals and treatment strategies. 714 BE patients were included in a multicenter prospective cohort study and followed during surveillance according to the ACG guidelines. We used a multi-state-Markov model to calculate misclassification and true progression rates from no dysplasia (ND) to low-grade dysplasia (LGD), high-grade dysplasia (HGD) and EAC. These progression rates were incorporated in a decision-analytic model, which included costs and quality of life data associated with different surveillance strategies. We evaluated different surveillance intervals for ND and LGD, endoscopic mucosal resection (EMR) followed by radiofrequency ablation (RFA), RFA alone or esophagectomy for HGD or early EAC and esophagectomy with neoadjuvant chemoradiotherapy for advanced EAC. The incremental cost-effectiveness ratio (ICER) was calculated in costs per quality-adjusted life year (QALY). The willingness-to-pay threshold was set at €35.000 per QALY gained.

P0482

	No dysplasia			Low-grade dysplasia		
Strategy	Costs	QALYs	ICER	Costs	QALYs	ICER
No surveillance	€5.695	12.62	€4.823	€21.806	10.95	€4.040
Surveillance every 5 years with RFA	€6.904	12.87	€61.821	€25.709	11.91	€28.741
Surveillance every 5 years with EMR and RFA	€7.139	12.87	€104.668	€27.447	11.91	€31.073
Surveillance every 5 years with esophagectomy	€13.965	12.64	€321.880	€50.909	11.33	€39.633
Surveillance every 4 years with RFA	€7.695	12.89		€28.006	11.99	€72.257
Surveillance every 4 years with EMR and RFA	€7.951	12.89		€29.959	11.99	
Surveillance every 4 years with esophagectomy	€15.229	12.63		€51.835	11.34	
Surveillance every 3 years with RFA	€8.868	12.90		€30.973	12.09	
Surveillance every 3 years with EMR and RFA	€9.148	12.90		€33.210	12.09	
Surveillance every 3 years with esophagectomy	€16.890	12.61		€52.851	11.34	
Surveillance every 2 years with RFA	€10.831	12.90		€34.956	12.19	
Surveillance every 2 years with EMR and RFA	€11.143	12.90		€37.575	12.19	
Surveillance every 2 years with esophagectomy	€19.325	12.59		€53.960	11.34	
Surveillance every year with RFA	€14.898	12.89		€40.542	12.27	
Surveillance every year with EMR and RFA	€15.257	12.89		€43.688	12.27	
Surveillance every year with esophagectomy	€23.686	12.54		€55.159	11.34	

RESULTS: The true annual progression rate for ND to LGD was 0.02, for LGD to HGD or early EAC 0.03 and for HGD or early EAC to invasive EAC 0.36. In patients with ND, surveillance every five or four years with RFA for HGD or early EAC and esophagectomy for advanced EAC had ICERs of €4.800 and €61.800 per QALY respectively. Strategies with shorter intervals provided higher costs with similar QALYs gained. In patients with LGD, surveillance every five to two years had ICERs of €4.040, €28.741, €31.073, and €39.633 per QALY respectively. EMR prior to RFA was slightly more expensive, but had additional value for tumor staging.
CONCLUSION: Surveillance with EMR and RFA for HGD or early EAC and esophagectomy for advanced EAC is cost-effective with 5-year intervals for patients with ND and 3-year intervals for patients with LGD, based on a willingness-to-pay threshold of €35.000 per QALY.
Disclosure of Interest: None declared

P0483 BOTH ESOPHAGEAL POSTERIOR AND RIGHT WALL ARE THE PREFERRED LOCALIZATIONS OF BARRETT'S ESOPHAGUS

S. Bibbò[1], **G. Ianiro**[1,*], L. Petruzziello[2], C. Spada[2], A. Larghi[2], M.E. Riccioni[2], A. Gasbarrini[1], G. Costamagna[2], G. Cammarota[1]
[1]*Dept of Internal Medicine, Division of Gastroenterology,* [2]*Department of Surgery - Endoscopy Unit, CATHOLIC UNIVERSITY SCHOOL OF MEDICINE, ROME, Italy*
Contact E-mail Address: *gianluca.ianiro@hotmail.it*

INTRODUCTION: Prevalence of Barrett's esophagus (BE) is higher in patient with gastroesophageal reflux disease (GERD) with a rate of prevalence of 10%. The risk of cancer associated to this condition is estimated to be approximately 0.5% per year. For this reason a careful endoscopic surveillance assumes a paramount importance. Only few literature data on the preferred esophageal location of BE are available to date.
AIMS & METHODS: The aim of this study is to identify the preferred area where BE can develop within esophageal circumference. We retrospectively analyzed patients with BE who underwent upper endoscopy between January 2010 and March 2014 at our Endoscopy Center. We included only patients with short BE. In the case of multiple BE tongues, each lesion was considered individually. The circumferential localization of the lesions was determined according to the numbers of a clock face.
RESULTS: In the study period, a total of 204 subjects were newly diagnosed of BE or had an endoscopic follow-up of BE. Twenty-four patients with circumferential lesions were excluded. Among the 180 remaining patients, multiple BE lesions were diagnosed in 110 of them, for a total amount of 332 areas of mucosal metaplasia. Our analysis of data showed a clear prevalence of BE in the position near 3 o'clock and 6 o'clock of the endoscopic image. The area between 5 and 7 o'clock (posterior wall) was the most affected (38.25% of the lesions). Other localizations were respectively the arc between 2 and 4 o'clock (right wall) with 27.71%, the arc 11 to 1 o'clock 23.80% (anterior wall) and the arc 8 to 10 o'clock 10.24% (left wall). For each of the four walls, difference between observed and expected (dividing equally the number of lesions for the number of quadrants) lesions was statistically significant ($P < 0.0001$ for each wall). Lesions were most commonly located in the right (1 to 6 o'clock) than in the left (7 to 12 o'clock) quadrant (207 versus 125 – two-tailed P value = 0.0189).
CONCLUSION: We first describe, in a large cohort of Italian patients, an uneven localization of BE in the distal esophageal circumference, with an higher prevalence on the posterior-right wall. Anatomical and environmental factors could explain this finding. The circumferential asymmetry of LES pressure (in particular, a lower pressure on the right quadrant) and the preference of supine position during sleep are two situations that may promote the reflux of gastric fluids preferably in the right and posterior wall of the distal esophagus. A more accurate observation of such areas during endoscopic surveillance is advisable in GERD patients.

P0484 A STUDY ON THE LONG-TERM PROGNOSIS AND PERFORMANCE ENDOSCOPIC SUBMUCOSAL DISSECTION FOR ESOPHAGOGASTRIC JUNCTION ADENOCARCINOMA

H. Kaneko[1,*], K. HIRASAWA[1], R. KOBAYASHI[1], M. MAKAZU[1], C. SATO[1], A. KOKAWA[1], S. MAEDA[2]
[1]*Division of Endoscopy, Yokohama City University Medical Center,* [2]*department of gastroenterology, Yokohama City University graduate school of medicine, yokohama, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) was becoming widespread as a treatment option for superficial adenocarcinoma of the esophagogastric junction (EGJ) including Barrett's esophageal adenocarcinoma; however, its long-term and treatment outcomes have not been fully evaluated.
AIMS & METHODS: The aim of this study was to assess the long-term and treatment outcomes of ESD for patients with superficial adenocarcinoma of the EGJ.
Between September 2000 and December 2013, we performed ESD for 104 superficial adenocarcinoma of EGJ (type II tumor according to Siewert's classification) in 103 patients. The rates of en bloc resection, positive for lateral and/or vertical margin, curative resection, and overall and disease-specific survival rate after ESD were evaluated during follow-up (median observation period 55.6 months).
We divided all patients into two groups, the adenocarcinoma of Barrett's esophagus (BE group: 20 lesions in 20 patients) and other adenocarcinoma of EGJ (Non-BE group: 84 lesions in 83 patients), then each outcomes were evaluated.
RESULTS: All lesions were treated by en bloc resection. None of BE group were positive lateral margin and 7 of Non-BE group were positive lateral margin.
The rate of curative resection was 74% (77/104) in all patients, and BE group and Non-BE group were 74% and 75%, respectively. The most frequent cause of non-curative resection was tumor invasion into the deep submucosa.
Ninety three patients (93%) were traceable prognosis, and 5 year overall survival rate was 91.2%. When we limited to the curative resections, 5 year overall survival rates were 66.7% in BE group and 89.4% in Non-BE group. There was no death of adenocarcinoma of EGJ, meaning that the disease-specific survival rate was 100%.
There was no statistical difference of the rate of positive margin, curative resection and 5 year overall survival rates between BE and Non-BE groups.
CONCLUSION: The treatment outcomes of ESD for adenocarcinoma of EGJ were favorable regardless of the evidence of Barrett's esophagus. However, the curative resection rate was relatively low. It was assumed that pre-operative recognition of the tumor invasion into the submucosa might be difficult for adenocarcinoma of EGJ.

INTRODUCTION: Confocal Laser Endomicroscopy (CLE) is a recent technology that provides microscopic imaging during endoscopy, thus *in vivo* and in real time. The currently recommended Seattle protocol is intended to provide a comprehensive mapping of the Esophagus, but its inherent constraints have impaired its application. CLE allows for unlimited sampling of the esophageal mucosa and several recently published studies have shown its ability to provide a comprehensive assessment of Barrett's Esophagus (BE) lesions.
AIMS & METHODS: The aim of thi study is to develop consensus recommendations on the role of CLE in the management of patients with BE.
Initial statements on the use of CLE for the characterization of BE were developed by a single CLE expert based on the available clinical evidence. Those preliminary statements were edited and submitted by an external group of 20 GI physicians experts in CLE using a modified Delphi approach. After two rounds of votes based on relevant data, quality of the evidence and strength of recommendation, statements were validated if the threshold of agreement was higher than 75%.
RESULTS: 12 recommendations were adopted and 4 were rejected. CLE should be considered in the evaluation of BE. CLE is clinically indicated in patients with BE dysplasia in lesions initially identified in surveillance, with or without electronic enhancement. CLE is able to distinguish cardia from intestinal metaplasia (IM), based on the presence/absence of goblet cells. CLE is superior to White-Light Endoscopy (WLE) in identifying IM. A negative CLE random sampling in an endoscopically benign appearing Esophagus is sufficient to reduce the need for a physical biopsy in patients with known BE. CLE can improve the yield for neoplasia compared to standard WLE and random biopsies. CLE and WLE targeted biopsies are superior to WLE targeted biopsies alone in the detection of dysplasia. A positive CLE random sampling in an endoscopically neoplastic appearing Esophagus is sufficient for therapeutic intervention. CLE can be used to define location and lateral extent of neoplasia prior to therapy. CLE should be cited as a valuable tool for an increased diagnostic yield in official surveillance guidelines. CLE should be combined with red flag techniques.
CONCLUSION: The panel of experts that participated in this initiative strongly believes that Confocal Laser Endomicroscopy is an important adjunct to the current endoscopy practice. This technique can improve the management of patients by more accurately characterizing neoplasia, identifying residual neoplasia in post-treatment surveillance and rationalizing the choice of the most appropriate treatment. This consensus report is based on a review of the clinical evidence and on a consensus opinion.

INTRODUCTION: The clinical impact of CLE has been demonstrated for the management of patients undergoing surveillance or treatment of Barrett's Esophagus. This study is the first one evaluating the economic impact of using CLE in clinical practice in a European healthcare system.
AIMS & METHODS: The aim of this study was to evaluate the cost-effectiveness of a CLE-based strategy compared to the standard Seattle protocol for the management of patients with Barrett's Esophagus and suspicion of neoplasia, in the setting of the French public healthcare system.
We used the data published by Canto et al (1) on a multicentric randomized controlled trial which compared 2 strategies: (i) high definition white light endoscopy (HD-WLE) + CLE and targeted physical biopsies (CLE-based strategy) and (ii) HD-WLE and random physical biopsies (Standard strategy). In that study, the CLE-based strategy had a higher sensitivity for the diagnosis of HGD/EC (95 versus 40%) without significant change in specificity (92% versus 98% respectively). The average number of biopsies performed was reduced from 5.91 to 1.26 per patient by the use of CLE. These data were entered into a health economics model (piggyback study) to compare the costs of both strategies when performed in public academic hospitals. French costs were associated to each procedure in order to estimate the medical cost of the two strategies from a public health payer perspective. CLE was priced as a therapeutic endoscopy procedure that is valued 20% more than a standard diagnostic endoscopy.
RESULTS: In spite of a higher procedure cost, the total costs for a cohort of 100 patients associated to the CLE-based strategy were 89,313.29 € compared to 90,658.90 € for the standard strategy. The cost per patient adequately diagnosed and treated was also inferior for the CLE-based strategy (960.36 € vs. 1,054.17 €). Different sensitivity analyses (including a Monte-Carlo modeling) were performed which confirmed the robustness of previous results.
CONCLUSION: In the restricted context of this evaluation, the CLE-based strategy is not only more effective but also less costly than the standard strategy i.e. corresponding to the definition of a dominant strategy.

INTRODUCTION: The role of endoscopic submucosal dissection (ESD) in Barrett's neoplasia has not yet been well defined, although this technique could potentially achieve a higher curative resection rate and improved histological assessment compared to endoscopic mucosal resection (EMR).
AIMS & METHODS: This study sought to assess ESD efficacy, safety, and long-term results in a large patient cohort. Seventy-five consecutive Barrett's esophagus (BE) patients who underwent ESD between January 2007 and February 2014 were retrospectively analyzed. ESD was performed for either visible lesions that were multiple, over 15mm, or poor-lifting, or for suspected submucosal infiltration. Primary endpoint was curative resection rate of carcinoma (CRC).
RESULTS: Median patient age was 68 years (IQR, 61-76), median patient follow-up was 20 months (IQR, 8.5-37.5), and median maximum specimen diameter was 52.5mm (IQR, 43-71). Median maximum diameter of visible lesion was 20mm (IQR, 10-30). *En bloc* resection and CRC rates were 90% and 85%, respectively. G3 differentiation and invasion >pT1m2 were observed in 25% and 55% of cases, respectively. Five early (<48h) adverse events occurred (two delayed hemorrhages; three perforations), all treated endoscopically. No ESD-specific death was observed. Esophageal strictures manifested in 60% of patients, all treated endoscopically. Additional treatment methods for residual BE were proposed to 64% of patients, with a median number of two sessions (IQR, 2-3). At latest follow-up, complete remission of neoplasia and intestinal metaplasia was achieved in 92% and 73%, respectively.
CONCLUSION: ESD appears to be safe and effective, with a high curative resection rate. ESD should be the favored treatment for Barrett's neoplasia cases at risk of incomplete resection or poor pathology assessment with conventional EMR.

P0488 AUTOFLUORESCENCE-TARGETED PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY CAN DETECT THE FIELD OF MOLECULAR CHANGE IN BARRETT'S OESOPHAGUS

M. Di Pietro[1,*], E. Bird-Lieberman[2], M. O'Donovan[1], H. Bertani[3], R. Fitzgerald[1]
[1]*MRC CANCER UNIT - University of Cambridge, Cambridge,* [2]*Oxford University Hospital, Oxford, United Kingdom,* [3]*Endoscopy, Nuovo Ospedale Civile S. Agostino Estense, Modena, Italy*

INTRODUCTION: Probe-based confocal laser endomicroscopy (pCLE) allows optical biopsies in Barrett's oesophagus (BO) to predict histological outcome but it is subject to sampling error if performed in a random fashion. We used autofluorescence imaging (AFI) to direct pCLE and added molecular biomarkers to the histopathological diagnosis.
AIMS & METHODS: The aims of this study were to assess the diagnostic accuracy for dysplasia of AFI-targeted optical biopsies and to investigate the correlation between pCLE patterns and field of molecular change.
53 patients with BO (non-dysplastic BO n = 22, indefinite for dysplasia (ID) n = 5, low grade dysplasia n = 13, high grade dysplasia (HGD) or intramucosal cancer (IMC) n = 13) were recruited at a single centre. Patients underwent high-resolution endoscopy followed by AFI and then pCLE was performed on AFI positive (AFI+) areas. Targeted biopsies were taken from AFI+ areas, followed by random biopsies as per Seattle protocol. pCLE sequences were graded according to published criteria. Cyclin A and p53 expression were assessed by immunohistochemistry and aneuploidy by flow-cytometry on AFI-targeted biopsies. Statistical analyses were performed using chi-square test
RESULTS: AFI-targeted pCLE correctly classified all the HGD/EC patients and had a sensitivity and specificity for any grade of dysplasia of 94% and 86%, respectively. The Seattle protocol had similar sensitivity for HGD/IMC and any grade of dysplasia (85% and 92.5%, respectively). For the per-location analysis, a total of 185 endoscopic areas were analyzed with pCLE and molecular biomarkers. pCLE had a sensitivity and a specificity for HGD/IMC and any grade of dysplasia of 100%/67% and 77%/77%, respectively. Overall, 40% of pCLE irregular sequences corresponded to non-dysplastic areas (false positive). We found a statistically significant enrichment ($p < 0.001$) of the three molecular biomarkers in pCLE irregular areas. After exclusion of dysplastic areas, a significant correlation between pCLE irregularity and biomarker positivity was retained ($p = 0.008$). The presence of at least 1 positive biomarker significantly correlated with dysplasia both in pCLE irregular ($p = 0.01$) and pCLE regular areas ($p = 0.05$). Using a cut-off of two positive biomarkers, this panel classified as high risk all the patients with HGD/IMC and 45% of patients with LGD, but none of the patients with ID and non-dysplastic BO
CONCLUSION: AFI-targeted pCLE has a high diagnostic accuracy for dysplasia in BO. Tissue biomarkers are a useful adjunct to characterize the field of molecular abnormality associated with optical dysplasia. These results suggest that the presence of pCLE irregularity, even in the absence of histological dysplasia, relates to molecular changes and may warrant close follow up. A 3-biomarker is a useful adjunct to optical biopsy to provide further stratification

INTRODUCTION: Oesophageal adenocarcinoma (OAC) arises within Barrett's oesophagus (BE). Obesity is associated with metabolic syndrome (MS) and cancer progression. Body composition has a direct impact in obesity-related diseases. Normal weight individuals with increased fat mass are considered metabolically obese.
AIMS & METHODS: To evaluate the prevalence of obesity, altered body composition and metabolic indexes in patients (pts) with and without BE; and association with cancer progression in BE.
In sequential pts undergoing gastroscopy, MS, waist/hip ratio (WHR) and body fat% (BF by bioimpedance analysis) were obtained. In BE pts, histological findings were correlated with metabolic data. Pts were classified according to Body Mass Index (BMI), abdominal obesity (AO by WHR) and in females, Normal Weight Obese (NWO). Identified risk factors significantly associated with BE at univariate analysis were subsequently entered into a multivariate logistic regression analysis.
RESULTS: 250 cases and 230 controls (F/M: 193/287) were enrolled. Age (cut off: 57 years) and male gender (M/F 193/57; OR 5.01, $p < 0.0001$) were identified risk factors for BE. AO (76 *vs* 51%; OR 3.13; $p < 0.001$), increased BF% (30.7 *vs* 17.6%; $p = 0.001$), higher BMI (overweight: 39.6 *vs* 30%; OR 2.09; $p = 0.0008$; obese: 32 *vs* 22%; OR 2.3; $p = 0.004$) and MS (33.2 *vs* 20%; OR 1.95; $p = 0.0017$) were significantly associated with BE. A positive trend, possibly related to the small number of female cases, was demonstrated for NWO (28.1 *vs* 19.1%; OR 1.06; $p = 0.1$). More cases were affected by hypertension (37.4 *vs* 21.3%; OR 2.4; $p < 0.001$) and hyperlipidaemia (72.8 *vs* 53.9%; OR 2.28; $p < 0001$) but not diabetes.
When adjusted by gender, age and race into a multivariate analysis, independent risk factors for BE were BF% (OR 1.90; $p = 0.01$) and AO (OR 1.67; $p = 0.03$).

Metaplasia and dysplasia were present in 57.2 and 42.8%. AO was the only metabolic parameter independently correlated with high grade dysplasia (38 *vs* 21%; OR 2.44; p = 0.001).

CONCLUSION: Abdominal obesity, and body fat mass are strong risk factors for BE. A positive trend association was demonstrated in NWO. Furthermore, abdominal adiposity plays a role in progression to OAC. BE might therefore be considered in the metabolic syndrome spectrum and as such, in this group screening interventions may be considered.

INTRODUCTION: Dysplasia arising in Barrett's oesophagus (BE) can lead to oesophageal adenocarcinoma. Endoscopic surveillance is performed to detect dysplasia in BE so early treatment can be offered. Current practice relies on white-light endoscopy (WLE) to obtain random quadrant biopsies every 2cm from the BE segment, sampling less than 5% of the surface and therefore potentially missing areas of dysplasia.

An endoscopic image enhancement technology, *i-Scan* (PENTAX HOYA, Japan), has been developed to help improve lesion recognition in the gastrointestinal tract. *i-Scan* utilises post-processing light filtering technology to provide real-time analysis and enhancement of different elements of the mucosa and microvasculature to improve dysplasia detection.

Previous endoscopic classification systems for BE have used image enhancement technologies combined with magnification endoscopy. We report the accuracy of a novel classification system using *i-Scan* without magnification amongst expert endoscopists based at 3 high-volume European tertiary referral centres for detecting BE dysplasia.

AIMS & METHODS: High definition (HD) video recordings were collected from patients with non-dysplastic (ND-BE) and dysplastic (D-BE) BE undergoing endoscopy at University College London Hospital. A protocol was used to record areas of interest and a corresponding biopsy was taken to confirm pathology.

A simple classification system based on mucosal (M) and vascular (V) patterns was used: M1 or M2 - regular oval or villous pits respectively (ND-BE), M3 – irregular or featureless mucosa (D-BE); V1 – regular vessels (ND-BE), V2 – irregular (dilated, corkscrew) vessels (D-BE).

In a blinded manner, videos of normal and abnormal lesions were interpreted by 3 expert endoscopists using the above classification. Predicted pathology was also recorded for each lesion. Acetic acid (ACA) chromoendoscopy was used in some cases. Agreement in relation to predicted histology was calculated using κ statistics.

RESULTS: Videos from 47 patients (including 13 before and after ACA to generate 60 videos in total) were analysed. 24 were ND-BE and 23 D-BE. Cases in which ACA was used, 7 had ND-BE and 6 D-BE.

Experts' accuracy for detection of D-BE and ND-BE was 69% (62–72%) and 68% (39-80%) respectively. The sensitivity and specificity for dysplasia detection using our classification system were both 68%. ACA improved the sensitivity and specificity to 78% and 71% respectively. Inter-observer agreement for dysplasia prediction in all cases was 'moderate' ($\kappa = 0.42$) but improved to 'good' ($\kappa = 0.70$) with ACA.

CONCLUSION: Using a simple non-magnification endoscopic classification system combined with i-Scan and ACA, experts are able to accurately diagnose D-BE in 78% of cases. ACA chromoendoscopy appears to improve the sensitivity and inter-observer agreement for dysplasia detection over HD-WLE alone. These data are comparable to similar classification systems using zoom enhanced imaging and ACA previously published and could be used by the general endoscopists performing BE surveillance to target sampling and improve dysplasia detection. The addition of zoom endoscopy to i-scan has the potential to increase the accuracy further.

INTRODUCTION: Patients with a confirmed histological diagnosis of low-grade dysplasia in Barrett's oesophagus have an increased risk of neoplastic progression to high-grade dysplasia and oesophageal adenocarcinoma. We recently reported on a multi-center randomised controlled trial, in which endoscopic radiofrequency ablation reduced neoplastic progression from 26.5% to 1.5% compared to endoscopic surveillance. As part of this trial, we prospectively investigated whether these approaches also lead to differences in quality of life and illness perception.

AIMS & METHODS: Patients with a confirmed histological diagnosis of low-grade dysplasia in Barrett's oesophagus were randomly assigned to ablation or endoscopic surveillance. Quality of life and illness perception were assessed at baseline, 2, 8, 14, 26, and 38 months follow-up. QOL was measured with the SF-36 (general), the EORTC-QLQ-C30 (cancer-specific), and the EORTC-QLQ-OES18 (esophageal cancer-specific). Illness perception was measured with the brief-illness perception questionnaire (8 dimensions (scale 0-10); overall score (scale 0-80)). To compare ablation with surveillance for longitudinal data with repeated measurements, a linear mixed model was used.

RESULTS: Quality of life and illness perception were investigated in 96 patients (47 ablation, 49 surveillance) with a median follow-up of 36 months. There were no significant differences between the groups for SF-36 (general) and the EORTC-QLQ-C30 (cancer-specific). Apart from less reflux symptoms in the ablation group, there was no difference between the groups for EORTC-QLQ-OES18 (esophageal cancer-specific).

Compared to surveillance patients, ablation patients perceived their disease as lasting for a significantly shorter period of time (6.2 out of 10 vs 8.1 out of 10; $p < 0.001$), experienced fewer symptoms (2.4 out of 10 vs 3.3 out of 10 $p < 0.001$), had fewer concerns about their illness (3.6 out of 10 vs 5.2 out of 10; $p < 0.001$), and were less emotionally affected by their illness (2.8 out of 10 vs 3.3 out of 10; $p = 0.012$). As a result, ablation patients experienced their disease as less threatening compared to surveillance patients (overall illness perception score 26.6 out of 80 vs 34.2 out of 80; $p < 0.001$).

CONCLUSION: In this multi-center randomised controlled trial of ablation versus surveillance for low grade dysplasia in Barrett's oesphagus, ablation not only reduced the neoplastic progression by 25% compared to surveillance, but also led to fewer concerns and a less threatening view of the illness during a median follow-up of 36 months. This further strengthens the indication for prophylactic ablation of confirmed low grade dysplasie in Barrett's oesophagus.

INTRODUCTION: Before gastric cancer becomes clinically noticeable, a prolonged precancerous process takes place which includes atrophic gastritis and intestinal metaplasia (IM). There is no validated evidence available to support surveillance of gastric intestinal metaplasia. Therefore, the aim of this study was to investigate whether systemic inflammatory response markers such as mean platelet volume, plateletcrit, platelet/lymphocyte ratio (PLR) and neutrophil/lymphocyte ratio (NLR) in peripheral blood may have a role in the differentiation of patients with gastric precancerous lesions.

AIMS & METHODS: 1139 patients with atrophic gastritis, intestinal metaplasia and gastric cancer were evaluated by means of mean platelet volume, plateletcrit, PLR and NLR. Patients were further divided into four groups according to updated Sydney classification: Group 0: IM negative, Group I: IM 1+, Group II: IM2+, Group III: IM3+, also two groups consisting of Group IV: gastric cancer and Group V: atrophic gastritis were included into the study in order to maintain appropriate comparisons.

RESULTS: As for PLR values, there were significant differences between groups indicating that PLR was significantly higher in group IV compared to groups 0, I, II, III, and V (209.4±216.6 vs 131.4±61.7, 131±60.4, 132.6±69.7, 131±76 and 141.9±53. p = 0.001, 0.001, 0.001, 0.001 and 0.048 respectively). NLR was also significantly higher in group IV compared to groups 0, I, II, III, and V (3.81±5.33 vs 2.4±1.65, 2.35±1.65, 2.42±1.91, and 2.34±1.57, p = 0.001).

Plateletcrit was significantly higher in group IV compared to group II (0.25±0.08 vs. 0.21±0.05%, p = 0.01). However, there were no statistically significant difference between groups by means of mean platelet volume. Receiver operating characteristic curve (ROC) analysis suggested that optimum PLR cut-off point according to Youden index was 137.6 (AUC: 0.718) with a sensitivity and specificity of 0.67 and 0.68 respectively, and optimum NLR ratio cut-off point was 2.2 (AUC: 0.702) with a sensitivity and specificity of 0.71 and 0.60 respectively.
CONCLUSION: No evidence from randomised studies exists to support surveillance of gastric intestinal metaplasia. Although sensitivity and specificity are not high enough, PLR and NLR may be used in clinical practice in order to decide which patients should be scoped and biopsied during the follow-up of patients with IM and atrophic gastritis.

P0494 IMPACT OF CARCINOMATOSIS AND ASCITES STATUS ON LONG-TERM OUTCOMES OF PALLIATIVE TREATMENT FOR PATIENTS WITH GASTRIC OUTLET OBSTRUCTION CAUSED BY UNRESECTABLE GASTRIC CANCER: STENT PLACEMENT VERSUS PALLIATIVE GASTROJEJUNOSTOMY

C.H. Park[1,*], E.H. Kim[1], H. Chung[1], J.Y. An[2], H.-I. Kim[2], S.K. Shin[1], S.K. Lee[1], J.-H. Cheong[2], W.J. Hyung[2], Y.C. Lee[1], S.H. Noh[2], C.B. Kim[2], **J.C. Park**[1]

INTRODUCTION: Self-expandable metal stent (SEMS) placement and palliative gastrojejunostomy (GJJ) are palliative treatment options for malignant gastric outlet obstruction.
AIMS & METHODS: We aimed to compare clinical outcomes of palliative treatments for gastric outlet obstruction caused by unresectable gastric cancer to identify optimal treatment modalities according to carcinomatosis and ascites status. We analyzed 217 and 39 patients who underwent SEMS placement and palliative GJJ, respectively, for gastric outlet obstruction caused by unresectable gastric cancer.
RESULTS: Treatment modality was not an independently associated factor of clinical success ($P = 0.992$). Treatment modality, however, affected re-obstruction after clinical success ($P = 0.001$). In addition, carcinomatosis with ascites was an independent associated factor of clinical success ($P = 0.006$) and re-obstruction ($P = 0.045$). In a subgroup of patients with good performance who had neither carcinomatosis nor ascites, patency duration and overall survival duration did not differ between the two groups. In patients with good performance who had carcinomatosis without ascites, patency duration was longer in the palliative GJJ group than in the SEMS placement group. Overall survival, however, did not differ between the two groups. In a subgroup of patients with good performance who had carcinomatosis with ascites, both patency duration and overall survival were longer in the palliative GJJ group than in the SEMS placement group.
CONCLUSION: Long-term clinical outcomes of the palliative treatment modality for gastric outlet obstruction caused by unresectable gastric cancer were affected by carcinomatosis and ascites status, according to which a palliative treatment modality can be chosen.

P0495 HIGH PREVALENCE OF GASTROINTESTINAL STROMAL TUMOURS (GISTS): A CASE SERIES IN UK SECONDARY CARE

C. Shekhar[1,*], N.C. Fisher[1]
[1]*Gastroenterology, Russells Hall Hospital, Dudley, United Kingdom*
Contact E-mail Address: *drcshekhar@gmail.com*

INTRODUCTION: Gastrointestinal Stromal Tumours (GISTs) are mesenchymal tumours, predominantly affecting the GI tract. Diagnosis and classification require specialist review and there are few published data on the incidence of GIST in the UK. Reported incidences elsewhere vary between 6.5/ million/ year in Norway and 14.5/ million/year in Sweden[1,2]. We have analysed our caseload of GISTs in a UK secondary care setting with a population of approx 350,000, in order to estimate incidence and review outcomes.
AIMS & METHODS: A retrospective case note reviews of all patients with GIST, as identified from upper GI cancer multidisciplinary team meeting (MDT) minutes, from 2008 to 2013 inclusive (6 years). The diagnosis of GIST was considered valid, if characteristic imaging and/ or pathological features were verified by CT scanning, endoscopic ultrasound (EUS) needle aspiration/ biopsy and/ or surgical resection.
RESULTS: We identified 34 cases with a final diagnosis of GIST. The observed incidence of presentation to hospital varied year on year, and estimated annualised incidence was calculated at 16.2 / million/year. The age range was 28-91 years (M 15, F19). Nineteen cases (59%) presented with signs or symptoms of GI blood loss; five (15%) with other GI symptoms and remaining cases were found incidentally. The size of GIST at presentation ranged from 1cm to 20 cm in diameter. One case had metastasised at the time of diagnosis. EUS was used for diagnosis and staging in 15 cases; 13 had fine needle aspiration, of which 10/13 were diagnostic. 26/34((76%) cases underwent resection surgery. 6 cases were treated with Imatinib (Glivec). Case follow up range from 3 months to 6 years. Two patients died, one patient presented with metastatic disease other was managed with palliative approach due to advance age and co-morbidities.
CONCLUSION: Our review suggests a higher than expected incidence of GISTs in this population compared with other published series[1,2]. Most cases present with GI blood loss and surgery is curative in most cases with good prognosis. The incidence of GISTs in the UK is deserving of further study.

P0496 ENDOSCOPIC CHARACTERISTICS PREDICTING LYMPHOVASCULAR INVASION OF EARLY GASTRIC CANCER: A RETROSPECTIVE COHORT STUDY USING PROPENSITY-SCORE MATCHING

C.N. Shim[1,*], P.-S. Kim[1], H. Chung[2], J.C. Park[2], S.K. Shin[2], S.K. Lee[2], Y.C. Lee[2]

INTRODUCTION: The most important factor concerning endoscopic resection (ER) for early gastric cancer (EGC) is the prediction of regional lymph node (LN) metastasis before treatment. Of the main risk factors associated with LN metastasis, lymphovascular invasion (LVI) of tumor is the strongest predictor for LN metastasis in EGC. However, risk factors of LVI have not been securely established. The purpose of this study was to evaluate endoscopic characteristics predictive of LVI of EGC treated by ER.
AIMS & METHODS: A total of 1214 consecutive patients with 1240 EGCs underwent ER between January 2007 to June 2013. The lesions studied were grouped into groups of either no LVI group (n = 1166) or LVI group (n = 74), according to the presence of LVI in ER specimen. Propensity-score matching for adjustment of confounding variables including lesion size and submucosal invasion yielded 148 matched patients. Endoscopic characteristics including macroscopic type, erythema, whitish discolorization, ulcer, marginal delineation, and folds change were investigated among the matched cohort.
RESULTS: Lymphovascular tumor invasion was diagnosed in 6.0% of enrolled lesions. Of clinicopathologic characteristics in the overall cohort, larger size ($P < 0.001$) and submucosal invasion determined by endoscopic ultrasound ($P < 0.001$) and histology ($P < 0.001$) were significantly higher in the LVI group. In the 148 matched cohort after propensity-score matching, endoscopic elevated macroscopic type ($P = 0.020$) and whitish mucosal discolorization ($P = 0.022$) were significant endoscopic characteristics related to LVI of EGC, while no significant difference of age, sex, lesion size, location of tumor, submucosal invasion, and histology were detected between the matched two groups.
CONCLUSION: Endoscopic elevated macroscopic type and whitish mucosal discolorization in EGC carry a significant risk for LVI of tumor, which results in non-curative ER for EGC. Further prospective studies of preoperative prediction for LVI are warranted.

P0497 MAGNIFYING ENDOSCOPY WITH CRYSTAL VIOLET STAINING HAS NO ADDITIONAL DIAGNOSTIC VALUE COMPARED WITH NARROW-BAND IMAGING IN THE DIAGNOSIS OF SPORADIC NONAMPULLARY DUODENAL ADENOMA/ CARCINOMA

D. Maruoka[1,2,*], M. Arai[2], K. Okimoto[2], S. Minemura[2], T. Matsumura[2], T. Nakagawa[2], T. Katsuno[2], O. Yokosuka[2]

INTRODUCTION: Sporadic nonampullary duodenal adenomas rarely occur but are precancerous lesions [1]. It recently became clear that high-grade dysplasia (HGD) shows a high risk of progression to adenocarcinoma [2]. Therefore, HGD and intramucosal carcinoma (HGD/IMC) are indications for endoscopic resection. We previously reported that magnifying endoscopy with narrow-band imaging (NBI-ME) was extremely helpful in the differential diagnosis of sporadic nonampullary duodenal low-grade dysplasia (LGD) or HGD/IMC. Magnifying endoscopy with crystal violet staining (CV-ME) is useful for diagnosing colorectal adenomatous tumors [3], but no report has analyzed the utility of CV-ME in diagnosing duodenal tumors.
AIMS & METHODS: In this study, we analyzed whether CV-ME has additional diagnostic value compared with NBI-ME in the diagnosis of sporadic nonampullary duodenal adenoma/carcinoma. The final diagnosis was determined by histopathological analysis of endoscopically resected specimens. Nineteen patients with sporadic nonampullary duodenal adenoma or adenocarcinoma without polyposis syndrome who were treated by endoscopic resection between November 2012 and October 2013 were prospectively evaluated. Twenty lesions were diagnosed using CV-ME after NBI-ME and then resected. In NBI-ME, we evaluated the presence of the following: (a) irregular villi of various sizes, (b)

small villi area (alternatively tubule-like structures), (c) intravillous irregular microvessels, and (d) network-like microvessels. If any one of these findings was observed, we diagnosed HGD/IMC. On the other hand, we diagnosed the lesion that had none of these findings as LGD. In CV-ME, we made a final diagnosis by adding the findings of (a) and (b) using CV-ME in addition to NBI-ME.
RESULTS: Eight of the 20 lesions were LGD, while 12 were HGD/IMC. The following values were obtained for NBI-ME and integrated diagnosis, respectively: sensitivity, 1.0 and 1.0; specificity, 0.375 and 0.500; positive predictive value, 0.706 and 0.750; negative predictive value, 1.0 and 1.0; and accuracy, 0.750 and 0.800. No significant differences were noted between groups (chi-squared test).
CONCLUSION: CV-ME does not have additional diagnostic value compared with NBI-ME in the diagnosis of sporadic nonampullary duodenal adenoma/carcinoma.

P0498 A ROLE OF PALLIATIVE SURGERY IN STAGE IV GASTRIC CANCER

D. Yamaguchi[1,*], S. Fujii[1], T. Kusaka[1]
[1]*Department of Gastroenterology, Kyoto Katsura Hospital, Kyoto, Japan*
Contact E-mail Address: *tetsu_kumohayuni64000@msn.com*

INTRODUCTION: Standard treatment for patients with Stage IV gastric cancer is systemic chemotherapy. Some patients receive palliative surgery before chemotherapy to relieve gastric obstruction or uncontrollable bleeding. However, few data is available about the impact of palliative surgery on following chemotherapy in patients with Stage IV gastric cancer.
AIMS & METHODS: We aimed to compare the clinical outcomes between patients with advanced gastric cancer who initially received surgical resection for their primary lesion and those who initiated palliative chemotherapy without surgery. Data of consecutive 123 patients with pathologically confirmed advanced gastric cancer who received palliative chemotherapy between January 2005 and March 2014 were reviewed. A total of 57 patients received palliative chemotherapy following surgical resection for their primary lesion (Group A) and 50 patients initiated palliative chemotherapy without surgery (Group B). Overall survival was defined as the period between the date of surgery or chemotherapy initiation and the date of death for any reason or the last follow-up visit.
RESULTS: Both groups were similar in age and gender. Median survival time was 13.2 months (95% CI 7.2-19.2) for Group A and 10.2 months (95% CI 8.4-12.1) for Group B. In group A, 10 patients could not proceed to palliative chemotherapy because of postoperative complications (n = 3) and/or deteriorated general conditions (n = 7). In group B, 15 patients (37.5%) developed adverse events related to residual primary lesion: gastric hemorrhage (n = 6), gastric stenosis (n = 6), gastric perforation (n = 3). Among these 15 patients, only 2 patients who developed gastric perforation could resume chemotherapy. Duration of chemotherapy did not differ between two groups.
CONCLUSION: Our data suggested that surgical resection of primary lesion before initiating palliative chemotherapy could reduce the risk of developing severe adverse events related to residual primary lesion during chemotherapy without hampering its efficacy.

INTRODUCTION: The benefit of perioperative chemotherapy (POC) in patients with resectable gastric cancer (GC) and esophagogastric junction cancer (EGJC) was demonstrated in MAGIC trial (2006), which was associated to high morbidity.
AIMS & METHODS: Aims: To evaluate the clinical applicability of perioperative chemotherapy (POC) in patients with resectable gastric and esophagogastric junction (EGJ) cancer treated in a Portuguese cancer institute, as stated in the MAGIC Trial. **Methods:** Selection of patients with GC and EGJC referred to our institution from 2009 to 2013. Patients were staged with thoraco-abdomino-pelvic CT, endoscopic ultrassonography (if T < 3, N0 and M0) and laparoscopy (if T > 2 or N+ and M0). POC was proposed to those staged as T > 2 or N+ and M0 (3 pre and 3 postoperative cycles of epirrubicine, cisplatin and 5-fluorouracil; surgery with D2 lymph node dissection). Non-surgical candidates or stage IV patients received palliative care. Those staged as T1/2 and N0, age > 80 years or with an obstructive or bleeding tumor had direct surgery. Evaluation of clinical characteristics, adhesion, complications, survival and recurrence. Statistical analysis performed with chi2, t-Student tests, Kaplan-Meier.
RESULTS: We evaluated a total of 418 patients: 315 with GC and 103 with EGJC; 57% males; mean age 65.4 ± 21-93 years. POC proposed to 150 patients. *Preoperative chemotherapy* in 143 patients; not performed due to disease progression-5; obstructive symptoms-1; associated diseases-1; major morbidity-7%, mortality-3%. *Surgery* in 134 patients (94%); not performed due to death during chemotherapy-4, toxicity-1, disease progression-1, refusal-2. R0 surgery was performed in 102 patients (76.1%), R1 surgery in 5 patients and R2 surgery/unressecable in 28 patients; major morbidity-16%, mortality-3%. *Postoperative chemotherapy* in 74 patients (72.5%); not performed due to previous chemotherapy/surgery complications in 26 patients and disease progression in 2 patients; major morbidity-6%; mortality-0%. Median time from chemotherapy to surgery: 50 days; from surgery to chemotherapy: 35.5 days. Surgical complications were identical in those that had direct versus perioperative chemotherapy resections. Overall, 69 patients (47%) did not complete the proposed protocol. *Survival at 36 months*: a) general 37.4%; b) proposed to POC 51.2%; c) treated with curative intention-66.5%, d) completed the proposed protocol-70.7%.
CONCLUSION: In our series, one third of all patients were eligible for POC. The rates of treatment conclusion, R0 surgery and postoperative chemotherapy were higher in our series, compared with those described in the MAGIC study. POC is feasible and applicable in clinical practice, but similar to that described in the MAGIC study, only half of patients completed the proposed protocol, either due to complications of treatment, either due to disease progression.

P0500 THE PROGNOSTIC SIGNIFICANCE OF TUMOR ANGIOGENESIS IN GASTRIC CANCER

D. Lazar[1,*], S. Taban[2], M. Cornianu[2], I. Sporea[1], I. Ratiu[1], A. Goldis[1]
[1]*Gastroenterology,* [2]*Pathology, UNIVERSITY OF MEDICINE AND PHARMACY TIMISOARA, Timisoara, Romania*
Contact E-mail Address: *lazar_daniela@yahoo.com*

INTRODUCTION: Angiogenesis, the process by which new blood vessels are formed, plays an essential role in the survival of the malignant cells, in the local expansion and tumor invasion, as well as in the appearance of distant metastases. The intratumoral microvessel density (MVD), which can be evaluated immunohistochemically, seems to have an influence on the prognosis of various malignant tumors. The forming of new intratumoral microvessels depends on the elaboration of the angiogenic growth factors by the malignant cells (such as vascular endothelial growth factor – VEGF). These factors' expression is correlated with the tumor angiogenesis, neoplasia progression and severe prognosis. Among the known angiogenic factors, VEGF plays a central role in angiogenesis process control in cancerous disease.
AIMS & METHODS: We evaluated the relation between MVD, VEGF expression, the clinicopathologic factors and the survival in patients with gastric cancer. A prospective study has been carried out, regarding the evolution and aggressiveness of gastric cancer, with a duration of five years, 61 patients that underwent a surgery for gastric cancer being included in the study. The immunohistochemical reactions for CD34 and VEGF were performed for all gastric cancers cases included in the study group.
RESULTS: MVD has shown in the gastric carcinomas an average value significantly higher in comparison to the normal mucosa (38.7 vs. 12.5, $p < 0.001$). In the intestinal type we have noticed a much lower average MVD than the average MVD in the diffuse type of gastric carcinomas (36.8 vs. 41.6) ($p = 0.024$). Anaplastic carcinoma and the signet ring cell carcinoma are differentiating as histological forms associated to an intense neoangiogenesis activity. The neoangiogenesis activity is correlated with the histologic grade, the lymphovascular invasion, the level of extend, the lymph node metastasizing, the distant metastasizing and the TNM stage. Positive immunoreactions for VEGF are significantly more frequent in gastric carcinomas, in comparison to the normal gastric mucosa (65.6% vs. 6.5%, $p < 0.001$). The immunoreactions to the VEGF protein were positive in 71.1% of the intestinal carcinomas, significantly more frequent in comparison to the diffuse type carcinomas (52.9%) ($p = 0.018$). Our results show a tight correlation between the histologic grade, the level of the tumor invasion and the VEGF expression. Our results prove the major correlation between the VEGF expression and the 5 year survival rate of the patients with gastric cancer, the survival rate for the carcinomas with VEGF +/++ being significantly lower than for the VEGF negative ones (12.5% vs. 23,8%) ($p = 0.027$).
CONCLUSION: Our study proves a tight correlation between the VEGF expression and the MVD ($p = 0.039$), these factors playing an important role in the tumoral biologic behaviour, in the progression and the prognosis.

INTRODUCTION: Type I gastric carcinoids (T1-GCs) are rare tumors which may arise in pts with atrophic gastritis (AG). These tumors are well-differentiated with low proliferative index and a generally benign behavior, and constitute up to 80% of all gastric carcinoids. A major pathogenetic factor for T1-GCs is hypergastrinemia due to AG. Gastrin acts as a growth type factor for enterochromaffin-like cells, which in AG are chronically induced to proliferate, through a

Table to abstract P0501.

Patient	Gender	Age, years	Type of lesion	Diagnosis of gastric cancer	Locali-zation	Time of occurrence after diagnosis of type IGC, months (years)	Outcome
# 1	F	40	Low-grade dysplasia (intramucosal, endoscopically normal mucosa, detected on random biopsies) Diffuse gastric cancer (signet-ring cells) in situ (endoscopically normal mucosa, detected on random biopsies)	Gastroscopy according to follow-up protocol	Antrum Antrum	17 (1.4) 156 (13)	Gastric surgery alive
# 2	M	78	Intestinal-type adenocarcinoma (gastric ulcer, 3 cm)	New onset of anemia	Angulus	80 (6.7)	No surgery due to comorbidities dead
# 3	F	58	Intestinal-type adenocarcinoma (gastric ulcer, 2 cm)	New onset of epigastric pain	Antrum	63 (5.2)	Gastric surgery dead (complications of surgery)
# 4	F	49	Intestinal-type adenocarcinoma in situ (endoscopically normal mucosa, detected on random biopsies)	Gastroscopy according to follow-up protocol	Antrum	61 (5.1)	Gastric surgery alive

multistep process passing from hyperplasia to dysplasia and then to carcinoid. Epidemiological data suggest that AG is associated not only with T1-GCs, but also with intestinal-type gastric cancer. The occurrence of gastric cancer in AG pts with type I gastric carcinoids has not yet been described.
AIMS & METHODS: The aim of this study was to describe in a retrospective case-series the occurrence of gastric cancer in AG pts with type I gastric carcinoid in a single tertiary referral center. Between 1994 and 2012, 17 new cases of T1-GCs were diagnosed amongst a cohort of AG pts. The clinical charts of these 17 T1-GCs pts were retrospectively evaluated for the occurrence of gastric cancer at follow-up (median 4.2 years, range 0.5-13). AG diagnosis was based on the presence of hypergastrinaemia and atrophy of the body mucosa. Diagnosis of T1-GCs was performed when enterochromaffin-like cells proliferation was $>500\mu$ (WHO 2010 criteria).
RESULTS: In 4/17(23.5%) T1-GCs pts (3F, age 40-78yrs), gastric cancer occurred (median follow-up 5.9 yrs, range 5.1-13; Table1). Three cases were intestinal-type adenocarcinomas and one a signet-ring cells diffuse gastric cancer, localized in 3 cases in the antrum. In two pts it was detected on random biopsies during follow-up-gastroscopy, in the other two gastroscopy was performed due to new symptoms. All pts with gastric cancer had associated autoimmune features (pernicious anemia, autoimmune thyroid disease and a spared antrum), compared to 77%, 46% and 54% of those without gastric cancer.
Table1. Pts with type I gastric carcinoid who developed an epithelial neoplastic lesion
CONCLUSION: This case-series shows that in pts with T1-GCs gastric cancer may frequently occur at long-term follow-up. Thus, these pts should be monitored by a long-term surveillance programme, including an accurate bioptic sampling of antral mucosa.

P0502 THERAPEUTIC OUTCOMES OF ENDOSCOPIC RESECTION IN FOREGUT NEUROENDOCRINE TUMORS

H.J. Jung[1,*], Y.S. Myung[1], J.P. Han[1], S.J. Hong[1], B.M. Ko[1], M.S. Lee[1]
[1]*Department of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon, Digestive Disease Centerand Research Institute, Bucheon, Korea, Republic Of*
Contact E-mail Address: *95970@schmc.ac.kr*

INTRODUCTION: Endoscopic resection (ER) may benefit to treat the low grade foregut neuroendocrine tumors (NETs). This study aimed to evaluate therapeutic outcomes of ER for foregut NETs.
AIMS & METHODS: From January 2003 to February 2013, a total of 40 patients were confirmed histologically as foregut NETs from the ER (stomach = 16, duodenum = 13) and surgical resection (SR, stomach = 9, duodenum = 2). The clinicopathological characteristics and therapeutic outcomes were evaluated retrospectively.
RESULTS: Of 29 patients underwent ER (EMR = 23, ESD = 6), 28 were diagnosed as NET-G1 and 1 as NEC. Of 11 patients underwent SR, 9 were diagnosed as NET-G1 and 2 as NEC. Tumor size of ER group was significantly smaller than SR group (7.4 mm vs. 18.2 mm, $P<0.01$). Depth of invasion was limited to mucosa and submucosa in 28 NETs of ER group, However, all NETs of SR group invaded the submucosa or proper muscle. Complete resections were achieved in 22 patients (75.9%) of ER group and achieved in 11 patients (100%) of SR group. In ER group, immediate procedure-related complications occurred in 2 cases (bleeding = 1, perforation = 1), and they were successfully treated by conservative treatment. There was no complication in SR group. There was no recurrence in 7 NETs reported as incomplete resection in margin, but all of 3 NEC patients (ER = 1, SR = 2) had recurrence during follow up period. They were treated by additional chemotherapy and had no more disease progression. One metachronous recurrence occurred after complete ER, and it was treated by ER.
CONCLUSION: ER can be used as an effective method as treatment for a small sized and low grade foregut NETs. However, additional treatment should be considered in the patients who diagnosed as NEC from histological result after endoscopic treatment because it has high risk of recurrence rate.

Contact E-mail Address: *itoh777-lj@infoseek.jp*

INTRODUCTION: Surgical gastroenterostomy used to be the first line treatment for palliation of malignant gastroduodenal obstruction. Recently endoscopic placement of self-expandable metal stents (SEMS) has become a broadly accepted treatment for patients with advanced malignant gastroduodenal obstruction as a minimally invasive therapy.
AIMS & METHODS: We attempted to elucidate the current status of endoscopic SEMS for palliation of malignant duodenal obstruction in comparison with surgical gastroenterostomy. A total of 39 consecutive duodenal tumor obstruction patients who were treated at Okayama Saiseikai General Hospital from January 2006 to Dectmber 2011 were reviewed (23 pancreatic cancer, 5 gallbladder cancer, 4 duodenal cancer, 2 renal pelvis cancer, 2 colon cancer, 1 gastric cancer, 1 liver cancer, 1 occult primary cancer). 25 patients were treated by SEMS and 14 patients by surgical gastroenterostomy. We compared procedure time, time from the procedure to starting oral intake, time from the procedure to starting chemotherapy, technical success rate, complication, hospital stay, and mortality.
RESULTS: In each and every patients, treatment (eather endoscopic stent implantation or surgical gastroenterostomy) was clinically successful. Endoscopic stenting was found to be associated with a shorter time of procedure (mean 31.7 vs. 146 min, $P<0.01$), a shorter time from the procedure to starting oral intake (mean 2.96 vs. 6.64 days, $P < 0.01$) and a shorter hospital stay (mean 15.3 vs. 25.6 days, $P < 0.02$) than the surgical gastroenterostomy. There was no significant difference between the two groups in the analysis of mortality (mean 91.5 vs. 158.8 days, $p=0.107$) and time from the procedure to starting chemotherapy (mean 8.6 vs. 13 days, $p=0.177$). A single case of complication was seen in each group, one case of intestinal perforation in SEMS group (4%) and one case of intra-abdominal abscess in surgical gastroenterostomy group (7%). Both cases were able to recover by conservative treatment.
CONCLUSION: Endoscopic SEMS insertion was superior against surgical gastroenterostomy in terms of procedure time, start of oral intake period and the length of hospital stay. SEMS in duodenal obstruction is a feasible alternative of surgical gastroenterostomy for the palliation of inoperable malignant duodenal obstruction. With a high clinical success and low complication rate, endoscopic implantation of SEMS seems to be a safe and tolerable procedure for palliative treatment of malignant duodenal obstruction.

P0504 CLINICAL OUTCOMES OF SALVAGE ENDOSCOPIC THERAPY AFTER CHEMORADIOTHERAPY FOR ESOPHAGEAL CANCER

H. Osumi[1,*], Y. Toshiyuki[1], K. Chin[1], A. Ishiyama[1], T. Tsuchida[1], J. Fujisaki[1], M. Igarashi[1]
[1]*Department of Gastroenterology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*
Contact E-mail Address: *hiroki.osumi@jfcr.or.jp*

INTRODUCTION: Chemoradiotherapy (CRT) for esophageal cancer, especially at stage I, has comparable survival rates to surgery, with a median survival rate of 5 years. Therefore, in some cases, it is chosen as a first-line treatment for stage I, II, and III esophageal cancer. However, about 30% of patients who are administered chemoradiotherapy experience a local recurrence after complete response, so it is important to consider salvage therapy to treat such recurrences. Commonly administered salvage therapies include surgery, endoscopic therapy, and argon plasma coagulation (APC).
AIMS & METHODS: The aim of this study is to illuminate the results of administering salvage endoscopic therapy in cases of recurrent esophageal cancer that had previously been treated with chemoradiotherapy. 161 patients with UICCI-III esophageal cancer who received chemoradiotherapy at the Cancer Institute Hospital between 2005 and 2013 without previously being treated were retrospectively studied. 11 of these patients had local recurrences after receiving chemoradiotherapy, and received salvage endoscopic therapy as treatment for the recurrence. Their overall survival (OS) and time of recurrence after CRT and salvage endoscopic therapy were studied. Kaplan-Meier analysis and Cox proportional hazard modeling were used for statistical analysis.
RESULTS: The median observation period for the 11 patients studied was 75.2 months (39.1-107.6). The clinical stages of esophageal cancer of the 11 patients studied were as follows (stage I/II/III: 6/1/4). The salvage endoscopic therapies administered were as follows (EMR/ESD/APC: 7/3/1). The clinical responses of the patients to chemoradiotherapy were as follows (CR/PR: 8/3). 5 patients experienced local recurrences again after salvage endoscopic therapy (EMR/ESD/APC: 4/0/1). Disease-free survival in patients who received salvage EMR therapy was a median 24 months (8.9-50.1). Patients who were administered salvage APC therapy experienced relapses twice, and recurrence-free survival among those patients was a median 9 months (3.4-14.6). None of the patients who were administered ESD experienced a relapse, and disease-free survival among those patients was a median 25.3 months (13.3-32). The complications usually associated with endoscopic therapies were also not observed. There was no significant difference between salvage therapies in terms of overall survival (EMR 74.8 months (46.1-100.1), ESD 78.9months (39.1-107.6), APC 66.5 months).
CONCLUSION: ESD can be considered to be a better salvage therapy than the other endoscopic therapies as the local recurrence rate was lower than that for either EMR or APC. Even for less serious cases of esophageal cancer, ESD is a preferable choice as a salvage endoscopic therapy after chemoradiotherapy. It should be noted, however, that there was no difference in the long-term prognoses among the different salvage therapies, even after recurrence. In some cases, ESD may not be ideal as a treatment, such as in patients who have other pre-existing diseases that make long-term treatment difficult, or in cases of esophageal stenosis, which renders it difficult to use ESD scopes. For such cases, other salvage therapies can be considered, including surgery and photo-dynamic therapy (PDT).

P0505 LOW-DOSE ASPIRIN-ASSOCIATED GASTRIC AND DUODENAL ULCERS IN JAPANESE PATIENTS WITH NO PREVIOUS HISTORY OF PEPTIC ULCERATION

A. Tanabe[1,*], Y. Ito[1], Y. Yamaguchi[1], N. Okaniwa[1], H. Noda[1], K. Yanamoto[1], Y. Tamura[1], Y. Kondo[1], R. Masui[1], S. Izawa[1], Y. Hijikata[1], K. Tokudome[1], N. Kawamura[1], A. Iida[1], N. Ogasawara[1], Y. Funaki[1], M. Sasaki[1], K. Kasugai[1]
[1]*Aichi medical university, Nagakute, Japan*

INTRODUCTION: Long-term administration of low-dose aspirin (LDA) is associated with a greater risk of adverse events, including gastroduodenal ulcers and their potentially fatal complications (e.g., gastrointestinal bleeding and perforation). The identified risk factors for ulcer bleeding with aspirin use are history of ulcer bleeding; aspirin dose; advanced age (>70 years); concomitant use of NSAIDs or anti-coagulants; use of dual anti-platelet therapy; *Helicobacter pylori* infection; and history of alcohol abuse, diabetes, or renal failure. Proton pump inhibitors (PPIs) are used to decrease LDA-associated gastroduodenal mucosal and NSAID-induced injuries. In Japan, since 2011, treatment with half-dose PPI (lansoprazole 15 mg/day) has been permitted as a medical service under health insurance for the prevention of NSAID- or LDA-induced peptic ulcers in patients in the high-risk group who have a history of peptic ulcers. However, there are few reports in which the use of PPIs reduced the risk of LDA-associated peptic ulcers in patients without pre-existing peptic ulcers
AIMS & METHODS: AIM: To assess the risk factors and the efficacy of medications for development of peptic ulcer disease in Japanese with no prior history of peptic ulceration.
METHODOLOGY: We conducted a matched background study using esophagogastroduodenoscopy (EGD) record collected from January 2010 through December 2010. Consecutive 219 outpatients receiving LDA (75 mg) who had no peptic ulcer history were matched to 1 control by age and sex who were not receiving LDA and had no peptic ulcer history. Clinical parameters, concomitant drugs, the reason for endoscopy, and endoscopic findings were analyzed.
RESULTS: Of 219 patients receiving LDA, 20 (20%) was diagnosed endoscopically with peptic ulceration, which was significantly higher than 7 (3.2%) of 219 patients not receiving LDA (OR, 3.0; 95% CI, 1.26–7.35; $P=0.016$). From multiple logistic regression analysis, LDA smoking habit, NSAID, and PPI were detected as increased and decreased risk factors for peptic ulcer, respectively (OR, 9.6; 95% CI, 2.27–38.63; $P=0.002$), (OR, 3.9; 95% CI, 1.03–14.72; $P=0.045$), (OR, 7.4; 95% CI, 1.73–31.67; $P=0.007$), (OR, 0.11; 95% CI, 0.02–0.45; $P=0.002$). Age, current alcohol consumption, H_2-receptor antagonists, and abdominal symptom were not significantly associated with the presence of peptic ulcers.
CONCLUSION: Long-term administration of LDA increases the risk of peptic ulcer even in the patients who had no peptic ulcer history, and PPIs reduces the risk of developing gastric or duodenal ulcers. However this risk is significantly increased in patients with concomitant smoking habit and NSAID. These results may help identify patients who require more intensive prophylaxis against aspirin-induced ulcerations.

P0506 CORRELATION BETWEEN THE PREVALENCE OF GALLSTONE AND HELICOBACTER PYLORI INFECTION

B.J. Kim[1,*], J.G. KIM[1], J.-H. Jung[1]
[1]*Internal Medicine (Gastroenterology), Chung-Ang University College of Medicine, Seoul, Korea, Republic Of*
Contact E-mail Address: *gikbj@cau.ac.kr*

INTRODUCTION: Several studies have reported that the presence of *Helicobacter* DNA in human bile sample, although its pathological role is not clear. Moreover, little is known about the association between *Helicobacter pylori (H. pylori)* infection and gallstone.
AIMS & METHODS: The aim of this study was to determine whether *H. pylori* infection is associated with an increased risk of gallstone in an asymptomatic population.
We examined 2782 subjects (1635 men and 1147 women) who underwent both upper endoscopy with CLO test and abdominal ultrasound at the Health Examination Center at Chung-Ang University Yong-san Hospital in Korea from January 2007 to December 2009. We compared the prevalence of gallstone on ultrasound and endoscopic findings such as reflux esophagitis, gastric diseases in the *H. pylori* infected subjects with that of the *H. pylori* uninfected subjects.
RESULTS: The overall prevalence of *H. pylori* infection in our study was 45.6% (1271/2782). When the subjects were divided into two groups according to the *H. pylori* infection status, there was no significant differences of the baseline characteristics between the two groups. The prevalence of gallstone in the *H. pylori* infected subjects was higher than that of the *H. pylori* uninfected subjects (5.4% vs 3.2%, $P=0.032$). The prevalence of peptic ulcer in the *H. pylori* infected subjects was higher than that of the *H. pylori* uninfected subjects (8.2% vs 3.4%, $P<0.001$). The prevalence of reflux esophagitis in the *H. pylori* infected subjects was lower than that of the *H. pylori* uninfected subjects (6.2% vs 14.0%, $P=0.012$).
CONCLUSION: These findings suggest that *H. pylori* infection is associated with an increased risk of gallstone in asymptomatic population.

Contact E-mail Address: *dboltin@gmail.com*

INTRODUCTION: *Helicobacter pylori* has been associated with hyperemesis gravidarum in some geographical regions. The prevalence of *H. pylori* in Arab Israeli women in the Upper Galilee and its association with hyperemesis gravidarum, has not been previously studied.
AIMS & METHODS: The aim of this study was to examine whether *H. pylori* infection is associated with hyperemesis gravidarum in Arab Israeli women. Subjects with hyperemesis gravidarum carrying a singleton fetus, were prospectively recruited. Women with an uncomplicated pregnancy served as controls. All patients underwent C13-urea breath testing to assess for *H. pylori* infection.
RESULTS: A total of seventy two subjects, including 24 patients with hyperemesis gravidarum and 48 controls, aged 28.8±5.3 years, were included. *H. pylori* infection was identified in 73.9% (17/24), and 60.4% (29/48) of cases and controls, respectively (p = ns). *H. pylori* infection did not correlate with age or the number of previous pregnancies (p = ns). Control subjects with a history of early trimester vomiting were not more likely to be infected with *H. pylori*, compared to controls without a history of early trimester vomiting (p = ns).

CONCLUSION: *H. pylori* does not seem to increase the likelihood of hyperemesis gravidarum in Arab Israeli women. However, given the apparently high background prevalence of *H. pylori* in this population, a larger study is required to corroborate these findings.

INTRODUCTION: It is assumed that the prevalence of Helicobacter pylori (H.p.) is decreasing in wealthy countries. There are however no recent prospective population based studies confirming this.
AIMS & METHODS: We aimed to evaluate the prevalence of positive H.p. serology in random population sample in a Swedish community over 23 years. In 1989 we mailed the validated Abdominal Symptom Questionnaire (ASQ) (age 22-80), and 1097 (87%) responded. H.p.serology (HM-CAPTM immunoassay) was measured on a stratified sample (n = 145 with either dyspepsia, IBS or symptom free) (1). In late 2011 the ASQ was mailed again with the same sampling procedure in the same community (age 20+) and 1175 (64%) replied. A total of 388 out of 1034 participants 20-79 years of age and suitable for an upper endoscopy had an upper endoscopy spring 2012. H.p. serology (*H. pylori* IgA/IgG ELISA) was measured on 386, 32 of those had participated in 1989. The effect of time on H.p. prevalence was calculated using random effects logistic regression models using H.p. as the dependent variable and gender, age and time as independent variables. All participants in all surveys are included in the analyses (499 participants, 531 observations).
RESULTS: The prevalence of H.p. positivity in 1989 and 2012 in total and in age groups for the 499 participants who participated in either or both studies is presented in the table. H.p. positivity decreased significantly with time, the odds ratio for H.p. positivity corresponding to 0.25 per decade (OR:0.25; 95%CI:0.11-0.59, p = .001) independent of gender and age. There was no difference in H.p. prevalence between men and women (OR:0.92; 95%CI:0.40-2.08). The odds of H.p. positivity increased with age by 11% per year (OR:1.11; 95%CI:1.04-1.18, p = 0.001).
Table. Prevalence of Hp positivity in 1989 and 2012 in total and by age group

	1989 N hp positive/total	%	2012 N hp positive/total	%
Total	55/145	37.9	61/386	15.8
20-39	8/47	17.0	4/60	6.7
40-59	21/40	34.4	17/161	10.6
60-80	26/37	70.3	40/165	24.4

CONCLUSION: In this random sample of the adult general population in Sweden, H.p. prevalence has decreased radically over the last two decades across all ages. Among adults below 40 years it has reached the level where the "test & treat" strategy might be questioned (2). Among adults older than 60 years the risk of complications (3) is most probably reduced.

INTRODUCTION: The incidence of obesity is increasing worldwide. The involvement of Helicobacter pylori (*H. pylori*) in the pathophysiology of obesity is still debated. Among the possible related factors reported, *H. pylori* infection has been proposed to play a role by interfering with the release of gastric hormones involved in the regulation of appetite and food intake. However, the data available until now are conflicting are derive from small series of cases.
AIMS & METHODS: To analyze the distribution of *H. pylori* infection in a large cohort of consecutive patients stratified according to sex, age and body mass index (BMI).
We enrolled 4653 subject referred to our Gastroenterology Unit between January 2006 to January 2014 to perform 13C-urea breath test (13C-UBT). In all cases we recorded: age, sex, weight, height, previous esophagogastroscopy results, previous eradication therapy and *H. pylori* status. BMI was calculated according to the following formula: mass (Kg)/height (m)2. The 13C-UBT was performed by administering a solution of 100 ml tap water containing 100 mg of 13C-urea and 1.4 g of citric acid. Breath samples were taken at baseline and 30 minutes after ingestion of the urea. The 13C enrichment in breath was determined by isotope ratio mass spectrometer. The 13CUBT was considered positive if the δ-value over baseline at 30 minutes was $> 5‰$.
RESULTS: Overall, there were 1916 (41%) male. Mean age was 43.75 years (range 3-88), 323 (7%) subject were ≤15 year-old. Forty-seven percent (2183) subjects reported previous eradication therapy. BMI was ≤ 18 in 188 (4%), ≥18.1-≤25 in 2322 (50%), ≥25.1-≤30 in 1576 (35%) and ≥30.1 in the remaining 514 (11%) of the cases. *H. pylori* infection was detected in 1892 (40.7%) with a progressive increasing trend according to BMI (≤ 18: 36%; ≥18.1-≤25: 34%, ≥25.1-≤30: 46% and ≥30.1: 56%; p < 0.0001).
CONCLUSION: *H. pylori* infection is significantly more frequent in obese than in normal weight individuals, irrespective of sex and age.

INTRODUCTION: Helicobacter pylori (*H. pylori*) infection has been suggested to protect against the development of erosive esophagitis (ERD) and Barrett's esophagus (BE). A possible explanation represents the development of corpus pre-dominant and/or atrophic gastritis in the natural course of *H. pylori* infection with an associated decrease in gastric acid secretion.
AIMS & METHODS: Aim of the study was to assess whether *H. pylori* infection, decreased serum pepsinogen levels as a marker for gastric atrophy and different forms of gastritis are associated with the occurrence of BE and ERD.
For this, we reviewed prospectively collected data of 332 patients with an age above 50 years that underwent gastro-duodenoscopy and colonoscopy. *H. pylori* status was determined by serology and serum pepsinogen I levels were measured in fasting state by commercially available assay. Intestinal metaplasia (IM), glandular atrophy and mucosal inflammation were diagnosed from histological specimens and graded according to the updated Sydney-classification.
RESULTS: In *H. pylori* infected patients (n = 101; 30.4%), the overall prevalence of ERD (20.8%) was comparable to non-infected patients (25.5%) (p = 0.215) and the same accounted for BE (7.9% vs. 11.7%) (p = 0.214). *H. pylori* infection was not associated with an increased risk for both ERD (OR = 0.76, 95% CI: 0.43-1.35) and BE (OR = 0.65, 95% CI: 0.28-1.49). The histological proof of intestinal metaplasia and/or gastric atrophy independently of the *H. pylori* status did not show an association to neither ERD (OR = 0.61, 95% CI: 0.28-1.49) or BE (OR = 0.73, 95% CI: 0.32-1.67). The same accounted for the different phenotypes of gastritis, including antrum- and corpus pre-dominant as well pangastritis for both ERD and BE. Furthermore, no association was seen between a decreased pepsinogen I level and the occurrence of ERD (OR = 0.75, 95% CI: 0.37-1.54) and BE (OR = 0.82, 95% CI: 0.31-2.22).
CONCLUSION: *H. pylori* infection does not show any association to the occurrence of ERD and BE. Furthermore, different types of gastric inflammation and a hypoacid gastric function do not have an influence on the development of ERD and BE.

INTRODUCTION: There is a well established association between *Helicobacter pylori* (*H. pylori*) infection and peptic ulcer disease (PUD). This association is known to be stronger in duodenal ulcers (DU) in comparison to gastric ulcers (GU). Over recent years, trends worldwide have shown a decreasing prevalence of *H. pylori* infection with some studies suggesting the rate of decline may be as high as 26% per decade[1]. Consequently due to its prominent association with PUD it would be interesting to identify the change in prevalence of PUD over the same timescale.
AIMS & METHODS: Using oesophagogastroduodenoscopy (OGD) as our chosen diagnostic tool, we have set out to determine whether the trend of decreasing *H. pylori* prevalence has been reflected in our sample population over the last 12 years and whether there has also been a decrease in PUD prevalence in particular with respect to duodenal ulcers.
1781 diagnostic OGD procedures carried out by the same endoscopist in a single District General Hospital in the South East of England were analysed retrospectively. For each procedure the age, gender, *H. pylori* status and PUD diagnosis were recorded. Prevalence data was calculated for three sequential time periods with comparable patient numbers: 2002 to 2005 (Period 1: n = 346), 2006 to 2010 (Period 2: n = 677), 2011 to 2014 (Period 3: n = 681).
RESULTS: The data showed that prevalence of *H. pylori* infection decreased in each successive period ($p = 0.0012$). The prevalence across the three time periods were as follows: period 1- 36 cases (10.4%), period 2- 38 cases (5.60%, $p = 0.005$ with respect to (WRT) Period 1) and finally period 3: 32 cases (4.70%, $p < 0.001$ WRT Period 1, $p = 0.446$ WRT Period 2).
The prevalence of PUD also decreased in each successive period ($p < 0.001$). The prevalence across the three time periods were as follows: period 1 - 27 cases (7.80%; DU = 24; GU = 3), period 2 - 32 cases (4.73%, $p = 0.046$ WRT Period 1; DU = 24; GU = 8) and period 3 - 11 cases (1.62%, $p < 0.001$ WRT Period 1, $p = 0.001$ WRT Period 2; DU = 8; GU = 4). The prevalence of duodenal ulcers decreased in each successive period ($p < 0.001$), however the prevalence of gastric ulcers remained consistently low ($p = 0.502$).
CONCLUSION: Prevalence of *H. pylori* has fallen significantly over the time period studied. Key reasons for this include continually improving sanitation and living conditions as well as more effective treatment of *H. pylori* infection, making recurrence less frequent. The falling prevalence of *H. pylori* is likely to have contributed to the significant decrease in prevalence of PUD in the same time period. Other reasons for this trend include the introduction of effective *H. pylori* treatment and increasing effective use of acid suppressive medication. Another possible factor for the decrease in PUD prevalence is more careful prescription of non steroidal anti-inflammatory drugs. The stronger association between *H. pylori* and DU may explain the significant reduction in the prevalence of DU in comparison to GU.

INTRODUCTION: The most commonly used second-line regimens for *H. pylori* eradication are bismuth-containing quadruple therapy and levofloxacin-containing triple therapy, both offering suboptimal results. Combining bismuth and levofloxacin in the same regimen may be an option as rescue regimen.
AIMS & METHODS: To evaluate the efficacy and tolerability of a second-line quadruple regimen containing levofloxacin and bismuth in patients whose previous *H. pylori* eradication treatment failed.
Design: Prospective multicenter study. *Patients*: Patients in whom a standard triple therapy (PPI, clarithromycin, and amoxicillin) or a non-bismuth quadruple therapy (PPI, clarithromycin, amoxicillin and metronidazole, either sequential or concomitant) had failed. *Intervention*: Esomeprazole (40 mg b.i.d.), bismuth (240 mg b.i.d.), levofloxacin (500 mg o.d.), and amoxicillin (1 g b.i.d.) for 14 days. *Outcome*: Eradication was confirmed using the ^{13}C-urea-breath test 4-8 weeks after therapy. *Compliance/tolerance*: Compliance was determined through questioning and recovery of empty medication envelopes. Incidence of adverse effects was evaluated by means of a questionnaire.
RESULTS: 78 patients were consecutively included. Mean age 46±16 years, 64% women, 14% peptic ulcer. Previous failed therapy included: standard clarithromycin triple therapy (57 patients), sequential (12), and concomitant (9). One patient did not return after treatment. 92% took all medications correctly. Per-protocol and intention-to-treat eradication rates were 89.5% (95%CI = 82-97%) and 87.2% (95%CI = 79-95%). Cure rates (per-protocol) were similar when compared depending on the diagnosis (peptic ulcer 100% vs. functional/uninvestigated dyspepsia 88%) and previous treatment (standard triple therapy 89% vs. sequential 83% vs. concomitant 100%). Adverse effects were reported in 60% of patients (95%CI = 49-72%), most commonly nausea (27%), metallic taste (26%), diarrhoea (23%), abdominal pain (22%), asthenia (17%), and vomiting (6.4%). In 2 cases, the adverse effects (nausea) were classified as severe (one patient discontinued the treatment), but none of them was serious.
CONCLUSION: 14-day bismuth-and levofloxacin-containing quadruple therapy is an effective (≈90% cure rate) and safe second-line strategy in patients whose previous standard triple therapy or non-bismuth quadruple (sequential or concomitant) therapy has failed, providing a simple and probably more effective alternative than bismuth-quadruple or levofloxacin-triple standard regimens.

INTRODUCTION: Non-bismuth quadruple "concomitant" regimen is increasingly used as first-line *H. pylori* eradication treatment.
AIMS & METHODS: To evaluate the efficacy and tolerability of the standard and optimized "concomitant" regimens.
Design: Prospective multicenter study. *Patients*: Consecutive *H. pylori*-infected patients. *Treatment*: In a first phase, patients received a standard concomitant therapy (CONC10): omeprazole 20 mg, amoxicillin 1 g, clarithromycin 500 mg and metronidazole 500 mg for 10 days b.i.d. In a second phase, patients received the same regimen but with esomeprazole 40 mg b.i.d. and lasting 14 days (CONC14+). *Outcome*: Eradication confirmed with ^{13}C-urea breath test 4-8 weeks after therapy. *Compliance/tolerance*: Compliance and adverse events were determined through questioning and recovery of empty medication envelopes.
RESULTS: 827 consecutive patients were included (mean age 48 years, 46% males, 21% peptic ulcer): 356 in CONC10 and 471 in CONC14+. Compliance with treatment was 94% and 95% respectively (non-statistically significant differences). Per-protocol eradication rates with CONC10 and CONC14+ were 86%(95%CI = 83-91%) and 93%(91-96%) ($p < 0.01$). Respective intention-to-treat cure rates were 86%(83-90%) and 91%(90-92%) ($p < 0.01$). Adverse effects (mostly mild) were reported in 32% of patients in CONC10 and in 44% in CONC14+ ($p < 0.05$), the most common being metallic taste, diarrhoea, nausea and abdominal pain.
CONCLUSION: An optimized (fourteen-day and high-dose esomeprazole) non-bismuth quadruple "concomitant" regimen for the eradication of *H. pylori* is more effective than the standard one, and achieves over 90% cure rate. Although the incidence of adverse events is higher with the optimized treatment, these are mostly mild, and do not negatively impact the compliance.

INTRODUCTION: Second-line bismuth-containing quadruple therapy is complex and frequently induces adverse effects. A triple rescue regimen containing levofloxacin is an alternative for *H. pylori* eradication. However, resistance to quinolones is rapidly increasing and may jeopardize its future efficacy. Moxifloxacin, a new generation quinolone, may be less affected by quinolone resistance than levofloxacin.
AIMS & METHODS: To evaluate the efficacy and tolerability of a second-line triple regimen containing moxifloxacin in patients whose previous *H. pylori* eradication treatment failed.
Design: Prospective multicenter study. *Patients:* Patients after failure of either:
- standard triple therapy (PPI, clarithromycin, and amoxicillin)
- non-bismuth quadruple therapy (PPI, clarithromycin, amoxicillin and metronidazole, either sequential or concomitant)
Intervention: Moxifloxacin (400 mg o.d.), amoxicillin (1 g b.i.d.), and esomeprazole (40 mg b.i.d.) for 14 days. *Outcome:* Eradication was confirmed using the 13C-UBT 4-8 weeks after therapy. *Compliance/tolerance*: Compliance was determined through questioning and recovery of empty medication envelopes. Incidence of adverse effects was evaluated by means of a questionnaire.
RESULTS: 250 patients were consecutively included. Mean age 48±15 years, 58% women, 11% peptic ulcer. Previous failed therapy included: standard triple therapy (179 patients), sequential (27), and concomitant (44). Four patients did not return after treatment. 97% of patients took all medications correctly. Per-protocol and intention-to-treat eradication rates were 85.7% (95%CI = 81-90%) and 82.4 (95%CI = 77-87%). Cure rates were similar when compared depending on the diagnosis (peptic ulcer 77% vs. functional/uninvestigated dyspepsia 82%) and previous treatment (standard triple therapy 83% vs. sequential 89% vs. concomitant 77%). In the multivariate analysis, age was the only variable associated with eradication success (OR = 0.957; 95%CI = 0.93-0.98). Adverse effects were reported in 25% of patients (95%CI = 20-30%), most commonly diarrhoea (9.6%), abdominal pain (9.6%), nausea (9.2%), metallic taste (4.5%), asthenia (4.5%), and vomiting (2.5%). In 13 cases, the adverse effects were classified as "intense", but none of them was severe.
CONCLUSION: 14-day moxifloxacin-containing therapy is an effective (>80%) and safe second-line strategy in patients whose previous standard triple therapy or non-bismuth quadruple (sequential or concomitant) therapy has failed, providing a simple alternative to bismuth quadruple or levofloxacin triple regimens.

P0515 THE ROLE OF A DUAL THERAPY CONTAINING HIGH-DOSE PPI IN ERADICATION IN PATIENTS WITH HELICOBACTER PYLORI POSITIVE DYSPEPSIA

A.T. Ince[1,*], M. Tozlu[1], B. Baysal[1], H. Şentürk[1], S. Arıcı[2], A. Özden[3]
[1]Gastroenterology, [2]Pathology, Bezmialem Vakıf University, İstanbul, [3]Gastroenterology, Ankara University Medical Faculty, Ankara, Turkey
Contact E-mail Address: *dralince@gmail.com*

INTRODUCTION: *H. pylori* eradication rates vary by society and usually do not exceed 80%. Some publications have reported that this rate was even higher with dual therapies containing high-dose proton-pump inhibitors. *H. pylori* eradication is recommended in patients with dyspepsia. The objective of the present study is to determine eradication rates with dual therapy containing high dose omeprazole in *H. pylori*-positive patients with dyspepsia.
AIMS & METHODS: The patients were treated orally with either dual (n:74, omeprazole 20mg q.i.d and amoxicillin 1g b.i.d) or triple therapy (n:116, omeprazole 20mg b.i.d and amoxicillin 1g b.i.d and clarithromycin 500mg b.i.d) for 14 days. HpSA test was requested 3 months later. The results were evaluated statistically, p values <0.05 were considered significant.
RESULTS: The study included 190 patients (80♂,110♀, $p>0.05$). The mean age was 35.6±11 years ($p<0.001$). The mean duration of dyspeptic symptoms was 28.2±33.7 months (median:18, range:3–338). Bloating was more frequent in the triple therapy group ($p<0.01$) while epigastric pain/burning and early satiation did not differ significantly between the groups ($p>0.05$). Alcohol and smoking, endoscopic findings and *H. pylori* rates with pathological examinations were not significantly different between groups whereas there was a significant difference in *Hp*Fast tests ($p<0.01$). When examined with HpSA tests 3 months after the treatment, eradication rate was 81.1% in the dual therapy group versus 63.8% in the triple therapy group ($p=0.011$). Dual therapy was more economic compared to triple therapy (144USDvs.107USD,$p<0.001$).
CONCLUSION: Dual therapy in patients with dyspepsia was more successful, cost-effective and is less risky in terms of side effects compared to standard triple therapy.

P0516 SECOND-LINE REGIMEN'S EFFICACY AGAINST HELICOBACTER PYLORI INFECTION AFTER STANDARD TRIPLE THERAPY WITH PPI, AMOXICILLIN & CLARITHROMYCIN: META-ANALYSES

A.C. Marín[1,2], A.G. McNicholl[1,2], **J.P. Gisbert**[1,2,*]
[1]Gasttroenterology Unit, Hospital de La Princesa and IP, [2]CIBERehd, Madrid, Spain
Contact E-mail Address: *aliciacmarin@gmail.com*

INTRODUCTION: *Helicobacter pylori* infection is usually treated with a proton pump inhibitor (PPI), amoxicillin and clarithromycin, but it fails in ≥ 20% of patients.
AIMS & METHODS: *Aim*: To estimate, by a systematic review and meta-analyses, the most effective rescue treatments after the failure of a first-line therapy with PPI, amoxicillin and clarithromycin in *H. pylori* eradication. *Methods*: *Selection of studies:* Meta-analyses were performed with randomized clinical trials (RCT) that assessed the efficacy of second-line regimens; the generic inverse variance was applied on prospective and retrospective studies. *Inclusion criteria:* Studies treating *H. pylori*-positive patients after clarithromycin-amoxicillin-PPI failure. *Exclusion criteria:* Second-line treatment based on the antibiotic sensitivity, or if the confirmation of eradication was made only by serology, PCR or polyclonal stool antigen test. *Search strategy:* Bibliographical searches were performed in PubMed, CINAHL, Cochrane Library, ClinicalTrials.gov, and several international congresses, up to April 2014. *Data synthesis:* Intention to treat eradication rate.
RESULTS: The efficacies of the second-line treatments are shown in the table attached. A meta-analysis comparing the triple therapy with levofloxacin-amoxicillin-PPI against the quadruple bismuth-metronidazole-tetracycline-PPI regimen showed a non-statistically significant tendency towards better results with levofloxacin (OR = 1.62; 95% C. I. = 0.84-3.14; p = 0.15; $I^2 = 75\%$; 7 studies; 1,158 patients).

SECOND-LINE TREATMENT	E. R.	N. S.	N. P.	95% C. I.	I^2
Levofloxacin + Amoxicillin + PPI					
-Overall	75%	21	2,919	70 - 80%	88%
-7 day treatment	69%	11	632	64 - 74%	53%
-10 day treatment	83%	11	1,946	77 - 89%	89%
-10 days with L(500 mg/24h) + A(1 g/12h)+PPI	87%	7	373	81 - 94%	77%
*Removing 1 outlier study	**92%**	6	273	89 – 95%	0%
-14 day treatment	74%	3	341	70 – 78%	96%
*Removing 1 outlier study	86%	2	151	81 – 92%	0%
Bismuth + Metronidazole + Tetracycline + PPI					
- Overall	77%	43	3,685	74 - 81%	86%
-7 day treatment	75%	31	2,345	71 - 80%	84%
-10 day treatment	77%	2	142	60 - 93%	76%
-14 day treatment	**81%**	15	1,187	76 - 86%	83%
Metronidazole + Amoxicillin + PPI					
- Overall	88%	24	1,642	85 - 91%	75%
-7 day treatment	75%	24	1,160	85 - 91%	75%
-7 days with M(250 mg/12h) +A(750 mg/12h)+PPI	**92%**	12	751	89 - 95%	48%
-10 day treatment	84%	4	314	77 - 91%	69%
-14 day treatment	81%	2	127	75 - 88%	0%
Amoxicillin + PPI (14 days –all the studies were done in Japan)					
- Overall	82%	5	200	69 - 95%	87%
-14 day with A (500 mg/6h) + PPI(10 mg/6h)	**93%**	3	106	88 - 98%	3%
-14 day with A (1 g/12h) + PPI (20 mg/12h)	66%	2	94	51 - 81%	58%

E. R.: eradication rate; N. S.: Number of studies; N. P.: number of patients.
CONCLUSION: The most effective second-line treatments, after a clarithromycin-amoxicillin-PPI failure, are the metronidazole-amoxicillin-PPI or a 10 day levofloxacin-amoxicillin-PPI therapy. More high quality trials, performed outside Japan, are needed to verify the efficacy of the 14 day dual therapy with amoxicillin-PPI.

P0517 SEVEN-DAY NON-BISMUTH CONCOMITANT QUADRUPLE THERAPY IS SUFFICIENT IN ACHIEVING A GRADE A REPORT CARD FOR FIRST-LINE ANTI-HELICOBACTER PYLORI THERAPY: A PILOT STUDY

C.-M. Liang[1,*], W.-C. Tai[1], S.-K. Chuah[1], K.-L. Wu[1], Y.-C. Chiu[1]
[1]*Division of Hepato-gastroenterology, Department of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, Kaohsiung, Taiwan, Province of China*
Contact E-mail Address: *gimy54861439@gmail.com*

INTRODUCTION: The eradication rate of the standard triple therapy has generally declined to unacceptable levels (i.e., 80% or less) recently because the increasing incidence of clarithromycin-resistant strains of *Helicobacter pylori (H. pylori)*. **10-day** concomitant therapy (non-bismuth concomitant quadruple therapy) can achieve a promising success rate of 90-94% in the presence of clarithromycin resistance. This therapy is superior to standard triple therapy for *H pylori* eradication and less complex as this regimen does not involve changing drugs halfway through.
AIMS & METHODS: This study is to assess the efficacy of 7-day concomitant therapy and to investigate the host and bacterial factors influencing the treatment outcomes of all eradication therapies. One hundred and eighty consecutive *H. pylori*-infected patients are randomly assigned to a 7-day non-bismuth quadruple therapy (EACM group, Esomeprezole 40 mg bid., amoxicillin 1 g bid., clarithromycin 500 mg bid., and metronidazole 500 mg bid. for 7 days) or a 7-day standard triple therapy (EAC group, Esomeprezole 40 mg bid., amoxicillin 1mg bid., clarithromycin 500 mg bid., and for 7 days). Patients are asked to return at the 2nd week to assess drug compliance and adverse events. Repeated endoscopy with rapid urease test, histological examination and culture is performed at the 8th week after the end of anti- *H. pylori* therapy. If patients refuse follow-up endoscopy, urea breath tests are conducted to assess *H. pylori* status. Additionally, antibiotic susceptibility of *H. pylori* will be examined. Finally, the rates of eradication, adverse events and compliance will be compared between groups by chi-square test, and the host and bacterial factors influencing each efficacy of the regimen are assessed by multivariate analysis.
RESULTS: Our results demonstrated that the eradication rates for EACM therapy and EAC standard triple therapy in intention-to-treat analysis were 86.7% vs. 72.2%, $P=0.016$ and 95.1% vs. 79.2%, $P=0.002$) in the per-protocol analysis. Drug compliances were 100% in both groups although more adverse events were reported in the EACM group (35.3% vs. 18.3%, $P=0014$). Clarithromycin resistance was the only independent predictors of treatment failure in multivariate analysis. In the subgroup analysis according to antibiotics susceptibility, none of the patients with clarythromycin resistant strains and 33.3% with metronidazole resistant strains were eradicated in the EAC group while 75% of those with resistant strains were eradicated in the EACM group.
CONCLUSION: This study suggests that a 7-day non-bismuth concomitant quadruple therapy is sufficient in achieving a grade A report card for first-line anti-*H. pylori* therapy. Clarithromycin resistance was the factor responsible for eradication failures.

P0518 EMPIRICAL RESCUE THERAPY AFTER *H. PYLORI* TREATMENT FAILURE. A 15-YEAR SINGLE CENTER STUDY OF 1,000 PATIENTS

D. Burgos Santamaría[1,*], A.G. McNicholl[1], J.L. Gisbert[1], S. Marcos[1], M. Fernández-Bermejo[2], J. Molina-Infante[2], J.P. Gisbert[1]
[1]*Hospital Universitario de La Princesa, IP, CIBEREHD, Madrid,* [2]*Hospital San Pedro de Alcántara, Cáceres, Spain*
Contact E-mail Address: *diegoburgossantamaria@gmail.com*

INTRODUCTION: The most commonly used empirical therapies for *H. pylori* eradication fail up to 20-30% on first line, and even more in "rescue" therapies. This is mainly due to increasing antibiotic resistances and poor compliance. Therefore it is necessary to evaluate the efficacy and safety of the overall eradicating strategy, including multiple and consecutive lines of treatment.
AIMS & METHODS: To evaluate the efficacy of different "rescue" therapies empirically prescribed during 15 years to 1,000 patients in whom at least one eradication regimen had failed to cure *H. pylori* infection.
Design: Retrospective single-center study. *Patients:* 1,000 consecutive patients who had failed at least one eradication therapy (1998-2013). *Intervention:* The most common eradication treatments were: 1) PPI-Amoxicillin-Levofloxacin (PPI-A-L), 2) Ranitidine bismuth citrate-Tetracycline-Metronidazole (Rcb-T-M), 3) Classic Quadruple therapy (PPI-Bismuth-Tetracycline-Metronidazole) (PPI-B-T-M), 4) Esomeprazole-Moxifloxacin-Amoxicillin (E-Mox-A), 5) PPI-Amoxicillin-Rifabutin (PPI-A-Rif). Rifabutin was prescribed only as 4th line, and the other treatments were used both as 2nd and 3rd line. As antibiotic susceptibility was unknown, "rescue" regimens were prescribed empirically. Rescue regimens were prescribed without retreating with the same drugs. *Outcome:* Eradication was defined as a negative ^{13}C-urea breath test 4-8 weeks after completing therapy. Modified "intention-to-treat" analysis was used, considering patients with poor compliance, but not those who were lost during the follow-up.
RESULTS: Overall eradication rates of *H. pylori* with 2nd, 3rd and 4th lines of "rescue" therapies were 74.6%, 71.1% and 50% respectively, with a cumulative eradication rate after consecutive administration of 4 treatments of 99.2%. Compliance with 2nd, 3rd and 4th line regimens was 95.6%, 93% and 93.5% respectively, with an overall compliance of 95.1%. The efficacy and adverse effects of treatments were 83.5% and 24.2% with E-Mox-A, 77.8% and 24% with PPI-L-A, 68.9% and 21.5% with PPI-B-T-M, 66% and 33.3% with Rcb-T-M, and 62% and 37.9% with PPI-A-Rif. The highest rate of eradication was achieved with E-Moxi-A (83%) as a 2nd line treatment, regardless of the first-line regimen prescribed.
CONCLUSION: *H. pylori* eradication rates may reach 99% without performing bacterial culture by using a rescue strategy of 4 consecutive empirical treatments. The best rescue strategy to eradicate *H. pylori* is the consecutive administration of quinolones (2nd line), PPI-B-T-M (3rd line) and PPI-A-Rif (4th line).

P0519 LETS TRY QUINTUPLE THERAPY AS A RESCUE ERADICATION REGIMEN FOR REFRACTORY *H. PYLORI* INFECTION

F. Mansour-Ghanaei[1,*], A. Shafaghi[1], F. Joukar[1], M. Naghipour[2]
[1]*Gastrointestinal and Liver Diseases Research Cente,* [2]*Epidemiology, GUILAN UNIVERSITY OF MEDICAL SCIENCES, Rasht, Iran, Islamic Republic Of*
Contact E-mail Address: *ghanaie@yahoo.com*

INTRODUCTION:
To compare the efficacy, tolerability and side effect profiles of two quintuple regimens for helicobacter pylori (*H. pylori*) eradication in patients who failed the first line quadruple therapy.
AIMS & METHODS: Between April 2011 and March 2012, a total of 208 patients with dyspepsia who failed *H. pylori* eradication using the standard quadruple therapy with BOAC (Bismuth subcitrate, Omeprazole, Amoxicillin, Clarithromycin) or BOAM (Bismuth subcitrate, Omeprazole, Amoxicillin, Metronidazole) were recruited for this study. The patients were randomized into two equal groups using random block method. Patients in BOACT group were treated by omeprzole 20 mg, combined with bismuth subcitrate 240 mg, and three antibiotics clarithromycin 500 mg, amoxicillin 1000 mg and tinidazole 500 mg all twice daily for seven days. Patients in the BOTMO group were given omeprazole 20 mg and bismuth subcitrate 240 mg along with tetracycline 500 mg and ofloxacin 200 mg in the same manner as in BOACT group. The eradication was confirmed at 12 weeks after end of therapy by C14 urea breath test. Patients' compliance and drugs side effects were evaluated at the end of treatment. The success rates were calculated separating by intention-to-treat (ITT) and per-protocol (PP) analyses.
RESULTS: A total number of 208 patients were included in the study and 205 patients completed the treatment course. The intention-to-treat and per-protocol eradication rates were 75.5% and 76% in the BOACT group and 86.5% and 86.7% in the BOTMO group, respectively. The eradication rates of the BOTMO group was significantly higher than BOACT group ($p=0.04$). Side effects were reported from 33.2% of the patients which were mild and did not necessitate interfere with therapy although 3 patients (2 patient in BOACT group and 1 patient in BOTMO group were excluded from the study due to severe drug side effects.
CONCLUSION: Quintuple therapy with BOTMO could be an alternative second-line rescue therapy for Iranian patients who have failed one previous standard treatment for *H. pylori* eradication, but its efficacy needs to be confirmed in other populations before we can generalized our findings, considering regional antimicrobial resistance. Considering the short length of treatment in our study, further studies to assess the effects of quintuple therapies by BOTMO regimen with periods longer than 7 days is recommend

P0520 HELICOBACTER PYLORI ERADICATION RATES AND PLASMA PANTOPRAZOLE LEVELS IN TYPE 2 DIABETIC AND NONDIABETIC PATIENTS

F. Sapmaz[1,*], I.H. Kalkan[1], I. Süslü[2], S. Güliter[1]
[1]*Gastroenterology, Kırıkkale University Faculty of Medicine, Kırıkkale,* [2]*Pharmeceutics, Hacettepe University Faculty of Medicine, Ankara, Turkey*
Contact E-mail Address: *ferda-sapmaz@hotmail.com*

INTRODUCTION: The eradication rate of Helicobacter pylori has been reported as being lower in patients with type 2diabetes mellitus (DM) than in those without DM.
AIMS & METHODS: The first aim of this study was to compare the efficacy of a bismuth-based quadruple regimen as first-line therapy for Helicobacter pylori (HP) eradication in diabetic and non-diabetic patients. The second aim of the study was to compare plasma Pantoprazol levels in these patient groups during *H. pylori* eradication treatment.
Forty consecutive type 2 DM and 40 non-diabetic naïve *H. pylori* infected patients were enrolled in this study. All patients received Pantoprazole (40 mg b.i.d.), bismuth citrate (120 mg q.i.d.), tetracycline (500 mg q.i.d.), and metronidazole (500 mg t.i.d.) for 14 days as the eradication regimen. We used Square-Wave Voltammetry method to determine plasma Pantoprazole levels in both groups.
RESULTS: The overall compliance rates among the diabetic patients and control group were 90.0% (36/40) and 92.5% (37/40), respectively. The per-protocol HP eradication rates (63.9% vs 89.2%, $p=0.01$), Intention-to-treatment HP eradication rates (60% vs 87.5%, $p<0.001$) and Plasma Pantoprazole levels ($0.25\mu gmL^{-1}$ vs. $0.34\ \mu gmL^{-1}$, $p=0.005$) were significantly lower in diabetic patients.
CONCLUSION: Our study showed that diabetic patients had lower plasma Pantoprazole levels which led to lower *H. pylori* eradication rates with a bismuth and Pantoprazole including regimen. Clinical and pharmacokinetic investigations are required to improve plasma proton pump inhibitor levels in diabetic patients for satisfactory *H. pylori* eradication rates.

INTRODUCTION: Quantifying excess cause specific mortality among people with coeliac disease (CD) compared to the general population accounting for competing risks (which takes into account that patients may die due to other causes before dying from the cause of death of interest) will allow accurate information to be given on prognosis and risks of adverse outcomes.
AIMS & METHODS: This study quantifies the excess cause specific mortality among people with CD by 10 year of diagnosis compared to the general population while accounting for competing risks. We identified from the Clinical Practice Research Datalink (CPRD), all patients with CD for whom linkage to Office of National Statistics (ONS) data to determine cause of death if it occurred was available. We selected controls by frequency matching from the registered GP population within 10 year age bands. We calculated the adjusted cumulative incidence (including adjustment for competing risks) for different causes of death up to 10 years from diagnosis. We also calculated the excess cumulative incidence (eCI) for each cause of death compared to controls.
RESULTS: Of the 5,310 patients with CD, 352 died within the study period. The overall mortality rateamong CD patients was 124 per 10,000 person-years compared to 111/10,000 in controls. By 10 years after CD diagnosis, the cumulative incidence of death (Table 1) from cardiovascular related deaths was slightly lower compared to those without CD diagnosis (CD 0.16% versus Controls 0.26%) with a corresponding eCI of 0.1% (95% CI -0.14 to -0.06). Overall there was no difference in the cumulative incidence of respiratory, digestive or cancer related death among cases and controls. However, CD patients had 0.1% excess risk (95%CI;0.01-0.16) of deaths death from non-Hodgkin's lymphoma or leukaemia.
Table 1: Cumulative incidence and excess risk by 10 years after diagnosis adjusted for competing risks, gender, age and social class

Cause of death	With CD	Without CD	Excess	95% CI	
Cardiovascular overall	0.16	0.26	-0.10	-0.14	-0.06
Ischemic heart disease	0.10	0.15	-0.05	-0.08	-0.16
Respiratory overall	0.07	0.07	0.00	-0.02	0.03
Neoplasm overall	0.78	0.72	0.06	-0.11	0.23
Non-hodgkins/leukemia	0.13	0.04	0.08	0.01	0.16
Digestive overall	0.15	0.11	0.05	-0.03	0.13

CONCLUSION: Overall, people with CD have no major excess risk of cancer, digestive, cardiovascular or respiratory related mortality compared to the general population over the 10 year period following initial diagnosis. In addition they have only a very small excess risk of dying of haematological malignancy. These findings should be reassuring to both patients with CD and clinicians managing their care.

P0522 NUTRIENTS INTAKE IN NON CELIAC PATIENTS ON GLUTEN FREE DIET BECAUSE OF PERCEIVED GLUTEN SENSITIVITY: COMPARISON WITH CELIAC PATIENTS AND WITH NATIONAL NUTRITIONAL GUIDELINES

B. Zanini[1,*], M. Marullo[1], A. Ferraresi[1], F. Caselani[1], C. Ricci[1], F. Lanzarotto[1], A. Lanzini[1]

INTRODUCTION: Non celiac and non wheat allergic patients that spontaneously adhere to gluten free diet (GFD) because of adverse gastrointestinal and extra-intestinal reactions to gluten containing food are frequently encountered in clinical practice and are commonly referred to as "gluten sensitive" (GS) patients. In most cases GS patients do not seek dietician advice on GFD, and no information is available on the nutritional adequacy of their self-made diet.
AIMS & METHODS: We carried out a prospective clinical study to assess macro- and micro-nutrients of GFD in GS patients compared with that of a cohort of patients with celiac disease (CD) matched according to gender and age (range +/-4 years), and with the recommendations of the Italian nutritional guidelines (LARN 2012). Patients in the 2 study cohorts were asked to fill in a standardized 7-day food diary. Data from diaries were analyzed with Microdiet© software (Downlee systems, ltd. UK) that returns very detailed information on diet composition. Nutritional characteristics included: total Kcal, proportion of total energy values of CHO, free sugars, proteins, fats, SFA and PUFA, and total amounts of fibres, vitamins A, C, D, B12, folates, sodium, calcium, iron, zinc, selenium, magnesium and alcohol. For statistical analysis Fisher's exact test and Wilcoxon matched paires test were used as appropriate.
RESULTS: Twenty-two GS patients (mean ± SD 40 ±9 years, BMI 22±3) and 22 CD patients were enrolled. Total Kcal were 1767 ±501 Vs 1544 ±539 in GS and CD respectively, with no difference in % contribution of CHO, fats and proteins to total calories. The proportion of macro-nutrients in the diet that was correct according to the LARN recommendations was 54%, 59% and 32% in GS and 18%, 41% and 5% in CD for CHO, proteins and fats, respectively. Comparison of selected nutrient composition in GS Vs CD patients and Vs LARN are reported in the table.

Nutrients	GS	CD	GS Vs LARN %[§]
PUFA, % TEV	4.6±2.2	3.4±1.2*	- 50
Fibres, g	20.0±24.9	11.9±6.5	-86
Alcohol, g	2.3±4.4	4.0±8.9	NA
Vitamin B12, µg	3.9±1.8	1.0±1.6*	-14
Vitamin D, µg	2.2±1.2	1.5±0.9*	-100
Folates, µg	324.5±381.5	131.7±74.7*	-73
Magnesium, mg	146.7±101.4	44.6±64.4*	-77
Iron, mg	9.0±5.4	5.4±2.7*	-68
Selenium, µg	39.0±16.3	10.4±16.0*	-55

CONCLUSION: Patients spontaneously adhering to a GFD for perceived GS have, despite no dietetic instruction, a more balanced intake of macro- and micro-nutrients in comparison with CD patients. This phenomenon may be the result of a behavioural attitude towards healthy food more pronounced in GS than in CD patients, although LARN recommendations are not met for most nutrients.

INTRODUCTION: Red cell distribution width (RDW) has been shown in previous studies to be a sensitive predictor for coeliac disease (CD), but it lacks specificity. Splenic hypotrophy is also noted frequently in celiac patients. Our aim was to evaluate if spleen size/RDW can be used as an indicator for celiac disease.
AIMS & METHODS: We evaluated 32 patients with small bowel disease (12 newly diagnosed CD patients and 20 patients with Crohn's disease, IBD-CD) and 32 age-matched patients with irritable bowel syndrome (IBS), admitted to our clinic over a one-year period. We evaluated the differences in spleen diameter, RDW and their ratio among the three groups.
RESULTS: Of the 32 patients with small bowel disease, 11 were males, with a mean age of 38.34 years. Mean RDW was significantly higher in the CD and IBD-CD groups than the IBS group (14.49 and 16.73 vs. 13.51, $p = 0.0099$), whereas mean spleen size was lowest in the CD patients (84.08, 107.85 and 112.62 mm respectively). The mean spleen diameter/RDW was 5.82 in the CD group, 6.65 in the IBD-CD group and 8.34 in the IBS group ($p = 0.0001$). A ratio under 6 had a sensitivity of 75% and a specificity of 88.46% in detecting CD.
CONCLUSION: Spleen diameter/RDW is a simple, widely available score, which can be used to select patients for futher diagnostic tests. This should be repeated in larger patient cohorts.

INTRODUCTION: The gluten free diet (GFD) is the only available therapy for patients with celiac disease (CD). Medical research is actively focused on the search for drug-based solutions as an alternative to GFD, which requires lifelong, strict adherence.
AIMS & METHODS: We aimed at evaluating the actual need for other-than-GFD therapies perceived by CD patients, along with the impact of GFD itself on their life.
During the 2012 meeting of the Lombardy section of the Italian CD Patients Association, adult CD subjects on GFD were invited to fill in a questionnaire investigating their clinical profile in relation to GFD compliance, health status and quality of life as well as their opinion on GFD, alternative therapies and research priorities.
RESULTS: 372 patients (76 M, mean age at diagnosis and at entry 29.7 ± 16.9 and 41.7 ± 13.9 years, respectively) completed the questionnaire. 94% patients reported strict adherence to GFD. Patients reported a significant improvement in health status and quality of life after the diagnosis of CD was made and GFD was started ($p < 0.001$), with a greater improvement of health status than quality

of life (82% vs 56%, $p<0.001$). GFD was favourably considered and accepted by 88% patients, but a demand for alternative therapies was reported by 65% patients. Subjects expressing the need for a drug-based therapy showed a significantly lower increase of quality of life on GFD ($p=0.002$), but no differences were observed in health status changes. The preferred option for an alternative therapy was the "on demand" assumption of drugs, i.e. enzymes (145 subjects), followed by a vaccine-based strategy (111 subjects). Almost two thirds of the cohort stated they would accept to be enrolled in *ad hoc* designed clinical trials.
CONCLUSION: GFD is favourably accepted and followed by most CD patients, with significant health status improvement. Nevertheless, a considerable proportion of patients pronounce themselves in favour of the development of alternative drugs, although a chronic drug therapy is not considered a likely opportunity.

INTRODUCTION: We have recently identified a significant deterioration of trabecular and cortical microarchitecture in peripheral bones of patients with undiagnosed celiac disease (CD) by using high resolution-peripheral quantitative computed tomography (HR-pQCT). Such finding may underlie bone fragility and lead to fractures in these patients. Up to now, the effect of the gluten-free diet (GFD) on microstructural parameters of peripheral bones has not been assessed.
AIMS & METHODS: Aim: To explore one-year changes of bone microstructure associated with the GFD in a prospective cohort of premenopausal women with newly diagnosed CD.
Materials: We prospectively enrolled 31 consecutive females with newly diagnosed CD. Up to now, 25 patients have been reassessed one-year after diagnosis. Clinical and biochemical status, CD specific serology, assessment of the degree of compliance with the GFD, bone densitometry and microstructural determinations (HR-pQCT) were performed at both time points. HR-pQCT bone volumetric and structural measurements were determined at the distal non-dominant radius and tibia. Parameters of patients were also compared with those of 22 healthy women of similar age and body mass index.
RESULTS: Compared with the baseline *z*-score, the one-year bone mineral density measured by dual energy x-ray absorptiometry (DXA) improved significantly at the distal radius (mean±SD) (-1.94±1.27 vs. -1.43±1.06; $p<0.02$) but not at the lumbar spine level. The microstructure of the trabecular compartment in the distal radius was significantly improved (trabecular/bone volume fraction, trabecular density and trabecular thickness: $p<0.0001$) at the one-year time point. At the level of tibia, treatment was associated with significant increment of the total volumetric density ($p<0.01$), cortical density ($p<0.002$), trabecular density ($p<0.0001$), trabecular/bone volume fraction ($p<0.0001$) and trabecular thickness ($p<0.002$). In contrast, the cortical thickness decreased significantly in both sites ($p<0.001$). Compared to the control group there were no statistically significant differences in most trabecular parameters measured by HR-pQCT.
CONCLUSION: This is the first study exploring the effect of a one-year GFD on microstructural parameters measured by HR-pQCT in patients with newly diagnosed CD. Our study shows that trabecular parameters impaired at the time of diagnosis improved significantly by treatment reaching values comparable to those in healthy controls. We postulate that bone microarchitecture improvement underlie the decreased risk of fractures observed after treatment with a GFD.

P0526 HOW DOES SPECIFIC SEROLOGY MATCH WITH ESPHGAN SEROLOGIC GUIDELINES FOR DIAGNOSIS OF CELIAC DISEASE IN A PROSPECTIVE COHORT OF ADULTS WITH HIGH PRETEST PROBABILITY?

G. **I. Longarini**[1,*], E. Sugai[1], H. Hwang[1], F. Nachman[1], A. Cabanne[1], H. Vazquez[1], M.L. Moreno[1], A.F. Costa[1], M. I. Pinto[1], S. Niveloni[1], E. Smecuol[1], R. Mazure[1], E. Mauriño[1], J.C. Bai[1]

INTRODUCTION: Intestinal biopsy is considered mandatory for the diagnosis of celiac disease (CD). This has been recently challenged by several studies and the 2012 ESPGHAN guideline proposing an appropriate clinical and serological algorithm that could be used to reduce the need for duodenal biopsy. This provocative strategy has been confirmed by some studies but rejected by others. However, all these studies were performed on the basis of retrospective analyses of biased populations. Prospective evaluation of patients in whom diagnosis was based on histological grounds is important to clarify this controversy.
AIMS & METHODS: 1-To review the performance of serology tests in a prospective and consecutive series of adult patients with high pretest probability for CD; 2- to compare performance of serologic tests with the ESPGHAN serologic algorithm; and 3- to establish the best serologic algorithm for diagnosing CD using antibody tests detecting different antigens.
We performed a *post hoc* analysis of data from all patients enrolled in a previous prospective study (WJG 2010; 16: 3144) where consecutive adults suspected of intestinal disorders (high pretest population) were enrolled. Diagnosis of CD was based on histology (Marshs stages ≥3a) in all patients irrespective of serology. CD-related serology consisted of seven different assays but we only report the performance of tissue transglutaminase (tTG) IgA, deamidated gliadin peptides (DGP) IgG and the combination of both (INOVA Diag. Inc.). Serologic performance was compared with the ESPGHAN serologic criterion (cut-off >10 times the upper limit of normal -ULN-), the best cut-off (area under the ROC) and the cut-off suggested by the manufacturer.
RESULTS: Sixty-three of 161 patients (39%) had histological criteria for CD. According to the ESPGHAN criterion, IgA tTG sensitivity was 22% with 100% positive predictive value (PPV). The best cut-off value (34 AU/mL) would detect 93.6% of patients with 100% of PPV. Finally, the manufacturer cut-off (20 AU/mL) had 95.2% sensitivity and 97.9% PPV. The ESPGHAN criterion used for IgG DGP was 3.2% sensitive with a PPV of 100%. The best cut-off (was similar to that of the manufacturer: 20AU/mL) was 95.2% sensitive and had 100% PPV. Any test was positive (>20AU/mL) in all patients and both were concomitantly positive in 90.5% of cases with100% of PPV.
CONCLUSION: This prospective study indicates that, under particular clinical circumstances, a serologic strategy can be used to avoid duodenal biopsy in the diagnosis of adult patients with CD. The need for biopsy could be avoided in a minority of patients by using the ESPGHAN serologic criterion. Our results suggest that the best serologic strategy for a high pretest population seems to be the association of tTG IgA and DGP IgG. In such context, biopsy could be avoided in more than 90% of the cases when both tests are positive.

P0527 HIGH RATES OF PRIOR CELIAC DISEASE OVERDIAGNOSIS AMONG PATIENTS REFERRING TO AN ITALIAN TERTIARY CARE CENTER

G. Ianiro[1,*], G. Bruno[1], S. Bibbò[1], S. De Martino[1], V. Arena[2], A. Gasbarrini[1], G. Cammarota[1]
[1]*Dept of Internal Medicine, Division of Gastroenterology,* [2]*Histopathology Unit, CATHOLIC UNIVERSITY SCHOOL OF MEDICINE, ROME, Italy*
Contact E-mail Address: *gianluca.ianiro@hotmail.it*

INTRODUCTION: Celiac disease (CD) was formerly considered a rare condition and frequently underdiagnosed. Interest in CD has grown in recent years, not only among gastroenterologists but also among general practitioners and patients. Furthermore, focus of media on gluten-free diet (GFD) is increasingly spreading worldwide. Therefore many patients are labeled as celiacs and start a GFD even without completing the correct diagnostic process.
AIMS & METHODS: Our aim is to assess the impact of overdiagnosis in an Italian tertiary referral center for CD. We reviewed the clinical history of all patients referring to our Centre from October 2012 to December 2013. We included only patients at their first examination. We questioned diagnoses for the following reasons: EMA/TTG absence or negativity; duodenal biopsy not performed or unclear; DQ2/DQ8 negativity. Following data of patients with a doubtful diagnosis were extracted: people who have diagnosed CD (physicians or patients); reasons for diagnosis (symptoms, DQ2/DQ8, specific antibodies, duodenal biopsy), gluten consumption status. Number of patients undergoing a proper diagnostic process was determined, as well as of patients with a prior undebatable diagnosis. Diagnosis was revaluated by repetition of serology and by second-reading of duodenal tissue slides by an experienced pathologist. DQ2/DQ8 was searched in pertinent cases.
RESULTS: Over the study period, 293 patients attended our Centre, of whom 150 for the first time. Of them, 47 (31.3%) presented with an undebatable diagnosis of CD, and 37 (24.7%) were newly diagnosed because of EMA/TTG positivity associated with duodenal Marsh lesions. In 15 patients (10%) referring for

family history of CD, gastrointestinal symptoms or anemia, CD was excluded by serology and histology assessment. The remaining 51 patients (34%) came for a revaluation of previously diagnosed CD. Forty-five of them (88%) were on a GFD at the time of the examination. Thirty-five patients (68.6%) were diagnosed of CD by their trusted doctor (gastroenterologist, gynaecologist, dermatologist or general practitioner), while the remaining 16 (31.4%) believed to be affected of CD on their own. Motivations for prior CD diagnosis were often multiple for each patient: serologic positivity (9 AGA, 5 EMA, 2 TTG) in 16 cases, histological features in 19 cases, DQ2/DQ8 positivity in 20 cases, amelioration of symptoms after GFD in 16 cases. Reasons for questioning previous diagnosis were also multiple for each patient: EMA/TTG absence or negativity in 45 cases; lack of duodenal biopsy in 20 cases; unclear histology in 24 cases; DQ2/DQ8 negativity in 2 cases. Diagnosis of CD was rejected in 78.4% of doubtful cases (n = 40), being confirmed in only 19.6% (n = 10) of them. In one patient, diagnosis is still ongoing.
CONCLUSION: Our retrospective study shows that a considerable number of patients referring to an Italian tertiary care center experience previous misdiagnosis and/or overdiagnosis of CD. Such behavior may lead to both a diagnostic delay of other diseases and a remarkable waste of economic resources (tax exemptions, gluten-free food vouchers, diagnostic exams), with damage for both patients and health services. Greater accuracy in the application of the adequate diagnostic process and a higher adherence to guidelines are needed to minimize misdiagnosis of CD.

P0528 GLUTEN AVOIDANCE BEFORE A DEFINITE DIAGNOSIS IS MORE COMMON AMONG NON-CELIAC SUBJECTS THAN CELIAC ONES

G. Ianiro[1,*], G. Bruno[1], S. Bibbò[1], S. De Martino[1], V. Arena[2], A. Gasbarrini[1], G. Cammarota[1]

INTRODUCTION: Gluten is known to trigger not only celiac disease, but also other conditions, such as non-celiac gluten sensitivity (NCGS) and wheat allergy, recently grouped together as "gluten-related disorders". Gluten has recently shown to cause depression in subjects with NCGS. Furthermore, gluten is able to cause gastrointestinal (GI) symptoms and to alter bowel barrier functions in patients with diarrhea-predominant irritable bowel syndrome (IBS-D). Gluten-free claims are increasingly spreading on the Web and other media, and many subjects start a gluten-free diet (GFD) without any prior medical consultation. Such a behavior may lead to a considerable waste of resources and to diagnostic delay both in celiac and in non-celiac subjects.
AIMS & METHODS: Our aim was to assess the impact of gluten avoidance before a definite diagnosis in both patients with and without celiac disease. We reviewed the clinical history of all patients referring to our CD outpatient clinic from October 2012 to December 2013. We included only patients without a definite diagnosis of CD at their first examination at our Centre. Patients were grouped according to their gluten consumption status at the time of examination. Gluten was reintroduced for at least 2 months before any diagnostic assessment in all subjects already on GFD. The following data were extracted from patients on GFD at the time of examination: gender, age, reasons for gluten avoidance without definite diagnosis (GI/extraintestinal symptoms, DQ2/DQ8, specific antibodies, duodenal biopsy), proposer of GFD (physicians or the patient itself). All patients underwent blood dosage of EMA, TTG and total IgA levels, as well as upper endoscopy with duodenal biopsy. In all patients CD was diagnosed because of EMA and TTG positivity associated with Marsh-type intestinal lesions. Correlation between gluten avoidance and further diagnosis of CD was assessed by Chi-square test.
RESULTS: Over the study period, a total amount of 293 patients attended our Centre, of whom 150 (M 41, F 109 – mean age 39 y) for the first time. Ninety-two patients came without a definite diagnosis of CD. Of them, 32 (34.8%) were on GFD at the time of examination, and 60 (66.2%) were not. Reasons for GFD without definite diagnosis were: GI symptoms (12 cases), extraintestinal symptoms (7 cases), DQ2/DQ8 positivity (9 cases), antibody positivity (6 cases), histological features (9 cases). Sixteen patients started a GFD on their own (41%), and 23 upon medical advice (58%). Gender did not influence gluten consumption status ($p = 0.8376$). Respectively, CD was diagnosed in 21.9% (7/32) of patients on GFD and 71.8% (43/60) of patients on a gluten-containing diet at the time of first examination ($P < 0.0001$).
CONCLUSION: Our study shows that gluten avoidance before a clear definition of diagnosis is more common among subjects in whom CD is ruled out at a later stage than ones diagnosed of CD afterwards. The increasing interest of physicians and patients in gluten-related diseases, and unmotivated gluten-free claims may explain such reasons. Also symptom burden and gluten influence on mental component of patients may play a role in this phenomenon. However, the retrospective nature of our study represents a limitation in data analysis. Further, prospective trials are warranted to clarify this issue.

P0529 IS VISCERAL ADIPOSE TISSUE A RISK FACTOR FOR SMALL BOWEL ANGIOECTAISA?

A. Yamada[1,*], R. Niikura[1], Y. Kobayashi[1], H. Suzuki[1], H. Watabe[1], S. Yoshida[2], Y. Hirata[1], K. Koike[1]
[1]*Department of Gastroenterology, Graduate School of Medicine,* [2]*Department of Endoscopy and Endoscopic Surgery, The University of Tokyo, Tokyo, Japan*

INTRODUCTION: Small bowel angioectasia (SBA) is one of the major bleeding sources of obscure gastrointestinal bleeding (OGIB). Little is known about etiology of SBA. Visceral adipose tissue (VAT) expresses some bioactive molecules including vascular endothelial growth factor (VEGF), which is implicated in normal or pathological vessel formation. In the present study, we investigated VAT in association with the risk of small bowel angioectasia.
AIMS & METHODS: We retrospectively investigated 198 consecutive patients (male: female; 117: 81, mean age 65.8 ± 12.8 years) who underwent capsule endoscopy (CE) and CT for investigation of overt and occult OGIB at the University of Tokyo Hospital between January 2009 and September 2013. VAT and subcutaneous adipose tissue (SAT) were measured by CT, and medical history of concomitant disease and body mass index were obtained from their medical records. Logistic regression analyses were used to evaluate associations.
RESULTS: Out of 198 OGIB patients, CE found SBA in 18 patients (9.1%). Compared with patients without SBA, those with SBA had significantly higher VAT (96 ± 76.0 $cm^{2,}$ vs. 63.4 ± 51.5 cm^2, $p = 0.016$) and higher prevalence of liver cirrhosis (11(61%) vs. 41(23%), $p = 0.0011$). Prevalences of SBA progressively increased according to VAT; 7.2% in patients with VAT less than 100 cm^2, whereas 12.5% in those between 100 cm^2 and 150 cm^2, 21.4% more than 150 cm^2 ($p = 0.058$ by trend test), respectively. Multivariate analysis showed that VAT (odds ratio for each 10 cm^2 increment, 1.1; 95% confidence interval (CI), 1.01-1.19; $p = 0.025$), liver cirrhosis (odds ratio, 5.5; 95% CI, 1.98-16.6; $p = 0.0011$) were related to significant risk factors of SBA.
CONCLUSION: In addition to liver cirrhosis, visceral adipose tissue is one of the risk factors for small bowel angioectasia.

INTRODUCTION: Small bowel bleeding is still poorly studied in patients with long-term anticoagulation therapy. Capsule endoscopy (CE) is the first-line method for evaluation of bleeding in patient after negative upper endoscopy and colonoscopy.
AIMS & METHODS: In this retrospective study, we had investigated the types and frequency of small bowel GI bleeding lesions in patients undergoing oral anticoagulant therapy, by CE. Of a total of 1085 CE obtained between January 2003 and June 2013, 679 were performed in patients with obscure gastrointestinal bleeding. Of these 96 were obtained in patients undergoing oral anticoagulant therapy, 55 males and 41 females, mean age 70.6 years (range 23-87 years). At the time of evaluation by capsule endoscopy, the mean level of haemoglobin was 8.3 g/dl for males (normal values 14-18 g/dl) and 6.7 g/dl for females (normal values 12-16 g/dl). The mean number of blood units used for transfusions was 5.7 per patient (range 2-20). All patients underwent upper and lower gastro-intestinal endoscopy, prior to capsule endoscopy (CE). If upper and lower examinations were negative, CE was performed. The following data were recorded in the data base: patient age, gender, indication for the examination, medical and surgical history, bleeding history (including type of bleeding, total number of transfusions, hospitalizations), number and type of prior diagnostic testing, and details of the capsule examination.
RESULTS: In the series of patients undergoing oral anticoagulant therapy: 35/96 (36.4%) patients had negative examination; 22/96 (22.9%) had small-bowel angiodysplasias, small bowel erosions 21/96 (21.8%), small bowel ulcerations 5/96 pts (5.2%), neoplasia 4/96 (4.1%). In the series of patients with OGIB without anticoagulant therapy: 102/583 (17.4%) had angiodysplasias, small bowel erosions 48/583 (8.2%), small bowel ulcerations 25/583 (4.2%), neoplasia 44/583 (7.5%)
CONCLUSION: Small bowel angiodysplasias remain the main cause of occult GI bleeding. In our series, patients undergoing oral anticoagulant therapy had high prevalence of small bowel angiodysplasias (36.4% for anticoagulant group and 17.4% for control group). Furthermore in the anticoagulant group we have seen a major occurrence of erosions (21.8% VS 8.2%).

P0531 FREQUENCY AND RISK FACTORS FOR REBLEEDING EVENTS IN PATIENTS WITH SMALL BOWEL ANGIOECTASIA

E. Sakai[1,*], H. Endo[1], S. Umezawa[1], A. Fuyuki[1], S. Uchiyama[1], H. Ohkubo[1], T. Higurashi[1], T. Nonaka[1], A. Nakajima[1]
[1]*Gastroenterology, Yokohama City University School of Medicine, Yokohama, Japan*

INTRODUCTION: Small bowel angioectasia is reported as the most common cause of bleeding in patients with obscure gastrointestinal bleeding (OGIB). Although the safety and efficacy of endoscopic treatment have been demonstrated, rebleeding rates are relatively high. To establish therapeutic and

follow-up guidelines, we investigated the long-term outcomes and clinical predictors of rebleeding in patients with small bowel angioectasia.
AIMS & METHODS: A total of 68 patients were retrospectively included in this study. All the patients had undergone CE examination, and subsequent control of bleeding, where needed, was accomplished by endoscopic argon plasma coagulation. Based on the follow-up data, the rebleeding rate was compared between patients who had/had not undergone endoscopic treatment. Multivariate analysis was performed using a Cox proportional hazard regression model to identify the predictors of rebleeding. Rebleeding was defined as evidence of recurrent visible gastrointestinal bleeding (hematochezia or melena) with recent negative upper and lower endoscopic examinations and/or a reccurent drop of the hemoglobin level by more than 2 g/dl from the baseline. We defined the OGIB as controlled if there was no further overt bleeding within 6 months and the hemoglobin level had not fallen below 10 g/dl by the time of the final examination.
RESULTS: The overall rebleeding rate over a median follow-up duration of 30.5 months (interquartile range 16.5–47.0) was 33.8% (23/68 cases). The cumulative risk of rebleeding tended to be lower in the patients who had undergone endoscopic treatment than in those who had not undergone endoscopic treatment, however, the difference did not reach statistical significance ($P = 0.14$). In the majority of patients with rebleeding (18/23, 78.3%), the bleeding was controlled with additional endoscopic treatment by the end of the follow-up period. Multiple regression analysis identified multiple lesions (≥ 3) (OR 3.82; 95% CI 1.30–11.3, $P = 0.02$) as the only significant independent predictor of rebleeding.
CONCLUSION: In conclusion, patients with small bowel angioectasia show relatively high rebleeding rates. Although a single session of endoscopic treatment was not sufficient to control future rebleeding, in most cases, rebleeding could be controlled with repeated endoscopic treatment and/or iron replacement therapy. Careful follow-up is needed for patients with multiple lesions, which was identified as a significant risk factor for rebleeding.

INTRODUCTION: Angiodysplasias are known to account for 50% of small bowel bleeding sources, but diagnosis and effective treatment of these lesions is limited by a poor understanding of the pathophysiology of the condition. By measuring serum angiogenic factors in patients with small bowel angiodysplasias (SBA), we have already identified abnormalities in the angiopoietin pathway; with elevated levels of Ang2 and decreased levels of Ang1, associated with the condition. To determine the significance of these findings we need to determine whether these factors and their receptors are specifically located in SBA tissue.
AIMS & METHODS: The aim of this study was to measure gene expression levels of various angiogenic factors and receptors in SBA tissue compared to adjacent normal tissue and to normal SB tissue in controls. Following informed consent, patients aged 18-80 years of age undergoing double balloon enteroscopy for a variety of small bowel disorders at Tallaght hospital were invited to participate. From patients with SBA, one standard biopsy was taken from a single angiodysplasia lesion, and a further biopsy was taken from macroscopically adjacent normal mucosa. In controls, a single small bowel mucosal biopsy was taken at random. Biopsy samples were immediately placed in RNAlater solution and stored in a fridge overnight before being stored at -80°C for batch analysis. Using a standard technique, RNA was isolated and a reverse transcription reaction was performed on each sample using the Fermantas first strand cDNA synthesis kit (Thermo Scientific). The resulting cDNA was used in quantitative PCR reactions to determine the relative expression of Ang1, Ang2, Tie2, VEGF and TNF. Relative gene expression was calculated using the comparative cycle threshold (CT) method and was normalised to the control gene GAPDH. Statistical analysis was performed using SPSS version 20. Fold differences of each gene were expressed as a mean and compared between groups, with a p value of < 0.05 considered significant.
RESULTS: In total, 20 biopsy samples were collected; including 9 from angiodysplasia mucosa, 7 from adjacent normal mucosa, and 4 from normal mucosa in controls. Detectable levels of genes encoding Ang1, Ang2, Tie2, TNF and VEGF were found in all biopsy samples. There were significantly higher levels of Ang1 and its receptor Tie2 in angiodysplasia tissue compared to adjacent normal mucosa and to controls, with mean fold differences of 1.77 vs 0.82 and 0.81 for Ang1 ($p = 0.049$), and 1.66 vs 0.76 and 0.52 for Tie2 ($p = 0.02$) respectively. Levels of Ang2 appeared higher in angiodysplasias than both adjacent mucosa and controls, however; this was only statistically significant between the angiodysplasias and their adjacent mucosa ($p = 0.04$). There were no differences in levels of TNF or VEGF expression between any of the samples.

	Ang 1	Ang 2	Tie2	TNF	VEGF
Control	0.8175	0.5625	0.76	0.79	1.1
Angiodysplasia	1.7667	0.7333	1.66	0.82	1.1367
Patient normal tissue	0.8129	0.3957	0.9714	0.8057	1.4057
p value	<0.05	0.04	0.02	0.46	0.42

CONCLUSION: Expression of levels of genes encoding Ang1 and Ang2 and their receptor Tie2 are higher in the mucosa overlying small bowel angiodysplasias than unaffected mucosa. This further strengthens the identification of the angiopoietin pathway as a key factor in the pathophysiology of SBA formation.

P0533 WHAT IS THE LONG-TERM SAFETY OF A NEGATIVE CAPSULE ENDOSCOPY IN PATIENTS WITH OBSCURE GASTROINTESTINAL BLEEDING?

I. Ribeiro[1,*], R. Pinho[1], A. Rodrigues[1], T. Pais[1], C. Fernandes[1], J. Silva[1], A. Ponte[1], S. Leite[1], J. Carvalho[1]
[1]*Centro Hospitalar Vila Nova Gaia, Vila Nova Gaia, Portugal*
Contact E-mail Address: *iolandacribeiro@gmail.com*

INTRODUCTION: Although capsule endoscopy (CE) is the investigation of choice in obscure GI bleeding (OGIB), the clinical outcomes of a negative capsule remain contradictory according to different studies.
AIMS & METHODS: The aim of the study was to compare the long-term outcome of patients with OGIB after a negative and a positive CE and identify risk factors for rebleeding.
Methods: Retrospective study of 173 patients who underwent CE for OGIB, from 2005 to 2013; patients with a follow-up time < 6 months were excluded. CE with no lesions or with lesions P0 (petechial lesions; mucosal congestion) or P1 (isolated erosions; small angiodysplasias) were considered negative. Rebleeding was defined as a documented fall in hemoglobin of 2 g/dL from baseline, evidence of melena or hematochezia, and the need for blood transfusion, at least 30 days after the index bleed.
We evaluated the demographic characteristics, type of OGIB (overt vs occult), medication, rebleeding rate after a negative and a positive CE, type of treatment (endoscopic/surgical) performed in patients with positive CE and the influence on rebleeding. Statistical tests: t-student, $\chi 2$.
RESULTS: The mean age was 61.7 years; 67% of patients underwent CE because of occult GIB; 54.3% of CE were negative; the mean follow-up time was 27 months ($\pm$ 23.4) and the overall rebleeding rate was 22.5%. The rebleeding rate after a negative CE was significantly lower than after a positive CE (16% vs 30.4%, $p = 0.024$). Patients who rebleed needed more transfusions of red blood cells (mean = 6.0) prior to CE when compared with those who did not rebleed (mean = 1.2, $p < 0.001$). Age, sex, anticoagulants or anti-agregants did not influence the rebeeding rate.
Almost 50% of patients with a positive study underwent endoscopic (56.4% - argon plasma coagulation) or surgical treatment (28.2%), with significantly lower rebleeding rate than patients who did not undergo any treatment (23.1% vs 37.5%, $p < 0.02$).
CONCLUSION: Conclusions: A negative CE study in patients with OGIB is associated with a low rate of recurrent bleeding in the long term (16%). It is reasonable to take an expectant approach with these patients, thus avoiding the need for unnecessary additional investigations. The endoscopic/surgical treatment decreases the rebeeding rate after a positive CE.

INTRODUCTION: Given the aging of the European population a growing number of elderly patients need to be subjected to small bowel capsule endoscopy. In our study we aimed to determine the indications and findings of patients aged > 80 years old subjected to small bowel capsule endoscopy in our Department, in comparison to those aged < 80 years old.
AIMS & METHODS: From March 2003 till August 2013, 3410 patients have been subjected to small bowel capsule endosopy (Given imaging) in our Department. Among them, 131 were > 80 years old. We analyzed the indications and findings of these patients in comparison to the rest of the patients subjected to the test.
RESULTS: Among the 131 patients aged > 80 years old, the 106 (80.9%) have been subjected to small bowel capsule endoscopy because of obscure gastrointestinal bleeding. The corresponding percentage for patients aged < 80 years old was 60.2%. The remaining patients have been subjected to the test because of suspected Crohn's disease (n = 9, 6.8%), chronic diarrhea (n = 9, 6.8%) and abdominal pain (n = 7, 5.3%). The corresponding figures for those patients aged < 80 years old were 21.7%, 3.7% and 4.3% respectively. The findings of the test in both age groups in cases of obscure gastrointestinal bleeding are presented in table 1. No patient aged > 80 years old had any complication due to the small bowel capsule endoscopy investigation.
Table 1. Findings of small bowel capsule endoscopy

	Patients > 80 years old	Patients < 80 years old
Angiodysplasias	86.3%	59.2%
Apthoid ulcers	0.9%	13.0%
Ulcerations	5.4%	12.0%
Polyps	2,7%	9.9%
Tumors	4,6%	5.8%

CONCLUSION: Small bowel capsule endoscopy in elderly patients is mainly done for the investigation of obscure gastrointestinal bleeding. The test appears to be safe in these cases and angiodysplasias are detected more frequently than in younger patients.

P0535 NON ANEMICS WITH EROSIVE GASTRITIS MORE FREQUENTLY PRESENT SMALL BOWEL ULCERATIVE LESIONS

P. Tsibouris[1], P. Apostolopoulos[1], C. Kalantzis[1], E. Houda[1], K. Dimopoulos[1], C. Beltsidou[1], **E. Vlachou**[1,*], G. Alexandrakis[1]
[1]*GASTROENTEROLOGY, NIMTS GENERAL HOSPITAL, Athens, Greece*

INTRODUCTION: Although erosive gastritis can cause iron deficiency anemia, its presence cannot prevent small bowel evaluation with capsule endoscopy.
AIMS & METHODS: Aim: To define the risk to find small bowel ulcerative lesions and anemia in patients with erosive gastritis.
Methods: 1010 patients undergone small bowel capsule endoscopy, gastroscopy and colonoscopy were evaluated. 537 were evaluated for iron deficiency anemia or recent obscure bleeding, 324 for diarrhea, 60 for unexplained abdominal pain and 89 for other causes. 176 patients excluded from the analysis, as they presented either inflammatory bowel disease or celiac disease and 81 because they presented a gastric or a duodenal ulcer, leaving a study population of 753 patients (mean age 64±16 years, 421 men, 159 active smokers). Erosive gastritis was present in 132 (mean age 65±15 years, 77 men, 32 active smokers). Stat: X2, logistic regression analysis.
RESULTS: 50 (38%) patients with erosive gastritis and 161 (26%) without presented small bowel erosions ($p = 0.006$). 27 (48%) patients with erosive gastritis consuming aspirin or NSAIDs and 50 (33%) NSAIDs consumers without erosive gastritis presented small bowel erosions ($p = 0.04$). 13 (41%) patients with erosive gastritis on clopidogrel and 23 (29%) clopidogrel consumers without erosive gastritis presented small bowel erosions ($p = 0.26$). Among patients not on antiplatelets, 10 (23%) with erosive gastritis and 88 (23%) without presented small bowel erosions ($p = 0.97$). Among anemics, 19 (42%) patients with erosive gastritis consuming aspirin or NSAIDs and 44 (34%) NSAIDs consumers without erosive gastritis presented small bowel erosions ($p = 0.04$). 12 (30%) patients with erosive gastritis on clopidogrel and 18 (28%) clopidogrel consumers without erosive gastritis presented small bowel erosions ($p = 0.26$). No patient with erosive gastritis not consuming antiplatelets and 40 (20%) without erosive gastritis presented small bowel erosions ($p = 0.048$). In logistic regression analysis old age, erosive gastritis, AF and use of aspirin were related with increased risk for small bowel ulcerative lesions and diabetes with reduced risk.
CONCLUSION: Non anemics with erosive gastritis are at risk for small bowel erosions, especially if they consume aspirin or NSAIDs, because small bowel mucosa is possibly more vulnerable to noxious stimula. On the other hand, among anemics erosive gastritis was related with less small bowel ulcerative lesions among no antiplatelet consumers. Possibly because erosive gastritis is an independent cause of iron deficiency anemia.

P0536 PATIENTS WITH ATRIAL FIBRILLATION ON CLOPIDOGREL ARE AT HIGH RISK TO DEVELOP SMALL BOWEL ULCERATIVE LESIONS AND ANEMIA

P. Tsibouris[1,1], P. Apostolopoulos[1], I. Koumoutsos[1], C. Kalantzis[1], E. Chounta[1], K. Dimopoulos[1], C. Beltsidou[1], **G. Alexandrakis**[1,*]
[1]*GASTROENTEROLOGY, NIMTS GENERAL HOSPITAL, Athens, Greece*

INTRODUCTION: Patients with atrial fibrillation are usually on antiplatelet treatment or anticoagualants.
AIMS & METHODS: Aim: To define the risk to find small bowel ulcerative lesions and anemia in patients with atrial fibrillation on antiplatelet or anticoagulant treatment.
Methods: 1010 patients undergone small bowel capsule endoscopy, gastroscopy and colonoscopy were evaluated. 537 were evaluated for iron deficiency anemia or recent obscure bleeding, 324 for diarrhea, 60 for unexplained abdominal pain and 89 for other causes. 176 patients excluded from the analysis, as they presented either inflammatory bowel disease or celiac disease, leaving a study population of 834 patients (mean age 64±16 years, 476 men, 176 active smokers). Atrial fibrillation (AF) presented 78 patients (mean age 76±7 years, 41 men, 8 active smokers). Stat: X2, logistic regression analysis.
RESULTS: 246 (29%) patients presented small bowel ulcerative lesions; 164 (31%) anemic and 78 (26%) non-anemic ($p = 0.19$). 33 (42%) AF patients and 213 (28%) without AF presented small bowel ulcerative lesions. Small bowel ulcerative lesions were present in 14 (48%) AF aspirin/NSAID users, 13 (42%) AF clopidegrel consumers and 6 (33%) AF patients not receiving antiplatelets. In addition they were present in 132 (38%) aspirin/NSAID users without AF ($p = 0.31$), 23 (29%) clopidogrel consumers without AF ($p = 0.02$) and 109 (23%) patients without AF not receiving antiplatelets ($p = 0.33$). Thus small bowel ulcerative lesions were more common among aspirin users without AF ($p = 0.001$), but not those with AF ($p = 0.41$). Moreover there was no difference between aspirin and clopidogrel (AF: $p = 0.62$; no AF: $p = 0.14$). Among anemics small bowel ulcerative lesions were present in 14 (56%) AF aspirin/NSAID users, 14 (47%) AF clopidegrel consumers and 2 (17%) AF patients not receiving antiplatelets. In addition they were present in 67 (37%) aspirin/NSAID users without AF ($p = 0.08$), 17 (27%) clopidogrel consumers without AF ($p = 0.02$) and 109 (22%) patients without AF not receiving antiplatelets ($p = 0.33$). Thus small bowel ulcerative lesions were more common among aspirin users with ($p = 0.02$) and without AF ($p = 0.0006$). Moreover there was no difference between aspirin and clopidogrel (AF: $p = 0.49$; no AF: $p = 0.13$). In logistic regression analysis old age, erosive gastritis, AF and use of aspirin were related with increased risk for small bowel ulcerative lesions and diabetes with reduced risk.
CONCLUSION: Small bowel ulcerative lesions are more common among aspirin users. Clopidogrel is generally safer, nevertheless both presence of anemia and small bowel ulcerative lesions are more common among patients with atrial fibrillation, possibly because small bowel mucosa is more vulnerable to develop inflammatory lesions in this patient group.
Disclosure of Interest: None declared

P0537 REDUCTION OF NSAID-INDUCED SMALL INTESTINAL DAMAGE IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING SULFASALAZINE

A. Balabanceva[1], **S. Tkach**[2,*]
[1]*Crimea Medical University, Simferopol, Russian Federation,* [2]*National Medical Univercity, Kyiv, Ukraine*

INTRODUCTION: Recent studies have demonstrated that nonsteroidal anti-inflammatory drugs (NSAIDs) often cause damage to the small intestine, and NSAID-induced enteropathy is mediated by different inflammatory cytokines. Sulfasalazine is being widely used in patients with rheumatoid arthritis (RA), and this drug have the potential to induce mucosal healing in patients with intestinal diseases such as inflammatory bowel diseases.
AIMS & METHODS: To evaluate the preventive effect of sulfasalazine against small intestinal damage due to chronic NSAID use in RA patients. Between March 2009 and June 2011, capsule endoscopy was performed in 51 consecutive RA patients who received NSAIDs for more than 3 months with or without sulfasalazine therapy over a period of 3 months. The findings were scored as follows according to the method described by Graham et al. (Clin Gastroenterol Hepatol. 2005): 0, normal; 1, red spots; 2, 1 to 4 erosions; 3, >4 erosions; and 4, large erosions/ulcers. Scores of 3 and 4 indicated severe damage. The relationship between the use of sulfasalazine therapy and risk of severe damage (score 3 or 4) or severest damage (score 4) were assessed using multiple logistic regression.
RESULTS: Comparative data were analyzed for 47 patients, and 4 patients were excluded because the entire small bowel could not be visualized in these patients. Of the 25 patients who did not receive sulfasalazine therapy, 12 (48%) had severe damage (score of 3 [n = 8] or 4 [n = 4]). On the other hand, of the 26 patients receiving sulfasalazine therapy, 5 (19.2%) had severe damage (score of 3 [n = 3] or 4 [n = 2]). On stratifying the patients by sulfasalazine therapy, we obtained a crude odds ratio (OR) of 0.26 for severe damage with a 95% confidence interval (CI) of 0.10 to 0.66, and of 0.38 for severest damage with a 95% CI of 0.17 to 0.88. This effect of sulfasalazine therapy on NSAID-induced enteropathy remained robust to adjustment for age, gender, history of peptic ulcers, disease activity score-28 (a disease activity index for RA), use of selective cyclooxygenase-2 inhibitors or steroids, blood hemoglobin concentration, and all these variables, with the adjusted ORs for severe damage ranging from 0.19 to 0.25 and those for severest damage ranging from 0.30 to 0.40.
CONCLUSION: Sulfasalazine therapy may protect against NSAID-induced small intestinal damage in RA patients and may be effective in the treatment of NSAID-induced enteropathy.

NUTRITION I - POSTER EXHIBITION - HALL XL

P0538 IS THE TRADITIONAL DIET DISAPPEARING AT THE SAME TIME AS THE PREVALENCE OF OBESITY IS INCREASING IN ITALY? EVALUATION OF EATING HABITS IN A GROUP OF ITALIAN OBESE FEMALE PATIENTS

A. Guida[1,*], A. Frascari[1], E. Canducci[1], B. Ravani[1], G. Bersani[2], A. Rossi[2], R. Arena[1], A. Maimone[1], V. Alvisi[3], G. Ricci[1]

Contact E-mail Address: *ada.guida@student.unife.it*

INTRODUCTION: The nutrition transition from traditional to Western dietary patterns could account for the dramatic rise in the prevalence of obesity in Italy (1).
AIMS & METHODS: We describe the dietary patterns in a group of obese Italian female patients. A retrospective survey was conducted on the records of 113 obese (BMI 40.2±7.0 kg/m2) female inpatients aged 19-60 y (mean 40.5 y). Anthropometric measurements and dietary patterns were obtained from the records. Dietary habits were recorded by detailed questioning and computed database determined the nutrient intakes. The recommended dietary allowances (RDAs) for the Italian population were used as the reference range. The sample was also divided, according to age, into three groups (19-35y, 36-45y, 46-60y). Statistical analysis was performed by PASW 18.0.
RESULTS: The table shows the variations, as percentages, of the nutrient intakes over or below the RDAs. The values are expressed as 50^{th} (25^{th}, 75^{th}) percentile. Animal protein intakes averaged 266% over the RDAs in the whole sample, with median variations from 241 to 278% among the age groups. The intake rates of total carbohydrates (CHO) were minimally higher on average (15-19%) than the RDAs. The simple CHO intake averaged 67-90% over RDAs. The ω-6/ω-3 fatty acid ratio was about 100% over the RDA, without significant differences among age groups. Moreover the intakes of ω-6 fatty acids was 64% over the RDA, but in the younger group the variation rate from the RDA was significantly higher (72%, $p < 0.05$) than in the older group (50%). Nutrients with protective effects, such as PUFA and ω-3 fatty acids, averaged 35-48% and 11-19% below RDAs, respectively.

Nutrient intakes	RDAs (g)	all (113)	19-35 y (37)	36-45 y (36)	46-60 y (40)
Protein	64 (59, 66)	100 (71, 132)	95 (75, 108)	119 (70, 166)	112 (80, 130)
Animal Protein	74 (55, 100)	266 (171, 349)	241 (171, 316)	248 (164, 385)	278 (214, 354)
Fat	136 (112, 165)	129 (88, 175)	151 (113, 175)	129 (85, 195)	118 (80, 162)
PUFA	10 (7, 13)	-44 (-57, -23)	-35 (-53, -15)	-35 (-57, -19)	-48 (-59, -31)
ω-3	1.2 (1.1, 1.3)	-16 (-34, 11)	-11 (-28, 44)	-19 (-43, 8)	-18 (-34, 9)
ω-6	4.8 (4.6, 5.3)	64 (27, 123)	72 (42, 164)	74 (27, 126)	50 (23, 90)
ω-6/ω-3	4	100 (66, 123)	89 (49, 119)	102 (69, 133)	102 (67, 123)
Total CHO	363 (347, 380)	19 (2, 40)	19 (-2, 42)	31 (9, 51)	15 (-2, 28)
Simple CHO	69 (66, 72)	84 (27, 146)	90 (32, 142)	84 (14, 166)	67 (33, 117)

CONCLUSION: We observed that the highest variation rates were not found for total carbohydrates or simple carbohydrates, as could be expected, but for fat and protein, and especially for animal protein. Moreover the excessive consumption ω-6 fatty acid, with unbalanced ω-6/ω-3 fatty acid ratio, could show a tendency to change the traditional Italian diet towards Western eating habits. However there was no significant difference between younger and older people.

P0539 CAN INTERVENTION ON LIFESTYLE HAVE AN IMPACT ON CARDIORESPIRATORY FITNESS IN THE NON-OPERABLE SEVERELY OBESE PATIENT?

D.A. L. Hoff[1,*], F. Wammer[2], A. Haberberger[3]
[1]*Dept.of Medicine, Div. of Gastorenterology and Hepatology,* [2]*Dept.of Medicine, Div. of Pulmonary diseases, Aalesund Hospital, Aalesund,* [3]*Centre of achievement and rehabilitation, Muritunet, Valldal, Norway*

INTRODUCTION: Severe obesity (BMI > 40 kg/m^2 or 35 kg/m^2 and complications) is associated with higher frequency of comorbidities such as respiratory failure and higher premature mortality compared to less obese patients. Diet change, physical exercise and lifestyle modifications are the only therapeutic options for a substantial proportion of patients. The literature on cardiorespiratory fitness in these patients is sparse.

AIMS & METHODS: To examine whether or not a systematic rehabilitation program providing lifestyle intervention has a significant positive impact on cardiorespiratory fitness in the non-operable severely obese patients.

Forty non-operable severely obese patients (F 29, M 11, mean age 44 y, range 23-62 y) were consecutively enrolled in a rehabilitation program. In total 33 patients stayed in the program 12 months after enrolment, but 6 of them did not complete all tests due to acute illness. Eligible for enrolment was patients in groups of 12-15, in all 4 groups. The first stay lasted 4 weeks, the consecutive stays 2 weeks every 6 months. At each stay a team of nurses, physician, dietician, psychologist and physical activity therapist provided education and physical exercise to each patient individually or to patients assembled as a group, including matched patient's conversations. At enrolment patients were classified as respiratory healthy or as having chronic respiratory illness. Furthermore at the beginning of each stay body weight, peak oxygen uptake (VO_2peak) and functional residual capacity % (FRC %) were registered and body mass index (BMI) calculated. The test was performed on a treadmill programmed in a standard fashion regarding velocity and inclination. All tested patients reached anaerobic threshold (VO_2peak).

Mean ± standard deviation are reported at inclusion and one year after inclusion. FRC% is regarded normal above 80 %.

RESULTS: We report on cardiorespiratory fitness in 27 patients (F 19, M 8, mean age 45 y, range 23-62) 12 months beyond baseline. Ten patients were respiratory healthy and 17 had respiratory illnesses; asthma (N = 4), chronic obstructive lung disease (N = 1) and obstructive sleep apnoea syndrome (N = 12). Body weight: 125.5 ± 21.7 kg vs 120.1 ± 23.1 kg, p = 0.004. BMI: 42.1 ± 3.9 kg/m^2 vs 40.6 ± 5.2 kg/m^2, p = 0.016. FRC%:76.9 ± 12.1 % vs 80.4 ± 13.8 %, p = 0.069. VO_2peak during exercise: 22.7 ± 3.0 ml*kg^{-1}min^{-1} vs 24.0 ± 4.5 ml*kg^{-1}min^{-1}, p = 0.032.

CONCLUSION: We found a significant improvement in cardiorespiratory fitness in a group of 27 non-operable severely obese patients that participated in a systematic rehabilitation program for one year. Our results should be verified in larger scale studies. This would also make it possible to stratify patients according to respiratory health.

P0540 THE RELATIONSHIP BETWEEN OSTEOPOROSIS AND LEPTIN IN OBESE FEMALES

D. Neagoe[1,*], G. ianosi[2], A. amzolini[1], A. farmazon[3], M. popescu[4], A. turculeanu[5], C. deliu[3], T. ciurea[1]
[1]*internal medicine,* [2]*surgical, university of medicine and pharmacy,* [3]*internal medicine, emercency hospital no.1,* [4]*endocrinology,* [5]*laboratory, university of medicine and pharmacy, craiova, Romania*

INTRODUCTION: The pathogenesis of decreased bone mineral density (BMD) in NAFLD is unclear. Hyperleptinemia, hormone mainly secreted by white adipose tissue, is associated with inflammatory process, suppress bone formation and increase bone resorbtion. Aim of our study was to correlate leptin level with decreased BMD in obese females.

AIMS & METHODS: We included obese females in postmenopausal period for at least 1 year: 54 with NAFLD and 56 without NAFLD, age, waist circumference (WC) and body mass index (BMI) matched. Exclusion criteria: diabetes mellitus, chronic use of corticosteroids, supplementation with calcium products, secondary obesity due endocrine diseases, renal disease, alcohol intake, smoking, previous fractures. Blood samples were collected in both groups for lipid profile, hepatic enzymes and leptin (references values 4.9-24ng/ml). Lumbar BMD was measured by DEXA and abdominal ultrasonography was performed by the same physician and steatosis was graded using a semi-quantitative scale of 1 (mild) to 3 (severe).

RESULTS: In NAFLD group mean age was 49.5 years, BMI 32,5±3 and WC 99±5cm, in second group mean age was 51,3 years, BMI 30,3±3 and WC 97±5, without statistic significance between the two groups. In NAFLD group 24 females had mild steatosis, 18 had moderate and 12 had severe steatosis. No evidence of steatosis in group B. Leptin level was 8.7ng/ml±1.2 in group B and 15.2ng/ml±5.1 in NAFLD group, with significance statistic differences between the two groups. In NAFLD group we found 9 patients with normal T score, 21 patients with osteopenia and 24 with osteoporosis. In group B we found 15 patients with normal T score, 25 with osteopenia and 16 with osteoporosis. BMD was lower in NAFLD women than these without NAFLD and osteoporosis in NAFLD group seemed to be associated a more severe liver disease. In NAFLD group the highest levels of serum leptin were found in moderate or severe steatosis with osteoporosis and we found a positive correlation with BMI and WC (p = 0.000 and p = 0.002). In the other group, leptin level had no significant differences in relationship with BMI, WC or decreased BMD.

CONCLUSION: In our study, leptin level was correlated with osteoporosis in NAFLD group. In obeses females without NAFLD, leptin level was similar despite the presence or absence of osteoporosis.

P0541 ENDOSCOPIC REMOVAL OF GASTRIC BANDS – A HEAVY ISSUE

D. Branquinho[1,*], D. Gomes[1], N. Almeida[1], C. Sofia[1]
[1]*Gastroenterology, Coimbra University Hospital (CHUC), Coimbra, Portugal*
Contact E-mail Address: *diogofbranquinho@yahoo.com*

INTRODUCTION: One of the most popular methods in bariatric surgery is the gastric band. However, its migration into the gastric lumen has frequently been described as a long-term complication. There is no consensus on how to handle such cases, but its removal through endoscopy is increasingly being documented as a safe and effective alternative. The authors present a Gastroenterology department 5-year experience.

AIMS & METHODS: To describe our experience in a relatively novel endoscopic technique useful to handle a common bariatric surgey complication.
Review of clinical files and endoscopic imaging.

RESULTS: A total of eight procedures were undertaken in morbidly obese female patients (average age: 38.7 years old). Median time between initial surgery and band removal was about 69±31.9 months. Clinical manifestation was weight increase in 5 patients and upper abdominal pain in the remaining three. All cases were diagnosed through upper digestive endoscopy.

During such procedures, a 0.035 inch guidewire and a Soehendra lithotripter were used to cut through the band, which was then pulled with a polypectomy snare. Extraction of the cutaneous port was done by the assisting surgeon. Average duration of the procedure was about 30 minutes.

A peritoneal leak was the only major complication, due to the passage of air from the stomach lumen to the peritoneum through the band internal canal.

CONCLUSION: Considering the high number of gastric band procedures undertaken in the last few years, its intra-gastric migration will be a common clinical issue. This endoscopic approach, although technically demanding, is a safe and effective alternative, thereby avoiding morbidity associated with a major surgical intervention.

Contact E-mail Address: *machytka@obezita-balon.cz*

INTRODUCTION: The original Spatz Adjustable Balloon System for weight loss was introduced in 2010. It was the first intragastric balloon approved for 1 year implantation with the added feature of balloon volume adjustability. This enabled changes to balloon volume during the course of the 1 year implantation period. It contained a rigid catheter and metal chain that caused duodenal migration. The new Spatz 3 intragastric balloon device, CE Mark approval in 2012, has a soft catheter to simplify the procedure and decrease complications. In addition, reports of volume adjustments using a mean 177 ml yields additional 1.7 kg/month wt loss. It has been suggested that adjusting with larger volumes will yield better results. We report our experience with the Spatz 3 device in 7 centers.
AIMS & METHODS: To determine the difference between the reported results of the original Spatz Adjustable balloon System and the new Spatz3 Adjustable balloon System with respect to ease of use, complications, weight loss results and the effect of larger volume adjustments. 158 patients with mean BMI 40.1; mean weight 109 kg; mean age 37; were implanted with the Spatz3 device. Mean balloon volume was 473 ml (400-600). Adjustments were made for intolerance or weight loss plateau.
RESULTS: All endoscopists felt that the Spatz 3 device was easier to use than the original Spatz adjustable balloon system device. Mean wt loss at 12 weeks was 12.5 kg with an 11.7% wt loss and 28.8 % EWL (% excess wt loss). At 24 weeks mean wt loss was 16,2 kg; 16.7% wt loss, and 35,3 % EWL. 94 patients reached 9 months with a reported mean wt loss of 23.2 kg; 20.4 % weight loss; and 44.9 % EWL. And 48 patients after 12 months with mean wt loss of 24.1 kg; 20.6 % weight loss; and 48.1 % EWL. There were 49 balloon volume adjustments: 11 downward adjustments of 100 cc alleviated early intolerance, with added mean wt loss of 15.3 kg after the adjustment; 38 upward adjustments (mean 327 ml; range 150-500) at a mean month 4,1 yielded additional mean wt loss of 8.7kg after the adjustment. 7 balloons were extracted; early intolerance and refusal to adjust volume downward (4); gastric ulcer (2); deflation (1).
CONCLUSION: The Spatz 3 adjustable balloon is easier and less complicated than the original Spatz device. Complications associated with the original catheter have not been seen in the Spatz 3 device. Larger volume adjustments yield greater weight loss results.

P0544 WEIGHT MAINTENANCE 2 YEARS AFTER EXTRACTION OF THE SPATZ ADJUSTABLE BALLOON

E. Machytka[1,*], L. Bene[2], G. Lopez-Nava[3], M. Buzga[1]
[1]*Faculty of Medicine, UNIVERSITY OF OSTRAVA, Ostrava, Czech Republic,* [2]*Rozsakert Medical Center, Budapest, Hungary,* [3]*Hospital Sanchinarro, Madrid, Spain*
Contact E-mail Address: *machytka@obezita-balon.cz*

INTRODUCTION: The Spatz Adjustable Balloon System was developed to provide an adjustable intragastric balloon approved for 1 year implantation. Weight loss results > 20 kg/year have been reported in the literature. The question is whether treatment with an intragastric balloon also leads to better weight loss maintenance after balloon removal. A prospective study on the BIB balloon has reported maintenance of > 10% weight loss in 25% of patients for up to 2.5 years after BIB balloon removal.
AIMS & METHODS: 79 patients from 3 centers who were implanted with the Spatz Adjustable Balloon for 1 year were contacted and asked to provide their weight 1 year and 2 years post balloon extraction. Net weight changes were recorded, and % weight loss was calculated based on weight prior to balloon implantation. Net weight loss > 10% was considered successful weight maintenance.
RESULTS: 70 of the 79 patients contacted (88.6%) were responsive in providing their weight data. The group's data at the original implantation was as follows: mean weight 120.3 kg (80-180); mean BMI 38.8 (30-65). At the time of balloon extraction (12 months) the group's mean weight loss was 24 kg with a 23.8% weight loss. All of the 70 patients had reached at least 12 months post Spatz balloon extraction. Fifty three of the seventy (75.7%) retained at least 10% weight loss at 1 year post balloon extraction. 34 of the 70 patients had reached 2 years post extraction, and 26 (76.4%) retained at least 10% weight loss. The group's mean weight change was +6.7 kg at 1 year and +3.4 kg at 2 years after balloon extraction.
CONCLUSION: The maintenance of > 10% Weight loss at 1 year and 2 years after Spatz Adjustable Balloon extraction has been retrospectively documented in 75.7% and 76.4% of patients, respectively. This study is limited by its retrospective review and the small numbers in year 2 and requires prospective review to confirm these findings. Nonetheless, it suggests a long term benefit to longer implantation time and/or adjustable balloon function and warrants further study.

INTRODUCTION: Obesity and type 2 diabetes are associated with an altered gut microbiota and inflammation. Growing evidence suggest that the gut microbiota is involved in the regulation of energy homeostasis. We and others have shown that gut microbiota modulation using prebiotics constitute an interesting target in the physiopathology of obesity.
AIMS & METHODS: So far, probiotic yeast have not been investigated in this context. The aim of this study is to evaluate the role of the most studied probiotic yeast (i.e., *Saccharomyces boulardii* Biocodex) on obesity and associated metabolic disorders. *S. boulardii* was administrated daily by oral gavage to leptin-resistant obese and type 2 diabetic mice (*db*/*db*) for 4 weeks.
RESULTS: We found that *S. boulardii* treated mice exhibited reduced body weight, hepatic steatosis, fat mass and both hepatic and systemic inflammation. These effects were associated with local effects in the intestine, such as an increased caecum weight and caecum tissue weight. Importantly, we also found that *S. boulardii* induced dramatic changes in gut microbial communities at the phylum, family and genus levels. We also found that microbial changes in response to *S. boulardii* were correlated with host metabolism response.
CONCLUSION: In conclusion, our study demonstrated that *S. boulardii* acts as a beneficial probiotic treatment in the context of obesity and type 2 diabetes.

INTRODUCTION: The Western diet is characterized by a high-energy intake, saturated fats and refined sugars. Excess calorie intake, associated with reduced physical activity, leads to obesity, type 2 diabetes mellitus, cardiovascular disease and non-alcoholic fatty liver disease (NAFLD).
AIMS & METHODS: Within the FP7 - European FLIP (Fatty Liver Inhibition Program) program we tried to investigate the role of diet in NAFLD, in a large cohort of patients from three different Italian Centers (Modena, Bologna and Turin). We used the EPIC questionnaire to investigate energy intake (Ei) and intake of food in a well-characterized series of 163 NAFLD patients. Anthropometric measurements, blood tests, insulin resistance, liver ultrasound (Hamagouchi score) and liver stiffness were analysed. Nutrient intakes were compared with Italian reference values.
RESULTS: The daily intake of simple sugars (18.4% *vs.* a reference intake <15%), saturated fats (12% *vs.* <10%) and the ratio between animal proteins/vegetal protein in the diet (68% *vs.* <50%) was higher than recommended, whereas the fiber intake was lower (19g *vs.* 25g). In the patients, a significant direct correlation ($p<0.005$) was observed between BMI, waist circumference, insulin resistance, transient elastography values, Hamagouchi score, and lipid intake.
CONCLUSION: The dietary intakes of NAFLD patients are systematically different from the recommended daily intakes for the Italian population. In particular the higher-than-recommended intake of simple sugars might be one of the possible causes of NAFLD (Supported by FLIP Project, (FP7/2007–2013) under grant agreement no. HEALTH-F2-2009-241762).

P0547 FOOD INTOLERANCE AND OBESITY: NEW STRATEGY IN THE TREATMENT OF OBESITY

M. Rotter[1,*]
[1]*Dietology, UKRAINIAN RESEARCH INSTITUTE OF NUTRITION, Kyiv, Ukraine*
Contact E-mail Address: *rottermaria@mail.ru*

INTRODUCTION: Challenges associated with the treatment of obesity still remain high, in spite of efforts made by professionals combating the public health issue. A low-calorie diet, which is considered as the most effective

treatment, is hard for many patients to incorporate due to the discomfort brought by hunger. An effective treatment should focus on increasing the quality of a patient's life, by creating a treatment that reduces symptoms associated with obesity, while allowing patients to not experience hunger during the treatment period.
AIMS & METHODS: The aim of the study was to compare the difference in effectiveness between the traditional low-calorie diet and the elimination diet. A Survey was completed by 60 patients, 30 women and 30 men, with the average age 37.6 ± 4.7 years. In addition to routine methods of investigation, all patients were analyzed on food intolerance using the FED- test, which is based on the immunetermistometrical principle, a new term we used to describe the conductivity and viscosity change in the blood after making contact with certain food extract. The FED- test uses 96 different food extractions to evaluate food intolerance. To evaluate the improvement of a patients condition, questionnaires were used before and after the treatment to receive any complaints patients had throughout the treatment period. Information about complaints was assessed on a Harington scale of a unit from 1 (no symptoms) to 0.1 (maximum symptom). Patients were divided into 3 equal groups - overweight, and 1 or 2 class obesity. Each group was divided into two subgroups. Patients in the (A) subgroup were on a low-calorie diet: 1200-1600 Kcal, depending on the age, sex, and physical activity. Patients of the (B) sub-group were on the individual eucalorie (with normal energetic value) elimination diet, based on the results from the FED- testing.
RESULTS: 1. The influence that the type of diet had on weight reduction. Among the first two groups with overweight patients, greater weight loss was observed in those patients who adhered to the elimination diet. The difference in BMI accounted for 0.776 ± 0.222 kg \ m2 in the group A and 1.788 ± 0.449 kg/m2 in the group B. In obese patients, the following similar results were observed: in the elimination diet weight loss was 3.764 kg \ m2 and 4.065 kg \ m2 in in patients with class 1 and 2 obesity accordingly. In low-calorie diet, BMI reduction was 1.291 kg \ m2 and 2.280 kg \ m2 in patients with class 1 and 2 obesity accordingly.
2. Improvements in patients' condition. On the elimination diet improvement of the patient's condition amounted to 0.292 in the obese group, and 0.222 in the overweight group. In groups in which patients followed the low-calorie diet, no significant dynamics in the state of the patients were observed: 0.046 in a group of obese patients and 0.034 patients in the overweight group.
CONCLUSION: Under the influence of elimination diet BMI reduction was significantly better in patients with 1 and 2 class obesity compared to the dynamics of BMI on the standard low-calorie diet ($p = 0.0037$). Between groups of patients who were overweight, no significant differences were found ($p = 0.087$).
The patients' quality of life after 6 months of treatment differed significantly in subgroups of those treated with the elimination diet, compared to the subgroups of those that received the standard low-calorie diet treatment ($p = 0.004$).

P0548 ARGON PLASMA FULGURATION TO TREAT WEIGHT REGAIN AFTER BARIATRIC SURGERY

R.J. Fittipaldi-Fernandez[1,*], C.F. Diestel[2,3]
[1]*Digestive Endoscopy, Endogastro Med Service,* [2]*Nutrition Division, UNI-RIO Rio de Janeiro University,* [3]*Nutrition Division, Endogastro Med Service, Rio de Janeiro, Brazil*
Contact E-mail Address: *ricfittipaldi@hotmail.com*

INTRODUCTION: The weight regain is a problem after bariatric surgery and occurs, in part, by dilatation of the gastro-jejunal anastomosis, which causes a faster gastric emptying and increased food intake.
AIMS & METHODS: Objective: To evaluate the efficacy of endoscopic fulguration of the anastomosis and of the gastric stump using argon plasma (APF) aiming to reduce the diameter thereof.
Methods: We analyzed 32 patients. 30 of them underwent at least 02 sessions of FPA. Two patients underwent only one session due to an immediate reduction of the anastomosis to a diameter smaller than 10 mm after the first session, wich is the procedure target. The coagulation was held at the anastomosis and in gastric stump. 80 w power was used in the 1st session, and 70w power FPA in the following, with an Agon flow of 2L/min. The objective is to obtain an anastomosis with a diameter less than or equal to 10 mm. Data were analyzed with descriptive statistics, student's t test and Spearman correlation.
RESULTS: Of the 32 patients, 87.5 % were women ($n = 28$). The mean regained weight in relation to the maximum weight lost (Nadir) after bariatric surgery was 46.9 % (14 to 76.9). The mean duration of treatment was 170 days (56-338). There was a significant reduction in body mass index (BMI) at the end of the analysis (32.42±4.45 kg/m2) compared to the initial mean BMI (mean BMI = 37.05±4.76 kg/m2) ($p < 0.0001$). The average loss of the regained weight was 66.92% (22.08-211.11). The average weight loss in Kg was 12.73 (6.3-25.5). There was significant correlation between the reduction in the BMI and the highest number of sessions of FPA ($p = 0.0003$) and between the longer duration of the treatment ($p = 0.0212$). The analyzed patients remain in treatment.
CONCLUSION: The FPA has demonstrated great efficacy in the treatment of weight regain after bariatric surgery of gastric bypass in Roux-Y.

P0549 ANALYSIS OF 1973 PATIENTS SUBMITTED TO ENDOSCOPIC TREATMENT OF EXCESS WEIGHT WITH AN INTRAGASTRIC BALLOON

R.J. Fittipaldi-Fernandez[1,*], C.F. Diestel[2,3], B. Sander[4], A.F. Teixeira[5], M. Galvão Neto[6]
[1]*Digestive Endoscopy,* [2]*Nutrition Division, Endogastro Med Service,* [3]*Nutrition Division, UNI-RIO Rio de Janeiro University, Rio de Janeiro,* [4]*Digestive Endoscopy, Clínica Sander, Belo Horizonte,* [5]*Digestive Endoscopy, Gastros Bahia, Feira de Santana,* [6]*Digestive Endoscopy, Gastro Obeso Center, São Paulo, Brazil*
Contact E-mail Address: *ricfittipaldi@hotmail.com*

INTRODUCTION: Endoscopic methods, especially the intragastric balloon (IGB), have been shown to be effective for the treatment of excess weight.
AIMS & METHODS: OBJECTIVE: To assess the efficacy and complications of excess weight treatment with an IGB in patients seen at the Endogastro Med Service clinic, Gastro Obeso Center and Sander clinic.
METHODS: A total of 1973 patients were analyzed. An Allergan IGB (BIB®) with a volume of 600 to 700 ml was used. The patients had a minimum initial body mass index (BMI) of 27 kg/m2 and were followed up by a multidisciplinary team consisting of a nutritionist, a doctor and a psychologist. For statistical analysis, the patients were divided into groups according to sex and degree of excess weight (overweight and grade I, II and III obesity). Data were analyzed using descriptive statistical methods, the Student t-test, and analysis of variance followed by the Tukey post-test. The level of significance was set at $p < 0.05$.
RESULTS: 107 patients were excluded from the analysis: 70 (3.55%) due to early IGB removal, 13 (0.66%) due to absence of weight loss, 14 (0.71%) due to weight gain, and 10 (0.51%) due to incomplete data. The incidence of fungus was 0.2% ($n = 4$) and the incidence of leakage was 0.25% ($n = 5$), pregnancy was 0.1% ($n = 2$); Wernick Korsakoff syndrome due to excessive vomiting was 0.05% ($n = 1$), gastric perforation and upper digestive bleeding was 0.05% each ($n = 1$). Of the 1866 remaining patients, 1402 were women and 464 were men. Mean age was 37.32 years. The patients showed a significant weight loss, with a significantly lower final BMI (mean: 28.93±4.71 kg/m2; range: 18.98-57.38) than the initial BMI (mean: 36.47±5.61 kg/m2; range: 27-74.74) ($p < 0.0001$). Mean BMI reduction was 7.55±3.49 kg/m2 (range: 0.36-29.79). Mean percent weight loss was 20.43±7.82% and mean percent excess weight loss (EWL) was 73.48±36.71% (range: 2.22-431.1). Percent EWL was higher in the overweight group, followed by obesities grades I, II and III sequentially ($p < 0.0001$). Percent EWL was also higher in women than in men ($p < 0.0001$).
CONCLUSION: Endoscopic treatment of excess weight with an IGB has been established as an excellent therapeutic option for patients of both genders with overweight or different degrees of obesity.

P0550 PREDICTIVE RISK FACTORS FOR SUCCESS OF BARIATRIC THERAPY WITH BIOENTERICS INTRAGASTRIC BALLOON

R. Cerqueira[1], **M. Correia**[1,*], M.C. Manso[2]
[1]*Gastroenterology, Centro Hospitalar entre Douro e Vouga, Santa Maria Feira, Santa Maria Feira,* [2]*Biostatistics - Requimte-up, University Fernando Pessoa, Porto, Portugal*
Contact E-mail Address: *rute.cerqueira@chedv.min-saude.pt*

INTRODUCTION: In obese patients, a large amount of data shows that bariatric therapy with Bioenterics intragastric balloon (BIB) results in weight loss in some patients. However there is a paucity of data about predictive risk factors for BIB success.
AIMS & METHODS: The aim of this study was to determine the effectiveness of this device on weight loss and predictive risk factors for BIB success. A prospective study with 147 patients [(75.5% females, mean age 40 (±11.9)] submitted to BIB insertion, which was removed after 41.4 (±12.7) weeks. Anthropometric and laboratory parameters were assessed when BIB was positioned and when BIB was removed. BIB success was defined as weight loss ≥ 50% of the weight excess (pre BIB weight – calculated weight to lower the BMI to 24.9).
RESULTS: At baseline, mean weight was 97.2 Kg (± 16.1), mean body mass index (BMI) was 36.5 (±5.9) kg/m2, 19 (12.9 %) patients had type II Diabetes Mellitus and mean insulin resistance (HOMA-IR) was 2.9 (± 2). With BIB intervention, mean weight and mean BMI decreased, respectively, to 83.5 (± 16.9), $p < 0.001$ and 31.4 (±6.3), $p < 0.001$. Regarding laboratory parameters, cholesterol, triglycerides and HOMA-IR were significantly reduced ($p < 0.05$). There was no significant improvement in TGP, G-GT, HDL cholesterol and ferritin. BIB success was observed in 57 (38.8%) patients. Predictive risk factors for BIB success were mean pre-operative weight, 92.8 (±13) vs 99.7 (± 16.9)kg, $p = 0.011$ and mean pre-operative BMI, 35 (±3.5) vs 37.5 (±6.9), $p = 0.007$; a trend was observed for baseline HOMA-IR, 2.7 (±2.3) vs 3 (±1.7), $p = 0.056$.
CONCLUSION: BIB therapy achieves significant weight loss and significantly improves laboratory parameters of the metabolic syndrome in obese patients. BIB success is associated with baseline weight and baseline BMI further emphasizing that the endoscopic technic has major impact in mild obese, those that are not surgical candidates.

P0551 PREOPERATIVE ENDOSCOPY IN ASYMPTOMATIC BARIATRIC PATIENTS – IS IT STILL WORTH IT?

S.R. Fernandes[1,*], L. Meireles[1], L.A. Correia[1], L.C. Ribeiro[1], J. Velosa[1]
[1]*Gastrenterologia e Hepatologia, Hospital Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa, Portugal*
Contact E-mail Address: *Samuelrmfernandes@gmail.com*

INTRODUCTION: Obesity represents a major public health problem associated with increased risk of diabetes, cardiovascular and cerebrovascular disease and cancer. Surgery has shown to be an effective long term treatment. Preoperative endoscopy (POE) is recommended by the current "guidelines", but evidence supporting this recommendation in asymptomatic patients is scarce.
AIMS & METHODS: We sought to determine whether endoscopic findings justify routine POE before bariatric surgery. Obese (BMI > 30 kg/m2) and morbidly obese (BMI > 35 kg/m2) patients undergoing endoscopy in our institution were retrospectively selected. Endoscopic and histological findings and their impact on surgical strategy were assessed.
RESULTS: Of 557 patients (78.3 % female, mean age 46.9±11.5 years), 43.3 % had a normal endoscopy. Esophageal, gastric and duodenal disease were present in 22.6 %, 44.2 % and 11.0 % respectively. The most frequent esophageal findings were hiatus hernias (17.2 %) and esophagitis (8.0 %, 97.5 % Class A and B of Los Angeles). Gastric changes included erosive (18.3%) and non-erosive gastritis (19.7%), polyps (4.8%) and ulcers (1.6%, all Forrest III). Bulbitis (10.4%), ulcers (0.5%) and polyps (0.2%) composed most common duodenal findings. From a total of 218 gastric biopsies 46.3% revealed the presence of Helicobacter pylori (Hp) bacilli. In 3 patients Barrett's esophagus was diagnosed (without dysplasia) and in 2 gastric low grade MALT lymphoma (which regressed after eradication of Hp).
CONCLUSION: Our findings were of little relevance and did not alter the operative strategy. Given the high prevalence of Hp, which has been associated with higher postoperative complications, its screening by non-invasive methods prior to surgery may be a less expensive alternative. This study suggests that EPO might be dispensable in asymptomatic bariatric patients.

P0552 MODIFIED PROBIOTIC ESCHERICHIA COLI NISSLE INCREASES COLONIC SHORT CHAIN FATTY ACIDS AND FECAL BIFIDOBACTERIA AND LACTOBACILLI COUNT IN RATS

A.K. Singh[1,*], S. Pandey[1], A.S. Parihar[1], N.K. Gattupalli[1]

Contact E-mail Address: *singhashish1186@gmail.com*

INTRODUCTION: Short Chain Fatty Acids (SCFAs) are considered as one of the most important metabolite produced by commensal organism in the gut. Dietary consumption of complex carbohydrates such as inulin, fructo-oligosaccharides and sodium gluconate are known to increase SCFAs in the colon. However, they limit in their efficacy if not consumed daily. *E. coli* represents a major commensal population the human colon. *E. coli* expresses an apo- form of membrane bound enzyme, glucose dehydrogenase, which converts glucose to gluconic acid. However, it is unable to synthesize the cofactor, PQQ (Pyrroloquinoline quinone). *E. coli* produces gluconic acid when PQQ is supplied in the medium.
AIMS & METHODS: We hypothesized that, recombinant probiotic *E. coli* Nissle 1917 (EcN) expressing PQQ synthesis genes is able to synthesize large amount gluconic acid in the intestine and subsequently increased production of SCFAs.
pqqABCDE gene cluster was cloned and expressed in EcN. Rats were fed with starch containing diet along with recombinant probiotic EcN for 60 days.
RESULTS: Recombinant EcN expressing *pqqABCDE* gene cluster produces high amounts of gluconic acid in M9 minimal medium supplemented with glucose under laboratory conditions. Weekly treatment of recombinant EcN producing gluconic acid results in increased production of gluconic acid in the colon. Additionally, SCFAs (Butyrate and Acetate) concentration was also found to be elevated by approximately 3 fold and 1.6 fold respectively. mRNA profile of colon showed increased expression of mucin and intestinal trefoil factor genes in treated rats. The treated rats also had increased fecal *Bifidobacteria* and *lactobacilli* number.
CONCLUSION: The present study suggest that engineered probiotic could be a potent nutritional supplement against intestinal dysbiosis and other related pathologies.

P0553 NUTRIENT INTAKES AT THE TIME OF DIAGNOSIS IN PATIENTS WITH HIV INFECTION: COMPARISON WITH NATIONAL NUTRITIONAL GUIDELINES AND WITH A COHORT OF HEALTHY SUBJECTS

B. Zanini[1,*], R. Bosio[1], N. Brianese[1], A. Ferraresi[1], A. Arrighi[1], E. Quiros-Roldan[1], F. Castelli[1], A. Lanzini[2]
[1]*Department of Clinical and Experimental Sciences,* [2]*UNIVERSITY AND SPEDALI CIVILI OF BRESCIA, Brescia, Italy*
Contact E-mail Address: *b_zanini@tin.it*

INTRODUCTION: Assessment of nutrient intake is an important key element in healthcare of HIV patients because nutritional status is a determinant of HIV outcomes and of many co-morbidities including gastrointestinal problems, osteoporosis, cardiovascular diseases, diabetes and other metabolic changes (1,2). Little is known about nutritional adequacy among HIV patients at the time of diagnosis and prior to pharmacological treatment.
AIMS & METHODS: We carried out a prospective clinical study to assess macro- and micro-nutrient components of diet in a cohort of HIV patients at the time of diagnosis, and to compare them with Italian recommended levels of nutrient intake (LARN 2012) and with those of a cohort of healthy subjects, matched with HIV cohort according to gender and age (range ± 4 years). Patients in the two cohorts were instructed to fill in a standardized 7-day food diary. Data from diaries were analyzed with Microdiet© software (Downlee system, ltd. UK) and nutritional characteristics studied were: total Kcal, proportion of total energy value of CHO, free sugars, proteins, fats, SFA and PUFA, and total amounts of fibre, vitamins A, B12, C, and D, folates, sodium, calcium, iron, zinc. For statistical analysis Fisher's exact test and Wilcoxon matched pairs test were used as appropriate.
RESULTS: 22 HIV patients signed informed consent, 21 returned the diary and 14 were at present analyzed. Eleven were male, age 42 ±1 year (mean ± SD), BMI 23.8 ±3.3 Kg/m2 with 4 patients in overweight class, 1 in grade 1 obesity class and 9 in normal BMI class. Comparison of selected nutrient composition with LARN and with healthy subjects are reported in the table.

Nutrients	HIV patients	Healthy subjects	HIV Vs LARN§ %
CHO, % TEV	48.2±6.9	40.0±5.6*	- 21
Fats, %TEV	33.2±6.0	37.0±3.4*	+36
Proteins, %TEV	16.3±2.2	16.6±2.6	+79
Vitamin B12, µg	3.7±1.4	2.5±0.8*	-21
Vitamin D, µg	2.5±1.8	3.4±1.6	-100
Folates, µg	191.6±44.6	140.3±49.8*	-100
Calcium, mg	508.9±133.0	771.0±253.9	-100
Iron, mg	7.0±1.4	9.7±2.3*	-100
Zinc, mg	8.4±1.5	8.8±2.1	-79

CONCLUSION: Daily intake is inadequate in HIV patients at time of diagnosis for most macro- and micro- nutrients, but is closer to LARN recommendations than in healthy subjects. Nutritional counseling must be provided in HIV naïve patients in order to improve their nutritional status and to contribute to prevention of gastrointestinal and metabolic co-morbidities.

P0554 SUPPLEMENTATION WITH A PROBIOTIC MILK DRINK DOES NOT ALTER GUT MICROBIOTA COMPOSITION IN PATIENTS WITH METABOLIC SYNDROME

B. Leber[1,*], N. Tripolt[2], S. Trajanoski[3], C. Högenauer[4], H. Sourij[2], V. Stadlbauer[4]

INTRODUCTION: Metabolic syndrome (MetS) is associated with disturbances in gut microbiota including changes in the Bacteroidetes/Firmicutes ratio. In animal models, modulation in the composition of gut microbiota through supplementation with probiotics is possible. It is not known to date if this is also possible in humans.
AIMS & METHODS: We therefore aimed to study whether supplementation with a probiotic milk drink containing *Lactobacillus casei* Shirota (LcS) is able to modulate gut microbiota composition in patients with MetS. In a single-center, prospective, randomized-controlled pilot study, 28 subjects with MetS received either LcS (YAKULT® light 3 bottles a day, 65 ml each, containing LcS at a concentration of 10^8/ml) for 12 weeks (LcS group; n = 13) or received standard medical therapy (n = 15). 6 healthy subjects served as controls. Stool samples were collected at baseline and after 3 months. Gut microbiota composition was characterized using 454 pyrosequencing of the amplicon libraries from V1 to V3 hypervariable regions of 16S rRNA genes. Generated sequencing data was analyzed with Quantitative Insights Into Microbial Ecology (QIIME version 1.7.0) pipeline in stool samples.
RESULTS: No significant differences in Unifrac distances or Bray-Curtis distances between samples from the same patients in two time points were found

(p = 0.70 and 0 = 0.48, respectively). The Bacteroidetes/Firmicutes ratio was not different compared to healthy controls and was not influenced by probiotic supplementation (Controls: 0.783; LcS baseline: 0.961; LcS 3 months: 1.007; Standard baseline: 0.921; Standard 3 months: 0.995). Diversity (using Shannon index) and richness of gut microbiota in MetS showed similar distribution compared to healthy controls and was not influenced by probiotic supplementation. LcS was only detectable in 1 individual of the treatment group after 3 months of supplementation with LcS.

CONCLUSION: In our study no difference in gut microbiota composition was found between healthy subjects and patients with MetS. The supplementation of LcS did not change gut microbiota composition, so we conclude that the microbiota variations occurring in the treatment group were not larger than the normally expected variations during this time period. This is in accordance with our previous findings that supplementation with LcS did not influence clinical and biochemical parameters of glucose metabolism, inflammation and innate immune response.

P0555 QUANTIFICATION OF IN VIVO COLONIC SHORT CHAIN FATTY ACID PRODUCTION FROM INULIN

E. Boets[1,*], E. Houben[1], S. Gomand[2], J. Delcour[2], K. Verbeke[1]
[1]*Translational Research for Gastrointestinal Disorders, Leuven Food Science and Nutrition Research Centre,* [2]*Laboratory of Food Chemistry and Biochemistry, Leuven Food Science and Nutrition Research Centre, KU Leuven, Leuven, Belgium*

INTRODUCTION: Short chain fatty acids (SCFA; acetic (Ac), propionic (Pr) and butyric (Bu) acid) are produced during bacterial fermentation of undigested carbohydrates in the colon. In this study, we determined the bioavailability of each SCFA and applied a stable-isotope dilution method to quantify the colonic production of SCFA after consumption of inulin.

AIMS & METHODS: Six healthy subjects (3F/3M; 29±7y) each performed 4 test days with minimal 1 week interval. On the first 3 test days they received either 400mg ^{13}C-Ac or 340mg ^{13}C-Pr or 990mg ^{13}C-Bu in a pH-dependent colon delivery capsule with a standard breakfast. After collection of a basal blood sample, they received a primed constant infusion of ^{2}H-labelled SCFA (Ac:20µmol/kg.h; Pr:2µmol/kg.h; Bu:1µmol/kg.h) for 12h. On the 4th test day, the SCFA production from inulin fermentation was quantified. The subjects received 15g of inulin (Raftilin HP, Beneo-Orafti) with a standard breakfast and an infusion with ^{13}C-SCFA (Ac:12µmol/kg.h; Pr:1.2µmol/kg.h; Bu:0.6µmol/kg.h) for 12h. Additional blood samples were collected at regular times during the day. Plasma total SCFA concentrations, ^{13}C- and ^{2}H-SCFA enrichments were measured using gas chromatography (GC), GC combustion isotope ratio mass spectrometry (IRMS) and GC pyrolysis IRMS, respectively. The bioavailability index (F) of the respective SCFA was calculated from the area under the curve (AUC) of the ^{13}C-SCFA concentration time curve (F = AUC x Cl x 100/administered dose). The clearance rate (Cl) was determined using the ^{2}H-SCFA infusion (Cl = infusion rate (i)/steady state (SS) ^{2}H-SCFA concentration). SCFA turnover was calculated using stable-isotope dilution. The infusion with ^{13}C-SCFA results in a constant ^{13}C-SCFA enrichment in the blood. After fermentation of inulin in the colon, SCFA enter the blood and dilute the ^{13}C-SCFA resulting in a decrease of ^{13}C-SCFA enrichment. The total turnover (T) of the SCFA at each time was calculated as follows: T = i x [(Tracer enrichment/Plasma enrichment)-1]. The turnover at SS was subtracted from the total turnover to obtain the exogenous SCFA turnover. The AUC was calculated to yield total SCFA appearance in plasma. Finally, the bioavailability index and SCFA plasma concentrations were used to quantify the SCFA produced in the colon. Results are expressed as medians and interquartile ranges.

RESULTS: The bioavailability index of Ac, Pr and Bu were 37 [30-57]%, 21 [17-25]% and 4 [3.5-9]%, respectively. SS turnover of Ac, Pr and Bu were 13 [8-16], 0.23 [0.19-0.31] and 0.26 [0.15-0.34] µmol/kg.min, respectively. The total amount of Ac in plasma was 661 [512-991] µmol/kg; corresponding to a production of 112 [88-194] mmol of Ac in the colon within 12h after inulin ingestion. The AUC of Pr and Bu were 14 [9-22] and 13 [10-15] µmol/kg, respectively. Twelve hours after inulin ingestion a total of 0.9 [0.6-1] and 0.7 [0.6-1] mmol of Pr and Bu appeared in the circulation. The colonic produced Pr and Bu levels were 4 [2-6] and 19 [11-24] mmol, respectively.

CONCLUSION: In conclusion, inulin is mainly fermented into acetate followed by butyrate and propionate. Stable isotope technology allows to quantify *in vivo* SCFA production from carbohydrate fermentation and will facilitate the evaluation of health benefits attributed to SCFA.

P0556 ABDOMINAL HEMODYNAMIC IN PATIENTS WITH MALNUTRITION AND HEREDITARY CONNECTIVE TISSUE DISORDERS

G. Nechayeva[1], M. Livzan[1], **E. Lialiukova**[1,*]
[1]*Omsk state medical academy, Omsk, Russian Federation*

INTRODUCTION: The aim of the research is to study the peculiarities of abdominal hemodynamic in patients with malnutrition and hereditary connective tissue disorders.

AIMS & METHODS: To study mechanisms of malnutrition at the patients with hereditary connective tissue disorders.

121 patients with hereditary connective tissue disorders were included in the research (The revised Ghent nosology for the Marfan syndrome, 2010). The control group was represented by 40 healthy subjects to be comparable by sex and age. The assessment of malnutrition and ultrasonic dopplerography of the abdominal vessels (vena portae, arteria *hepatica communis*, arteria mesenterial superior and arteria splenica) were performed for the patients. The investigation was undertaken with fasting after feeding test, with the ultrasound scanner Sonoace-8000 (Medison, South Korea).

RESULTS: The signs of malnutrition in patients with hereditary connective tissue disorders have been revealed in 70,9% of cases. The degree of malnutrition has been correlated with the expression of hemodynamic disturbances (r = -0,55; p < 0,001).

By estimating the abdominal blood flow in persons with hereditary connective tissue disorders more lower volume rates of a blood flow were recorded: along vena portae - 1853,0 [1688,0-2297,0] ml/min., in the group of comparison -2149,0 [1827,0-2400,0] ml/min (p < 0,05); along arteria mesenterial superior - 988,0 [837,0-1272,0] ml /min, in the group of comparison - 1136,5 [992,0-1465,0] ml/min (p < 0,05); along the vessels of a celiac trunk: arteria hepatica communis - 480,5 [425,0-587,0] ml/min, in the group of comparison - 591,5 [536,0-689,0] ml/min. (p < 0,001) and splenic arteries - 600,0 [452,0-709,0] ml/min, in the group of comparison - 700,0 [591,0-795,0] ml/min (p < 0,01). After meal the persons with hereditary connective tissue disorders had fewer high-speed indicators gain and it didn't exceed 30% from the initial indicators (p < 0,001).

The data of the abdominal blood flow were correlated with some central hemodynamic changes (minute volume of circulation): at the vena portae (r = 0.55, p < 0,05), at the arteria hepatica communis (r = 0.60, p < 0,05), at the splenic artery (r = 0.77 p < 0,05); by the extent of vegetative sympathetic influences on a vascular tonus: at the arteria hepatica communis (r = -0,48, p < 0,05), at the splenic artery (r = -0,27, p < 0,05), at the arteria mesenterial superior (r = -0,36, p < 0,05); by splanchnoptosis degree: at the portal vein (r = -0,210; p < 0,05), at the arteria hepatica communis (r = -0,38; p < 0,05), at the arteria mesenterial superior (r = -0,86; p < 0,05).

CONCLUSION: The signs of malnutrition in patients with hereditary connective tissue disorders have been revealed in 70.9% of cases. The degree of malnutrition has been correlated with the expression of systemic connecting tissue involvement. The postprandial period abdominal blood flow has been characterized by the low values of volume rate at the vessels of the celiac trunk, arteria mesenterial superior, and portal vein. Some disturbances of a cardiac hemodynamic, prevalence of sympathetic influences on vascular tonus, splanchnoptosis presence may be considered to be the main causes of blood flow decreasing.

P0557 OPTIMIZATION OF DIAGNOSIS AND TREATMENT OF NUTRITIONAL INSUFFICIENCY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

A.A. Iakovlev[1,*], T.S. Kazaryan[1]
[1]*gastroenterology, ROSTOV ON DON STATE MEDICAL UNIVERSITY, Rostov on Don, Russian Federation*
Contact E-mail Address: *gastroklinika@yandex.ru*

INTRODUCTION: Development of nutritional deficiency (ND) due to the loss of nutrients, water and electrolytes with frequent stools, nutrients malabsorption, anorexia and increased catabolism is typical for patients with IBD relapse. To determine the frequency and structure of ND in patients with IBD relapse and to evaluate the therapeutic effect of nutritional support (NS) of nutritive mixtures during the course of therapy.

AIMS & METHODS: Two-phase three step study with prospective monitoring in patients with IBD was conducted during 3 years in the period from 2010 to 2012. The first phase was carried out using a one-time screening scales MUST and NRS, further in phase 2, the NS structure was refined. 520 patients with IBD were examined: 410 with ulcerative colitis (UC) and 110 with Crohn's disease (CD).

RESULTS: The 1st, 2d and 3d degree of ND was detected in 111 (27.1%), 96 (23.4%) and 42 (10.2%) patients with UC, respectively. 2d and 3d degree of ND was recorded in 48 (43.6%) and 29 (26.4%) cases in patients with CD, respectively. At the second stage of the study, 80 patients with UC were randomized into two major groups, depending on the degree of NN, were divided into groups A (2d degree of ND) and B (3d degree of ND). On basic therapy, patients of the Ist group received a diet with a high amount of protein (HAPD) and increased calorage (2500 kcal / day), while to the patients of the IId group in addition to the basic therapy, nutritional mixtures: peptamen and modulen IBD (Nestle) in the amount of 1/3 of the daily calorage were prescribed. Efficacy of treatment was evaluated on the 3 d, 4th, 12th week. At the third stage of the study, during 3 years, the long-term results were studied using index of the relapse frequency (IRF). Pick of the IRF was in the 1st group and by the end of the study it was 15 (75%) and 17 (85%) cases, respectively. In the second group IRF was significantly lower: 9 (45%) and 12 (60%) (p < 0,05).

CONCLUSION: In patients with UC and CD relapse ND of the 1st and 3d degree was recorded an average of 20.3% and 35%, respectively. Use of NS provides a low rate UC relapse, and thus stable remission of the disease.

P0558 TEDUGLUTIDE FOR PATIENTS WITH SHORT BOWEL SYNDROME-INTESTINAL FAILURE. A SINGLE CENTER EXPERIENCE

A. Ukleja[1], **A. Alvarez**[1,*], K. Alvarez[2], L. Lara[1]
[1]*Gastroenterology, CLEVELAND CLINIC FLORIDA, Weston, United States,* [2]*Nutrition, Licda Nutrición Clínica & Bariátrica, Guatemala City, Guatemala*
Contact E-mail Address: *uklejaa@ccf.org*

INTRODUCTION: Teduglutide (TG) is a novel agent recently approved for the treatment of parenteral support (PS) dependent patients with short bowel syndrome (SBS). PS dependence is a major concern for patients with SBS because of PS caries a risk of serious complications and affects quality of life. In phase III

trial, TG use lead to significant reduction in PS volume in SBS patients. Limited data is available regarding clinical results outside the research protocols.
AIMS & METHODS: Aims: To evaluate short and long-term outcomes of SBS patients receiving TG and assess patients' interest in TG therapy. **Methods:** Retrospective medical chart review was conducted. 19 pts. with SBS were identified. Demographics, length of small bowel, primary diagnosis, past surgical history, PS (TPN/IV fluids) volume and duration, TG dose and related complications were collected. SBS patients who received TG from 04/2013 to 03/2014 were included in the final analysis.
RESULTS: 6 of 19 SBS pts. received TG (Females 4, Males 2); Race: Caucasian 4, Hispanic 1, African-American 1. Mean age: 45.8 yrs. (range 26-71). Cause of SBS: vascular 3, RYGB/strangulation 1, surgical resections 2. SB length: range 30-120 cm. Colon in continuity 4, stoma 3 (ileostomy 2, colostomy 1). TPN duration: range 1–14 years. PS volume/week 1-8 Liters. Duration of TG therapy:1-12 months. Complications: bowel obstruction (SBO) 1, stoma swelling 2, bloating 4 (subsided). TG discontinuation 1 (SBO*), TG dose reduction 1 (stoma swelling). PS discontinued 4. Volume reduction in 6/6 pts. Gain or stable weight in all while on TG. No biliary/pancreatic complications, TG injection aversion were seen. Reason for no TG therapy in 13 pts.: No TG candidates 4 (recent cancer 2, post surgery <12 months 1, massive small bowel dilation 1), no insurance approval 1, no interest in TG therapy 8. **Characteristics of SBS patients who received TG therapy**.

Pts.	Age	Sex	SB length (cm)	Colon present	PS Duration (years)	PS Volume (Week)	PS Reduction >20%	PS Stopped	TG duration (months)
1	52	F	90	N	1.5	8L	Y	N	1
2	29	F	~30	Y	14	7.2L	Y	Y	12
3	26	F	70	Y	5	6.4L	Y	Y	9
4	36	M	50	Y	2	7.5L	Y	Y	6
5	61	F	~120	N	2	1L	Y	Y	5
6	71	M	90	Y	2	7L	Y	N	4 (TG stopped*)

CONCLUSION: From our eligible SBS patients only 6/14 (43.8%) received TG and > 50% of them expressed no interest in TG therapy. Three PS/nutrient dependent patients with colon in continuity and one with end-stoma discontinued PS completely with TG therapy. All patients had >20% reduction in PS volume while on TG. All had significant reduction in stoma/stool output. TG was well tolerated. Further studies with a larger sample size are needed in SBS patients to assess clinical benefits of TG and address patient decision process regarding this therapy.

P0559 BEDSIDE ELECTROMAGNETIC GUIDED PLACEMENT OF NASOJEJUNAL FEEDING TUBES IN PATIENTS AFTER PANCREATODUODENECTOMY: PROSPECTIVE SINGLE-CENTER PILOT STUDY

A. Gerritsen[1,*], A.C. Duflou[2], M. Ramali[2], O.R. Busch[1], D.J. Gouma[1], L.M. Mathus-Vliegen[2], M.G. Besselink[1]
[1]*Department of Surgery,* [2]*Department of Gastroenterology, Academic Medical Center, Amsterdam, Netherlands*
Contact E-mail Address: *a.gerritsen@amc.nl*

INTRODUCTION: Early oral feeding is now considered the routine feeding strategy after pancreatoduodenectomy. Some 35-45% of patients will develop delayed gastric emptying postoperatively and consequently require nasojejunal tube feeding. Endoscopic placement of a nasojejunal feeding tube by gastroenterologists is relatively labour-intensive and a cumbersome procedure for patients. Bedside electromagnetic (EM) guided placement using the Cortrak® Enteral Access System by nurses has been found to be a simple, safe and cost-effective strategy in several patient categories. To date, however, an altered anatomy of the upper gastrointestinal tract is seen as a relative contraindication for EM-guided tube placement.
AIMS & METHODS: The aim of this study was to determine the success rate of bedside EM-guided placement of nasojejunal feeding tubes in patients after pancreatoduodenectomy.
We performed a prospective single-center pilot study in all patients requiring a nasojejunal feeding tube after pancreatoduodenectomy between July 2012 and March 2014. EM-guided nasojejunal tubes were placed by two specialized nurses with extensive experience with the technique. EM-guided placement was not performed in patients with upper gastrointestinal stenosis or oesophageal varices or when it was not possible for logistical reasons. Primary endpoint was the success rate of primary tube placement confirmed on plain abdominal x-ray (AXR). Success was defined as the tip of the tube positioned in the efferent jejunal limb.
RESULTS: In our study period, 55 of 126 (44%) patients who underwent pancreatoduodenectomy required a nasojejunal feeding tube. In 36 patients the tube was placed under EM-guidance at a median of 8 (6-11) days after pancreatoduodenectomy. Initial tube placement was successful according to the nurse in 25 (69%) patients and on AXR in 21 (58%) patients. Median procedure time was 25 (15-35) minutes. 22 (61%) patients underwent 50 replacement procedures after previously failed placement attempts ($n=31$) or after luxation or blockage of the tube ($n=19$). 36 replacements were performed endoscopically, with a success rate of 67%, and 14 under EM-guidance, with a success rate of 71%. No tube (re)placement related complications occurred. There was no learning curve effect when comparing the first 10 with the subsequent 26 procedures concerning success rate, but median procedure time decreased from 33 (18-45) to 20 (15-30) minutes.
CONCLUSION: Bedside EM-guided placement of nasojejunal tubes after pancreatoduodenectomy was successful in 58% of patients, which seems acceptable given the potential benefits for the patient. Based on these findings we have included patients after pancreatoduodenectomy in an ongoing randomized multicenter trial focussing on the magnitude of benefits of EM-guided placement, such as reduced patient discomfort and costs as compared to endoscopy.

P0560 PROSPECTIVE STUDY OF PERISTOMAL INFECTIONS AFTER PERCUTANEOUS ENDOSCOPIC GASTROSTOMY OVER A FOUR-YEAR PERIOD

C.R. Chimakurthi[1,*], S. Lewis[1], N. Pitts[2], V. Chudleigh[3]
[1]*Gastroenterology,* [2]*Endoscopy,* [3]*Remedial Services, Plymouth Hospitals NHS Trust, Plymouth, United Kingdom*
Contact E-mail Address: *cchimakurthi@nhs.net*

INTRODUCTION: Incidence of peristomal infections following percutaneous endoscopic gastrotomy in the community is not well known. Data on subsequent site infections and the organisms responsible is limited. Despite the use of prophylactic antibiotics, the incidence of peristomal infections is significant and result in substantial morbidity in patients with PEGs.
AIMS & METHODS: We aim to evaluate the prevalence of peristomal infection in our local community over a four year period after their PEG placement. Other objectives were to characterise the microbiology from wound site swabs and to identify any correlation between peristomal infection and patient characteristics. Our study also looked at incidence of subsequent peristomal infection rates in the community prospectively over a 4-year period.
Patients aged 16 and over who have had percutaneous endoscopic gastrostomies placed at Derriford hospital, Plymouth, UK during years 2008 to 2012 were included in the study period. Patients with venting gastrostomies and those who had their gastrostomies placed while undergoing treatment for Head & Neck cancer were not included in this study. All patients had their PEGs placed according to British Society of Gastroenterology guidelines with pre-procedure prophylactic antibiotics. Community enteral feed dieticians followed all patients at clinically appropriate intervals in the community following discharge from hospital. They recorded incidence of infections and various other complications over the four-year period. Endoscopy reports, clinical case records, and microbiological investigation results were also reviewed. Excel and Stata 10 were used for data collection and analysis.
RESULTS: 341 patients underwent percutaneous endoscopic gastrostomy during the study period. 110 patients (31%) needed treatment for an insertion site infection. The median time from PEG insertion to first wound site infection was 85 days (14, 363). Mixed skin commensals (42.7%) followed by Staphylococcus aureus (29%) were most frequently isolated from gastrostomy wound site swab. Only one patient had Methicillin resistant staphylococcus aureus isolated. The spectrum of organisms for subsequent peristomal infection was similar to those causing the first infection. The majority of infections resolved with appropriate treatment. Indications for PEG insertion, age, sex and residence did not correlate with peristomal infection. Two patients needed replacement with new PEG tubes in view of infection. Both of them needed their PEG tubes replaced thrice further. No specific organisms were associated with the removal and replacement of PEG tubes.
CONCLUSION: Our rates of peristomal infection are similar to previous studies[1]. Although staphylococcus aureus was frequently isolated from insertion site, the prevalence of MRSA was much lower in our cohort[2]. The time from PEG insertion to initial infection was also much longer[2].

P0561 RESTORATION OF BOWEL CONTINUITY CAN REDUCE THE RISK OF CHRONIC CHOLESTASIS IN PATIENTS WITH A SHORT BOWEL

F. Adaba[1,*], C. Vaizey[1], S. Gabe[1], J. Warusavitarne[1], J. Nightingale[1]
[1]*St Marks Hospital, Harrow, United Kingdom, London, United Kingdom*
Contact E-mail Address: *f.adaba@nhs.net*

INTRODUCTION: Patients with a short bowel and on home parenteral nutrition (HPN) have an increased risk of chronic cholestasis. This is may be due to recurrent sepsis, reduced bile flow with biliary stasis or associated with HPN. Restoration of bowel continuity can result in HPN requirements being reduced or stopped. This study aims to determine the effect of restoration of bowel continuity on the risk of chronic cholestasis (CC).
AIMS & METHODS: A retrospective review of patients with short bowel due to mesenteric infarction from 2000-2010. Chronic cholestasis (CC) was defined as two of bilirubin, alkaline phosphatase and gamma-glutamyl transferase being 1.5 times the upper limit of normal for more than 6 months.
RESULTS: Number of patients with data on liver functions was 101 (55 females, median age 54 years). Fifteen (54%) of 28 patients with a jejunostomy had CC while 4 (25%) of 16 patients who had a primary anastomosis and 11(19%) of 57 patients who had a delayed anastomosis had CC. Univariate analysis showed restoration of bowel continuity reduced the risk of chronic cholestasis

($p = 0.002$). Of 11 patients with delayed anastomosis and CC, 3 had resolution of CC, 3 patients died and 5 had continuing CC.
CONCLUSION: Restoration of bowel continuity can reduce the risk of chronic cholestasis in patients with a short bowel.

Contact E-mail Address: *n.kawata@scchr.jp*

INTRODUCTION: Indication of endoscopic resection for early gastric cancer (EGC) has been determined by the analysis of node-negative cancer using a large database of surgically resected EGC patients. Pathological assessment of tumor depth and lymphovascular infiltration among surgically resected specimens are likely to be underestimated compared to that of endoscopically resected specimens because the section interval is thick (five and two millimeters, respectively). The aim of this study was to clarify the related factors for lymph node metastasis (LNM) among additional gastrectomy in EGC patients who were judged as having a non-curative endoscopic submucosal dissection (ESD).
AIMS & METHODS: Clinical and pathological records of 455 patients who underwent gastrectomy with lymph node dissection for a non-curative ESD during September 2002 to December 2013 were retrospectively studied. Patients with (1) multiple synchronous or metachronous non-curative lesions, (2) recurrent lesions, (3) histological special type, (4) remnant stomach and (5) insufficient pathological data of preceding ESD were excluded. Main histological type (differentiated-type (D-type) or undifferentiated-type (UD-type)), lesion diameter ($\leq$2cm or 2cm$<$), tumor depth (mucosa (pT1a) or submucosa (pT1b)), lymphovascular infiltration, vertical tumor margin (VM) and ulcerative finding (UL) were examined.
RESULTS: A total of 359 patients (male/female: 287/72) with a median age of 70 year were enrolled. Additional gastrectomy was performed a median of 70 days after ESD. Main histologic type were D-type/UD-type 301/58, lesion diameter were $\leq$2cm/2cm$<$ 109/250, tumor depth pT1a/pT1b 82/277, lymphovascular infiltration was positive in 177, VM positive or indefinite was observed in 76, and UL was positive in 91 patients. LNM was found in 32 patients (9%). Univariate analysis revealed that tumor depth (OR: 4.8, 95%CI: 1.1-20.4) and lymphovascular infiltration (OR: 11.7, 95%CI: 3.5-39.1) were significant related factors for LNM. Multivariate analysis revealed that lymphovascular inflitration was an independent related factor for LNM (OR: 9.78, 95%CI: 2.76-34.59). LNM was found in 29 patients (16.4%) among 177 patients with positive lymphovascular infiltration. In contrast, LNM was found only 3 patients (1.6%) among 182 patients with negative lymphovascular infiltration.
CONCLUSION: Lymphovascular inflitration was an independent related factor for LNM among additional gastrectomy after non-curative ESD. Detailed search of lymphovascular infiltration is the most important factor in the pathological evaluation of endoscopically resected specimens.

INTRODUCTION: Metformin has been recently reported to provide anti-inflammatory or antitumor activity in colitic and colitic tumor animal models through inhibition of nuclear factor kappaB (NF-κB) signaling. There is no evidence of metformin induced attenuation of gastric mucosal inflammation by alcohol.
AIMS & METHODS: The aim of this study is to investigate the effect of metformin on NF-κB signaling and endoplasmic reticulum (ER) stress in human gastric epithelial cells in vitro and on ethanol-induced acute murine gastritis in vivo. Human gastric epithelial MKN-45 cell lines were pretreated with metformin and then stimulated with tumor necrosis factor-α (TNF-α). Interleukin-8 (IL-8) expression was determined by real-time RT-PCR. NF-κB DNA-binding activity in the nuclear extracts was assessed by electrophoretic mobility shift assay (EMSA). The molecular marker of ER stress, including CHOP and XBP1 was evaluated using PCR. In the ethanol-induced acute gastritis model, mice were given absolute ethanol (50 mg/kg, 250 mg/kg) by oral gavage with or without metformin. Using the extracted gastric tissue, macroscopic assessment, histological evaluation and immunohistochemical staining for phospho-IκB kinase (IKK) was performed.
RESULTS: Metformin significantly inhibited the upregulated expression of IL-8 in MKN-45 cells stimulated with TNF-α in a dose dependent manner. Pretreatment of MKN-45 cells with metformin decreased activity of NF-κB in TNF- α -stimulated cells. CHOP and XBP1 mRNA expression was enhanced in the presence of TNF-α, and it was dampened by pretreatment of metformin. Administration of metformin significantly attenuated the severity of ethanol-induced acute murine gastritis, as assessed by macroscopic and histological evaluation of gastric mucosal damage.
CONCLUSION: These results indicate that metformin inhibits NF-κB activation and ER stress in gastric epithelial cells and that it ameliorates experimental murine gastritis. These results suggest that metformin is a potential gastroprotective agent.

Contact E-mail Address: *piotrowicz.grazyna@interia.eu*

INTRODUCTION: The purpose of the study was to assess the differences in brain activity during resting-state fMRI (rs-fMRI) in patients with non-specific digestive tract diseases (Functional Dyspepsia-FD, Inflammatory Bowel Diseases-IBD and Irritable Bowel Syndrome-IBS) in comparison to healthy group.
AIMS & METHODS: Twelve patients (FD, IBS, IBD) and eleven in control group were included into the study.
The functional and anatomical images were acquired with a 3T Achieva TX Scanner (Philips Healthcare) with the use of the 8-channel head coil. To evaluate and exclude subjects with brain pathology standard T1 and T2 sequences were applied. No contrast agent was administered. For functional imaging a $T2^*$ Gradient Echo-Planar Imaging sequence was used. The rs-fMRI analyses were performed with the use of the standard preprocessing. Afterwards an Independent Component Analysis was applied resulting in maps of the Default Mode Network for each of the participants. Those were further compared across the groups. The following psychological tests were applied: STAI, EAS, EPQ-R, CISS, BPCQ.
RESULTS: Compared to patients with non-specific digestive tract diseases the healthy controls' DMN comprised additional areas in right hemisphere involving the Medial Frontal Gyrus and Cingulate Gyrus. The DMN network of the patients involved additional area in the medial frontal area. See table for detailed stereotactic coordinates and Z-scores.
Table 1 Significant additional brain regions of the Default Mode Network of the healthy controls compared with patients with non-specific digestive disorders

	Anatomical region	x	y	z	Z	No. of voxels
healthy > patients	Medial Frontal Gyrus	0	66	9	4.16	9
	Cingulate Gyrus	12	24	30	4.25	5
	Cingulate Gyrus	-9	0	36	4.08	6
patients > healthy	Superior Frontal Gyrus	-15	63	6	4.06	8

Results of the 2nd level between-group analysis, $p < 0.05$ FDR corrected, x, y, z are MNI coordinates of the most significant center of the activation within the activated cluster. Z = Z-value, BA = Brodmann
CONCLUSION: Our study showed that the DMNs of the patients and the control altered in the involvement of the medial structures of the prefrontal cortex (Medial Frontal Gyrus and Superior Frontal Gyrus) as well as the dorsal anterior cingulated cortex (the Cingulate Gyrus). Combined with the psychological results, the rs-fMRI indicates differences regarding emotional self-control. Further studies are required to establish clinical significance of those findings.

P0565 MEDIUM-TERM EFFICACY OF SACRAL NERVE STIMULATION FOR IRRITABLE BOWEL SYNDROME

J. Fassov[1,2,*], L. Lundby[2], S. Laurberg[2], S. Buntzen[2], K. Krogh[1]

Contact E-mail Address: *janfas@rm.dk*

INTRODUCTION: In a recent randomized, controlled, crossover study we concluded that sacral nerve stimulation (SNS) is an effective treatment for severe IBS.[1]
AIMS & METHODS: In the present study, we aimed at evaluating the medium-term results of SNS in the same group of patients.
Our criteria for permanent SNS were at least 30% reduction in IBS-specific symptom score (GSRS-IBS questionnaire) during the percutaneous nerve evaluation (PNE) test. Primary endpoint was change in the IBS-specific symptom score. Secondary endpoint was change in the IBS-specific quality of life score.
RESULTS: Forty-three selected patients with severe diarrhoea predominant or mixed IBS underwent a PNE test at our tertiary centre. Among these, 31 (76%, as 2 tests were inconclusive) qualified for permanent SNS and 26 (60%) were actually implanted. Of patients receiving permanent SNS 22 (85%) were eligible for the present study. At follow-up after median 42 months (range; 12-60) the median IBS-specific symptom score (26; range 13 to 64) remained significantly lower than at baseline (62, range 45 to 80) ($P < 0.0001$). The effect was observed in all IBS symptom clusters. Also, the median IBS-specific quality of life score remained significantly improved at follow-up (52, range 26 to 162) compared to baseline (134, range 82 to 180) ($p = 0.0001$). The effect was observed in all IBS quality of life domains. Therapeutic success was maintained in 18 patients (82%) of whom 5 had had the stimulator for 5 years.
CONCLUSION: The positive effect of SNS for selected patients with severe IBS is maintained at medium-term (1-5 years) follow-up.

P0567 PREVALENCE AND SEVERITY OF IRRITABLE BOWEL SYNDROME IN MORBID OBESITY

A.S. Schneck[1], D. Pishvaie[1], R. Anty[1], R. Dainese[1], M. Vivinus[1], X. Hébuterne[1], J. Gugenheim[1], A. Tran[1], A. Iannelli[1], **P. Thierry**[1,*]
[1]*CHU Nice, Université de Nice Sophia Antipolis, Nice, France*
Contact E-mail Address: *piche.t@chu-nice.fr*

INTRODUCTION: The relationship between irritable bowel syndrome (IBS) and obesity has been poorly investigated. Only few recent reports have suggested an interesting correlation between obesity and IBS (1,2).
AIMS & METHODS: We aimed to determine the prevalence and severity of IBS and associated co-morbidities in a prospective cohort of obese patients. Ninety morbid obese patients (BMI 40.9±4.3 kg/m^2) were included prospectively before gastric bypass. The diagnosis of IBS and each subtype (predominance of constipation, diarrhea, alternant or undetermined) was performed according to the Rome III criteria using a Bristol scale for stool consistency. Patients were also asked for IBS related co-morbidities including chronic fatigue, migraine, low back pain, gastroesophageal reflux (GER), genitourinary problems and dyspepsia. Patients had to complete a set of questionnaires at the same time to assess the severity of IBS (IBS Severity Score), gastroesophageal reflux (Reflux Qol), psychological factors including anxiety and depression scale (HAD), fatigue (Fatigue Impact Scale), and quality of life (SF-12).
RESULTS: Among 90 obese patients, 26 of them (28.8%) fulfilled the Rome III criteria for IBS (IBS-D, n = 11, IBS-C, n = 9, IBS-A, n = 1, IBS-U n = 5). Obese patients with or without IBS were similar in age (41.7±13.1 vs 41.5±12.0 years $p = 0.9$), sex (69% vs 65% of females, $p = 0.3$) and BMI (40.9±3.9 vs 41.1 kg/m^2 $p = 0.8$). Obese patients with IBS reported significantly higher prevalence of GER (84% vs 25.9%, $p < 0.001$), migraines (75 % vs 25% $p = 0.01$), low back pain (80% vs 57% $p = 0.03$), genitourinary problems (19% vs 5% $p = 0.03$), chronic fatigue (80% vs 43% $p = 0.001$) and dyspepsia (69% vs 32% $p = 0.001$). Obese patients with IBS had significant higher score of fatigue (33±35 vs 63±39, $p = 0.0009$), anxiety (7.0±3.3 vs 10.4±3.8 $p = 0.0001$), depression (4.9±3.4 vs 6.8±4.1 $p = 0.03$), severity of IBS (58±55 vs 165±100 $p = 0.0001$), and poorer quality of life (39.1±4.7±36.0±5.4, $p = 0.01$) than those without IBS. Obese patients having both IBS and GER had significant higher IBS severity scores than those without GER (171.4±106 vs 95±42, $p = 0.05$). BMI did not correlated with IBS severity whatever the presence of Rome III criteria. In a logistic regression model including BMI, anxiety, depression, fatigue and GER score, only anxiety was significantly and independently associated with the presence of IBS (RR 1.25 CI 95% 1.1-1.51).
CONCLUSION: A relatively high 28.8% prevalence of IBS was found in obese patients. The severity of IBS was not correlated with BMI. However, anxiety was independently associated with IBS in obese patients suggesting that psychological factors are key features of IBS whatever the presence of obesity.

P0568 CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CIPO): A MULTI-LEVEL NEUROMUSCULAR-BASED DIAGNOSTIC APPROACH

R. D'Angelo[1], R. Rinaldi[1], V. Stanghellini[2], L. Pironi[2], R.F. Cogliandro[2], E. Ruggeri[2], G. Cenacchi[3], V. Donadio[3], R. Liguori[3], V. Carelli[3], R. Lodi[3], C. Tonon[3], **R. De Giorgio**[2,*] on behalf of CIPO Bologna Group
[1]*Int Med Aging Nephrol, S. Orsola-Malpighi Hospital, Bologna, Italy,* [2]*Med Surg Sci,* [3]*Biom NeuroMot Sci, Univ of Bologna, Bologna, Italy*
Contact E-mail Address: *rdangelo81@libero.it*

INTRODUCTION: Chronic intestinal pseudo-obstruction (CIPO) is a failure of gut motility leading to recurrent episodes of intestinal sub-occlusion with no demonstrable mechanical reason. CIPO diagnosis and management is often very difficult because of the lack of standardized approach in relation to underlying causes.
AIMS & METHODS: We report our approach to diagnosis of CIPO patients with the aim to identify possible underlying neurological causes by using a multi-level investigation. Forty-nine CIPO patients (M: 15; age range: 19-63 yrs; F: 34; age range: 16-61 yrs) performed first-level exams including laboratory tests, neurological assessment and electromyography. Three patients did not comply to the diagnostic protocol and were excluded. Second-level examinations included muscle/skin biopsy and/or biochemical/molecular assays based on previous results. MR imaging and spectroscopy were performed if mitochondrial encephalomyopathy was suspected. Biochemical/molecular tests included thymidine phosphorylase activity and a-galactosidase enzyme assay as well as gene analysis of mitochondrial disorders; transthyretin or enteric smooth muscle actin genes were also performed. Full-thickness gut biopsies were obtained only in cases undergoing either elective or emergency surgery (because of intestinal sub-occlusion).
RESULTS: At the end of the complete diagnostic work up 46 out of 49 patients (94%) were thoroughly investigated. Three groups of CIPO patients were identified: A) n = 11 had mitochondrial diseases; specifically n = 6 had mitochondrial encephalomyopathy proved by genetic analysis (4 MNGIE, 1 MERRF, 1 POLG) and other n = 5 had a likely mitochondrial encephalomyopathy, although not yet confirmed by genetic analysis; B) n = 21 had a neuromuscular non-mitochondrial diseases; specifically n = 16 had neuropathy, in particular n = 3 polyneuropathy (1 associated with lymphoma, 1 Hu-related autoantibody, 1 idiopathic polyneuropathy), n = 12 small fiber neuropathy demonstrated by skin biopsy, n = 1 enteric neuropathy; finally, n = 5 had myopathy, in particular n = 1 myofibrillar myopathy and n = 4 an undefined myopathy; C) n = 14 had an idiopathic CIPO with no underlying neurological causes including abnormalities of the intrinsic or extrinsic innervation of the gut, as indicated by full thickness analysis and/or intestinal manometry.
CONCLUSION: After an accurate neurological evaluation and tests, only a third of CIPO are actually 'idiopathic'. Mitochondrial disorders should be always sought in patients with CIPO, while skin biopsy is suggested as an aid to unravel a 'small fiber' disorder, a peripheral neuropathy affecting also the autonomic nerve component. Taken together our data suggest that a thorough neurological evaluation and tests represent an important part in the management of patients with CIPO.

P0569 THE SAME DAY SPLIT CLINIC – A PRESCRIPTION FOR EFFICIENCY IN THE GASTROENTEROLOGY OUTPATIENT CLINIC

M.F. Jaboli[1,*], M. Grimes[1], H. Palmer[1], C. Clayman[1], T. Rayne[1], C. Durcan[1], I. Mason[1], O. Epstein[1]
[1]*Gastroenterology, Royal Free Hospital, London, United Kingdom*

INTRODUCTION: Worldwide, healthcare providers are striving to balance escalating costs with the patient's expectation of efficient access to specialist opinion, rapid investigation and treatment. Over the past 65 years, the NHS gastroenterology outpatient journey has remained unchanged. Patients are assessed at the first visit, followed by one or more hospital visits for gastrointestinal investigations and a return hospital attendance for final assessment. The same day split clinic has been designed, wherever possible, to condense the journey from months to hours.
AIMS & METHODS: Over a period of three months, each gastroenterology referral letter was previewed in advance of the outpatient appointment. Each patient was triaged as "solution" or "complex". For the "solution" cohort, investigations were predicted and scheduled for the same day as the outpatient attendance. Patients were asked to attend the clinic starved and told to expect one or more same day gastrointestinal investigations. On the appointment day, "solution" patients attended the same day split clinic for: 1) an initial specialist assessment, 2) scheduled investigation(s), 3) a return to the specialist clinic for a summative assessment & management plan.
RESULTS: Of 174 referrals, 95 patients were triaged from the referral letter as "Solution" patients, and 81 attended the split clinic (7 did not arrive, 4 postponed, 3 direct to surveillance colonoscopy). In those who attended, 46 same day tests were performed (14 upper endoscopies, 11 sigmoidoscopies, 5 barium swallows, 6 Eso Capsule endoscopies, 5 ultrasound scans, 1 electrogastrogram, 2 CT abdomen and 2 CT colonoscopy). Twenty-seven patients (34%) were discharged, and twenty-two (27 %) were discharged after a single follow up telephone consultation. Overall, 49 patients designated as "Solution" patients (60%) required only a single hospital visit. Sixteen patients (17%) were re-designated as "Complex" requiring further tests and 3 (3%) were referred elsewhere. Overall, 95 (46 same day tests and 49 return to follow up clinic in old system) return hospital visits were avoided. The visits were reduced by 40% and the follow up appointments were down by 60%.

CONCLUSION: Analytical triage of GP referral letters allows identification & triage of most "solution" patients. This facilitates pre-emptive investigation planning and scheduling which, in turn, supports a same day split clinic designed to condense months of investigation and follow up into a few hours. The well planned same day split clinic meets the patient's expectation for an efficient journey and a quick diagnosis. The inconvenience of numerous hospital attendances is minimized, whilst appointment capacity is freed up.

P0570 DEVELOPING A EUROPEAN CLINICAL RESEARCH NETWORK FOR PAEDIATRIC GASTROENTEROLOGY, HEPATOLOGY AND NUTRITION

N. Croft[1,*], V. Tailor[1], L.de Ridder[2], S. Hussey[3] on behalf of PEDDCReN Steering Group
[1]*Centre for Digestive Diseases, Blizard Institute, Queen Mary University of London, London, United Kingdom,* [2]*Erasmus MC, Rotterdam, Netherlands,* [3]*University College Dublin, Dublin, Ireland*
Contact E-mail Address: *n.m.croft@qmul.ac.uk*

INTRODUCTION: Paediatric European Digestive Diseases Clinical Research Network (**PEDDCReN)** was established in April 2013. The need for this initiative was identified by ENPR-EMA (The European Network of Paediatric Research at the European Medicines Agency). The Project is supported by LINKS funding from the UEG (United European Gastroenterology) and is led by the British, Irish and Dutch Societies of Gastroenterology in collaboration with ESPGHAN and ENPR-EMA.
AIMS & METHODS: The aim of PEDDCReN is to support the development of large studies in paediatric patients in the speciality of Gastroenterology, Hepatology and Nutrition (GHN).
We report the preliminary results of an online survey as a first step of PEDDCReN, identifying investigators' resources, expertise and interest in studies in this area in the UK, Ireland and the Netherlands.
The survey was designed by the steering group of PEDDCReN and utilised the web based system REDCap. It takes 5 minutes to complete with 1 respondent per hospital. To date the survey has had responses from paediatric gastroenterologists in the UK, Ireland and the Netherlands as members of BSG, BSPGHAN, Irish and Dutch Gastroenterology Societies. As a result of PEDDCReN promotions in UEG & ESPGHAN newsletters one centre from Italy, Germany, Serbia and Poland has also responded.
RESULTS: After six months 25 units (including 53 investigators) had replied representing children's services with a median of 211 beds (range 15-800). 10 were stand alone children's hospitals, 11 were children's hospitals co-located with adult hospitals, 2 were smaller children's units in adult hospitals and one was a neonatal unit. 76% of responding units had neonatal ICUs on site with almost all of these carrying out neonatal surgery. All wished to be part of PEDDCReN and were happy for contact details to be passed on to both industry and non-industry investigators. The survey identified each unit's interest in recruiting into a range of GI and liver diseases (eg 88% wished to recruit for IBD studies whereas only 24% for infant diarrhoea). Less than 33% would also recruit to liver studies including infective hepatitis. Of the respondents 60% have been a principle investigator (in their hospital) and 40% had been chief investigators for their country. 68% were willing to take on phase I or II studies but only 36% had done any in the last 3 years. 64% had a clinical research facility available on site and 68% have access to research nurses. Sites were also asked whether they currently followed up any patients with rare GI or liver diseases such as congenital enteropathy (12/25), congenital transport defect (7/25), polyposis syndromes (17/25), chronic intestinal pseudo-obstruction (15/25).
CONCLUSION: This shows the ability of PEDDCReN to identify interest, expertise and resources in 3 countries. This will shortly be extended to the rest of Europe. The potential for investigators and industry to utilise this network to support the development of large scale clinical trials and rare diseases studies within this speciality is a major benefit.

P0571 THE EFFICACY OF RECOMBINANT HUMAN SOLUBLE THROMBOMODULIN IN PATIENTS WITH SEPSIS AND DISSEMINATED INTRAVASCULAR COAGULATION IN THE GASTROENTEROLOGY FIELD

T. Ito[1,*], A. Nagahara[1], T. Osada[1], J. Kato[1], H. Ueyama[1], H. Saito[1], S. Watanabe[1]
[1]*gastroenterology, Juntendo University, Tokyo, Japan*
Contact E-mail Address: *tmitou@juntendo.ac.jp*

INTRODUCTION: Inpatients with digestive disease often have coexisting serious infections. Some of them result in disseminated intravascular coagulation (DIC). Recently, recombinant human soluble thrombomodulin (rTM) was approved and has been used in clinical practice for DIC treatment in Japan. However, there are few studies to evaluate the efficacy of rTM for DIC in the gastroenterology field. The purpose of this study is to make a comparison between rTM-treated patients and patients treated other agents, and to evaluate the efficacy of rTM.
AIMS & METHODS: The purpose of this study is to make a comparison between rTM-treated patients and patients treated other agents, and to evaluate the efficacy of rTM. Fifty-three inpatients at our department with sepsis-induced DIC between January 2009 and February 2014 were retrospectively analyzed. The patients were classified into the rTM treatment group (n = 25), and conventional treatment group (rTM was not used) as the control group (n = 28). Diagnosis of DIC was made according to the criteria of acute DIC of the Japan Association of Acute Medicine (JAAM). Platelet count, prothrombin time-international normalized ratio (PT-INR), levels of fibrin/fibrinogen degradation products (FDP), C-reactive protein (CRP), DIC scores based on JAAM criteria were measured on days 0,3, and 7 to evaluate therapeutic results. Furthermore, DIC resolution rate were assessed 3 and 7 days after the start of DIC treatment.
RESULTS: Before treatment, DIC scores based on JAAM criteria were 5±0.95 in the rTM group, and 5.9±1.3 in the control group ($p < 0.05$), respectively. However, there were no significant differences between two groups regarding age, sex, and causative disease of DIC. The duration of rTM administration was 3.6±1.44 days (range 1 to 7 days). As shown in the table, significant intra-group improvement was observed in all parameters except for FDP in both groups. However, there were no significant inter-group differences in comparison of all parameters. Result from the repeated measures analysis of variance, significant improvements were seen in the DIC scores in the rTM treated group ($p = 0.001$).

		Day0	Day3	Day7
Platelet count ($10^4/\mu L$)	rTM	11.1±6.5	10.5±4.7	17.9±9.0*
	control	10.6±6.9	8.4±5.7	14.9±8.7**
PT-INR	rTM	1.39±0.32	1.18±0.16**	1.21±0.22**
	control	1.43±0.32	1.22±0.3**	1.2±0.19**
FDP (μg/ml)	rTM	32.3±19.4	19.8±24.5	17.6±13.7
	control	37.4±34.1	24.9±14.5	22.2±13.0
CRP (mg/dL)	rTM	14.1±8.8	9.7±5.4*	6.6±5.6**
	control	14.5±7.6	12.2±6.1	7.5±5.2**
DIC score	rTM	5±0.95	3.1±1.8**	2.0±1.7**
	control	5.9±1.3	4.5±1.9**	3.2±2.3**
DIC resolution rate (%)	rTM		48	68
	control		28.6	50

Data are shown with Mean±SD *$p < 0.05$ vs Day0, **$p < 0.01$ vs. Day0

CONCLUSION: These results suggest that rTM would be the useful medicine for treatment DIC in the gastroenterology field.

P0572 THE EFFECT OF ACUTE SLIGHTLY INCREASED INTRA ABDOMINAL PRESSURE ON INTESTINAL PERMEABILITY AND OXIDATIVE STRESS IN A RAT MODEL

Y. Leng[1,*], G. Yao[1]
[1]*Intensive care unit, Peking University Third Hospital, Beijing, China, Beijing, China*
Contact E-mail Address: *lengyuxin1980@126.com*

INTRODUCTION: The harm of Intra-abdominal hypertension (IAH) on critically ill patients has gained great attention. However, there are still 60% under-IAH patients in critical care units, whose intra abdominal pressure (IAP) runs slightly higher, at 5 to 7 mmHg. Among the frequently IAH-affected organ systems, the intestine is initially influenced. Nevertheless, the adverse effect of transient exposure to slightly raised IAPs on intestinal mucosa remains unclear.
AIMS & METHODS: To study the acute effects of different grade nitrogen pneumoperitoneum on colon mucosa, male Sprague- Dawley rats were assigned to six groups with different IAPs (baseline, 4mmHg, 8mmHg, 12mmHg, 16mmHg, 20mmHg, n = 6 per group). During the 90 minutes' exposure, we dynamically monitored the heart rate and noninvasive hemodynamic paramaters. After decompression slowly, the arterial blood gas analyses were conducted. Then the structural injury to the colon mucosa was confirmed by light microscopy. The colon permeability was revealed by expression and localization of tight junction proteins (claudin 5 and occludin), combined with the absorption of fluorescein isothiocyanate dextran (FD-4, with another proportion of rats, n = 6 per group). The pro-oxidant–antioxidant balance of the colon was determined by the levels of malondialdehyde (MDA), glutathione peroxidase (GSH-Px), catalase (CAT) and serum super oxide dismutase (SOD).
RESULTS: IAPs greater than 12 mmHg significantly disturbed the colonic integrity, expression of tight junction protein, mucosal permeability to FD-4 and the pro-oxidant–antioxidant balance. Interestingly, slight elevation of IAPs not reaching the level of IAH also showed a similar undesirable effect. In 8mmHg group, mild hyponatremia, hypocalcemia and hypoxemia occurred, accompanied with the reduction of blood pressure and abdominal perfusion pressure. What's more, mild microscopically inflammatory infiltration and increase of MDA were also detected in under-IAH groups. 8mmHg-IAP markedly inhibited the expression of claudin 5 and occludin, though no significant differences were found in permeability to FD-4 between control and 8mmHg groups.
CONCLUSION: Acute exposure to slightly raised IAPs may bring adverse effects on intestinal permeability and pro-oxidant–antioxidant balance. Accordingly, we concluded that for critically ill patients, IAPs should be monitored dynamically and intervened as soon as possible to avoid the intestinal mucosal injury and the subsequent gut- derived sepsis.

INTRODUCTION: Post-inflammatory peri-pancreatic fluid collections are frequent sequelae of severe acute pancreatitis. Collections are at risk of suppurative infection complicated by pancreatic necrosis. Over the last decade there has been an increasing emphasis on minimally invasive drainage procedures, including EUS-guided cyst-gastrostomy, and these approaches seem to be associated with lower morbidity and mortality. Access to the necrosis cavity has however been severely limited by having to maintain the tract with small diameter plastic stents. Recently, a novel flanged fully covered self-expanding metal stent (FCSEMS; NAGI stent, Taewoong Medical, Korea) has been developed to allow for better drainage of infected necrosis and easier endoscopic access into the cavity. Setting: A non-randomised prospective multicentre phase II study to determine the safety and efficacy of FCSEMS endoscopic cyst- gastrostomy in the management of complex/infected pancreatic fluid collections.
AIMS & METHODS: Patients were included if they had evidence of a pancreatic fluid collection which was deemed to be amenable for EUS- guided drainage after discussion at a HPB multidisciplinary meeting. Patients selected for EUS-guided drainage had cross sectional imaging (MR or CT) performed within 2 weeks of the procedure and then an EUS assessment was made of the necrotic component. The collection was punctured using a cystotome and the FCSEMS inserted over a guidewire with fluoroscopic control. Repeat procedures were performed as necessary.
RESULTS: A total of 11 patients (8 male, 3 female) were included in the study. Median age was 57.3 years. The aetiology of the collection was gallstones in 6 patients, idiopathic in 3, ischaemic in 1 and drug-induced in 1. Ten patients had evidence of at least 30% necrosis within the collection. Mean diameter of the collection was 15cm and EUS-guided puncture was initially performed in all patients. The tract was dilated with a balloon in 6 patients. Stent insertion was either with a 20mm (7 patients) or 30mm (4 patients) length FCSEMS. Ten patients underwent endoscopic necrosectomy, with a median of 3 procedures (range 1-10). Significant reduction in the size of collection was achieved in all patients. Adverse events included stent migration in 3 (2 spontaneously and 1 during necrosectomy). Two patients died of complications of severe acute pancreatitis.
CONCLUSION: FCSEMS insertion is feasible and safe for drainage of pancreatic fluid collections. It allows repeated through the stent necrosectomy procedures and appears to be a major advance in the management of infected pancreatic necrosis.

P0574 "LUCKY LOOP": A VARIANT OF AN ENDOLOOP + CLIP WOUND CLOSURE TECHNIQUE AFTER COLONIC DEFIANT POLYP REMOVAL

E. Rosa-Rizzotto[1,*], C. Lucchini[1], F. De Lazzari[1]
[1]*Dpt of Specialized Medicine, Gastroenterology Unit, St Anthony Hospital, Padua, Italy*

INTRODUCTION: This report describes a variant of an iatrogenic wound closure technique after endoscopic mucosal
resection (EMR) or endoscopic submucosal dissection (ESD). After removal of defiant polyps without signs of perforation or important bleeding, iatrogenic wounds are generally not closed as second intention healing is expected. In the past patients were often hospitalized after those procedures for 2-3 days, but when discharged a 6.5% prevalence of delayed bleeding persists(1). The combined technique of endoloop plus clip or clip alone to close iatrogenic wounds or perforations during operative endoscopies is a well established practice. Clips plus endoloop technique have been coined King Closure(2) or "clutching rose stems" techniques(3).
AIMS & METHODS: We propose "a tobacco-pouch" suture technique for wounds that are a maximum of 4 cm diameter, anchoring a single endoloop with 5-6 long type clips cirumferencially to the wound edge perimeter and closing the loop using a single double channel endoscope. A hemoclip short type is placed over the plastic tube that tightens the loop to fix the suture at the end of the procedure.
Sixteen (8 ESD and 12 EMR) patients underwent endoscopic removal of polyps >25 mm <40 mm between June and December 2013. All the iatrogenic wounds were closed with the technique described in the video. The mean time to perform the procedure was 8 min (range 6-13 min). High definition endoscopes PCF-H180AL and GF-H180J (OLYMPUS, Tokyo, Japan) with an external artificial second channel, a 30 mm diameter endoloop (PolyLoop®, OLYMPUS, Tokyo, Japan) and Clips HX-610-090L and HX-610-135S (EZ-Clip®, OLYMPUS, Tokyo, Japan) were used. Carbon dioxide insufflation was used during all of the procedures. The patients were examined three, seven and thirty days after the procedure.
RESULTS: All the patients were discharged 2 hours after the endoscopic procedure was completed and none had any post procedural complications (fever, delayed bleeding, perforation or abdominal pain).
CONCLUSION: These results demonstrate that when this closure is utilized patients can be safely discharged from the hospital 2-3 hours after endoscopic removal of a polyp. The technique is quick, (it was coined "Lucky Loop" in honor of Luky Luke the fast solitary gunslinger cartoon character created by Maurice De Bevere) easy and economic and can be also used in cases of large gastrointestinal perforations or in patients that can't stop double or triple antiplatelet therapy.

P0575 PERFORMANCE CHARACTERISTICS OF COLORECTAL FULL SPECTRUM ENDOSCOPY (FUSE) – PROSPECTIVE, PARALLEL, RANDOMIZED STUDY

H. Neumann[1,*], G.E. Tontini[1,2], M. Vieth[3], C. Günther[1], M. Grauer[1,4], M.F. Neurath[1]
[1]*UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen, Germany,* [2]*IRCCS Policlinico San Donato, San Donato Milanese, Italy,* [3]*Klinikum Bayreuth, Bayreuth,* [4]*Klinikum Neumarkt, Neumarkt, Germany*

INTRODUCTION: Full Spectrum Endoscopy (FUSE) provides a 330° field of view, thereby potentially allowing the endoscopists to see more anatomy in comparison to standard forward viewing endoscopes (FVE). Recent data has already shown that FUSE is feasible to significantly reduce adenoma miss rates.
AIMS & METHODS: The aim of this prospective, parallel, randomized study was to assess the performance characteristics of FUSE in comparison to FVE. Patients were randomly assigned to undergo colonoscopy with FUSE (Group A) or FVE (Group B) after a previous sample size calculation. Performance characteristics including time to cecum, withdrawal time, total examination time, medication, patient and endoscopists' satisfaction, and polyp detection rates were recorded.
RESULTS: 57 patients were included (male 52%; mean age 56 years, Range 21–88 years). Time to cecum (minutes, mean ± SD) was 4.05 ± 0.6 minutes for FUSE and 5.48 ± 0.6 for FVE ($P < 0.05$). Withdrawal times were 12 ± 4.4 minutes and 15 ± 4.5 minutes for FUSE and FVE, respectively. Total examination time was 16.5 ± 4.4 minutes in the FUSE group and 20.1 ± 4.5 minutes in the FVE group. Sedation was less required in the FUSE group as compared to FVE (mean propofol dosage, 170 mg vs. 230 mg). Significantly more patients needed analgesia in the FVE group (meperidine; $p = 0.01$). Patient and endoscopists satisfaction were high throughout the cases and not different between both groups. Per patient polyp detection rates were 37% and 18% for FUSE and FVE, respectively.
CONCLUSION: Advancement times of the scope to the cecum and withdrawal times were faster with the FUSE scope as compared to standard FVE. Satisfaction rates of patients and endoscopists were similar in both groups while patients needed more sedation and analgesia in the FVE group. Although more polyps were found in the FUSE group the study was not powered to compare adenoma detection rates between both groups.

P0576 DEVELOPMENT AND VALIDATION OF A SIMPLE CLASSIFICATION SYSTEM FOR IN VIVO DIAGNOSIS OF COLORECTAL POLYPS USING VIRTUAL CHROMOENDOSCOPY – THE VISIBLE STUDY

H. Neumann[1,*], C. Günther[1], L.C. Fry[2], M. Vieth[3], G.E. Tontini[1,4], M. Grauer[1,5], M.F. Neurath[1], K. Mönkemüller[2]
[1]*UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen, Germany,* [2]*University of Alabama at Birmingham, Birmingham, United States,* [3]*Klinikum Bayreuth, Bayreuth, Germany,* [4]*IRCCS Policlinico San Donato, San Donato Milanese, Italy,* [5]*Klinikum Neumarkt, Neumarkt, Germany*

INTRODUCTION: Although the diagnostic performance of virtual chromoendoscopy (VCE) has already been reported, validated classification systems allowing both experienced and inexperienced endoscopists to apply VCE have not been established.
AIMS & METHODS: To develop and validate a simple classification system for differentiating hyperplasic and adenomatous colorectal lesions by using VCE.
In the first phase, the capacity of experienced endoscopists to predict the histology of colorectal polyps was assessed. In the second phase, a simplified classification was developed allowing histologic prediction. Thirdly, the validity of the classification was evaluated among inexperienced raters, including medical students and GI fellows. Last, a pilot clinical evaluation was performed during real-time colonoscopy. The study was performed in a multicenter, international setting.
RESULTS: A simple classification system for differentiating hyperplasic and adenomatous colorectal lesions by using VCE was developed and validated. Diagnosis was made in 78% to 89% (mean 82.5%) of polyps with high confidence. Sensitivity and specificity ranged from 95% to 98% and 78% to 100%, respectively. During real-time colonoscopy, diagnosis was made with high-confidence in 84% of polyps with sensitivity of 91%, specificity of 85%, and accuracy of 93%. Positive and negative predictive values were 93% and 93%, respectively.

CONCLUSION: We developed and validated for the first time a simple classification system for differentiating hyperplasic and adenomatous colorectal lesions by using VCE during real-time colonoscopy.

P0577 THE OBSERVATION OF SECOND-GENERATION AUTOFLUORESCENCE IMAGING (AFI) HELPS EASILY TO DETECT OF FLAT COLON NEOPLASIA FOR NON-EXPERT ENDOSCOPISTS

S. Saito[1,*], D. Ide[1], H. Inomata[1], T.R. Ohya[1], N. Tamai[1], T. Kato[1], M. Ikegami[2], H. Tajiri[3]

INTRODUCTION: We reported about the features of observation for colon polyps by using the AFI system 1). Namely, hyperplastic lesion is shown as dark green color similar to surrounding mucosa. In contrast, most of the neoplastic lesion is changed to magenta color at the localized tumor area. And also, this strength of change is suggested to correlate with the histological grading. In this study, we examined the benefits of using this system to detect the colon neoplasia for beginner endoscopists.
AIMS & METHODS: Two studies were used to clarify for the usefulness by second-generation AFI observation. One method used four pictures (white light conventional image (WHL), indigo carmine dye sprayed image (CE), NBI and AFI). Another method used short movies, which recorded WHL and AFI within about one minute, respectively. At first study, twenty-four cases (flat type intramucosal lesion 22 cases and depressed submucosal invasive cancer; 2 cases) were retrospectively reviewed. In contrast, thirty cases (sessile serrated (SS) lesion; 12 cases, intramucosal (IM) lesion; 13 cases and submucosal invasive cancer (SM); 5 cases) were reviewed at second study. These pictures and videos were shown to a group of 5 beginner endoscopists (non-experienced for using AFI system) and a group of 4 expert endoscopists (experienced more than 1000 cases). The used scope is CF: FH260AZI with second generation Lucera Elite system (Olympus Medical Systems, Tokyo, Japan).
RESULTS: At first study, the visualization score was defined as follows: the worst visualization was scored as 0 and the best as 10. And to evaluate the visualization of colon neoplasia, we calculated the average visual analog scale (VAS) scores for each groups. The mean AFI visualization score; 8.9 was significantly higher than that of WHL; 6.5, CE; 8.2 and NBI; 7.1 by non-experienced group. And there was difference in average visualization scores between AFI; 7.5 and another modalities (WHL; 4.8, CE; 7.2 and NBI; 5.8) by experienced group. At second study, the strength changing to the magenta color from dark green with excitation light was evaluated by 10-point VAS. In non-experienced group, the score of SS lesion, IM lesion and SM lesion were 2.3, 5.2 and 7.8, respectively. In contrast SS lesion, IM lesion and SM lesion were 2.4, 5.7 and 7.8 in experienced group, respectively. It was shown almost same as VAS scores between non-experienced and experienced as result.
CONCLUSION: AFI provided significantly better visualization to detect and differentiate non-neoplastic lesion and neoplastic lesion for beginner endoscopists. It suggested that it is not difficult to diagnose the indication of endoscopic treatment for neoplastic changes within intramucosal layer using AFI system for non-experienced endoscopist. It was also expected to detect flat elevated lesion more easily by non-experienced endoscopists.

P0578 THE ACCURACY OF REAL-TIME PROBE BASED CONFOCAL LASER ENDOMICROSCOPY FOR DIFFERENTIATION OF COLORECTAL POLYPS DURING COLONOSCOPY

T.D. Belderbos[1,*], M.G. van Oijen[1], L.M. Moons[1], P.D. Siersema[1]
[1]*Gastroenterology and Hepatology, University Medical Center Utrecht, Utrecht, Netherlands*
Contact E-mail Address: *t.d.g.belderbos@umcutrecht.nl*

INTRODUCTION: Reliable real-time differentiation between neoplastic and non-neoplastic colorectal polyps during colonoscopy may guide treatment decisions and reduce the need for post hoc histologic evaluation of resected polyps. In the hands of experts, probe based confocal laser endomicroscopy (pCLE) has been suggested to be a highly accurate technique for this. Previous studies have shown a short learning curve for offline interpretation of pCLE images of colorectal polyps. It is however not known whether colonoscopists starting to use this technique can also accurately differentiate colorectal polyps during routine colonoscopy by using real time pCLE to directly evaluate images.
AIMS & METHODS: The primary aim was to determine the diagnostic accuracy of real-time pCLE for the differentiation of colorectal polyps during the first 50 pCLE cases of two endoscopists routinely performing colonoscopy. The secondary aim was to compare the sensitivity for diagnosing neoplasia small polyps ($\leq$5 mm) in this study with a sensitivity threshold of $\geq$90% that is required for selective polypectomy or 'resect and discard' strategies. We included patients of 45 years or older undergoing colonoscopy for screening, surveillance or diagnostic work-up between August 2012 and April 2014. After a training to obtain and interpret pCLE images two senior endoscopists performed 50 pCLE procedures each. Intravenous fluorescein was used as contrast agent. All polyps were resected endoscopically and histologic diagnosis by an expert pathologist was used as reference. Primary outcome was the diagnostic accuracy, defined as the percentage of polyps for which pCLE correctly differentiated between non-adenomatous, adenomatous and carcinomatous polyps.
RESULTS: The overall diagnostic accuracy of real time pCLE for colorectal polyps was 75% and was not different between the endoscopists (74% vs. 76%, p = 0.81). Accuracy remained stable when comparing the first 25 procedures with the last 25 procedures of both endoscopists (respectively 76% vs. 72%, p = 0.75 and 76% vs. 76%, p = 1.00). According to the size of the polyps, accuracy was non-significantly different (67% for 68 polyps $\leq$5 mm, 86% for 21 polyps $\leq$10 mm and 89% for 18 polyps $>$10 mm; p = 0.08). Sensitivity for detecting neoplasia in polyps $\leq$5 mm was 65% (59% for right sided polyps and 73% for left sided polyps).
CONCLUSION: The diagnostic accuracy of two endoscopists starting to use real time pCLE for colorectal polyps was 75% and remained stable during the first 50 procedures. Sensitivity for detecting neoplasia in small polyps was below the required 90% and suggests that real-time pCLE cannot be used to guide follow-up decisions and that histologic evaluation of removed polyps is still required.

Contact E-mail Address: *ibusiginjp@hotmail.com*

INTRODUCTION: Endocytoscopy (EC) enables observation of nuclei at 450-fold magnification during gastrointestinal endoscopy, thus allowing precise prediction of lesion pathology, however it requires training and experience.[1,2]
AIMS & METHODS: The aim of the present study was to develop and evaluate a computer-aided diagnosis (CAD) system for EC imaging of colorectal lesions. The proposed CAD system comprised image acquisition, nuclear segmentation, feature extraction, and classification into three pathological groups (non-neoplastic, adenoma, and cancer). The classification algorithm was programmed based on six features of nuclei that were significantly relevant to pathological classification by multivariate analysis: area (p = 0.009), standard deviation of area (P $<$ 0.001), circularity (P $<$ 0.001), circularity of the top 20 nuclei (P $<$ 0.001), shortest diameter (P $<$ 0.001), and longest diameter (P $<$ 0.001). To validate this CAD system, we conducted a pilot study using test sets of EC images from 176 small colorectal polyps (132 neoplastic lesions and 44 non-neoplastic lesions, all $\leq$10mm). The performance of the CAD system for prediction of neoplastic change was compared with diagnoses by two expert endoscopists and two trainee endoscopists. The average time for diagnosis and intra-observer agreement (using 20 EC images at a 4-week interval) were also measured and compared among the three groups.
RESULTS: The CAD system automatically output the pathological prediction of all subject images immediately on their input. The CAD system provided a sensitivity of 92.0% and an accuracy of 89.2% which were comparable with those provided by the experts (p = 0.868 and 0.256, respectively) and significantly higher than those provided by the trainees (P $<$ 0.001 and 0.002, respectively). The CAD system achieved a feasible specificity of 79.5%, which was not significantly different from that achieved by the experts and trainees (p = 0.081 and 0.728, respectively). The CAD system also enabled instant diagnosis which took only 0.3 seconds for each lesion with perfect reproducibility (Kappa = 1). (See Table)

	Computer-aided diagnosis (CAD)	Experts	Trainees	P value (CAD vs experts)	P value (CAD vs trainees)
Sensitivitiy, %	92.0	92.7	81.8	0.868	$<$0.001
Specificity, %	79.5	91.0	75.6	0.081	0.728
Accuracy, %	89.2	92.3	80.4	0.256	0.002
Time for diagnosis, seconds	0.3	4.5	16.0	$<$0.001	$<$0.001
Intra-observer agreement	Almost perfect (Kappa = 1)	Substantial (Kappa = 0.79)	Substantial (Kappa = 0.71)	NA	NA

CONCLUSION: This fully automated CAD system provides excellent sensitivity and accuracy with acceptable specificity, ultra-rapidness, and perfect objectivity. Thus, it can be a powerful tool for decision support during screening colonoscopy.(This study was registered as UMIN000012797 and supported by JSPS KAKENHI Grant Number 25860564.)

P0580 TRANS-ANAL SUBMUCOSAL ENDOSCOPIC RESECTION (TASER): A NEW ENDO-SURGICAL APPROACH TO THE RESECTION OF BENIGN GIANT RECTAL LESIONS

Z.P. Tsiamoulos[1,*], J. Warusavitarne[2], T. Elliott[1], B.P. Saunders[1]
[1]*Wolfson Unit for Endoscopy,* [2]*Department of Colorectal Surgery, St Mark's Hospital/Academic Institute, London, United Kingdom*

INTRODUCTION: Trans-anal surgical (TEMS/TAMIS) and advanced endoscopic resection (ESD, P-EMR) procedures have the potential to provide complete and successful eradication of giant rectal polyps. Both approaches however have limitations in terms of practicality and safety. We describe a new endo-surgery technique called Trans-Anal Submucosal Endoscopic Resection (TASER) which combines the advantages of both the endoscopic and transanal surgical approach.
AIMS & METHODS: The GelPoint Path trans-anal access port allows simultaneous passage of an endoscope and two laparoscopic retractors. Working with the endoscopic image the laparoscopic retractors (Johen 33mm forceps) allow dynamic tissue retraction to facilitate endoscopic dissection (Flush knife –BT) or snare placement (Olympus snare master/spiral snare). All procedures were performed under general anesthesia and with patients in the lithotomy position.
RESULTS: Eleven patients (mean age 55 years, 3 male/8 female) underwent TASER for 11 lesions, distributed from the lower rectum to the recto-sigmoid junction and with a median size of 85mm, range 40-180mm. Polyp morphology was (3/11 flat (Paris 2a), 4/11 sessile (Paris 1s) and 4/11 mixed type (Paris 2a+1s). In all cases a circumferential mucosal incision was made and histology confirmed free lateral margins in all cases. 10/11 rectal polyps were adenomatous and one had a small focus of moderate differentiated adenocarcinoma (incomplete local excision).
Complete endoscopic excision in a single session was achieved in 10/11 cases (91%). Median completion time of the procedure was 215min, range 120-480min. Tissue retraction was used in every case and resection was completed by ESD alone (4/11), ESD + EMR (4/11) ESD + EMR + trans-anal surgical excision (3/11). Intra-procedural bleeding occurred in 8 cases, controlled with hemostatic clips and Coagrasper (Olympus); surgical suturing was required in one case (1/8). Prophylactic clips (2/11) and surgical sutures (1/11) were placed to treat deep muscle injury. There were no perforations and no delayed bleeding episodes. Patients were discharged the day following TASER in all cases. Surveillance at 3-6 months revealed no recurrence in 6 cases, whereas in four cases the follow up procedure is still pending. The malignant polyp case was referred to surgery with a good clinical outcome (T3, N0, M0).
CONCLUSION: TASER appears to be a safe and efficient approach providing an optimal platform for resection of large rectal lesions. In our experience it provides the optimal platform for the minimally-invasive management of these high risk lesions.

INTRODUCTION: Ferritin > 1000 has been associated with high grade fibrosis in hemochromatosis and in liver iron overload disorders.
AIMS & METHODS: To establish the nosologic characteristics of ferritin >1000 ng/ml to diagnose high liver iron overload (hepatic iron index > 1.9) (HIO) and for the diagnosis of significant iron overload in liver (> 60 micromol Fe/g) (SIO).
Cohort of consecutive patients studied by MRI for quantification of liver iron concentration (LIC). Variables: age, sex, ferritin and LIC. We calculate the mean and standard deviation for quantitative variables and absolute and relative frequencies for qualitative variables.
The relationship between ferritin and LIC is analyzed using a simple linear regression model.
To establish the nosological characteristics of ferritin we calculated the sensitivity (S), specificity (Sp), positive predictive value (PPV) and negative (NPV) with their 95% CI.
RESULTS: Total number of patients was 538 (449 men), with a mean age of 53.6 (SD 13.4). Mean ferritin value was 804.5 (SD 655.2). 56 patients (10.4%) had HIO and 125 (23.2%) had (SIO). Mean LIC in patients with ferritin > 1000 was 55.9 micromol Fe /g. The PPV for HIO is 27.1% (19.9 to 35.8) and NPV of 94.3% (91.6 to 96.1). With our prevalence of 10.4%, the expected results by chance alone would have been: PPV = 10.7% (5 to 21.5) and NPV = 89.6 (86.6 to 92), close to the values obtained with ferritin > 1000. To diagnose SIO, PPV of ferritin >1000 is 50% (41.1 to 58.9) and NPV of 84.3% (80.5 to 87.5). In this case, the expected results by chance would have been: PPV 24.6% (17.7 to 33.1) and NPV 77.1% (72.9 to 80.9).
CONCLUSION: Ferritin > 1000 has a low value for the diagnosis of HIO or for SIO.

INTRODUCTION: HIO is considered if the Hepatic iron index > 1.9 (estimated by MRI).
AIMS & METHODS: To develop and validate a diagnostic algorithm for high iron overload (HIO) based on laboratory and genetic variables.
We collected a retrospective cohort with all consecutive patients between 2001-2008 studied by Magnetic Resonance Imaging (MRI) to determine liver iron concentration (LIC). This cohort served as the derivation set. We analyzed all variables using univariate statistics with the MRI acting as the gold standard. We studied the best combination of the diagnostics variables to build the algorithm.
We validated the algorithm in a prospective cohort, collecting all patients referred to our hospital for study of iron metabolism alteration since 2009 onwards. We estimate the sensibility, specificity and predictive values with 95% CI.
RESULTS: *Retrospective cohort*: 242 patients (198 men/44 women), mean age 52,4 (SD 13.3). Thirty six of them had HIO. Nearly half of the patients (117/242 = 48.4%) had both Transferrin saturation index (TSI) and Ferritin elevated and 28 (11.5%) were C282Y homozygous. The final algorithm was as follows: We consider a patient as having HIO with the simultaneous occurrence of TSI and Ferritin elevated and C282Y homozygosis. HIO is discarded if TSI or Ferritin are within normal values. The rest should be studied by MRI.
Prospective cohort: 177 patients (148 men/29 women), mean age 56 (SD 13.9). The nosological characteristics of the algorithm in this validation study are:
CONCLUSION: MRI is not necessary in 77% of the patients for HIO diagnosis. MRI is indicated inpatients not C282Y homozygous with raised TSI and Ferritin.
Disclosure of Interest: None declared

P0583 LIVER IRON CONCENTRATION (LIC) IN PATIENTS REFERRED FOR HYPERFERRITINEMIA (HF) TO A SECONDARY HOSPITAL: ANALYSIS OF THE DIFFERENT GROUPS ACCORDING TO HFE MUTATIONS AND TRANSFERRIN SATURATION INDEX (TSI)

A. Castiella[1,*], E. Zapata[1], L. Zubiaurre[1], A. Iribarren[1], M.D. De Juan[2], J.M. ALUSTIZA[3], P. OTAZUA[4], F. MUGICA[5], E. Elosegui[5], A. Arriola[5], E. Utrilla[6], J. I. Emparanza[7]

INTRODUCTION: Olynyk et al (1) analyzed in Australia in 2009 the LIC by MRI of 52 consecutive patients who were referred for HF to a tertiary hospital. They described three different groups according to HFE mutations and TSI (A Group: no predisposing mutations (PM) for Hereditary Hemochromatosis (HH) and TSI > 45 %, B Group: PM for HH: C282Y/C282Y; C282Y/H63D, and TSI > 45 %; C Group: no PM for HH and normal TSI). They concluded that LIC in B Group was significantly higher than in A and C groups. In the Basque Country, predisposing mutations differ, with relevance of the H63D/H63D mutation (2).
AIMS & METHODS: To study the relevance of HFE mutations and TSI in determining LIC of HF patients attending the outpatient clinic at a secondary hospital.
Prospective study of 132 consecutive patients with HF. January to December 2010. In 120 HFE study was available. In 79 LIC was obtained by MR. In 71 patients values of HFE mutations, TSI, and LIC by MR were available. The LIC was measured in µmol / g (normal ≤ 36 µmol /g) by MR (Alústiza et al method (3)).
RESULTS: mean age: 55.68 ± 14.26 (23-83), 55 men and 16 women (77.5 %, 22.5 %). The mean age for men was 53.07 ± 13.61; 64.63 ± 13.14 in women. The mean LIC by MR in men was 35.66 ± 36.85; 38.81 ± 29.75 in women. Patients in A Group: 21, 14 with normal LIC, 7 raised LIC; B Group: 19-H63D/H63D; C282Y/H63D-, 11 normal LIC, 8 raised LIC; C Group: 31 patients, 23 normal LIC, 8 raised LIC. The mean LIC in A Group: 38.80 ± 45.18 (5-210), B group: 48.96 ± 37.51 (15-160), C group: 28.12 ± 18.85 (5-75). We compared the LIC mean values of the 3 groups using ANOVA, with no significant differences.
CONCLUSION: In our study, the LIC in different groups of patients referred for HF to a secondary hospital, with different predisposition to HH (PM, raised TSI), are similar. The different HFE mutations and TSI values do not appear to be relevant in the LIC of these patients.

P0584 GLUCAGON-LIKE PEPTIDE-1 (GLP-1) ANALOGUE, LIRAGLUTIDE, INHIBITS OXIDATIVE STRESS AND INFLAMMATORY RESPONSE IN THE LIVER OF RATS WITH DIET INDUCED NON-ALCOHOLIC FATTY LIVER DISEASE

H.T. Gao[1], **L.S. Xu**[1,*], Z.G. Zeng[1], L.C. Guan[1], W.P. Deng[1]
[1]*Guangdong General Hospital, Guangzhou, China*

INTRODUCTION: Liraglutide, a glucagon-like peptide-1 (GLP-1) analogue, has been demonstrated to reduce hepatic steatosis. However, the mechanisms of the lipid-lowering effect of liraglutide in the liver remains unclear. The aim of the present study was to investigate the beneficial effect of liraglutide on diet induced non-alcoholic fatty liver disease (NAFLD) and the underlying mechanisms in rats.
AIMS & METHODS: NAFLD was induced by in Sprague-Dawley rats by feeding a high fat and high cholesterol (HFHC) diet. Liraglutide (0.6 mg/kg body weight/day) was injected intraperatoneally to the rats subjected to HFHC diet 4 weeks before sacrificing. Body and liver weight, fasting blood glucose (FBG), fasting insulin, serum aminotransferase (ALT) and lipid accumulation in the liver were determined. Markers of oxidative stress, such as malondialdehyde (MDA), free fatty acid (FFAs), superoxide dismutase (SOD), and pro-inflammatory cytokine tumor necrosis factor-a (TNF-a) were detected with RIA or ELISA kits. Serum and hepatic adiponectin were measured. The expression of JNK-1 and phosphorylated JNK1 were examined with Western blot.
RESULTS: Liraglutide improved insulin resistance, decreased hepatic steatosis and reversed liver dysfunction. The hepatic levels of MDA, FFAs, TNF-a were significantly decreased. While, the SOD and adiponectin levels in the liver were significantly elevated by liraglutide treatment. Administration of liraglutide also inhibited the expression of JNK-1 and phosphorylated JNK-1.
CONCLUSION: Liraglutide exerted anti-oxidative and anti-inflammatory effects in the liver and consequently reverse hepatic steatosis and insulin resistance. Such effects might be mediated by the elevation of adiponectin levels and the inactivation of JNK1.

INTRODUCTION: Ceramides are members of the sphingolipid family and are an integral part of the lipid bilayer of cell membranes. Ceramides exert biological effects through cellular proliferation, differentiation and cell death. The role of changes in endogenous ceramides to the pathogenesis of NAFLD to NASH is sparse. In this study the effect of exogenous liposomes containing short chain C6-Ceramide (Lip-C6) was evaluated in a NASH model and in vitro in primary human Hepatic Stellate Cells (hHSC) as possible Lip-C6 target.
AIMS & METHODS: NASH was induced by feeding mice for 9 weeks a methionine-and choline-deficient (MCD) diet, or control diet (CD), followed by a single tail-vein injection of Lip-C6. The effect of Lip-C6-treatment was investigated by measuring ALT/AST, histology, Q-PCR and protein analysis. Possible changes in hepatic ceramide magnitude/species specificity and sphingosines were measured by employing untargeted LC-MS/MS lipidomics. The effect of Lip-C6 on primary hHSC proliferation, cytotoxicity and signaling pathways was investigated.
RESULTS: MCD-Lip-C6 treatment did not exacerbate MCD-induced NASH when analyzing ALT/AST, steatosis, lobular inflammation, ballooning, apoptosis and fibrosis. Protein analysis showed that Lip-C6-treatment affects the endogenous antioxidant system KEAP1-Nrf2-NQO1 in MCD-fed mice. MCD-fed mice showed a reduction in p-JNK, cleaved caspase-3/PARP, the mRNA stabilizing protein ELAV1/HuR and its downstream target phosphorylated p62 when compared to CD-fed mice which were not affected by Lip-C6-treatment. Exogenous liposomal short chain ceramide C6 treatment does not affect inflammation markers TNFalpha and NFKB signalling pathway. A strong phosphorylation of AMPK was induced in Lip-C6-treated MCD-fed indicating a stimulation of energy producing catabolic pathways. Of particular note, Lip-C6-treatment reverses the significant decreases in phosphatidylcholines (PC) and phosphatidylethanolamines (PE) species and rearranges the significant increases in specific sphingolipid species in MCD-fed mice. Moreover, Lip-C6-Rhodamine was taken up by primary hHSC and Lip-C6-treatment inhibits proliferation and cytotoxicity in a concentration-dependent manner.
CONCLUSION: These results demonstrate that a single injection of short chain C6-ceramide liposomes does not exacerbate inflammation, apoptosis, proliferation and oxidative stress in MCD-induced NASH, possibly by restoring changes in membrane lipid content induced by NASH.

INTRODUCTION: Genetic variation in apolipoprotein C3 (*APOC3*) was reported to be associated with nonalcoholic fatty liver disease (NAFLD), but its role in Chinese population is not well understood.
AIMS & METHODS: To investigate the association between the apolipoprotein C3 (*APOC3*, -455T > C) polymorphism and nonalcoholic fatty liver disease (NAFLD), we recruited 300 NAFLD patients and 300 healthy controls to a cohort representing Han Chinese at The First Affiliated Hospital, Sun Yat-sen University, from January to December 2012. Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and DNA sequencing were used to genotype the *APOC3* (-455T > C) variants.
RESULTS: After adjusting for age, gender, and BMI, TC and CC genotypes were found to increase the susceptibility to NAFLD compared to that of the TT genotype, with odds ratios (ORs) of 1.94 (95% CI, 1.26-2.98) and 3.01 (95% CI, 1.76-5.16), respectively. Further stratification analysis indicated that the CC genotype was more susceptible to insulin resistance (IR) than the TT genotype, with OR of 2.59 (95% CI, 1.26-5.30). The CC genotype also was associated with a much higher risk of hypertension, hypertriglyceridemia, and low levels of high-density lipoprotein cholesterol ($P < 0.05$). No association was found between the *APOC3* (-455T > C) polymorphism and body-mass index, level of fasting plasma glucose, serum uric acid, total cholesterol, and low-density lipoprotein cholesterol ($P > 0.05$).
CONCLUSION: *APOC3* (-455T > C) genetic variation is involved in the susceptibility to develop NAFLD, IR, and some metabolic syndrome disorders in the Han Chinese population.

Contact E-mail Address: *monasleman@hotmail.com*

INTRODUCTION: Non-alcoholic fatty liver disease (NAFLD) is considered to be among the most common liver diseases world-wide. NAFLD encompasses a broad spectrum of pathological conditions ranging from simple steatosis (SS) to steatohepatitis (NASH), fibrosis and finally even cirrhosis. Adiponectin (A) has been associated with inhibition of fibrogenesis and liver protection while leptin (L) contributes to fibrogenesis in various chronic liver diseases, notably in NASH.
AIMS & METHODS: To determine the validity of serum adipokines including leptin, adiponectin, and A/L ratio to act as a potential markers for NAFLD and to discriminate NASH from SS.
Patients and methods: Eighty four patients who have bright liver on abdominal ultrasonography and 28 healthy individuals served as control group. Serum Leptin and Adiponectin were estimated by ELISA technique. Liver biopsy was done for 46 patients and according to histopathological examination they were divided into 21 patients with SS and 25 patients with NASH.
RESULTS: The serum concentration of adiponectin was significantly lower in NASH than SS group ($P < 0.001$). There was no significant difference between serum concentration of leptin in both groups ($p = 0.4$). A/L ratio in NASH group was significantly lower than SS group ($P < 0.001$). Adiponectin was negatively correlated with BMI, total cholesterol and LDL-C in both groups. A/L ratio in NASH group was significantly positively correlated with adiponectin ($P < 0.001$) while it was significantly negatively correlated with leptin ($P < 0.001$). In SS group A/L ratio was significantly negatively correlated with leptin ($r = -0.863$, $P < 0.001$).
CONCLUSION: In patients with NAFLD, the serum adiponectin and A/L ratio can discriminate simple steatosis from NASH and predict the severity of liver injury.

INTRODUCTION: Myosin Light Chain Kinase (MLCK) plays a central role in the mechanisms of barrier dysfunction, and some studies showed nonalcoholic fatty liver disease (NAFLD) had intestinal barrier function change. The present study aimed to identify whether MLCK was involved in the pathogenesis of nonalcoholic fatty liver disease (NAFLD).
AIMS & METHODS: The NAFLD mice model was established by giving high-fat diet (HFD) and NASH was induced by lipopolysaccharide (LPS) administration. Mice received MLCK inhibitor ML-7 by intraperitoneal injection. The level

of ALT, AST was assessed. The degree of liver steatosis was observed by HE stain. Intestinal mucosal tight junction was observed by electron microscope, and the occludin protein was stained by immunofluorescence.
RESULTS: MLCK expression increased in NAFLD and NASH groups vs control group. ALT and AST elevated in the NAFLD and NASH group, which could be reduced by MLCK inhibitor ML-7 (Table.1, *P<0.05 vs NAFLD group, ** P<0.05 vs NASH group). The liver pathology showed no significant change after ML-7 administration. The intestinal tight junctions occludin protein were seemed to be ameliorated by ML-7,but there were no significant difference.

U/L	Control	NAFLD	NAFLD+ML-7	NASH	NASH+ML-7
ALT	20.33±0.843	20.00±2.014	13.80±0.663	31.70±3.208*	18.80±1.597**
AST	46.67±2.704	44.00±2.075	37.60±2.349	117.6±12.23*	73.10±5.382**

CONCLUSION: MLCK inhibitor ML-7 could protect liver function via improving the intestinal barrier of NAFLD mice.

INTRODUCTION: Myosin Light Chain Kinase (MLCK) plays a central role in the mechanisms of barrier dysfunction, and a lot of studies showed the intestinal barrier permeability increased in nonalcoholic fatty liver disease (NAFLD).
AIMS & METHODS: The research aimed to identify whether MLCK was a regulator in the intestinal barrier permeability change of nonalcoholic fatty liver disease (NAFLD). The NAFLD mice model was established by giving high-fat diet (HFD) and NASH was induced by lipopolysaccharide (LPS) administration. Mice received MLCK inhibitor ML-7 by intraperitoneal injection. The intestinal mucosal tight junction was observed by electron microscope, and the LPS concentration of portal vein was detectedd by ELISA.
RESULTS:
MLCK expression increased significantli in fatty liver (NAFLD) and NASH, which could be blocked by ML-7. The intestinal epithelial tight junction of NASH were broader compared with control group, which could be improved by MLCK inhibitor ML-7 (Table 1). The LPS in portal vein of NASH mice was higher, suggesting the intestinal barrier permeability dysfunction. After MLCK was blocked by ML-7, the LPS in portal vein decreased significantly.

nm	Control	NAFLD	NAFLD+ML-7	NASH	NASH+ML-7
TJ	14.90±0.329	19.80±1.197*	19.20±0.997*	26.6±1.200*	14.90±0.666#

Table 1: The tight junction of intestinal epithelial of different groups.
CONCLUSION: The intestinal barrier function was restored by specifically inhibiting MLCK, suggesting that MLCK activity was responsible for the change of barrier function in NAFLD.

INTRODUCTION: Liver disease is a leading cause of mortality among HIV-infected patients and has been related in some cases to combined Antiretroviral Therapy (cART). Little is known about the acute effects of nucleoside/nucleotide reverse transcriptase inhibitors (NRTI) on hepatic cells, although the purine analogue abacavir (ABC) has been reported to induce an acute mitotoxic effect *in vitro*. Since acetaminophen (APAP), a well-known hepatotoxic drug, is commonly prescribed to HIV-infected patients and also interferes with mitochondria, we hypothesised that its combination with antiretrovirals can specifically exacerbate the hepatotoxic effects of the latter drugs.
AIMS & METHODS: To analyse the acute mitochondrial effects of clinically relevant concentrations of the purine analogues ABC and didanosine (ddI), to assess their impact on mitochondrial function and the viability of hepatic cells, and to explore potential synergisms with APAP and other hepatotoxic drugs. Several parameters of mitochondrial function (oxygen consumption, mitochondrial membrane potential -$\Delta\psi_m$-, reactive oxygen species –ROS- production, intracellular ATP levels, GSH levels) and cellular viability were assessed in non-HIV-infected Hep3B and hepatocyte-like HepaRG cells treated (1-48h) with the purine analogues ABC and ddI. Further experiments were performed in the presence of sub-damaging concentrations of different hepatotoxic stimuli (APAP, the antiretroviral drugs ritonavir and nevirapine, and ethanol). Data were reported as mean+/-SEM, and their statistical significance versus vehicle was analyzed by one-way ANOVA. Correlations were analysed using Spearman's correlation coefficient.
RESULTS: Clinical concentrations of purine analogues produced an immediate and significant decrease in mitochondrial function, evident in a concentration-dependent inhibition of O_2 consumption, increased ROS production, and a reduction of $\Delta\psi_m$ and intracellular ATP levels. This mitochondrial dysfunction did not compromise cell survival, as the aforementioned parameters returned to previous values after 24h treatment. However, co-administration of these drugs with APAP concentrations below those considered toxic in hepatic cellular models exacerbated the deleterious effects of both treatments on mitochondrial function and cellular viability, thus decreasing intracellular GSH concentrations. Such effect was not observed with the other hepatotoxic stimuli evaluated. Interestingly, a significant positive correlation was detected between GSH levels and cell viability.
CONCLUSION: The combination of ABC or ddI with low concentrations of APAP significantly effects GSH concentrations in a way that increases the risk of APAP-mediated liver injury. Our findings are of considerable relevance given that APAP is currently prescribed to patients taking NRTI and that HIV infection itself has been reported to undermine intracellular GSH levels.

INTRODUCTION: Efavirenz (EFV) is the most widely used drug in the treatment of HIV-infection, but has recently been associated with oxidative stress, mitochondrial dysfunction and endoplasmic reticulum stress in hepatocytes. As mitochondrial damage and ER-stress are frequently related to inflammatory disease, we have evaluated the effects of EFV on the cytokine/chemokine expression pattern of hepatic cells. In addition, we have explored the possible involvement of the redox-sensitive transcription factor nuclear factor-kappaB (NF-kB) and NLRP3 inflammasome, both of which trigger signalling pathways implicated in hepatic inflammation and liver injury.
AIMS & METHODS: Non-HIV-infected Hep3B cells were treated with clinically-employed concentrations of EFV (10 and 25μM). Inflammation-related gene expression was studied with Real time PCR. Activation of NF-kB was confirmed by Western blot. An electrophoretic mobility shift assay (EMSA) was carried out to determine the binding of NF-kB to promoters of some of the genes whose expression was found to be up-regulated. Chemokine secretion was evaluated in culture supernatant samples using an immunoassay kit. Data ($n \geq 3$) were analysed with one-way ANOVA followed by a Newman-Keuls test. *$p<0.05$, **$p<0.01$, ***$p<0.001$ (vs control).
RESULTS: EFV induced mRNA expression of the inflammatory mediators TNFα, IL-6, PAI-1, TXNIP and NLP3 in a significant and concentration-dependent manner. Furthermore, EFV reduced IkBa protein levels, thus increasing NF-kB translocation to the nucleus. The EMSA assay demonstrated that trans-activation of PAI-1 was mediated by interaction of NF-kB with a consensus sequence located within the PAI-1 promoter. Nevertheless, EFV also significantly reduced the production and secretion of IL-8 and IP-10, chemokines involved in the progression of liver injury.
CONCLUSION: Due to its inhibitory effects on mitochondrial function, EFV promotes a pro-inflammatory response through NF-kB- and NLRP3-dependent pathways. Interestingly, EFV also reduced the secretion of IL-8 and IP-10, thus playing a dual role in regulating the inflammatory response. In the context of lifelong use of EFV, these effects could accumulate and exacerbate the liver toxicity induced by other stimuli such as other antiretroviral drugs, co-infections (hepatitis B and/or C) or co-morbidities associated with HIV infection.

[2]*Preobrazhenskaya Clinic, Ekaterinburg, Russian Federation*
Contact E-mail Address: *art_popov@mail.ru*

INTRODUCTION: Rheumatoid arthritis (RA) requires early intervention with disease modifying drugs (DMARDs) in order to prevent disease progression and disability [1]. Liver safety issues may delay or limit DMARDs administration [2].
AIMS & METHODS: Aim: to assess liver function tests and liver elasticity during first year of RA DMARDs treatment in everyday clinical practice.
Methods: 20 consecutive rheumatologists' out-patients (16 females) aged from 26 to 56 (mean 47.7) were enrolled in a prospective cohort study. All had newly diagnosed established seropositive RA according to ACR/EULAR 2010 criteria. Viral hepatitides being preliminarily excluded, anthropometry, serum ALT, AST, GGTP, bilirubine levels, were registered as safety measures by 2, 4, 12, 24, 36, 48 week. Liver ultrasound elastography (FibroScan, Echosens, France) was performed twice: at enrollment and end of study visit. RA disease activity was assessed by DAS28 index by 12, 24, 26 and 48 week. All patients were administered oral methotrexate 10-25 mg weekly or leflunomide 20 mg daily as DMARDs. Ibuprophen up to 1200 mg per 24 hours was allowed as on demand rescue treatment. Rescue medication consumption was registered by tablets count. All patients received advices on smoking cessation, diet optimization, physical exercises and daily activies adjusted to body mass index and comorbidities.
RESULTS: All patients had comorbidities by DMARDs initiation. The most frequent were arterial hypertension (11 pts.), dyslipidemia (20 pts.), obesity (5 pts.), high fasting glucose (7 pts.), type 2 diabetes mellitus (5 pts.). In 13 subjects metabolic syndrome (MS) was diagnosed. Non-alcocholic steatohepatitis (NASH) was diagnosed in 7 patients, while normal liver elasticity was found in only 1 subject.
DMARDs administration during 1 year resulted in DAS28 20% reduction in all subjects, 50% DAS28 reduction was registered in 16 subjects, and 70% response was found in 7 subjects. Liver elasticity has increased in 1 person with Type 2 diabetes mellitus. There had been 7 liver test worsening episodes during 1 year study. All liver test increases were seen in obese subjects with glucose metabolism disorders. No difference between methotrexate and leflunomide groups was found.
CONCLUSION: NASH had been frequent in RA patients before DMARDs were started. All liver test abnormalities during DMARDs administration were likely to be NASH related. The data support the hypothesis that conventional RA treatment is safe and does not cause liver lesions.

P0593 OSTEOPOROSIS AND BONE FRACTURES IN ALCOHOLIC LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

C.S. Bang[1], **D.J. Kim**[1], G.H. Baik[1], S.H. Park[1], **H.S. Kim**[1], **E.J. Kim**[1,*], K.T. Suk[1]

INTRODUCTION: Excessive alcohol consumption is an well-established risk factor for osteoporosis and bone fractures. However, moderate amount of alcohol ingestion is known to be associated with higher bone mineral density (BMD). Osteodystrophy is a frequently overlooked complication in patients with chronic liver disease, which could result in serious outcome. However, the exact prevalence or mechanism of osteodystrophy in patients with alcoholic liver diseases (ALD) have not been described.
AIMS & METHODS: The aim of this study was to evaluate the current evidence on osteoporosis and bone fractures in ALD. Case-control or cohort studies were identified from databases (Pubmed, EM-BASE, and the Cochrane Library). The searching keywords were 'alcoholic liver diseases', 'osteoporosis', or 'bone fractures' using Boolean operators. The prevalence of any fractures or osteoporosis, and BMD score were extracted and analyzed using risk ratios (RRs) and standardized mean difference (SMD). A random effect model was applied based on Higgins I^2 tests. Publication bias was evaluated using a funnel plot, Egger's test, trim and fill, and the rank correlation test.
RESULTS: In total, 16 studies performed between 1986 and 2011 were identified and analyzed. Overall, ALD showed an RR of 1.944 (95% CI: 1.354-2.791, $P < 0.001$) for the development of bone fractures. However, ALD showed an RR of 0.849 (95% CI: 0.523-1.38, $P = 0.509$) for the development of osteoporosis. BMD was not statistically different between ALD and control group, although lower trend in patients with ALD (SMD in femur BMD: -0.192, 95% CI: -0.48-0.096, $P = 0.191$) (SMD in spine BMD: -0.429, 95% CI: -0.925-0.067, $P = 0.09$). Subgroup analysis showed consistent results. Publication bias was only detected in the analysis of bone fractures.
CONCLUSION: Current publications indicate significant association between bone fractures and ALD, however insignificant association between osteoporosis and ALD. Due to the qualitative and quantitative heterogeneity among studies, further researches using homogenous population with common validated measurement of BMD and risk factors are needed to elucidate the mechanism of bone fractures in ALD.

P0594 IS SQSTM1/P62 A DEFENCE AGAINST EFV-INDUCED HEPATOTOXICITY?

F. Alegre[1,2,*], A. Blas-García[1,2], M. Polo[1,2], H.A. Funes[2], N. Apostolova[3,4], J. V. Esplugues[1,2]

INTRODUCTION: Sequestome 1/p62 is a multifunctional protein known to be involved in autophagy, during which it acts as a substrate carrier and becomes degraded. It has also been reported that p62 plays important roles in other cellular events, including oxidative stress responses, proteostasis, inflammation and cell survival, while, interestingly, it is implicated in several liver diseases, such as non-alcoholic steatohepatitis. The non-nucleoside reverse transcriptase inhibitor Efavirenz (EFV) is widely employed in combined antiretroviral therapy to treat HIV1 infection, and, though generally considered safe, has been associated with hepatotoxic events. Although the underlying mechanisms of the deleterious hepatic effects of EFV are still unclear, evidence points to altered lipid metabolism, mitochondrial dysfunction/mitophagy and endoplasmic reticulum stress in human hepatocytes.
AIMS & METHODS: To analyse the implication of p62 in EFV-induced toxicity in hepatocytes. The human hepatoma line Hep3B and cells lacking functional mitochondria (Hep3B rho-zero obtained through pharmacological interruption of mtDNA replication) were exposed to clinically relevant concentrations (10 and 25μM) of EFV for 4, 8, 24 and 48h. Key experiments were carried out with pharmacological inducers of oxidative stress (rotenone) or endoplasmic reticulum stress (thapsigargin). Quantitative PCR was performed to analyse p62 gene expression. Western Blot was employed to measure LC3 II (a marker of autophagy induction) and p62 protein levels and translocation to the nucleus of the transcription factors NF-kB and Nrf2, which have been reported to regulate p62 expression and to be involved in ER/oxidative stress and autophagy.
RESULTS: EFV clearly enhanced the protein expression of LC3 II (Microtubule-associated protein 1A/1B-light chain 3), but no reduction of p62 levels was observed. Conversely, both mRNA and protein expression of p62 were increased in EFV-treated cells in a concentration- and time-dependent manner. Western blot studies demonstrated that EFV promoted translocation of NF-κB, but not of Nrf2, to the nucleus. Moreover, the increase in p62 protein level triggered by EFV in wild type hepatocytes was less pronounced in rho-zero cells and completely absent in rotenone.
CONCLUSION: Despite inducing autophagy, clinical concentrations of EFV increase p62 expression, an effect that maybe related to NF-kB translocation to the nucleus. The results obtained in rho-0 cells suggest that overexpression of p62 is a defence mechanism against the mitochondrial and ER dysfunction triggered by EFV.

P0595 THE INCIDENCE RATE OF ALCOHOLIC FATTY LIVER RELATED TO ALCOHOL CONSUMPTION: A 4-YEAR RETROSPECTIVE COHORT STUDY

M.Y. Lee[1,*], Y.K. Cho[2], K.B. Bang[2], **D.S. Lee**[2], J.H. Yu[2], **H.A. Lee**[2], E.H. Park[2], C. I. Sohn[2]

INTRODUCTION: Alcohol consumption is one of the most well-known common causes of fatty liver. There is a lack of studies on incidence rate of alcoholic fatty liver related to alcohol consumption. We conducted a retrospective cohort study design to examine the relationship between alcohol consumption and alcoholic fatty liver among healthy Koreans.
AIMS & METHODS: A healthy cohort of 29,281 individuals, who had participated in a medical health check-up program in 2008, was followed up until 2012. Alcoholic fatty liver was diagnosed and defined based on both ultrasonographic finding and serum AST/ALT ratio ≥ 2. Alcohol consumption was divided into four groups (non-drinker, $<$20g/d in Female & $<$40g/d in Male, 20-40g/d in F & 40-60g/d in M, $>$40g/d in F & $>$60g/d in M). Cox proportional hazard model was used to determine if alcoholic fatty liver was associated with baseline alcohol consumption level.
RESULTS: During 100,233 person-years of follow-up, 4,889 cases of alcoholic fatty liver was diagnosed between 2009 and 2012. After adjusted for sex, age, interaction effect between sex and alcohol consumption level, the Hazard ratios (HRs) for incidence rates of alcoholic fatty liver increased according to the baseline alcohol consumption levels (HR: 0.926, 95% CI 0.827-1.038, HR: 3.257, 95%CI 2.323-4.565, HR: 3.728, 95%CI 2.238-6.213), compared to the non-drinker.
CONCLUSION: Alcoholic consumption was associated with an increased rate of alcoholic fatty liver. In female, incidence of alcoholic fatty liver was higher than the male. In addition, obesity was independent risk factors for incidence of alcoholic fatty liver.

INTRODUCTION: Many people who die from Alcohol Related Liver Disease (ARLD) have a history of recurrent hospital admissions. These episodes may represent missed opportunities for intervention. Universal screening of medical patients has been advised but little is known of the feasibility of this or its efficiency at detecting high risk cases. In 2011, we introduced a 7-day Alcohol Specialist Nursing Service (ASNS) coupled with universal screening of medical patients using a novel electronic data capture system. We now present our data on the feasibility of unselected screening and the resulting alcohol profiles of over 28,000 medical admissions in a major acute hospital serving a catchment population of 650,000.
AIMS & METHODS: From July 2011 to December 2012, all admissions via the Acute Medical Unit (AMU) were screened using the VitalPAC clinical observation system with a VitalPAC Alcohol Assesment Score (VPAAS) based on the Paddington Alcohol Test. At-risk patients (VPAAS of 6 or more) were referred to the ASNS and an Alcohol Use Disorders Identification Test (AUDIT) performed. Data analysis was performed on patient demographics, unit consumption, diagnosis, mortality and previous Emergency Department (ED) attendances and admissions.
RESULTS: There were 29,361 admissions of whom 28,098 (96%) completed VPAAS alcohol screening. Mean AMU population age was 67.4 years, 52.3% female. Of 1,123 high risk cases, 770 were seen by the ASNS and 636 defined as dependent (AUDIT >20). Compared to the general AMU cohort, the at-risk group had more ED attendances (7.8 vs 2.9) and hospital admissions (4.8 vs 3.1) in the previous 3 years and a lower age of death (58.3 vs 81.5). Dependent women had fewer recurrent attendances and admissions than men but had a higher mortality rate and lower age of death (52.2 vs 62.4). The maximum AUDIT score of 40 was recorded in 41% of cases seen by the ASNS and this subgroup had a mean age of death of 52.7 with 6.2 admissions and 10.8 ED attendances previously. The most frequent primary diagnoses in those with a VPAAS of 6+ were liver disease, mental health disorders and GI bleeding.
CONCLUSION: Our analysis of over 28,000 admissions demonstrates that screening of all medical patients for alcohol misuse is achievable. We successfully identified a cohort of high risk patients with recurrent admissions and ED attendances, high unit consumption and an elevated risk of liver disease and early death. This cohort can be targeted with interventions to reduce the burden of alcohol related harm.

P0597 CHEMOPROPHYLAXIS IN PORTUGUESE MILITARY PERSONNEL. SHALL MEFLOQUINE BE CONSIDERED A SAFE DRUG FOR THE LIVER?

T. Meira[1,2,*], D. Fernandes[1], L. Lopes[2]
[1]*Operational Health, Portuguese Navy Medical Center,* [2]*Healthcare Department, Portuguese Frigate D. Francisco de Almeida, Lisbon, Portugal*
Contact E-mail Address: *tania_meira@hotmail.com*

INTRODUCTION: Mefloquine is a drug administered in the chemoprophylaxis of malaria (*Plasmodium falcipurum*). The arising migration to malaria endemic areas has contributed to the increase of mefloquine prescription. This drug has a low potential hepatotoxicity induction, with only two reported cases of acute hepatitis.
AIMS & METHODS: Observational and analytical study. The military personnel who took part in NATO Operation Ocean Shield, on board Portuguese Navy Frigate D. Francisco de Almeida in 2011, having port visits of malaria endemic regions, such as Djibouti, were suggested to perform chemoprophylaxis (mefloquine 250mg / week), starting a week before entering Djibouti territorial waters and finishing 12 weeks after departure. A survey was conducted on the 11th week of prophylaxis, in order to assess the degree of adherence and adverse effects. Serum analyses before and after the mission were cumulatively conducted at the home port.
RESULTS: 85 military personnel participated in this study, showing no disease or chronic medication, reduced alcohol consumption, no remarkable pre-deployment blood analysis issues and that had completed the full course of chemoprophylaxis. 75% of the side effects were the gastroenterological related (29% upper abdominal pain, 24% diarrhea, 22% heartburn). Two weeks after the end of the deployment, analytical blood analysis of the military personnel revealed liver enzymes changes in 14% of the cases (mean values: AST 67 IU/ L, ALT 82 IU/L, gamma GT 98 IU/L, alkaline phosphatase174 UI/L). There were no changes in bilirubin values. Six weeks after chemoprophylaxis, an analytical reassessment was performed revealing that changes only persisted in two individuals, in who the presence of hepatic steatosis was found, on completion of further ecographic investigation.
CONCLUSION: Whereas a significant proportion of individuals had an increase in liver enzymes levels, the theoretical potential for liver injury is not to be discharged when planning prophylaxis, particularly when in synergy with other factors such as medication, alcohol consumption, and liver disease.

P0598 IS ALCOHOLIC FATTY LIVER DISEASE ASSOCIATED WITH THE METABOLIC SYNDROME?

Y.K. Cho[1,*], K.B. Bang[1], D.S. Lee [1], D. I. Park[1], W.K. Jeon[1], B. I. Kim[1], C. I. Sohn[1], J.H. Park[1]
[1]*Internal Medicine, Sungkyunkwan University Kangbuk Samsung Hospital, Seoul, Korea, Republic Of*
Contact E-mail Address: *choyk2004.cho@samsung.com*

INTRODUCTION: Accumulating evidence supports an association between nonalcoholic fatty liver disease (NAFLD) and metabolic syndrome (MetS). However, there still are not enough studies to date showing association between alcoholic fatty liver disease (AFLD) and metabolic abnormalities.
AIMS & METHODS: We conducted this study to investigate whether AFLD is associated with the MetS and its components. A total of 52303 subjects (63.1% men, and 36.9% women) were included in this cross-sectional study. The presence of fatty liver was assessed using standard ultrasound criteria. The term ''significant alcohol consumption'' was defined as weekly alcohol consumption exceeding 210 g in men and 140 g in women for the previous 2 years. The presence of metabolic abnormalities were compared according to the fatty liver status and its etiology. Logistic regression model was performed to assess the odds ratios (ORs)
RESULTS: The prevalence of NAFLD and AFLD was 29.1% and 4.6%, respectively. The MetS was more prevalent in AFLD (31%) and NAFLD (23.2%) than in control group (3.6%, $p<0.001$). All metabolic components of AFLD group, including waist circumference, blood pressure, serum triglyceride, high density lipoprotein, and fasting blood glucose were statistically worse or more severe than those of NAFLD group ($P<0.001$). After adjusting for other multiple covariates, the ORs (95% confidence interval [CI]) for MetS was higher in the AFLD (3.86; 3.44-4.34) than NAFLD group (2.89; 2.68-3.12).
CONCLUSION: MetS and its components are associated with both NAFLD and AFLD. However, AFLD has a higher risk of MetS than NAFLD. Further prospective studies are needed to investigate the effects of AFLD on the development of MetS.

P0599 THE BETA-BLOCKERS HAVE A BENEFICIAL OR A HARMFUL EFFECT IN PATIENTS WITH CIRRHOSIS AND PORTAL HYPERTENSION?

C. Sfarti[1,*], A. Trifan[1], A.-M. Singeap[1], C. Cojocariu[1], O. Chiriac[1], C. Stanciu[1]
[1]*Institute of Gastroenterology and Hepatology, UNIVERSITY OF MEDICINE AND PHARMACY IASI, Iasi, Romania*

INTRODUCTION: The possible harmful effect of non-selective beta-blockers for the treatment of portal hypertensive-related complications (esophageal varices and advanced ascites) in patients with cirrhosis has been suggested by few recent studies.
AIMS & METHODS: Thus, the aim of the study was to determine the risk of mortality in patients with cirrhosis and portal hypertension taking non-selective beta-blocker therapy for the prevention of variceal hemorrhage.
We performed a retrospective analysis of 3215 patients admitted with cirrhosis and portal hypertension to Institute of Gastroenterology and Hepatology Iasi from 2009-2013. There were considered two groups: patients with varices only (1436 cases) and those with both varices and ascites (1779 cases) (Table).
RESULTS: The primary outcome measure for this study was the in-hospital mortality by any cause. Overall, the mortality was 102/1851 (5.51%) for the patients in treatment with beta-blockers and significantly higher for patients not taking beta-blockers 189/1364 (13.85%) ($p < 0.01$).
When we assessed the correlation between the beta-blockers use and mortality in each sub cohort we obtained similar results (Table); In the sub cohort with varices only, the mortality was 4.62% (40/864) for the patients taking beta-blockers and 11.19% (64/572) in the group without treatment ($p<0.05$). In the sub cohort with varices and ascites the mortality was 6.28% (62/987) for the patients taking beta-blockers and 15.78 (125/792) in the group without treatment ($p<0.01$)
We evaluated several parameters for correlation with the in-hospital mortality. Multivariable regression analysis revealed that Child-Pugh score was associated with increased mortality, while the use of beta-blockers was associated with reduced mortality. The other parameters which were evaluated (hemoglobin, platelets, bilirubin, INR, creatinine) didn't influenced significantly the mortality.

	Beta-blockers therapy		
	Yes	No	P-value
Varices only	N = 864	N = 572	
Mortality	4.62%	11.19%	<0.05
Varices and ascites	N = 987	N = 792	
Mortality	6.28%	15.78%	<0.01
All patients	1851	1364	
Overall mortality	5.51%	13.85%	<0.01

CONCLUSION: In a very large cohort of cirrhotic patients with portal hypertension, the mortality was significantly lower in patients treated with non-selective beta-blockers than in those not taking beta-blockers. These data confirm that the use of non-selective beta-blockers provides a significant survival benefit in patients with cirrhosis and portal hypertension. Thus, we recommend the use of non-selective beta-blockers in patients with portal hypertension and its complications.

Contact E-mail Address: *ellen.berni@pharmatelligence.co.uk*

INTRODUCTION: Estimation of health-related utility is a vital component of the evaluation of the relative cost-effectiveness of healthcare interventions. The correlation between different measures of quality of life and health-related utility in hepatic encephalopathy (HE) has not been explored.
AIMS & METHODS: The aim of this study was to characterize for the first time the relationship between scores for the Chronic Liver Disease Questionnaire (CLDQ) and health-related utility as measured by the EQ-5D index in patients with HE. Data were available from a phase three trial of rifaximin-α in patients with recurrent HE. CLDQ and SF-36 scores were recorded at monthly visits. EQ-5D scores were derived from the SF-36 using a recognized mapping technique. Generalized, linear, mixed modelling methods were used to examine for any association in order to allow for repeated measures.
RESULTS: 202 of the 299 trial patients, with 920 corresponding observations, were included in this analysis, having excluded those with missing values at baseline. The average age of the cohort was 57 years, and 133 (66%) were males, with an average baseline MELD score of 13.8 units. The average time since diagnosis of HE was 23 months. The model had an r-squared value of 0.827, indicating a strong relationship between EQ-5D index and CLDQ. The model equation was EQ-5D = -0.010 + 0.136*CLDQ. Other potential covariates, such as age and sex, were tested but were not significant (at 0.05).
CONCLUSION: This is the first time that a direct association between the EQ-5D index and the CLDQ score has been reported. The r-squared value of this association suggests that liver-related morbidity may explain the majority of differences in health-related utility in these subjects.

P0601 OUTCOMES OF SECONDARY PROPHYLAXIS FOR GASTRIC VARICEAL BLEED WITH BETA BLOCKER AFTER GASTRIC VARICEAL OBTURATION FOR GASTRIC VARICEAL BLEEDING

G. Muzzaffar[1,*], **S.M. Gill**[1], M. Malik[1] on behalf of Gastroenterology, Maroof International Hospital, Islamabad
[1]*Gastroenterology, Maroof International Hospital, Islamabad, Pakistan*

INTRODUCTION: Gastric variceal obturation therapy using Histoacryl for the gastric variceal bleeding is the most appropriate treatment. However, the secondary prophylactic efficacy of beta blocker after gastric variccal obturation therapy has not been established. We wanted to evaluate the secondary prophylactic efficacy of beta blocker after gastric variceal obturation therapy. We conducted this study from January 2011 to January 2014.
AIMS & METHODS: We enrolled 100 consecutive patients, with gastric variceal bleeding who received gastric variceal obturation therapy using Histoacryl. Gastric variceal obturation therapy was continued until gastric variceal eradication. Among these 100 patients 48 patients underwent only gastric variceal obturation therapy (Group I) and 52 patients along with gasstric variceal obturation therapy did receive beta blocker therapy (Group II). We gave Carvedalolo 12.5 to 25 mg daily doses. In all patients, the desired heart rate was achieved. The rate of rebleeding free overall survival was observed in two groups by Kaplan-Meyer analysis.
RESULTS: This is ongoing study, we are reporting the interim results. The mean follow-up period was 24 months. During follow-up period, rebleeding occurred in 10 patients (20%) in group 1 and 20 patients (40%) in group 11 respectively.15 patients died in group 1 and 25 patients in group 11 over 2 years period, which was statistically significant at p = 0.05. The mean rebleeding free survival times were 70 and 40.months, respectively, and were statistically significant (p = 0.05). The mean overall survival time were 60 versus 40 months, respectively, and were significant differences between two groups (p = 0.001).
CONCLUSION: The beta blocker adding therapy after gastric variceal obturation therapy using Histoacryl for first gastric variceal bleeding could decrease rebleeding and mortality, as compared with gastric variceal obturation therapy alone. Further prospective large-scale studies are needed to confirm or refute our observation.

INTRODUCTION: Noninvasive assessment of chronic liver disease is of major importance. Spleen stiffness measurement (SSM) was proposed as a surrogate noninvasive marker for prediction of large esophageal varices (LEV) or clinically significant portal hypertension (CSPH). It was recently hypothesised that SSM may predict clinical decompensation (CD) during follow up in cirrhotic patients.
AIMS & METHODS: The aim of this study was to evaluate SSM as a predictor of decompensation in patients with cirrhosis.
Fifty-two consecutive compensated cirrhotic patients due to viral (HCV and/or HBV) or alcoholic aetiology were included. They were mainly men (27; 52%) with a mean age of 55.9 years. 25 patients (48%) had large (grade 2 and 3) oesophageal varices at inclusion. All patients underwent liver and spleen stiffness measurement at baseline as previously described, abdominal ultrasound and liver function was assessed by usual biochemical tests. Modified SSM (mSSM) was also calculated from each spleen elastogram using an alternate calculation algorithm so that an extension of the scale (up to 150 kPa) could be obtained. Clinical decompensation was defined as the occurrence of one of the following: variceal bleeding, development of ascites, hepatic encephalopathy (HE), jaundice (total bilirubin > 3 mg/dl), infection, spontaneous bacterial peritonitis (SBP), hepatorenal syndrome (HRS), hepatocellular carcinoma (HCC) or death or liver transplantation.
RESULTS: During the median follow-up period of 13 months (range 4-28), 23 patients (44%) decompensated. Most frequent cause of CD was ascites (7 patients, 30.4%), followed by infection/SBP (6 patients, 26.1%), variceal bleeding (4 patients, 17.4%), HE and HCC (3 patients, 13.05% in each group). 14 patients (26.4%) had more than one episode of decompensation and 3 (5.6%) died during the follow-up.
In multivariate analysis baseline values of mSSM (HR = 1.085; p = 0.01), albumin (HR = 0.17; p = 0.02) and total bilirubin (HR = 1.642; p = 0.05) were the only variables associated with CD in the follow-up, overcoming LSM, SSM and MELD.
CONCLUSION: Although conducted in a small heterogeneous population of cirrhotic patients for a limited period of time, the findings of this study supports the conclusion that modified SS measurement by transient elastography together with simple biological parameters (Albumin and Bilirubin) may have an important clinical relevance by selecting patients with high risk of decompensation.

INTRODUCTION: Portal hypertensive enteropathy (PHE) remains difficult to diagnose in patients with cirrhosis and portal hypertension. Small bowel capsule endoscopy (SBCE) would be ideal in this situation but it is rarely performed
AIMS & METHODS: We aimed to determine the prevalence of PHE using SBCE in a cirrhotic patient population from our centre
Methods. This was a retrospective study using the SBCE data base of our unit. We searched through 1,477 patients that had SBCE between 2005 and 2013. Patients with cirrhosis who underwent SBCE were identified, data retrieved and abstracted. The Fischer's exact test or the chi square test were used to compare between groups. A two-tailed P value of <0.05 was considered statistically significant.
RESULTS: We identified 53 patients with cirrhosis who underwent SCBE. We used PillCam®SB (Given®Imaging Ltd, Israel) system on 36 patients and the MiroCam® capsule (IntroMedic Co, Korea) on 17 patients. Thirty patients were referred for iron deficiency anaemia, 15 for obscure gastrointestinal bleeding and 4 for other indications. Four data sets were not available for review at the time of the study, leaving 49 patients to be reviewed. Mean age was 61.19±14.54 years (M/F = 27/22). The most common aetiology for cirrhosis in our patients was alcoholic liver disease (15 patients) followed by NAFLD (9 patients) and hepatitis C (7 patients). Thirty three patients had evidence of portal hypertensive gastropathy (PHG) and 17 patients had evidence of oesophageal varices. In total, 29 patients had SCBE evidence of PHE (67%). 28/29 (96.5%) of patients with PHE had also evidence of PHG. 13/17 (76.4%) patients with oesophageal varices had also evidence of PHE. Mean gastric transit time was 54 ± 9 minutes and mean small bowel transit time was 204 ± 64 minutes. There were no statistically significant differences between the mean gastric transit times in cirrhotic patients with and without PHE (p = 0.235) or the small bowel transit time (p = 0.49). Our mean follow up was 58.0 ± 13.7 months. Twenty patients died during the follow up period. There was no correlation between the presence of PHE and aetiology of liver disease ($p = 0.4261$) or subsequent death ($p = 0.2145$).
CONCLUSION: The prevalence of PHE in our study was 67%. SBCE is a useful tool in evaluating PHE in cirrhotic patients irrespective of aetiology.

INTRODUCTION: Minimal hepatic encephalopathy (MHE) is a complication of liver cirrhosis that does not show symptoms of overt hepatic encephalopathy (OHE). This state reflects alterations in cognitive function, but clinically exhibit a normal mental status examination. Patients with MHE have been shown to have higher rates of automobile accidents, it predicts the development of OHE, and is associated with poor survival.
Diagnosis of MHE is difficult, as the absence of clinical evidence of encephalopathy is key to its diagnosis. Neuropsychological testing, specifically the Psychometric Hepatic Encephalopathy Score (PHES), is accepted as a reference standard in the diagnosis of MHE. Newer computer-assisted techniques, such as the Inhibitory Control Test (ICT), have been studied to improve the detection of MHE. ICT is a simple computer-based test, consisting of presentation of several letters at 500-millisecond intervals. The ease of performing the test in the outpatient setting may make it a good test for detecting MHE.
AIMS & METHODS: This study aims to determine the sensitivity and specificity of Inhibitory Control Test in diagnosing minimal hepatic encephalopathy. COCHRANE and MEDLINE were searched for articles published between January 2003 to October 2013. Studies that compared ICT with psychometric tests in cirrhotics were included. Data analysis was performed using the validated application Meta-Disc version 1.4 (Universidad Complutense, Madrid, Spain). The DerSimonian-Laird random effects method was used to produce summary estimates of sensitivity, specificity, likelihood ratios (LR), and diagnostic odds ratio (DOR).
RESULTS: The search strategy identified 133 studies. Based on pre-stated criteria, three studies were included in the final review. There were 235 patients with liver cirrhosis and a matched control group that underwent both psychometric testing and ICT. Pooled data showed that the ICT had a sensitivity of 88% ($I^2 = 0\%$), specificity of 72% ($I^2 = 69.2\%$), and DOR was 21.2 (95% CI: 8.08–55.24). A symmetrical sROC depicted an area under the receiver operator curve (AUC) of 0.89 (standard error 0.03).
CONCLUSION: Inhibitory Control Test is a good tool to exclude cirrhotic patients without minimal hepatic encephalopathy. It is effective in discriminating patients with MHE from those without MHE and therefore has potential as a screening test. However, more high-quality studies are needed to establish test accurarcy.

INTRODUCTION: There is a lack in knowledge about the correlation of systemic circulation parameters and the degree of liver failure with respect to the presence of hepatopulmonary syndrome (HPS) and portopulmonary hypertension (PPH).
AIMS & METHODS: The aim of this study was to evaluate the changes in the systemic circulation by using non-invasive diagnostic approach in the patients fulfilling the criteria for HPS and PPS. The study sample included 70 patients with alcoholic liver cirrhosis;22 patients with grade A, 24 patients with grade B, and 24 patients with grade C according to the Child-Pugh clinical score. Systemic circulation measurements included: heart rate (HR), mean arterial pressure (MAP), cardiac index (CI), systemic vascular resistance (SVRI) and cardiac stroke volume (CSV)[1]. Neurohumoral parameters included: NT-proBNP, noradrenalin (NA) and plasma renin activity (PRA). HPS was diagnosed if the presence of impaired arterial oxygenation ($PaO_2 < 80$mmHg and alveolar-arterial oxygen gradient $\geq$15mmHg; for patients older than 64 years $PaO_2 \leq 70$ mmHg, and A-a gradient $\geq$20 mmHg) and pulmonary vascular abnormalities were found. PPH was characterized by increased mean pulmonary artery pressure >25 mmHg at rest and if the diameter of the main pulmonary artery is $\geq$29 mm with concomitant segmental artery–to-bronchus ratio $>$ 1:1 at least in three out of four pulmonary lobes, or the ratio of the main pulmonary artery diameter to the aortic diameter >1.
RESULTS: HPS and PPH were found in 28 (40%) patients. Patients with HPS were mostly patients from group B (57.2%) and C (42.8%) with respect to the degree of liver failure, while all patients with PPH were patients with advanced liver failure. When correlating systemic hemodynamic and neurohumoral parameters in relation to the presence of HPS and PPS no significant difference was found. (Table 1).
CONCLUSION: The combined application of the Doppler and contrast echocardiography is a simple, non-invasive and reproducible method that enables the diagnosis of both HPS and PPH. Systemic hemodynamic parameters remained unchanged among patients with HPS and PPS.

P0606 DO COAGULATION AND PLATELET FUNCTION DISORDERS INFLUENCE THE PREVALENCE OF VARICEAL BLEEDING IN PATIENTS WITH LIVER CIRRHOSIS?

P. Rogalski[1,*], E. Wroblewski[1], M. Rogalska-Plonska[2], A. Swidnicka-Siergiejko[1], A.A. Baniukiewicz[1], A. Dabrowski[1]
[1]*Department of Gastroenterology and Internal Medicine,* [2]*Department of Infectious Diseases and Hepatology, Medical University of Bialystok, Bialystok, Poland*

INTRODUCTION: Bleeding from gastro-esophageal varices is a life-threatening condition and occurs in approximately one third of patients with liver cirrhosis during their lifetime. On the other hand patients with history of variceal bleeding have 70% risk of recurrent bleeding within the next year since the first episode. Coagulation disorders in patients with liver cirrhosis are complex, and their role in variceal bleeding remains unclear. Previous studies have shown that the results of standard laboratory tests such as prothrombin time (PT) and activated partial thromboplastin time (APTT) provide a narrow measure of procoagulant system only and do not predict bleeding in cirrhotic patients. Thromboelastometry has been used for decades for intraoperative transfusion guidance and it can show defects in multiple components of hemostasis. Multiplate® impedance platelet aggregometry (IPA) allows rapid evaluation of platelet aggregation in whole blood.
AIMS & METHODS: The aim of our study was to compare the character of coagulation disorders in patients with liver cirrhosis and a history of variceal bleeding with non-bleeding cirrhotic patients. We compared standard laboratory clotting tests, thromboleastometry (ROTEM® thromboelastometer) and IPA parameters of cirrhotic patients with medium-large varices who have never bled (non-bleeding group) with patients with a history of variceal bleeding at least 3 weeks before (bleeding group). The following thromboelastometry parameters were measured: clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF) and the clot amplitude at 5, 10 and 15 minutes in three tests with specific activators to evaluate the extrinsic (EXTEM) and intrinsic (INTEM) systems, and the clotting factors alone after platelet inactivation (FIBTEM). In addition, IPA was performed with ADP as an activator and aggregation was quantified as area under the curve (AUO).
RESULTS: Blood was sampled from 44 patients (23- non-bleeding group, 21-bleeding group). Baseline characteristics of the bleeding and non-bleeding groups were comparable apart from a more prolonged PT in the bleeding group [15,8 (14,1 - 17,3) *vs* 14,3 (13,5-16,0), $p = 0.045$]. The severity of liver disease according to Child–Pough score was comparable in both groups [8,00 points (8,0-10,0) – non-bleeding group *vs* 9,0 (8,0-10,0) – bleeding group, $p = 0.889$]; 5 patients – class A, 23 patients - class B, 16 patients - class C. In FIBTEM there was significantly lower amplitude at 15 minutes in the bleeding group compared with non-bleeding group [12.0 (9,5-14,5) *vs* 15.0 (11,0-19,0), $p = 0.049$]. The

other results of thromboelastometry and aggregometry parameters did not differ significantly between both groups, which suggest a compensatory role of platelets in EXTEM and INTEM tests. The compensatory role of platelets is also supported by the results of IPA in which we demonstrated higher value of AUO in bleeding group in comparsion with non-bleeding group [273.0 (99,0-557,0) *vs* 189.00 (132,0-640,0), NS].
CONCLUSION: Despite prolonged PT in bleeding group, the patients with liver cirrhosis with and without history of variceal bleeding have similar efficiency of blood clotting, which may suggest compensatory role of platelets in these patients.

P0607 REAL WORLD EXPERIENCE OF RIFAXIMIN FOR HEPATIC ENCEPHALOPATHY - EFFECTIVE MAINTENANCE OF REMISSION AND REDUCTION OF HOSPITAL ADMISSIONS IN A LARGE SECONDARY CARE PATIENT COHORT

H. Preedy[1], A. Fowell[1], **R. Aspinall**[1,*]
[1]*Gastroenterology & Hepatology, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*
Contact E-mail Address: *r.j.aspinall@doctors.org.uk*

INTRODUCTION: Rifaximin has been shown to maintain remission of chronic hepatic encephalopathy (HE) and reduce hospital admissions (Bass et al 2010). However, the literature mainly reflects tertiary centres and could include referral bias. Therefore, we examined the ''real world'' utility of rifaximin in a large secondary care acute hospital, serving a population of 650,000.
AIMS & METHODS: All patients with cirrhosis and chronic HE who were commenced on rifaximin between May 2010 and November 2012 were identified from a departmental database and pharmacy records. Analysis included formal review of casenotes, pathology, hospital admission statistics and calculation of MELD, UKELD and Child's-Pugh scores. Data were analysed for the 6 months prior to rifaximin usage and at 3, 6 and 12 months later.
RESULTS: The study population comprised 42 patients, 62% male, mean age 59 years. Cirrhosis aetiology was alcohol 55%, NASH 24%, autoimmune 10%, HCV 5%, miscellaneous 6%. At initiation, 24% of patients were using alcohol and 19% took quinolone secondary prophylaxis against spontaneous bacterial peritonitis. Mean baseline prognostic scores were Child's-Pugh 9.4 (SD 2.1), MELD 15.0 (SD 7.9), UKELD 51.2 (SD 5.1). Survival at 3, 6 and 12 months post-rifaximin was 78%, 67% and 62% respectively. There was a significant reduction in Child's-Pugh scores at 3 and 6 months ($p<0.01$) but not 12 months and no significant change in MELD or UKELD. Comparing the 6 months pre/post rifaximin, hospitalisation days fell from 233 to 143, a mean of 5.6 per patient, representing a saving of €1,829 in healthcare tariff costs. The number of admission episodes fell from 25 to 11.
CONCLUSION: In an unselected ''real world'' cohort of patients with chronic hepatic encephalopathy, rifaximin was associated with fewer readmission spells and a reduction in bed days with potential savings in healthcare utilisation costs. The efficacy of rifaximin for the maintenance of remission in patients with chronic HE can be demonstrated in a secondary care environment.

Contact E-mail Address: *rzykus@gmail.com*

INTRODUCTION: Liver transient elastography (TE) can predict liver fibrosis with high specificity and sensitivity. However, there is only limited data if TE could predict clinically significant portal hypertension or presence of oesophageal varices.
AIMS & METHODS: The aim of our study was to assess correlation between liver and spleen transient elastography, hepatic venous pressure gradient (HVPG) and presence of oesophageal varices. In this prospective study the correlations of liver and spleen TE with HPVG and presence of oesophageal varices were assessed in 78 chronic liver disease patients (50 patients had chronic hepatitis C). Spleen TE was feasible in 72 of them. TE was measured at the same day before HPVG measurement. Interquartile range/median $<20\%$ and success rate $>60\%$ were considered as good quality criteria during TE both for spleen and liver investigations. Endoscopy was performed in one week period after TE was done. Oesophageal varices were classified into 0 - III grades (according Baveno consensus). Patients were categorised into those with and without oesophageal varices. HPVG was measured using catheter occlusion technique by experienced radiologist. Patients were classified in to $>=12$mmHg (clinically significant portal hypertension), and <12mmHg HPVG groups. Cut-off values were established by ROC analysis.
RESULTS: Strong correlation of liver stiffness R – 0.74 ($p<0.01$) and moderate correlation of spleen stiffness R – 0.52 ($p< 0.01$) with HVPG were established. To determine the patients with HVPG $>=12$mmHg, liver TE cut-off value 18.5kPa had sensitivity 0.91 and specificity 0.74; spleen TE cut-off value 57.0 kPa had sensitivity 0.75 and specificity 0.77. Area under the ROC curve was 0.90 for liver TE and 0.83 for spleen TE.
Strong correlation of liver stiffness R – 0.61 ($p<0.01$) and moderate correlation of spleen stiffness R – 0.48 ($p< 0.01$) with oesophageal varices grade were established. To predict the presence of oesophageal varices liver TE cut-off value 21.5kPa had sensitivity 0.86 and specificity 0.83; spleen TE cut-off value 57.0 kPa had sensitivity 0.73 and specificity 0.75. Area under the ROC curve was 0.86 for liver TE and 0.76 for spleen TE.
CONCLUSION: Liver transient elastography strongly correlates and spleen TE moderately correlates with HVPG and oesophageal varices grade. Liver TE accurately predicts significant portal hypertension and oesophageal varices in patients with chronic liver disease and is more sensitive and specific than spleen TE. Therefore liver transient elastography could be reproducible outpatient screening tool for portal hypertension or oesophageal varices.

P0609 NUTRITIONAL EVALUATION OF THE CIRRHOTIC PATIENT WITHOUT ASCITES: IS THERE A ROLE FOR ANTHROPOMETRIC PARAMETERS?

S.M. D. Giestas[1,*], **A. Giestas**[1], C. Agostinho[1], C. Sofia[1]
[1]*Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*
Contact E-mail Address: *silviagiestas@gmail.com*

INTRODUCTION: Malnutrition due to chronic liver disease is common and its assessment is difficult. The anthropometric parameters, often used in clinical practice, have limited use in the nutritional evaluation of cirrhotic patients mainly those with ascites/edema. Some studies demonstrate that Maastricht Nutritional Index (MI) is the best assessment in early stages of the disease, however the best method of nutritional evaluation in cirrhotic patients remains controversial.
AIMS & METHODS: Aim: To determinate the role for anthropometric parameters in the nutritional evaluation of cirrhotic patients without ascites and compare it with the MI.
Patients and Methods: Prospective study of cirrhotic outpatients without ascites (diagnosis based on histological evidence and/or high clinic/ biochemical /imagiological suspicion). Exclusion criteria: enteric nutrition, amputation, malabsorption syndrome, chronic pancreatitis, inflammatory bowel disease, chronic kidney disease, acquired immunodeficiency syndrome, neuromuscular diseases and oncologic advanced disease. Included patients where classified according Child-Pugh Score; weight (kg), height (cm) and body mass index (BMI) were evaluated; and based in MI they were stratified in mild (>0-3), moderate (>3-6) and severe (>6) impaired nutritional status.
RESULTS: 50 cirrhotic patients were included in the study, 84% (n = 42) had alcoholic cirrhosis, the mean age was 58+/-11.4 years and 60% were male (n = 30). Concerning cirrhosis severity: 88% (n = 44) were Child-Pugh A and 12% (n = 6) Child-Pugh B. 8% (n = 4) had a BMI $<18.5\%$, regardless of age, gender or etiology. MI detected malnourishment/malnutrition in 38% (n = 19) of patients: 24% (n = 12) mild and 14% (n = 7) moderate impaired nutritional status. In MI evaluation no statistically difference was found between etiology, gender and age. No association between malnutrition and disease severity (Child-Pugh Score) was found with both methods.
CONCLUSION: In this study anthropometric parameters underestimate malnutrition in cirrhotic patients when compared with the Maastricht Nutritional Index, which detected malnutrition in early stages of hepatic disease.

INTRODUCTION: Although several studies have elucidated the beneficial effects of TIPS on PVT in patients with cirrhosis[1, 2, 3] in short term, it is regrettable that the long term effects of TIPS in cirrhotic patients with PVT is not very clear, especially in patients with a history of oesophageal and gastric varices bleeding, therefore the aim of this retrospective study was to evaluate the feasibility, safety, and efficacy of TIPS for the prevention of variceal rebleeding in cirrhotic patients with PVT.
AIMS & METHODS: ***Aim*** The aim of this study was to evaluate the efficacy of TIPS for the prevention of variceal rebleeding in cirrhotic patients with PVT retrospectively.
Methods Forty consecutive cirrhotic patients with a history of variceal bleeding were referred for TIPS between August 2008 and December 2013. All patients were diagnosed with non-malignant PVT, including 37 partial PVT and 3 portal cavernoma. Patients were followed until last clinical evaluation, diagnosis of hepatocellular carcinoma, liver transplantation, or death.
RESULTS: TIPS were successfully placed in 85% of patients (34/40), 86.5% (32/37) in patients with partial PVT and 66.7% (2/3) with portal cavernoma, without complication or TIPS-related mortality. Patients with successful TIPS were followed up for a mean of 12.9 months (range1-37 months) and portosystemic pressure gradient (PSG) was reduced from a mean 21.6 ±4.0 to 14.4± 5.2mm Hg after TIPS placement, the decreasing amplitude of PSG reached 29.4% ± 5.0% from baseline. The 1- and 2-year cumulative variceal rebleeding rates were 11.8% and 48.5% in the success group and 16.7% and 37.5% in the failure group, respectively ($p=0.438$). The only independent predictor for variceal rebleeding in the success group was TIPS shunt flow velocity. The cumulative rate of TIPS dysfunction at 1-and 2-year was 11.8% and 31.4%. Hepatic

encephalopathy occurred in 44.1% (15/34) of patients, and all of them happened within the first year after TIPS. The 1- and 2-year cumulative survival rates were 80.1% and 49.9% in the success group and 100% and 75.0% in the failure group, respectively ($p = 0.471$).
CONCLUSION: TIPS placement is safe, feasible and has a fairly high success rate to prevent variceal rebleeding in cirrhotic patients with PVT. Moreover, TIPS can highly decrease the risk of variceal rebleeding because of the reduction of PSG, and the only independent predictor for variceal rebleeding was TIPS shunt flow velocity. We suggest TIPS should be considered a viable treatment option for cirrhotic patients with PVT, especially in patients with a high risk of variceal rebleeding.

P0611 CO-LOCALIZATION OF HBX AND COXIII PROMOTES HL-7702 CELL PROLIFERATION THROUGH CROSSTALK AND SYNERGY OF COX-2 AND B-CATENIN SIGNAL PATHWAYS

B. Zheng[1,*], X. Fang[1], L. Zou[2], D. Li[1], Y. Huang[1], Z. Chen[1], L. Zhou[3], X. Wang[1]

Contact E-mail Address: *drzhengby@163.com*

INTRODUCTION: Hepatocellular carcinoma (HCC) is one of the most common malignant diseases, and HBx leads to the development of HBV-associated HCC. Our recent studies have revealed that HBx can interact with the inner mitochondrial membrane protein, COXIII, by yeast two-hybrid system, mating experiment and coimmunoprecipitation.
AIMS & METHODS: To futher explore the co-localizaiton of HBx and COXIII in HL-7702 cell and to investigate the molecular mechanism of HBx in HL-7702 cell proliferation. A HL-7702 cell line stably expressing the HBx gene by lentivirus vectors were constructed. Confocal microscopy was utilized to assess the interaction between HBx protein and COXIII. The functional relevance of HBx protein–COXIII interaction was investigated in cell cultures.
RESULTS: Our studies first demonstrated that HBx co-localized with the inner mitochondrial protein, COXIII, in HL-7702 cells, causing the up-regulation of COXIII protein expression as well as COX activity. HBx elevated the generation of mitochondrial ROS and ROS was necessary for it to activate the expression of COX-2. Moreover, HBx promoted cell proliferation through COX-2/β-catenin signaling pathways.
CONCLUSION: Collectively, the major finding of this study is that the co-localization of HBx and COXIII leads to the changes of mitochondrial biogenesis and morphology. Besides, COX-2 and β-catenin signal pathways stimulated by mitochondrial ROS have crosstalk and synergy in the oncogenesis of HBV-associated HCC.

INTRODUCTION: HEV infection is fatal during pregnancy. The mortality rate in pregnant women with ALF is 15-20%, which is associated with an altered status of hormones and difference in immune response.
AIMS & METHODS: Aim of the study is to determine biochemical and haemotological factors associated with mortality in Hepatitis E related acute liver failure during pregnancy. A total of 73 consecutive ALF pregnant patients with HEV infection were recruited in the study during July 2008 to August 2013 and patients were followed up until death or complete recovery. Patients with viral co-infections and with history of pre-existing liver disease were excluded. Biochemical and pathological parameters included detailed liver function tests (AST, ALT, alkaline phosphatase and total serum bilirubin), total proteins, prothrombin time and complete haemogram. All the cases were screened for hepatitis virus markers by ELISA. ROC curve was drawn to predict cut-off level of serum albumin in ALF pregnant patients.
RESULTS: The mean maternal age and gestational at delivery were 25.32 $\pm$3.62years and 29.53$\pm$4.62 weeks respectively. Forty six out of 73 (63.01%) ALF pregnant patients were non survived and twenty seven out of 73 (36.98%) were survived. HEV was found to be the commonest cause of ALF in pregnancy. It was found that in univariate logistic regression analysis AST, ALP, bilirubin, prothrombin time, total protein and albumin were the statistically significant factors between survival and non-survival group. A multivariate logistic regression analysis was performed using significant independent variables, and it was found that variables that independently predicted mortality were serum alkaline phosphatase (OR = 5.21, 95% CI = 1.27-21.42; $p < 0.05$), prothrombin time (OR = 6.47, 95% CI = 1.69–24.77; $p < 0.01$), serum albumin (OR = 7.85, 95% CI = 1.73-35.55; $p = 0.01$) and serum total protein (OR = 3.88; 95% CI = 1.01–14.94; $p < 0.05$). A receiver operating characteristic curve was drawn for serum albumin. The area under the curve was 0.643. The serum albumin level of $\leq$2.1g/dl was found to be the cut-off for ALF pregnancy patients with 67% sensitivity and 63% specificity.
CONCLUSION: Serum albumin, serum total protein, serum alkaline phosphatase and prothrombin time were significant independent risk factors associated with mortality in ALF pregnant patients.

P0613 FAVORABLE ANTIVIRAL EFFECT OF NUCLEOSIDE ANALOGUES REDUCES HEPATOCELLULAR CARCINOMA DEVELOPMENT IN HIGH RISK PATIENTS WITH CHRONIC HEPATITIS B VIRUS INFECTION

INTRODUCTION: Chronic hepatitis B virus (HBV) infection leads to cirrhosis and hepatocellular carcinoma (HCC). Recently, HCC risk scales enable us to estimate the risk of developing HBV related HCC (REACH-B score, Lancet Oncol 2011;12:568). The objective of this study was to evaluate the on-treatment predictive factors of nucleoside analogues (NAs) to reduce HBV related HCC development for the high risk patients of chronic HBV infection in Japan, where genotype C is the most prevalent.
AIMS & METHODS: This study was retrospective cohort study including the patients treated with NAs for at least 12 months. The patients were applied into REACH-B score and risk scores were generated based on sex, age, serum ALT concentration, HBeAg status, and serum HBV DNA level. The favorable responses of NAs were defined as each of these cases, (1)decrease in serum ALT levels to within the normal range by 24 weeks, (2)decrease in HBV DNA less than 4.0 log copies/mL by 24 weeks, (3) achievement of HBeAg seroconversion or (4)decrease in HBsAg less than 100 IU/mL. We compared the incidence of HCC between favorable responder and poor responder.
RESULTS: A total of 76 Japanese patients with nucleoside-naïve chronic HBV infection were included. Thirty two patients were started with lamivudine, 44 patients were started with entecavir. Mean treatment duration was 1387 days (range 374-4360). Mean pre-treatment HBV DNA and ALT levels were 7.14 log copies/mL and 282 IU/L, respectively. The mean age was 50.0$\pm$11.9 years and 47 (61.8%) patients were male. Forty (52.6%) patients were HBeAg positive, 18 patients (23.7%) had clinical evidence of liver cirrhosis. Genotype C was the most prevalent (43 of 48, 89.6%). Nine patients developed HCC during follow-up. All 9 patients were from the group whose REACH-B scores were 11 points or more (52 patients, defined as high risk patients, in this study). Of the high risk patients, those who had achieved HBeAg seroconversion reduced HCC development significantly ($p = 0.0478$). The cumulative HCC incidence rates at 5-year were 4.7% and 40.0% for the patients who achieved HBeAg seroconversion (favorable responder) and those who did not (poor responder), respectively.
CONCLUSION: The high risk patients still have the risk of developing HCC. NAs can reduce HCC development for the high risk patients with chronic HBV infection (Hepatology 2013;58:98). From our study, favorable antiviral effect (for example, achievement of HBeAg seroconversion) of NAs may reduce HCC development in the high risk patients with chronic HBV infection.

INTRODUCTION: Entecavir (ETV) is a potent inhibitor of HBV replication.
AIMS & METHODS: The aim of the study was to explore if previous interferon (IFN) therapy might influence response to Entecavir in chronic hepatitis B.
A retrospective cohort study was performed, including all subjects who received ETV for chronic hepatitis B, in the south-Eastern Romania. We assessed viral response, HBeAg loss and seroconversion, HBsAg loss and seroconversion, biochemical response. Comparison of categorical data was performed by c^2-test or Fisher's exact were applicable.

RESULTS: 533 patients were followed for a median period of 24 months. The cohort was 64% male, 23% HBeAg-positive, 23% IFN-pretreated, 17% Lamivudine-pretreated, 8% cirrhotics. At baseline, the median hepatitis B virus DNA was 5.95 (interquartile range = 1.08-9.97) log10 IU/ml. At week 48, 71% of the patients (32% HBeAg-positive; 82% HBeAg-negative) achieved a virological response and 91% (78% HBeAg-positive; 95% HBeAg-negative) of those with elevated baseline alanine aminotransferase showed a biochemical response. Thirty-two per cent (39/123) of the HBeAg-positive patients lost HBeAg and 23% (28/123) achieved seroconversion to anti-HBe. Positive predictive factors for virologic response are: low score of fibrosis (p-0.006), low level of HBV DNA (p-0.003). Negative predictive factors for virologic response are: HBe antigen positive status (OR odds ratio 0.15, 95%CI confidence interval 0.07-0.30; p-value < 0.001), prior IFN therapy. (OR 0.45, 95% CI 0.24-0.86; p-value 0.015). Baseline level of ALT, age, sex, previous Lamivudine therapy had no impact on virologic response. Virological breaktrough was found in 0.8% of patients. Seven patients (1.31%) showed clearance of hepatitis B surface antigen.
CONCLUSION: ETV maintained and even increased the high initial response rate (from 71% to 90.6%). Low score of fibrosis, low level of HBV DNA, HBe antigen negative status, absence of prior interferon therapy predict a good virologic response. Lamivudine-resistant patients usually respond well to ETV, but 15.62% are non-responders, suspect of Entecavir resistance.

INTRODUCTION: Nucleos(t)ide analogues (NUCs) therapy reduced the risk of hepatitis B virus (HBV) disease progression. However, whether NUCs long-term therapy is more effective than short-term therapy remains controversial.
AIMS & METHODS: We conducted a nationwide cohort study based on Taiwan's National Health Insurance Research Database (NHIRD) between October 1, 2003 and December 31, 2011. Among the CHB patients, we used propensity scores to match 8,631 patients with NUCs therapy for at least 1.5 years (long-term therapy cohort) with 8,631 patients with NUCs therapy for at least 90 days, but less than 1.5 years (short-term therapy cohort). Major outcomes, including liver decompensation, hepatic failure, or overall mortality, between the 1.5 and 3 years after date of starting NUCs therapy were analyzed. Cumulative incidences and multivariable analyses were calculated after adjusting for competing mortality.
RESULTS: Compared with short-term therapy cohort, long-term therapy cohort had significantly lower risk of liver decompensation (1.05%; 95% confidence interval [CI], 0.81-1.30% vs. 2.13%; 95%CI, 1.82-2.45%; $P < 0.001$), hepatic failure (0.35%; 95% CI, 0.21-0.49% vs. 0.63%; 95% CI, 0.46-0.80%; p = 0.008), and overall mortality (1.67%; 1.37-1.98% vs. 2.44%; 95% CI, 2.10-2.77%; P < 0.001). After adjusting for competing mortality and other confounders, long-term therapy was associated with a reduced risk of liver decompensation (adjusted hazard ratio, aHR: 0.47; 95%CI, 0.36-0.62, P < 0.001), hepatic failure (aHR: 0.53; 95%CI, 0.33-0.86, p = 0.01) and overall mortality (aHR: 0.67; 95% CI, 0.53-0.84, p = 0.001).
CONCLUSION: NUCs long-term therapy was associated with reduced risks of liver decompensation, hepatic failure and overall mortality in CHB patients.

P0616 THE INACTIVE HBV-CARRIER PROFILE: THE LONG-TERM OUTCOME

H. Zejly[1,*], R. Afifi[1], Y. Cherradi[1], H. Benbrahim[1], I. Benelbarhdadi[1], F.Z. Ajana[1], W. Essamri[1], A. Essaid ElFeydi[1]
[1]*Hepatogastroenterology (Médecine C), Ibn Sina Hospital, Rabat, Morocco*
Contact E-mail Address: *hindzejly@gmail.com*

INTRODUCTION: The inactive HBV profile is one of the aspects of natural history of chronic hepatitis B (HVB). We aimed to define epidemiological, clinical and virological features of inactive HVB-carriers and to evaluate their long-term outcome
AIMS & METHODS: It's a monocentric and descriptive study including 575 chronic HVB-carriers - over 18 years old- followed since 1998. The inactive HBV profile was defined by normal serum aminotransferases, HBeAg-negative state and DNA levels < 2000 IU/ml. We excluded patients with HIV and/or HCV co-infection and alcohol consumers. HBV-reactivation was defined by an HVB DNA load up to 2000 IU/ml. All clinical, biological and serological data were collected. Serum HBV DNA levels were measured using real-time PCR quantification assays. Liver biopsy was indicated according to international recommendations
RESULTS: Of 575 considered patients, the inactive HVB-carriers represented 49.7% (n = 286). Mean age was 35.5 years old [18-63], male gender was prominent (sex-ratio = 1.93). Mean time of follow-up was 6 years [1- 15]. The most probable ways of HVB transmission were unprotected sexual practices and unsafe tooth-care (respectively 57 % and 34.5%). Ultrasonography found an heterogeneous hepatic parenchyma in 12% and steatosis in 4%. Liver biopsy was indicated in 6 patients: fibrosis was less than F2 according to Metavir score. HVB-reactivation was reported in 2 patients (0.01%) which indicates antiviral treatement. Spontaneous HBsAg loss was achieved in 5 patients. No case of hepatocellularcarcinoma was reported.
CONCLUSION: Our "real-life" experience confirms that the inactive HVB profile is associated to less complications and better long-term outcome.

P0617 ANTIVIRAL EFFICACY OF ENTECAVIR VERSUS ENTECAVIR PLUS ADEFOVIR FOR HEPATITIS B VIRUS RTA181V/T MUTANTS ALONE

M.J. Oh[1,*]
[1]*Department of Internal Medicine, CHA Gumi Medical Center, CHA University School of Medicine, Gumi, Korea, Republic Of*
Contact E-mail Address: *zenus1@hanmail.net*

INTRODUCTION: Hepatitis B virus (HBV) rtA181V/T mutants developed by long-term nucleos(t)ide analogues therapy are known to confer cross-resistance for other nucleos(t)ide analogues, except entecavir (ETV). Although ETV has primarily been used as rescue therapy for rtA181V/T mutants, some studies have reported that rtA181V/T mutants could induce cross-resistance to ETV. In practice, a clinical investigation reported that rtA181V/T mutants might confer HBV DNA persistence, and showed an association with incomplete response, despite rescue therapy with ETV.
AIMS & METHODS: The aim of this study was to investigate antiviral efficacy of ETV alone and in combination with adefovir (ADV) as rescue therapy for HBV rtA181V/T mutants alone. A total of 30 patients who received ETV (1.0 mg/day) monotherapy or ETV plus ADV (10 mg/day) therapy over 48 weeks against HBV rtA181V/T mutants only without other concomitant mutation between April 2008 and October 2011 were enrolled. The subjects were divided into the ETV group ($n = 16$) and the ETV + ADV group ($n = 14$). Virological, biochemical, and serological response after 48 weeks of rescue therapy were investigated retrospectively.
RESULTS: No significant difference in baseline characteristics, including serum HBV DNA levels (4.8 ± 1.7 vs. $4.1 \pm 1.8 \log_{10}$IU/mL) and the rate of HBeAg positivity (93.8 vs. 100%) was observed between the two groups ($p > 0.05$). Virological response at 48 weeks showed complete virological response (serum HBV DNA < 20 IU/mL) (62.5 vs. 42.9%), partial virological response (6.3 vs. 28.6%), non-response (25.0 vs. 28.6%), and virological breakthrough (6.3 vs. 0%), respectively. No statistical significance was observed in virological response ($p = 0.278$). No significant difference in mean reduction of serum HBV DNA and biochemical response rates was observed between both groups, respectively (4.3 ± 2.9 vs. $4.1 \pm 1.8 \log_{10}$IU/mL; $p = 0.294$, 88.9 vs. 100%; $p = 1.000$). In addition, no significant difference in HBeAg loss or seroconversion was observed between the two groups (26.7 vs. 28.6%; $p = 1.000$).
CONCLUSION: As rescue therapy for HBV rtA181V/T mutants alone, ETV monotherapy was clinically as effective as ETV plus ADV therapy.

INTRODUCTION: Antiviral therapy reduces but does not eliminate the risk of hepatocellular carcinoma (HCC) in chronic hepatitis B patients with or without cirrhosis. Retrospective or prospective observational cohort studies that provide HCC data for patients mainly treated with tenofovir are lacking.
AIMS & METHODS: We performed a single-center retrospective cohort study of 120 patients with chronic hepatitis B (age, 47±14; 83 male), 20% (n = 24) with clinical cirrhosis, who were treated with tenofovir 300mg daily (n = 85; 72%) or entecavir 0.5/1mg daily (n = 33; 28%) for at least 12 months. Patients co-infected with hepatitis C virus or human imunodeficiency virus were excluded. Univariate and multivariate analysis of risk factors associated with HCC development were performed. Accuracy of a recent validated HCC-risk score (REACH-B) was assessed.

RESULTS: Our population was mainly caucasian (n = 80; 67%) and african (n = 37; 31%). The most common serological profile was AgHBe negative (n = 82; 73%). 69 patients (60%) were treatment-naïve. Alcohol abuse was reported in 14 patients (12%). The rates of biochemical, total and partial virological response were: 96.5%, 89.2% and 8.3%. The mean time under antiviral therapy was 41±19 months. After a 82±54 months of follow-up, 9 patients (7.6%) developed HCC. The 1 and 3-year cumulative incidence of HCC was 2.7% and 11.1%. Patients who developed HCC were older ($p < 0.001$), alcoholics ($p < 0.05$), cirrhotic at baseline ($p < 0.05$; OR = 15.469; 95%CI: 3.454-69.272) and displayed a higher REACH-B score at baseline ($p < 0.05$). On an univariate analysis, a REACH-B baseline score ≥ 8 predicted relatively well HCC occurrence ($p = 0.071$; OR = 6.352; 95%CI: 0.754-53.486) however, a score ≥ 12 points predicted better ($p < 0.05$; OR = 10.595; 95%CI: 2.275-49.338). Gender, ethnic origin, AgHBe status, baseline viremia, previous treatment and time under antiviral therapy were not associated with HCC occurrence. Through logistic regression, multivariate analysis identified as risk factors associated with HCC occurrence: cirrhosis at baseline ($p = 0.016$; OR 7.975; 95%CI: 1.464-43.432) and REACH-B score baseline ≥ 12 ($p = 0.015$; OR 7.603; 95%CI: 1.480-39.070). The 1 and 3-year cumulative incidence of HCC in patients with REACH-B score baseline ≥ 8 was 7.4% and 16.8%, while a score ≥ 12 confered a risk of 12.6% and 42.7%, respectively. By Kaplan-Maier analysis, excluding alcohol abusers, patients who scored ≥ 8 points in REACH-B had a significantly higher risk of developing HCC ($p = 0.029$) compared with those with < 8 points. At baseline, the REACH-B score performed well, with a AUC of 0.811 (95%CI: 0.668-0.954). A cut-off score of ≥ 8 (at baseline) yielded 87.5% sensitivity, 47.6% specificity, 11.5% positive predictive value (PPV) and 98% negative predictive value (NPV).

CONCLUSION: Even with long periods under antiviral therapy, the occurrence of hepatocellular carcinoma in patients with chronic hepatitis B remains a problem. In our cohort, HCC mostly occured in older (≥ 50 y/o) and alcohol consuming patients, probably with an underlying cirrhotic liver. The performance of REACH-B score (with a cut-off ≥ 8) in non-alcoholic patients seems to perform well in predicting the risk of developing HCC.

INTRODUCTION: Viral hepatitis reactivation has been widely reported in patients undergoing immunosuppressive therapy; however, few data are available on the risk of HBV reactivation in patients with psoriasis receiving immunosuppressive drugs.

AIMS & METHODS: We conducted a retrospective study to value the effect of immunosuppressive therapy on HBV infection in psoriatic patients.

The study included all consecutive psoriatic patients who attended an Italian tertiary referral hospital from 2008 to 2012. A total of 412 patients were consecutively enrolled. We evaluated: HBV markers, type of immunosuppressive treatment and the occurrence of HBV reactivation. Reactivation was defined as reappearance of HBsAg, increase in HBV-DNA at least 1 log in comparison to basal level, in association with or without increase of aminotransferase levels. The observational period ranged from the beginning of immunosuppressive treatment to 6 months after the end of therapy.

RESULTS: A total of 225/412 (54.6%) patients with psoriasis and receiving immunosuppressive therapy (cyclosporine or methotrexate, and/or biological drugs, such as adalimumab, infliximab, etanercept, golimumab, ustekinumab) were tested for markers of HBV infection. We identified 23/225 subjects (10.2%) with isolated HBcAb positivity and 36/225 (16%) with HBcAb/HBsAb positivity. No patient was HBsAg positive. No patient underwent preemptive therapy with Lamivudine or other antiviral drugs. No patient showed episodes of HBV reactivation.

CONCLUSION: In dermatological setting the immunosuppressive therapy, in HBcAb+ and HBcAb+/HBsAb+ patients, seems to be safe regardless to the type of treatment schedule.

INTRODUCTION: The estimated prevalence for chronic hepatitis B virus (HBV) infection is 0-10 % in hemodialysis patients, with wide variations geographically and between units in the same country. The estimated prevalence in Spain was 3.1 % in 2003. Immunization in the vaccinated patients is 40-70 % compared to 97% of the general population.

AIMS & METHODS: National multicenter cohort study, approved by the Ethics and Clinical Investigation Committee of the coordinating center, conducted between January 2013 and January 2014. The aim of this study was to determine the prevalence of HBV in hemodialysis patients in Spain and their situation regarding immunization. A case report form was sent to all the hemodialysis units of Spain to collect information about the patients after informed consent. The data were included in a central database.

RESULTS: One hundred and forty two hemodialysis units participated (104 hospitals, 38 satellite centers). Of the 13,845 patients included, 125 were HBV-positive, resulting in a prevalence of 0.9%. A third of the centers had a HBV-positive patient. The mean age was 66.6 (20-98) in the HBV-negative patients and 45.5 years old in HBV-positive patients (26-72).

In HBV-positive patients, 17.3 % were coinfected with hepatitis C and/or human immunodeficiency viruses. 70 % of patients had positive antiHBe. 82% had a viral load below 2,000 IU/ml. The AST and ALT levels were 18.3 ± 10.5 IU / ml and 14.5 ± 9 IU / ml, respectively. 8.7 % had undergone a liver biopsy; 32% had received antiviral treatment; 37.5 % were candidates for renal transplantation and 65.2 % were followed for Gastroenterology.

In HBV-negative patients, 33.6 % had not been vaccinated; 14.2% had positive anti-HBc. Fourteen different vaccination schedules were used. The immune response stood at 66.4 %. The levels of anti-HBs after vaccination were 10-99 mIU/ml in 29.5 %, 100-999 mIU/ml in 23.9% and equal to or greater than 1000 mIU/ml in 8.4%. More than a half (56.7%) had received a vaccination course; 22.6 %, two cycles; 0.6%, three cycles; and 9.5%, an annual booster. The most likely to achieve an immune response was achieved with four doses of 40 mcg of adjuvanted vaccine (OR 4.9), for the same age and number of revaccination cycles and boosters. Age and dose and adjuvant vaccine usage influenced the immune response and the title of antiHBs reached ($p < 0.05$). 81.1 % of researchers agreed that the questionnaire had helped them to assess the management of HBV infection that performed on their patients.

CONCLUSION: Prevalence of chronic HBV infection in hemodialysis in Spain is low, and so are the rates of immunization against HBV. The vaccination schedules are diverse and have been correlated with the immune response. It would be necessary to formalize the most effective schedule in increasing immunization in these patients.

P0621 REACTIVATION OF HBV INFECTION IN HBSAG NEGATIVE ONCOHAEMATOLOGICAL PATIENTS TREATED WITH CHEMOTHERAPY CONTAINING OR NOT RITUXIMAB

S. Camera[1,*], M. Picardi[2], N. Pugliese[2], G. Maria[1], A. Vitiello[1], M. Raimondo[2], I. Loperto[1], C. Nicola[1], F. Pane[2], F. Morisco[1]
[1]*Department of Clinical Medicine and Surgery, Gastroenterology Unit,*
[2]*Department of Clinical Medicine and Surgery, Haematology Unit, University of Naples "Federico II", Naples, Italy*

INTRODUCTION: Routine prophylaxis for hepatitis B reactivation is recommended for oncohaematological HBsAg+ subjects undergoing immunosuppressive therapy, due the risk of reactivation. In particular, HBV reactivation occurs more frequent in patients receiving Rituximab. Nonetheless,the incidence in those receiving Rituximab-free therapy needs to be better investigated

AIMS & METHODS: This study evaluates the effects of chemotherapy with or without Rituximab in patients HBsAg negative/HBcAb positive with Non-Hodgkin Lymphoma (NHL) or Hodgkin Lymphoma (HL).

123 patients (21 with NHL and 102 with HL) were consecutively enrolled. We evaluated HBV markers, treatment schedule and occurrence of HBV reactivation (reappearance of HBsAg, increase in HBV-DNA at least 1 log in comparison to basal level with or without increase of aminotransferase levels during therapy and 6 months after the end of therapy).

RESULTS: 46 patients (M/F 24/22, median age 49 yrs, range 21-74 yrs), 33 with isolated HBcAb and 13 with HBcAb/HBsAb positivity, were observed. Six/46 were treated with therapeutic schedule containing Rituximab. Five/6 received successfully preemptive therapy with Lamivudine. HBV reactivation was observed in the only patient (HBcAb/HBsAb positive) treated with R-CHOP without Lamivudine prophylaxis. None of the other 40 patients treated with cytotoxic chemotherapy without Rituximab (ABVD-VEBEP) and without receiving preemptive therapy, showed HBV reactivation.

CONCLUSION: HBV reactivation is mainly related to the type of therapy. Our data revealed that patients with ''occult HBV infection'' receiving chemotherapy with Rituximab, in absence of prophylactic therapy, may be at high risk of reactivation. Otherwise, prophylaxis is not mandatory in patients HBcAb positive with or without HbsAb positivity undergoing Rituximab-free schedule. This results suggest that preemptive therapy will be tailored to the cytotoxic chemotherapeutic schedule.

P0622 HEPATITIS B SEROLOGIC MARKERS AFTER 14 YEARS OF UNIVERSAL NEW-BORN VACCINATION

S. Carvalhana[1,2], **R. Pinto**[3], J. Leitão[4], A.P. Silva[5], C. Alves[6], M. Bourbon[6], A. Carvalho[4], **H. Cortez-Pinto**[1,2,*]

Contact E-mail Address: *sofiacarvalhana@msn.com*

INTRODUCTION: The burden of hepatitis B infection around the world is very high. In Portugal, hepatitis B vaccination was part of the National Vaccination Programme, with vaccination of all adolescents, since 1995, extended to all newborns in the year 2000. The aim of the present study was to evaluate how it affected serological markers of hepatitis B in the general population and in high-risk groups.
AIMS & METHODS: Prevalence of HBs Ag was evaluated in a sample of three groups: adult general population (GP): 989 individuals, prison population (PP): 784, and drug-users (DU): 18305. Prevalence of HBsAg, HBsAb, HBcAb, and ALT and AST serum levels were determined in the general population.
RESULTS: Prevalence of HBsAg was GP: 12/989(1.2%); PP: 32/784 (4.1%) and DU: 927/18305 (5.0%). In the GP, the prevalence of HBsAg negative, HBsAb positive with HBcAb negative (suggesting effective previous vaccination) was: 315/989 (31.8%), with mean age: 38.8 years. Furthermore two thirds of the individuals aged less than 30 years had the latter pattern. Prevalence of HBcAb positive was 107/989 (11%): in 29 (2.9%) cases isolated, and in 75 (7.5%) associating with HBsAb positive, the latter suggesting past infection.
CONCLUSION: Prevalence of HBs Ag was higher in the risk populations, although no major differences were found. There is evidence of effective vaccination status in the younger population. Emphasis on continuing universal hepatitis B programmes is of utmost importance.

INTRODUCTION: In recent studies, polymorphisms near the IL28B gene are strongly associated with spontaneous and treatment-induced viral clearance in chronic hepatitis C patients. However, the role of IL28B in the prediction of treatment outcome in chronic hepatitis B (CHB) patients and association with the natural course of CHB is currently debated. This study aimed to determine the relationship between IL-28B polymorphisms and hepatitis activity in CHB.
AIMS & METHODS: 190 treatment-naïve CHB patients were identified and IL28B related SNPs were determined by pyrosequencing method. Active hepatitis in patients without liver cirrhosis was defined as persistent ALT $>$ 2 x upper limit of normal (ULN) for over 3 months or a peak ALT level $>$ 5x ULN. In patients with liver cirrhosis, active hepatitis was defined as persistent ALT$>$ ULN for over 3 months.
RESULTS: 143 patients were enrolled and 41(38%) had active hepatitis. rs12979860 CC and rs8099917 TT were 87%. and the two SNPs were found to be in strong linkage disequilibrium (D'$=1.0$, $r^2=0.9082$). The IL28B SNP rs12979860 minor allele "T" and rs8099917 minor allele "G" were correlated with active hepatitis in patients with HBeAg positve CHB ($p=0.029$). On the contrary, in HBeAg negative CHB there was no relationship between IL28B SNPs and active hepatitis.
CONCLUSION: We could find that host immune response related to IL28B polymorphism considering viral factor like genotype plays an important role in active hepatitis in HBeAg positive CHB patients.

P0624 TREATMENT OF HEPATITIS C IN PRISON IN FRANCE IN 2011-2012: MORE PATIENTS TREATED IN FEWER MEDICAL JAILHOUSE UNITS: RESULTS OF NATIONAL PRACTICE SURVEY

A.J. Remy[1,*] on behalf of UCSA DE FRANCE
[1]*hepatogastroenterology, centre hospitalier, perpignan, France*
Contact E-mail Address: *andre.remy@ch-perpignan.fr*

INTRODUCTION: In France inmates' health care was done by public hospitals since 1994. Access to antiviral treatment was normally equal as people outside. Treatment of hepatitis C was until 2011 dual therapy (peg-interferon and ribavirin); in 2011, two direct antiviral agents (AAD), telaprevir INCIVO* and boceprevir VICTRELIS*, were available in triple therapy. National 2005 study of practices had demonstrated that at time of dual therapy, only 14 % of inmates with hepatitis C were treated. Recent national health institute studies (PRI2DE and PREVACAR) did not allow to answer the question of percentage of inmates treated for hepatitis C. Did arrival of triple therapy increase or decrease patients' percentage treated in prison?
AIMS & METHODS: Our objective was to study in national survey, in retrospective vision (since compassionate use of AAD in January 2011) and prospective vision over 2011 and 2012, number of patients treated by dual therapy and triple therapy in MJU. It was postal and/or mail survey.
RESULTS: On December 31th 2013, 77 MJU over 182 participated and were already analyzed: they took care of 38998 inmates; hepatitis screening was systematically proposed in 100 % of MJU; 30290 serology C were annually realized in 2011 and 31580 in 2012; 2012 rate was 4.5 % positivity (677 patients). Followed patients were 1579 in 2011 and 1717 in 2012; 49 % of MJU had regular hepatology consultation (one per month to two per week) and 33 % regular infectious diseases consultation; to evaluate liver fibrosis 227 FIBROSCAN* and 511 FIBROTEST / FIBROMETRE were realized in 2012 but only 2 liver biopsy. In 2011, 301 patients were treated (19 % of patients with serology C positive) and in 2012, 497 patients (29 %). Triple therapy constituted 12 % of treatment in 2011 and 39 % in 2012 (telaprevir 80/72 %, boceprevir 20/28 % in 2011/2012); 42 % of the MJU introduced no treatment in 2011 (77 % any triple therapy) and 56 % in 2012 (66 % any triple therapy).
CONCLUSION: These results allowed following conclusions: 1/ frequent positive patients VHC in jailhouses, 2/ good screening and diagnosis and using widely not invasive methods of fibrosis 3/ but very different practices for hepatitis treatment between few MJU treating a lot of patients and a lot of MJU treating none. Compared with national study of 2005, percentage of treated patients was doubled but percentage of MJU involved decreases in 45 %. A score of care of people infected by hepatitis C will be calculated from answers to items screening, specialized consultation, treatments 2011 and treatments 2012.

INTRODUCTION: Interferon-containing protease inhibitor regimens have been associated with a high rate of serious adverse events (AEs) in patients with cirrhosis.[1] We report the safety of the 3 direct-acting antiviral (3D) regimen of ABT-450 (identified by AbbVie and Enanta) co-dosed with ritonavir (r), ombitasvir (formerly ABT-267) and dasabuvir (formerly ABT-333) with ribavirin (RBV) in the treatment of 380 HCV genotype 1-infected patients with cirrhosis.
AIMS & METHODS: Patients were randomized to receive the 3D+RBV regimen for 12 (N$=208$) or 24 weeks (N$=172$). Key eligibility criteria included: Child-Pugh A cirrhosis, platelet count $\geq$60.000 cells/mm3, serum albumin $\geq$2.8 g/dL, and total bilirubin <3 mg/dL. Treatment-emergent AEs from the time of study drug administration until 30 days after last dose for all patients who received $\geq$1 dose of study drug are reported.
RESULTS: The percentage of patients experiencing any AE, severe, or serious AEs were similar in both arms. AEs were mostly mild or moderate in severity. The most common AEs in the 12- and 24-wk arms respectively, were fatigue (32.7% vs. 46.5%), headache (27.9% vs. 30.8%), and nausea (17.8% vs. 20.3%). Four (1.1%) patients experienced AEs consistent with hepatic decompensation but were considered unrelated to study drugs. Five of 380 (1.3%) patients experienced serious AEs that were assessed by the investigator to have reasonable possibility of being related to the 3D regimen. All patients who modified RBV dose for any reason, 4 patients who received erythropoietin, and 2 patients who received a transfusion all achieved SVR12.

Treatment-Emergent AEs, n (%)	12-Wk 3D+RBV (N$=208$)	24-Wk 3D+RBV (N$=172$)
Any AE	191 (91.8)	156 (90.7)
Severe AE	14 (6.7)	13 (7.6)
Serious AE	13 (6.3)	8 (4.7)
AE Leading to Study Discontinuation	4 (1.9)	4 (2.3)
AE Leading to RBV Dose Reduction	17 (8.2)	22 (12.8)
Death	0[a]	0

[a]One patient died due to non-treatment emergent AEs that began 80 days after the last dose of study drug.

CONCLUSION: The 3D+RBV regimens were generally well tolerated, with no clinically significant differences in safety profiles based on treatment duration. AEs reported in this study of 380 patients with cirrhosis were generally consistent with those demonstrated for the 3D+RBV regimen in previous studies of patients without cirrhosis.

P0626 STUDY ON IL28B SNP RS12979860 AND SNP RS8099917 GENOTYPING AND TREATMENT RESPONSE WITH PEGYLATED INTERFERON AND RIBAVIRIN IN EGYPTIAN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION

INTRODUCTION: Hepatitis C virus (HCV) infection is a common universal problem especially in the Arab world. A single nucleotide polymorphism near the IL28B gene on chromosome 19 coding for interferon-lambda-3 is associated with an approximately 2-fold difference in SVR rates among patients of different ethnicities.

AIMS & METHODS: The aim was to assess the value of IL28B SNP rs12979860 and SNP rs8099917 as a predictor of virological response to Pegylated interferon plus ribavirin in treatment of Egyptian patients with chronic hepatitis C virus infection. Our study included 604 HCV infected Egyptian patients with genotype 4. All patients received pegylated Interferon 2a and 2b plus ribavirin. We divided our cases according to their response to treatment into two groups: group I (344 patients) responded to treatment and group II (260) non responder patients. Analysis of both IL28 rs8099917 and IL28rs12979860 by real time PCR technique were done to all patients.

RESULTS: TT genotype of IL28 rs8099917 was associated with a higher response rate to treatment than other genotypes. TT genotype was present in 53.2% of responders Vs 17.7% of non responders ($P<0.001$) while GG genotype was present in 6.4% of responders Vs 37.7% of non responders ($P<0.001$). T allele was present in 73.4% of responders Vs 40 % in non responders while G allele were present in 26.6% of respnders Vs 60% in non responders ($P<0.001$). The response rate was lower in patients with T allele compared to those with C allele of IL28 rs12979860 and CC genotype were present in 47.4% of responders Vs 5% of non responders and TT genotype were present in 6.1% of responders Vs 33.1 % of non responders ($P<0.001$). The C allele was present in 70.6% of responders Vs 36% of non responders while T allele was present in 29.4% of responders Vs 64% of non responders ($P < 0.001$).

CONCLUSION: *IL28B* polymorphisms are strong predictors of virological response in chronic hepatitis C with genotype 4 and analysis of IL-28B genotype might be used to guide treatment for these patients.

INTRODUCTION: The long-term impact of hepatitis C virus (HCV) infection on kidney allograft survival remains controversial. Some studies found a significant deleterious effect of HCV infection on allograft survival and also higher mortality in this group of patients.

AIMS & METHODS: In this retrospective, single-center study, we aimed to compare the differences in kidney allograft survival over a long-term follow-up period between non-infected vs infected patients. Study population (HCV infected patients) was selected from a kidney transplant center database (1985 - 2013) and compared to a random sample extracted from the same database. Groups were compared using Chi-square test, student-T test, Mann-Whitney U test and survival methods (Kaplan-Meier) when appropriate. Statistical analyses were carried using SPSS 20.0 IBM@ (Chicago, IL, United States).

RESULTS: We identified 34 patients with HCV infection and the random sample population was 80 patients. The mean follow-up period, for both groups, was 132 months (range: 67-290). There was no statistical differences between groups regarding age, gender, ethnic origin, previous dialytic support (or kind of dialytic support) or primary kidney disease. HCV infected patients remained longer on dialysis waiting-time period (median: 60 months; $P^{25/75}$: 48/132) and were younger at transplantation timing (37±12 y/o). Imunossupressive regimens using calcineurin inhibitors (75% vs 40%; $p < 0.05$) and azathioprine (44% vs 16%; $p< 0.05$) were more frequently applied on HCV infected patients. On the other hand, there was a significant lesser use of tacrolimus (28% vs 55%; $p < 0.05$). Regarding hospitalization (69% vs 65%), septic complications (35% vs 43%), primary allograft disfunction (31% vs 26%), new-onset diabetes after transplant (4% vs 13%) or malignancy, there were no significant differences between groups. A higher frequency of *major* cardiovascular events was detected on HCV infected group (32% vs 9%; $p < 0.05$). The global rate of allograft loss was significantly higher among HCV group (50% vs 20%; $p < 0.05$). The 1, 5 and 10 year-allograft survival rate in HCV group was 94.1%, 78.1% and 66.9%; for the sample group: 94.9%, 89.1% and 80.4%. Using a survival model (Kaplan-Meier), there was no statistical difference (log rank test: $p=0.154$) in allograft survival between HCV positive and negative patients. In order to isolate the effect of HCV on allograft survival we used a Cox regression model, showing that HCV infection, althought negatively impacted on allograft survival (HR: 1.657; IC95%: 0.817-3.364; $p=0.162$), that effect had no statistical significance.

CONCLUSION: Our findings suggest that, whilst HCV may play an ominous effect on allograft survival of renal transplants, its global effect is minor. Hence, in light of our findings, renal transplantation in HCV infected patients seem to foretell similar allograft survival as that in general population.

P0628 ASSOCIATIONS OF REACTIVE OXYGEN SPECIES AND IRON METABOLISMS WITH DEVELOPMENT OF HEPATOCELLULAR CARCINOMA AFTER PEGYLATED INTERFERON THERAPY IN JAPANESE PATIENTS WITH CHRONIC HEPATITIS C

S. Nanba[1,*], F. Ikeda[1], H. Seki[1], K. Yamamoto[1]
[1]*Department of Gastroenterology and Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, okayama, Japan*

INTRODUCTION: Chronic hepatitis C (CHC) may induce reactive oxygen species (ROS) and excessive iron deposition in the liver.

AIMS & METHODS: The present study was planned to clarify the impact of surplus ROS and iron deposition on virological response to the therapy with pegylated interferon plus ribavirin and development of hepatocellular carcinoma (HCC) thereafter for CHC patients. A total of 210 CHC patients who received combination therapy of pegylated interferon and ribavirin are enrolled. Liver histology was evaluated for all the patients before the therapy. Hepatic ROS was assessed with immunohistochemical staining of 8-hydroxy-2-deoxyguanosine (8-OHdG). Hepatic iron deposition was assessed by Prussian blue staining. Factors associated with hepatic 8-OHdG levels were analyzed by stepwise logistic regression analysis. Proportional hazard models were utilized to identify patient characteristics associated with HCC development after interferon therapy.

RESULTS: Severe hepatic iron deposition was significantly associated with high level of 8OHdG in stepwise logistic regression analysis ($p <0.0001$). Interferon therapy resulted in sustained virological responses (SVR) in 104 patients. Hepatic 8OHdG was significantly associated with SVR in univariate analysis for the patients with HCV genotype 1, without statistical significance in multivariate analysis. Hepatic iron deposition showed no significant associations with SVR for the patients with HCV genotypes 1 or 2. During the follow-up after interferon therapy (median period of 4.6 year), HCC development was observed in 14 patients (16%). Heavy alcohol drinking, low platelet counts, non-SVR and high levels of hepatic 8OHdG had significant associations with HCC development ($p=0.0276$, 0.0102, 0.0067, and 0.0003, respectively).

CONCLUSION: Hepatic 8OHdG level was useful in prediction of HCC development after interferon therapy for CHC patients.

INTRODUCTION: The burden of hepatitis B and C infections around the world is high. With the upcoming very effective treatments for hepatitis C and the rather effective treatments for hepatitis B, there is urge to identify these patients and estimate their prevalence in each country.

AIMS & METHODS: Hepatitis B and C prevalence was evaluated in a sample of three groups: adult general population (GP): 989 individuals, prison population (PP): 784, and drug-users (DU): 19832. HBsAg, HBsAb, HBcAb, anti-HCV (Cobas, Roche), ALT and AST were done. In the general population, anti-HCV positive individuals were tested for HCV PCR.

RESULTS: Prevalence of Anti-HCV was: GP: 5/989 (0.5%); PP: 147/784 (18.8%) and DU: 11862/19839 (59.8%). Prevalence of HBsAg was GP: 12/989(1.2%); PP: 32/784 (4.1%) and DU: 927/18305 (5.0%). Interestingly, among individuals that were anti- HCV positive in the GP, only 20% were HCV PCR positive. In Portugal, adult GP is estimated about 8 600 000

individuals, PP are about 14 000, and DU are about 30 000. So, according to the percentages found, it is expected that we have about 69 000 individuals with anti-HCV, and it is expected that 105 000 are HBs Ag positive. It is possible that the prevalence of HCV PCR positive individuals is much lower in the general asymptomatic population. Even assuming a 50% prevalence of HCV RNA positive among anti-HCV positive patients, it would result in about 34 500 individuals with active infection and potentially needing treatment. Prevalence of elevated aminotransferases among patients with either hepatitis B or C in the GP was not different from those with negative markers (17.6% vs. 8.1%, p = n.s.).
CONCLUSION: Hepatitis C showed high disparity in prevalence according to the risk groups, with low prevalence on the general population and very high in risk groups. Differently, the prevalence of hepatitis B showed a more homogeneous pattern of distribution. These results suggest that screening for hepatitis C in the general population is not cost-effective, but risk groups such as drug-users or people in prisons should be regularly screened.

INTRODUCTION: Despite great progress in the diagnosis and management of hepatocellular carcinoma (HCC), the molecular mechanisms underlying the tumor development and progression remain poorly understood, overall limiting the patients' outcome. ERK5 is a member of the MAPK family and has been implicated in fundamental biologic processes relevant for tumor development.
AIMS & METHODS: The aim of this study is to evaluate the relevance of this pathway ERK5 in HCC biology.
Huh-7 and HepG2 were cultured by standard methods. ERK5 was silenced by siRNA transfection or with shRNA and lentiviral vectors. The specific ERK5 inhibitor XMD8-92 was also used. *In vivo* development of HCC was evaluated using the Huh-7 xenograft model in athymic nude mice.
RESULTS: *In vitro* experiments demonstrated that ERK5 silencing or specific inhibition, using an inhibitor called XMD8-92, causes growth arrest of HCC cells, affecting in particular the G1/S transition. This phenotype was associated with an increase in p27Kip protein expression a critical negative regulator of cell cycle progression typically expressed in G0/G1 arrested cells. Additionaly knock down of ERK5 activity induces a marked inhibition of c-Rel expression, a member of NFkβ family required for the normal proliferative regeneration of hepatocytes. In a mouse model of HCC xenograft, administration of XMD8-92 significantly decreased tumor volume This reduction is associated with a reduced proliferation, as observed by Brdu incorporation assay. Moreover XMD8-92-treated xenografts the expression of c-Jun, a proto-oncogene essential for cell proliferation, was reduced compared to control samples. Finally as already observed *in vitro*, XMD8-92 treatment induced a strong decrease of c-Rel transcription factor expression.
CONCLUSION: This study disclose a strong regulation of cell proliferation in HCC, affecting the biological activity of different oncogenic targets. Affecting this pathway could be considered a novel and effective approach for the treatment of HCC.

INTRODUCTION: Heat shock factor 1 (HSF1), is the master regulator of genes encoding molecular chaperones and is involved in cellular processes such as stress response, cell differentiation and carcinogenesis. Recent studies identified a HSF1-regulated transcriptional program specific to high malignancy and distinct from the classical HSF1-induced heat shock response. We investigated the expression of HSF1 during tumour formation and after Radiofrequency Ablation (RFA) in vivo. In vitro experiments were employed to mimic radiofrequency ablation and to analyse the effect of shRNA-HSF1-nanoliposomes as a possible adjuvant thermo-sensitizing therapy in combination with radiofrequency ablation (RFA) in metastatic liver cancer.
AIMS & METHODS: Colon carcinoma CT26 cells, expressing HSF1, HSP70 and HSP90, were used to assess shRNA-HSF1-nanoliposomal uptake, toxicity/efficiency by employing immunofluorescence, Q-PCR and protein analysis. In vitro sub-lethal heat experiments were performed to mimic radiofrequency ablation, and this by using different time points/temperatures. An orthotopic murine model of coloncarcinoma cancer - liver metastasis was used to analyse HSF1 expression during tumour formation. Radiofrequency ablation (RFA) in small animals was optimized to investigate the HSF1-induced-and related signalling pathways in the treatment of liver metastasis.
RESULTS: shRNA-HSF1-nanoliposomes were taken up by 99% of cells without inducing cytotoxicity. Sub-lethal heat treatment of 45 and 50 degrees Celsius induced p-ERK, p-AKT and HSF1-related proteins at different timepoints investigated and this coincided with a nuclear to cytosolic shift of HSF1, HSP70/90, AKT and ERK. Apoptosis was only significantly induced after 10 days post-heat treatment. In vivo, tumours highly expressed HSF1, HSP70/90, AURBK and p-ERK and p-AKT. Radiofrequency-ablated tumours showed an increase in HSF1 and HSP70/90 protein expression after 6 and 10 days post-RFA, suggesting the involvement of HSF1 during the process of tumour recurrence.
CONCLUSION: This study demonstrates that HSF1 is highly expressed in CRC liver metastasis and suggest its possible involvement in tumour recurrence after employing radiofrequency ablation.

INTRODUCTION: Sorafenib is a multikinase inhibitor used to treat patients with hepatocellular carcinoma (HCC). The main obstacle to efficient cancer treatment with this agent is the acquired drug resistance that develops in many patients. We aimed to determine whether sorafenib-treated hepatoma cells release soluble factors that cause sorafenib resistance.
AIMS & METHODS: HepG2 cells were incubated with sorafenib for 24 hours. The culture medium was rinsed, the cells were maintained for 24 more hours, and cytokines released into the medium were analysed by enzyme-linked immunosorbent assay. The culture medium was transferred to the newly seeded HepG2 cells, which were then maintained with a different concentration of sorafenib for 2 to 48 hours. Cell growth and apoptosis in sorafenib-treated cells were analysed by MTT and annexin V assay. Cell signalling was analysed by western blotting.
RESULTS: The level of basic fibroblast growth factor (FGF-2) in the culture medium of sorafenib-treated cells was increased to 1.8-fold that of the controls (14.3 vs. 7.7 pg/mL, respectively; $p < 0.05$), while other growth factors such as transforming growth factor beta and insulin growth factor were unchanged. When the cells were maintained in the culture medium of sorafenib-treated cells, the cell numbers were increased by 1.35-fold ($p < 0.05$), and the levels of phosphorylated Akt, extracellular signal-regulated kinases 1/2, and nuclear factor kappa B were increased by 2.5- to 4.0-fold. The annexin V assay showed that the effect of sorafenib on cell apoptosis was inhibited in the cells maintained in the medium of sorafenib-treated cells (apoptotic rates after sorafenib treatment in control cells vs. cells maintained in the medium of sorafenib-treated cells: 76.5% vs. 17.7%, respectively; $p < 0.05$), which was rescued by pretreatment with the FGF receptor inhibitor PD173074.
CONCLUSION: FGF-2 might be an essential mediator of acquired resistance to sorafenib. Combination treatment with sorafenib and FGF-2 inhibitor may be effectively used to treat patients with HCC in the future.

P0633 HEPATOMA CELLS CAN BE REVERTED TO ORIGINAL NORMAL CELLS BY SINGLE SMALL RNA

N. Miura[1,*], S. Tsuno[1], J. Hasegawa[1]
[1]*Pharmacotherapeutics, TOTTORI UNIV., Yonago, Japan*
Contact E-mail Address: *mnmiura@med.tottori-u.ac.jp*

INTRODUCTION: The human ncRNA gene *RGM249* regulates the extent of differentiation of undifferentiated cancer cells. Because shRNA for *RGM249* induced the upregulation of hsa-miR-520d that converted 293FT cells to hiPSCs, we attempted to perform the functional analysis to examine the anti-cancer effects of it on an undifferentiated hepatoma cell.
AIMS & METHODS: To identify the crucial factors underlying this process, we investigated the effects of lentivirally inducing miR-520d expression in HLF cells (520d-HLF) *in vitro*. To clarify the underlying mechanism, we performed gene expression analysis, cell cycle analysis, cell sorting, metabolomic analysis, migration assay and DNA methylation assay in transfectants. Subsequently, we evaluated tumor formation in a xenograft model using 520d-HLF.
RESULTS: 520d-HLF cells or the cells sorted by both alkaline phosphatase and GFP were Oct4 and Nanog positive within 24 h, showed p53 upregulation and hTERT downregulation, and mostly lost their migration abilities. Cell cycle analysis revealed homogeneous growth and metabolomic analysis showed that the TCA cycle was not elevated. Methylation level in transfectants decreased to the similar level to that in hiPSC. After lentiviral infection, the cells were intraperitoneally injected into mice, resulting in benign teratomas (6%), the absence of tumors (87%) or differentiation into benign liver tissues (7%) at the injection site after 1 month.
CONCLUSION: We are the first to demonstrate the loss of malignant properties in cancer cells *in vivo* through the expression of a single microRNA (miRNA). This miRNA successfully converted 293FT and hepatoma cells to hiPSC-like

cells partly or mainly via both stemness- and demethylation-mediated process. The regulation of malignancy by miR-520d appears to be through the conversion of cancer cells to normal stem cells, maintaining p53 upregulation.

P0634 MATRINE INDUCED MITOCHONDRIAL-DEPENDENT APOPTOSIS AND AUTOPHAGY IN HEPATOMA CELLS

S. Yao[1,*] on behalf of Li Wang, Chun Gao
[1]*Department of Gastroenterology, China-Japan Friendship Hospital, Beijing, China*
Contact E-mail Address: *shukyao@126.com*

INTRODUCTION: Matrine is an active component monomer that is extracted from Sophora flavescens. Our previous study found that matrine could induce cell apoptosis, and dramatically increase the generation of autophagosomes in hepatocellular carcinoma cell lines. Autophagy, a self-defense mechanism, has been found to be associated with drug resistance in hepatocellular carcinoma (HCC) therapy. However, the effect and exact mechanisms of matrine-induced autophagy and apoptosis in therapy of HCC are still not very clear.
AIMS & METHODS: Our study was aimed to investigate the role and related mechanisms of matrine-induced apoptosis and autophagy in hepatoma cells HepG2 and Bel_{7402}.
Cell apoptosis was detected by flow cytometry analysis (Annexin V–FITC/PI double-staining assay), JC-1 probe, the activity and activating cleavages of caspase-3, -8, and -9. MTT assay and colony forming assay were used to assess the effect of matrine on viability and proliferation of HCC cells. Autophagic flux in HCC cells was analyzed using the expression of LC3BI/II and p62/SQSTM1, GFP-LC3 transfection and LysoTracker staining, and transmission electron microscopy. Moreover, regarding to the associated mechanisms, Genechip technique was used to find matrine-induced autophagic related gene.
RESULTS: 1. Matrine at different concentrations could inhibit the viability and proliferation of HepG2 and Bel_{7402} cells, and induce apoptosis in a concentration-dependent manner ($p < 0.05$).
2. Matrine could induce the decrease of mitochondrial membrane potential (MMP) and up-regulation of cytochrome-c expression. After treated with matrine, the expression of pro-caspase decreased and the cleaved caspase-8,-9,-3 increased.
3. The turnover of LC3BI/IIratio, the increasing number of GFP-LC3 positive cells ($P < 0.05$) and the formation of phagophores, autophagosomes, autolysosomes observed by transmission electron microscopy, implied that autophagy was induced in matrine-treated HCC cells.
4. Genechip results showed that the level of lamp-1 elevated at 7.4 times. The result was further proved by the detection of Realtime PCR and western blot. Immunofluorescence results showed that Lamp-1 colocalized with lysosomes in HepG2 cells, and localized at the autolysosomes after autophagy was induced.
CONCLUSION: 1. Matrine has the inhibitory effect of HCC celllines HepG2 and Bel7402,and could induce apoptotic cell death via mitochondrial mediated caspase dependent way.
2. Matrine could induce autophagy in HepG2 and Bel_{7402} cells, and lamp-1 is related to the formation of autolysosomes, and possibly involved in matrine-induced autophagy.

INTRODUCTION: Hepatic oval cells are unique bipotential progenitor cells that differentiate into both bile duct cells and hepatocytes. Although it has been widely recognised that oval cell-derived hepatocytes are possible progenitors of hepatocellular carcinoma (HCC), the functional properties of these cells are unclear.
AIMS & METHODS: To investigate the protein expression profile in oval cell-derived hepatocytes, we compared proteomes from lysates from normal hepatocytes and oval cell-derived hepatocytes using two-dimensional (2D) gel sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and matrix-assisted laser desorption ionization time-of-flight tandem mass spectrometry (MALDI-TOF/TOF MS). Hepatocytes were isolated from normal rat livers by the collagenase perfusion method, while oval cell-derived hepatocytes were obtained from cultured rat oval WB-F344 cells or rat littermates treated with 2-acetamidofluorene plus partial hepatectomy. To verify the results of 2D SDS-PAGE, the protein expression levels of ferritin light chain (FLC) in human liver tissue samples (33 patients without HCC and 28 with HCC) were examined by western blotting and immunohistochemical analysis.
RESULTS: Two-dimensional SDS-PAGE showed 11 major protein spots that changed in abundance between normal hepatocytes and oval cell-derived hepatocytes. Three of these differently expressed protein spots were analysed by MALDI-TOF/TOF MS. The level of FLC expression was significantly higher in oval cell-derived hepatocytes (7- to 10-fold, $p < 0.05$). Western blotting of human liver tissue samples showed that the levels of FLC expression were 4- to 8-fold higher in patients with than without HCC. Immunohistochemical analysis showed that hepatocellular FLC was strongly expressed in 21 of 28 patients with HCC, while strong expression of FLC was detected in 12 of 33 patients without HCC ($p < 0.05$).
CONCLUSION: Several proteins, including FLC, are distinctly overexpressed in oval cell-derived hepatocytes. FLC expression is increased in human liver tissues adjacent to HCC, indicating that FLC might be a useful biomarker for identification of the development of HCC.

P0636 RNA BINDING PROTEIN NOVA1 PROMOTES TUMOR GROWTH IN VIVO AND ITS POTENTIAL MECHANISM AS AN ONCOGENE MAY DUE TO ITS INTERACTION WITH GABAARΓ2

Y. Zhang[1,*], T. Liu[1], X. Shen[1]
[1]*Gastroenterology, Zhongshan Hospital affiliated to Fudan University, Shanghai, China*
Contact E-mail Address: *zyian2020@gmail.com*

INTRODUCTION: Our previous study discovered the expression of Nova1 in hepatocellular carcinoma and proved that high expression of Nova1 is associated with poor prognosis of HCC. Recent research proved that Nova1 regulates the alternative splicing of GABAA receptor $\gamma 2$(GABAAR$\gamma 2$) pre-mRNA in central nervous system. Moreover, the theory that the GABAergic system is involved in HCC progression has also been illustrated before. However, the expression of GABAAR$\gamma 2$ and its relations with Nova1 in hepatocellular carcinoma remain elusive.
AIMS & METHODS: The aim of this study is to explore the potential mechanism of Nova1 as an oncogene for HCC. To make clear the existence of interactions between Nova1 and GABAAR$\gamma 2$ in HCC and their relations with tumorigenesis. Immunohistochemical staining were used to identify the protein expression level of GABAAR$\gamma 2$ in HCC and its paired non-tumor tissue. Its relations with clinicopathologic features were calculated. The HCC tumor xenografts animal models were established. The tumor size was estimated and then removed for western blot analysis. For double immunofluorescence staining, the slides were incubated with DyLight 448 Affinipure Rabbit Anti-Goat IgG and DyLight 594 Affinipure Goat Anti-Rabbit IgG and analyzed via the microscope. The cell-lysated proteins were precleared with 2 μg anti-Nova1 or anti-GABA AR$\gamma 2$ antibodies and then incubated with protein G-agarose and antibodies. The precipitates were analyzed by western blotting.
RESULTS: The expression level of $GABA_AR\gamma 2$ positive cell in the cancerous tissue was lower than para-cancerous tissues. Univariate analysis and multivariate Cox analysis showed that intratumoral Nova1 was significantly associated with OS and TTR. Patients with higher intratumoral $GABA_AR\gamma 2$ had longer OS rate and TTR time. In vivo test, our results showed that, the volume of the xenotrans in the over-expression group surpassed that in the control group, and the volume of the xenotrans in the knockdown group far smaller than its control group. Immunohistochemical staining and Western blot showed down-regulation of Nova1 accompanied with increased expression of GABAAR$\gamma 2$ and GABA. Up-regulation of Nova1 resulted decreased expression of $GABA_AR\gamma 2$ and GABA. Furthermore, the localizations of GABA and $GABA_AR\gamma 2$ were visualized under microscopy. The SMMC-7721 cells expressing the GABA and $GABA_AR\gamma 2$ protein exhibited fluorenscence concentrated in the cytoplasm, and also in the nucleus. Co-localization of Nova1 and $GABA_AR\gamma 2$ proteins in the cytoplasm was evidenced by overlapping fluorescence signals in Huh7 cell. Co-IP results showed that Nova1 was easily detected through anti-Nova1 antibody in the $GABA_AR\gamma 2$-immunoprecipitates. Reciprocal co-IP experiments using anti-Nova1 antibody indicated the existence of $GABA_AR\gamma 2$, as confirmed by immunoblotting.
CONCLUSION: Nova1 not only interacts with $GABA_AR\gamma 2$ in CNS but also in the peripheral HCC tumor tissue. It is hypothesized that ectopic expression of Nova1 may down regulate the expression of GABAAR$\gamma 2$, and decrease the influx of cl- and tumor cells membrane potential diffences, thus leading to the proliferation of HCC.

P0637 EPIGENETIC SILENCING OF THE TUMOR SUPPRESSOR MICRORNA-122 DURING HEPATOCARCINOGENESIS FROM NONALCOHOLIC STEATOHEPATITIS

Y. Saito[1,*], Y. Takaki[1], K. Toshimitsu[1], T. Muramatsu[1], M. Kimura[1], H. Suzuki[2], K. Sugiyama[2], T. Kanai[2], **H. Saito**[1]
[1]*Division of Pharmacotherapeutics, Keio University Faculty of Pharmacy,* [2]*Division of Gastroenterology, Keio University School of Medicine, Tokyo, Japan*

INTRODUCTION: Nonalcoholic steatohepatitis (NASH) has emerged as a common cause of chronic liver disease and virus-independent hepatocellular carcinoma (HCC) in patients with obesity, diabetes and metabolic syndrome. However, little is known about the pathogenesis of HCC derived from NASH.
AIMS & METHODS: To reveal the molecular mechanism underlying hepatocarcinogenesis from NASH, microRNA (miRNA) expression profiles were analyzed. HCCs and non-tumor liver tissues from STAM mice, an animal model developing HCC from NASH, and tissue specimens obtained from primary HCC patients were used in this study. MiRNA expression profiles were analyzed by microarray and quantitative RT-PCR. To investigate the regulatory mechanism of miRNAs, DNA methylation assay and chromatin immunoprecipitation (ChIP) assay were performed in liver cancer cells treated with the DNA methylation inhibitor 5-aza-2'-deoxycytidine (5-Aza-CdR).
RESULTS: Histopathological images of the liver in STAM mice at the ages of 6, 8, 12, 18 weeks showed findings compatible with fatty liver, NASH, liver cirrhosis (LC), and HCC, respectively. *MiR-122* expression in non-tumor LC at the age of 18 weeks was significantly lower than that in LC at the age of 12 weeks. *MiR-122* expression was further decreased in HCCs compared with non-tumor LC at

the age of 18 weeks. *MiR-122* expression was also decreased in clinical HCC samples. Treatment of liver cancer cells with 5-Aza-CdR reactivated *miR-122* expression with decreased cell proliferation and down-regulation of its target, CyclinG1. The results of ChIP assay indicated that 5-Aza-CdR activated *miR-122* expression by enhancing binding of peroxisome proliferator activated receptor-gamma (PPAR-γ) to the *miR-122* promoter region.
CONCLUSION: These findings indicate that epigenetic silencing of the tumor suppressor *miR-122* plays a critical role during hepatocarcinogenesis from NASH. DNA methylation inhibitors such as 5-Aza-CdR may have clinical promise for the prevention and treatment of HCC derived from NASH.

P0639 PLASMA CYCLASE-ASSOCIATED PROTEIN 2 IS A NOVEL BIOMARKER IN EARLY STAGE AND ALPHA-FETOPROTEIN NEGATIVE HEPATOCELLULAR CARCINOMA PATIENTS

M. Chen[1], **Y. Yang**[1,*]
[1]*Department of Gastroenterology and Hepatology, People's Hospital of Zhengzhou University, Zhengzhou, China*

INTRODUCTION: Hepatocellular carcinoma (HCC) is the third leading cause of cancer related deaths worldwide, early detection of HCC is critical to monitor disease progression, selection of therapeutic options and post-surgery surveillance. Alpha-fetoprotein (AFP) is traditionally an indispensible marker for the diagnosis of HCC, since 33.3% of small HCC patients are AFP negative, it is crucial to discover new sensitive marker to compensate the negative AFP in HCC diagnosis and surveillance. Cyclase-associated protein 2 (CAP2) has recently been proposed to be a candidate biomarker for detection of early HCC.
AIMS & METHODS: We aim to evaluate the sensitivity and specificity of CAP2 as a biomarker for HCC patients with special attention to those at early stage and AFP negative. The CAP2 and AFP plasma levels were analyzed by enzyme-linked-immunosorbent assay in 86 HCC, 59 cirrhotic patients, and 30 normal individuals.
RESULTS: The results showed that both CAP2 and AFP plasma levels in HCC patients were significantly elevated when compared to cirrhosis. CAP2 level correlates well with HCC patient's histological grade, clinical stage and tumor size; but not with patient's age, gender, hepatitis B virus infection status and plasma AFP level. CAP2 had better sensitivity (82.6%) as compared to AFP (59.3%) alone for general HCC patients, and in early stage of HCC patients (78.6% vs 40.4%). In addition, CAP2 is able to complementary to AFP to predict 82.9% of HCC in AFP negative patients.
CONCLUSION: We concluded that CAP2 is a promising biomarker for the prediction of HCC in both AFP negative and early stages of HCC patients.

P0640 USEFULNESS OF CONTRAST-ENHANCED SONOGRAPHY (CEUS) IN THE SURVIVAL OF PATIENTS WITH HEPATOCELLULAR CARCINOMA (HCCC) SUBMITTED TO NON-SURGICAL TREATMENTS

F. Giangregorio[1,*], R. Solimando[1], G. Prati[1], G. Marinone[1], M.D. Stasi[1], G. Comparato[1], G. Aragona[1], F. Fornari[1]
[1]*Gastroenterology Unit, Guglielmo da Saliceto Hospital, Piacenza, Italy, Piacenza, Italy*
Contact E-mail Address: *f.giangregorio@alice.it*

INTRODUCTION: CEUS is an ultrasound technique with a good diagnostic agreement with spiral CT in the evaluation of efficacy of non-surgical treatments of HCC. The early evaluation of these treatments with CEUS may allow to obtain a more complete necrosis of the tumoural nodules.
AIMS & METHODS: We evaluated if CEUS is able to affect the outcome of these patients. 181 cirrhotic with HCC (M/F:112/69; mean age 71 yrs; Child A/B: 151/30), treated from 1/1999 to 12/2012 with non-surgical treatments for unresectable lesions: 116 with RFTA; 44 with combined treatment of RFTA and TACE and 21 with PEI; solitary nodule:132 pts; 2-3 hcc:32; multinodular HCC:17 cases. All patients underwent to spiral CT one month after the procedure; the first 66 patients (treated before January 2002), didn't perform CEUS, (group-A); 115 patients were submitted to CEUS (after January 2002) 24 hours after the treatments (group-B). We correlated the following variables with the survival (S) and the disease-free-survival (DFS): number and diameter of HCCs; AFP values; type of treatment; aetiology and class of Child; the early evaluation of the treatment with CEUS. Statistics was performed with chi-square and Kaplan-Meyer curves (SPSS release-18)
RESULTS: Mean follow-up of 181 pts: 52 months (group-A: 41,4; group-B: 60,2). During the follow-up 52/66(78,8%) pts in group-A and 49/115(42,6%) pts in group-B died. Recurrence was found: group-A:45/56(80.3%) pts, group-B:73/115 (63.47%) pts. The patterns of recurrence were: new lesions away from the treated nodules: group-A: 23 cases; group-B: 47 cases; local tumour regrowth: group-A: 22 pts; group-B:26 pts. At multivariate analysis the number and diameter of the nodules, sex, and type of the treatment weren't statistically correlated with S and DFS. Value of AFP and Child class were correlated with S (S:p = 0.001), the early evaluation of the efficacy of the treatment with CEUS and the association CEUS-AFP were statistically correlated (CEUS: DFS: p = 0.042);(CEUS and AFP: DFS: p = 0.036)
CONCLUSION: The early evaluation of the efficacy of the non-surgical treatments of HCC with CEUS lets to obtain a more complete necrosis of the tumour and to reduce the recurrence for local regrowth of the HCC achieving a higher percentage of disease-free survival

Contact E-mail Address: *dr.taiwan@yahoo.com.tw*

INTRODUCTION: Radiofrequency ablation (RFA) is the main minimal-invasive curative therapy for hepatocellular carcinoma (HCC). However, the recurrence rate remains unsatisfactory.
AIMS & METHODS: We aim to investigate the role of cumulative operator volume on HCC recurrence after RFA. We conducted a retrospective cohort study based on Taiwan's National Health Institute Research Database (NHIRD). We identified 52,096 patients with newly diagnosed HCC between 2004 and 2011. Among them, 5,890 received radiofrequency ablation (RFA) as their first therapy for HCC. Patients were categorized into five quintiles according the physicians experience (RFA volume). Patients in the lowest and highest RFA volume quintiles were 1:1 matched by propensity score. Cumulative incidences of HCC recurrence was analyzed.
RESULTS: Patients in the highest RFA volume quintile had significantly lower 5-year HCC recurrence cumulative incidence (65.8%; 95% CI: 59.5-72.1%) compared to the risk for lowest RFA volume quintile (71.4%; 95% CI: 66.2-76.5%) ($P < 0.05$). On multivariate analyses, the highest RFA volume was an independent protective factor for HCC recurrence (HR = 0.80; 95% CI: 0.67-0.97). Multivarate stratified analyses confirmed the association between higher RFA volume and lower HCC recurrence risk in nearly all subgroups.
CONCLUSION: More RFA experience was associated with reduced risk of HCC recurrence.

P0642 INCIDENTAL HEPATOCELLULAR CARCINOMA: RISK FACTORS AND LONG-TERM OUTCOME AFTER LIVER TRANSPLANTATION

R. Senkerikova[1], S. Frankova[1], J. Sperl[1], M. Oliverius[2], E. Kieslichova[3], H. Filipova[4], D. Kautznerova[4], E. Honsova[5], P. Trunecka[6], **J. Spicak**[1,*]
[1]*Department of Hepatogastroenterology,* [2]*Department of Transplant Surgery,* [3]*Department of Anesthesiology and Resuscitation,* [4]*Department of Radiodiagnostic and Interventional Radiology,* [5]*Department of Clinical and Transplant Pathology,* [6]*Transplantacentre, Institute for Clinical and Experimental Medicine, Prague, Czech Republic*
Contact E-mail Address: *renata.senkerikova@ikem.cz*

INTRODUCTION: Orthotopic liver transplantation (OLT) currently represents the treatment of choice for early hepatocellular carcinoma (HCC). Preoperatively known HCC (pkHCC) is diagnosed via imaging methods prior to OLT or HCC, denoted as incidental HCC (iHCC), is found postoperatively in the liver explant.
AIMS & METHODS: The aim of our study was a comprehensive analysis of post-transplant survival of patients with iHCC and identification of risk factors of iHCC occurrence in cirrhotic liver.
We retrospectively reviewed 33 adult cirrhotic patients with incidentally found HCC comparing them with 606 tumor-free adult cirrhotic patients with end-stage liver disease (group Ci) who underwent OLT in our center between January 1995 and August 2012. Within the same period, a total of 84 patients were transplanted for pkHCC. We compared post-transplant survival of iHCC, Ci group and pkHCC patients. In the group of cirrhotic patients (Ci + iHCC) we searched for risk factors of iHCC occurrence.
RESULTS: There was no difference in sex, MELD score and time spent on the waiting list in either group.
In the multivariate analysis we identified the age > 57 years (OR 3.37, 95% confidence interval (CI) 1.75-8.14, $P < .001$), HCV or alcoholic liver disease (ALD) (OR 3.89, 95% CI 1.42-10.7, $P < .001$) and alpha-fetoprotein (AFP) level > 6.4 μg/l (OR 6.65, 95% CI 2.82-15.7, $p = .002$) to be independent predictors of iHCC occurrence. Either 1-, 3- and 5-year overall survival (OS) or 1-, 3- and 5-year recurrence-free survival (RFS) differed in iHCC patients compared with Ci group (iHCC: OS 79%, 72% and 68%, respectively; RFS 79%, 72% and 63%, respectively, vs. Ci group: OS = RFS 93%, 94% and 87%, respectively; $P < .001$).
CONCLUSION: We conclude that the survival of iHCC patients is worse than in tumor-free cirrhotic patients, but comparable with survival of pkHCC patients. Independent risk factors for iHCC occurrence in cirrhotic liver are age, HCV or ALD etiology of liver cirrhosis and AFP level.

INTRODUCTION: To evaluate the feasibility, safety and efficacy of single-step balloon-occluded-RFA followed by TACE in patients with "complex" unresectable HCC, previously not suitable to RFA alone due to their localization.
AIMS & METHODS: 63 consecutive patients with at least one HCC lesion (mean diameter 4.35±1.8cm), adjacent to the diaphragm (25 lesions), proximal to the hepatic veins (17), portal vein (19), glisson's capsule (34), cholecistis (6) and/or located on the intra-abdominal free surface (5), considered as "complex" for their unfavourable location, and not suitable for RFA alone, were enrolled in our single-center multidisciplinary pilot study. The treatment was composed of RFA (single 2-cm or 3-cm monopolar needle insertion) during occlusion of the feeding artery followed by superselective TACE (conventional-TACE or with DC-BEAD). Adverse events and intra/periprocedural complications were clinically assessed. Tumor response was evaluated on 1-month, 6 months and 1 year follow-up multiphasic CT based on mRECIST criteria.
RESULTS: Technical success was achievied in all patients. 7 patients (11.2%) experienced intra and periprocedural complications, such as fistuale (2), bleeding (3), cholecistitis (1) and ascites (1), that resolved spontaneously. A mean total treated diameter (necrotic diameter plus circonferential peripheral lipiodol uptake for conventional TACE; mean necrotic diameter for TACE with DC-Bead) of 4.96±2.37 was obtained. Based on mRECIST criteria, on 1- and 3-months follow up CT, a tumor response was obtained in all patients, with a complete response achieved in 31 out of 63 patients (49.2%), a partial response in 38.1% (24 patients: residual tumor $< 30\%$ in 14 patients, $> 30\% > < 50\%$ in 6 patients, $> 50\%$ in 4 patients), and no response in 3 patients, without any progressive disease. 5 patients were lost to follow up. 18 out of 27 patients (66.6%) that underwent a CT-scan on 6-months follow up maintained a complete response.
CONCLUSION: Balloon-occluded-RFA plus TACE seems to be a safe and effective therapy for the treatment of "complex" HCC, allowing to obtain a high complete local response rate, without complications, also in patients not suitable to RFA alone.

INTRODUCTION: Hepatocellular carcinoma (HCC) is the most common primary liver tumor, and represents the third leading cause of cancer death worldwide [1, 2]. Chronic hepatitis C cirrhosis is one of the leading risk factors for HCC but increasing cases are seen in nonalcoholic fatty liver disease (NAFLD).
AIMS & METHODS: The aim of the study was to compare demographics, treatments and survival among hepatitis C virus (HCV/HCC) and NAFLD (NAFLD/HCC) cohort of patients. Data were collected from medical electronic case notes, imaging reports and reports from HCC multidisciplinary meetings.
RESULTS: Among 289 patients, 210 patients (73%) had underlying HCV/HCC and 79 patients (27%) had NAFLD/HCC. The median age at diagnosis was significantly higher in NAFLD/HCC patient cohorts ($p < 0.001$). The majority (more than 80%) were male. Body mass index (BMI) was significantly higher in NAFLD/HCC than HCV/HCC ($p < 0.001$). The majority of the patients in NAFLD. HCC were Caucasian (96%), whilst the HCV/HCC cohort was significantly more ethnically diverse ($p < 0.001$). Diabetes mellitus was more common in NAFLD/HCC patients ($p < 0.001$). The median alpha fetoprotein level in HCV/HCC patients were 33.0 compared to 14.1 in NAFLD/HCC although it did not reach the statistical significance ($p = 0.100$). The size of HCC and the numbers of HCC were similar between the two groups. Majority of patients in HCV/HCC and NAFLD/HCC were Barcelona stage A (51% vs 48%) and stage B (28% vs 39%). Treatment modalities such as radiofrequency ablation (RFA), trans arterial chemoembolization (TACE) or sorafenib used in both groups of patients were similar. Overall survival between the two groups did not differ significantly ($p = 0.122$), however we have found that HCV/HCC patients were more likely to be transplanted ($p = 0.003$).
Among 298 patients, 61 patients (29%) from HCV/HCC cohort and 11 patients (14%) from NAFLD/HCC were transplanted. The only significance factors were BMI ($p = 0.013$) and presence of underlying diabetes mellitus ($p = 0.002$) which were more common in NAFLD/HCC patients. 15% were treated with RFA and 18% received TACE therapy prior to liver transplantation (LT) in HCV/HCC compared to 18% and 9% in NAFLD/HCC respectively. Tacrolimus and Mycophenolate Mofetil were two most common immunosuppression regimes used post LT. Post transplant survival appeared to be slightly worsen in HCV/HCC patients compared to NAFLD/HCC, although it did not reach statistical significance ($p = 0.113$). Post LT freedom from recurrence of HCC among the two cohort was similar ($p = 0.848$).
CONCLUSION: Despite the NAFLD/HCC being older and with higher metabolic risk factors, a significant proportion could undergo active therapy. Furthermore, patients with NAFLD/HCC selected for transplantation seemed to have better long term outcomes, possibly due to stricter selection for transplantation as well as variations in tumor biology between the two groups.

P0645 HIGH ALPHA-FETOPROTEIN LEVELS AND PRESENCE OF CLINICALLY SIGNIFICANT PORTAL HYPERTENSION CAN PREDICT THE OCCURRENCE OF HEPATOCELULLAR CARCINOMA IN CIRRHOTIC PATIENTS

S. Bota[1,*], F. Hucke[1], M. Pinter[1], M. Mandorfer[1], T. Reiberger[1], A. Ferlitsch[1], M. Trauner[1], W. Sieghart[1], M. Peck-Radosavljevic[1]

INTRODUCTION: The international guidelines strongly recommend the screening of hepatocellular carcinoma (HCC) in cirrhotic patients by ultrasound every 6 months ± tumor markers (such as alfa feto protein – AFP), but because of the large number of patients and often limited resources some biomarkers for prioritizing patients for screening would be very helpful.
AIMS & METHODS: Our aim was to assess the HCC occurrence according to AFP values, presence of clinically significant portal hypertension (HVPG ≥ 10 mmHg), Child-Pugh score, MELD score, liver stiffness values assessed by Transient Elastography (TE), and liver disease etiology (viral vs. non-viral).
We retrospectively collected data of cirrhotic patients evaluated in our center between January 2007-July 2013. In the same session HVPG measurements, TE, lab values (used to calculate Child-Pugh and MELD score), and tumors markers (AFP) were determined. The presence of HCC at baseline was excluded by imaging techniques and patients were followed-up.
RESULTS: We identified 274 individual cirrhotic patients evaluated with all tests. We had to excluded 11 patients whose follow-up was not available. Thus in the final analysis 263 patients were included.
The median follow-up time was 21 months (3-83 months).
In our cohort of cirrhotic patients the HCC incidence was 5.7% and the median time until the HCC diagnosis was 15 months (3 -72 months).
In univariate analysis the AFP values ($r = 0.174$, $p = 0.006$) and presence of clinically significant portal hypertension ($r = 0.154$, $p = 0.012$) were statistically correlated with HCC occurrence, while MELD score ($r = 0.092$, $p = 0.13$), viral vs. non-viral etiology ($r = 0.050, p = 0.41$), TE ($r = 0.042$, $p = 0.56$) and Child-Pugh score ($r = 0.042$, $p = 0.49$) were not correlated.
The HCC incidence was 13.7% in patients with AFP values ≥ 10 ng/ml, 7.9% in cirrhotic with clinically significant portal hypertension and 16.6% in patients with both risk factors.
All the patients which developed HCC had clinically significant portal hypertension (HVPG ≥ 10 mmHg), while in the group without HCC it was present in 70.1% of patients ($p = 0.02$).
The proportion of cirrhotic patients with AFP ≥10 ng/ml at baseline was significantly higher in the cohort of patients that developed HCC as compared with the ones who did not: 46.6% vs. 20.4%, $p = 0.02$.
Combining both HVPG and AFP values, we observed that the percentage with both risk factors present (HVPG≥10 mmHg and AFP≥10 ng/ml) was three times higher in cirrhotic patients developing HCC compared with those without HCC during follow-up: 46.6% vs. 15.2%, $p = 0.005$.
No patient with HVPG < 10mmHg developed HCC during follow-up.
CONCLUSION: The absence of clinically significant portal hypertension seems to be a protective factor against HCC development. The combination of HVPG and APF values can identify the cirrhotic patients with high risk of HCC occurrence and probably a closer surveillance of patients with clinically significant portal hypertension and AFP values ≥ 10 ng/ml should be performed.

INTRODUCTION: This study investigated the survival benefits of sorafenib vs. radiotherapy (RT) in patients with unresectable hepatocellular carcinoma (HCC) and portal vein tumor thrombosis (PVTT) in the main trunk or the first branch.
AIMS & METHODS: Ninety-seven patients were retrospectively reviewed. Forty patients were enrolled by the Kanagawa Liver Study Group and received sorafenib, and 57 consecutive patients received RT in our hospital. Overall survival was compared between the two groups with PVTT by propensity score (PS) analysis. Factors associated with survival were evaluated by multivariate analysis.
RESULTS: The median treatment period with sorafenib was 45 days, while the median total radiation dose was 50 Gy. The Child-Pugh class and the level of invasion into hepatic large vessels were significantly more advanced in the RT group than in the sorafenib group. Median survival did not differ significantly between the sorafenib group (4.3 months) and the RT group (5.9 months; $P = 0.115$). After PS matching ($n = 28$ per group), better survival was noted in the RT group than in the sorafenib group (median survival, 10.9 vs. 4.8 months; $P = 0.025$). A Cox model showed that des-g-carboxy prothrombin < 1000 mAU/mL at enrollment and RT were significant independent predictors of survival in

the PS model ($P = 0.024$, HR, 0.508; 95% CI, 0.28 to 0.915; and $P = 0.007$, HR, 0.434; 95% CI, 0.235 to 0.798; respectively).
CONCLUSION: Regorafenib as a second-line therapy than sorafenib in patients who have advanced unresectable HCC with PVTT.

INTRODUCTION: It remains unclear whether response of alpha-fetoprotein (AFP) and protein induced by vitamin K absence or antagonist-II (PIVKA-II) to initial transarterial chemoembolization (TACE) are associated with improved survival in patients with unresectable hepatocellular carcinoma (HCC).
AIMS & METHODS: The aims of this study were to evaluate the prognostic significance of response of AFP and PIVKA-II to initial TACE and to identify risk factors associated with outcomes in patients with unresectable HCC. We retrospectively analyzed 114 patients with unresectable HCC not amenable to surgery and radiofrequency ablation who had been treated with TACE between September 2005 and October 2013. All laboratory values including AFP and PIVKA-II were measured 1 week before TACE and 1 month after TACE. The AFP or PIVKA-II response was assessed for patients who had a level before TACE of 100 ng/ml or $\geq$ 100mAU/ml; a positive response was defined as a reduction by $>$ 50% compared with the level before TACE. We compared three groups of pre-TACE AFP $\geq$ 100 ng/ml with response vs. pre-TACE AFP $\geq$ 100 ng/ml and no response vs. pre-TACE AFP $<$ 100 ng/ml using univariate analysis. Three PIVKA-II groups were also compared. Prognostic factors were evaluated using univariate (log-rank test) and multivariate analyses (Cox proportional hazard model).
RESULTS: The median overall survival (OS) was 20.9 months. Pre-TACE AFP level $\geq$100 ng/ml and tumor diameter $\geq$3 cm were associated with poor OS (AFP $\geq$100 ng/ml vs. AFP $<$ 100 ng/ml; 9.3 vs. 31.3 months; P $<$ 0.0001, tumor diameter $\geq$ 3 cm vs. diameter $<$ 3cm: 12.5 vs. 31.3 months; p = 0.0013) and remained significant negative predictors for OS on multivariate analysis (AFP $>$100 ng/ml; hazard ratio (HR) 3.5; p = 0.0003, tumor diameter $\geq$ 3 cm; HR 3.1; p = 0.0015). In the difference of AFP response to TACE, the OS of pre-TACE AFP $\geq$ 100 ng/ml with response compared with that of pre-TACE AFP $\geq$ 100 ng/ml and no response showed no significant difference (p = 0.992). Although there were not significant differences in OS between patients with pre-TACE PIVKA-II $<$ 100 mAU/ml and those with pre-TACE PIVKA-II $\geq$ 100 mAU/ml (p = 0.1642), the OS of responders of PIVKA-II to initial TACE was significantly longer than that of non-responders in those with pre-TACE PIVKA-II $\geq$ 100 mAU/ml (p = 0.0032).
CONCLUSION: The response of AFP to initial TACE does not prolong survival in patients with unresectable HCC. The response of PIVKA-II to initial TACE is associated with improved survival. Elevated AFP ($\geq$100 ng/ml) and tumor diameter $\geq$ 3 cm at diagnosis are associated with a dismal treatment response and prognosis after TACE.

INTRODUCTION: Although sorafenib has been shown to have significant survival advantages in patients with hepatocellular carcinoma (HCC), Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 may underestimate the efficacy because of modest tumor shrinkage. Additionally, discrepancy among evaluators may occur in the manual assessments.
AIMS & METHODS: The present study aimed to establish an objective evaluation method for anti-tumor response of sorafenib with regard to survival, using software that can automatically measure the diameter, volume and density of target tumors on computed tomography (CT). Among 81 patients with advanced HCC who were treated with sorafenib, 23 with Child–Pugh class A, Barcelona Clinic Liver Cancer stage C and performance status 0 or 1 were enrolled. Automatic measurements on CT were performed using MEDIAN Lesion Management Solutions. Conventional RECIST1.1 was compared with new methods: automated RECIST (a-RECIST), enhanced RECIST (e-RECIST) and Saga criterion. a-RECIST was RECIST1.1 using automatic measurements. e-RECIST used volume evaluation classified as follows: partial response (PR) as $\geq$50% reduction in tumor volume; progressive disease (PD) as $\geq$50% increase in tumor volume; and stable disease (SD) as $<$50% reduction or $<$50% increase in tumor volume. Saga criterion was the same as e-RECIST except that SD with $\geq$15% reduction in tumor density in the arterial phase was classified as PR. Overall survival (OS) time was estimated using the Kaplan–Meier method and expressed as median (95% confidence interval). The survival curves according to best response were compared using the log-rank test.
RESULTS: Conventional RECIST1.1 could not stratify OS. Meanwhile, OS was significantly stratified according to anti-tumor response in a-RECIST. Disease control rate (DCR) = 60.9%, DC vs. PD, 17.2 (6.3–28.1) vs. 9.3 (5.0–13.6) months (p = 0.048); objective response rate (ORR) = 8.7%, OR vs. non-OR, N/A vs. 10.4 (7.1–13.6) months (p = 0.048). e-RECIST was superior to a-RECIST: DCR = 56.5%, DC vs. PD, 20.4 (13.9–26.8) vs. 9.0 (4.5–13.4) months (p = 0.011); ORR = 8.7%, OR vs. non-OR, N/A vs. 10.4 (7.1–13.6) months (p = 0.048). In addition, Saga criterion was superior to e-RECIST: DCR = 56.5%, DC vs. PD, 20.4 (13.9–26.8) vs. 9.0 (4.5–13.4) months (p = 0.011); ORR = 30.4%, OR vs. non-OR, 20.4 (14.2–26.6) vs. 9.0 (5.4–12.5) months (p = 0.007).
CONCLUSION: Our findings suggest that Saga criterion, a new imaging assessment using automatic measurements of tumor volume and density on CT, has potential as a surrogate marker for anti-tumor response to sorafenib with regard to survival.

P0649 POPULATION SCREENING FOR LIVER DISEASE USING HEPATIC TRANSIENT ELASTOGRAPHY

B.M. Gonçalves[1,*], L. Malheiro[1], D. Fernandes[1], J.-B. Soares[1], C. Rolanda[1], **R. Gonçalves**[1], **P. Bastos**[1]
[1]*Gastroenterology, Hospital de Braga, Braga, Portugal*
Contact E-mail Address: *brunommgoncalves@gmail.com*

INTRODUCTION: Transient Elastography (TE), a noninvasive technique for liver fibrosis evaluation, has been used in patients with various types of chronic liver diseases. It is a simple, fast, painless, reproducible and well-accepted technique with instantaneous results that could be a valuable screening tool. However, there is a shortage of studies on its usefulness as a screening procedure in apparently healthy people.
AIMS & METHODS: The purpose of the study was to evaluate the impact of TE in the population screening of liver disease. It was conducted a prospective study where TE was performed in 365 individuals without known liver disease that attended general gastroenterology clinic in a referral hospital. A positive screening was defined for values of liver stiffness (LS) $\geq$8 kPa. For these individuals additional clinical, laboratory and ultrasonographic investigation was proposed for determination of liver disease.
RESULTS: Of the 365 individuals evaluated, 89 were excluded for invalid (n = 47) or failed (n = 42) TE. In the multivariate analysis, body mass index $>30Kg/m^2$ and waist circumference $>$102cm in men or $>$88cm in women were associated with failure of LS measurement (p = 0.031 and 0.001, respectively). Of the 276 valid exams, 21 (7.6%) obtained a LS value $\geq$8 kPa, including nine patients with LS $\geq$ 13 kPa. The average value of LS in the remaining participants with negative screening was 4.9 ± 1.2 kPa. In the group with positive screening it was observed that 28.6% patients had normal liver tests. In 17 (81%) patients a cause of liver disease was determined, while all participants with LS $\geq$ 13 kPa had a diagnostis. Alcoholic liver disease was the most prevalent etiology (47%) followed by non-alcoholic fatty liver disease (41%).
CONCLUSION: TE revealed to be a useful method to screen liver disease in the general population, diagnosing a significant number of asymptomatic patients. In the presence of an abnormal LS, the patient should be referenced for further evaluation.

P0650 MORBIDITY RISK IN AN ITALIAN COHORT OF HCV AND HBV PATIENTS

C. Stasi*[1,2,*], C. Silvestri*[1], S. Bravi[1], F. Voller[1], F. Cipriani[3]
[1]*Epidemiology Unit, Health Agency of Tuscany, Florence, Italy,* [2]*Department of Experimental and Clinical Medicine, University of Florence,* [3]*Health Agency of Tuscany, Florence, Italy, Florence, Italy*

INTRODUCTION: In Italy the HBV incidence progressively decreased from 1991 to 2005, because in 1991 infants' and adolescents' vaccination became mandatory. Effective screening since the early 90s has reduced the risk of HCV transmission through blood transfusion. Recently, World Health Organization (WHO) for the first time produced guidelines for the screening, care and treatment of persons with HCV infection. These guidelines are primarily targeted at policy-makers in ministries of health working in low- and middle-income countries that formulate country-specific guidelines for treatment. Treatment for HCV and HBV can reverse hepatic fibrosis and/or delay the development of long-term complications such as decompensated cirrhosis. A recent study shows that treatment of patients with compensated cirrhosis is cost-effective.
AIMS & METHODS: Therefore, the **aims** of this study were to evaluate the HBV and HCV epidemiology in Florence (Tuscany, region in central Italy) in 2012 and to investigate the hospital admissions of these patients at least once, as a risk of morbidity for cirrhosis, from 2000 to 2012. **Methods**: We analyzed the database of one Hospital in Florence (Careggi University Hospital) and prevalence of hospital admissions from 2000 to 2012 of HBV (based on the presence of antigene surface - HBsAg) and HCV patients (based on the presence of HCV RNA; limit of detection: 15 IU/mL) for "chronic liver disease and cirrhosis", "Fibrosis and cirrhosis of the liver", "bleeding from esophageal varices", using the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) and 10th revision (ICD-10).
RESULTS: Out of 24,368 individuals, a total of 2,697 hepatitis cases were reported, including 1,237 HBV and 1,460 HCV RNA positive patients. HBV occurred more often in males (63%) than in females (37%). HCV occurred slightly more often in males (59%) than in females (41%). In HCV group

1,270 (87%) had at least one hospital admission, while in HBV group were reported 492 hospital admissions (40%). When we divided the HBV patients into 5 age groups, hospital admission was detected in 1% of people aged 15-30 years; in 10% of people aged 31-45; in 50% of people aged 46-60; in 39% of people aged over 61 years; HCV hospital admission was detected in 1% in people aged 15-30; 6% in people aged 31-45; 48% in people aged 46-60; 45% in people aged over 61 years.

CONCLUSION: Our results show that there is a high prevalence of HCV and HBV hospital admissions in the central of Italy, especially in people aged over 46 years, with the higher prevalence for HCV than HBV patients. Therefore, its impact on the National Health Service could be important in the future. This study also suggests that early screening creates the conditions for early treatment in order to avoid the possibility of worsening of viral hepatitis on to develop cirrhosis of the liver.

P0651 A COST-CONSEQUENCE ANALYSIS OF SCREENING AND TREATMENT FOR CHRONIC HEPATITIS B (CHB) VIRUS INFECTION IN RESIDENT IMMIGRANTS OF AN ITALIAN NORTH-EAST REGION

E. Rosa-Rizzotto[1,*], A. Buja[2], D. Martines[1], A. Vinelli[2], G. Bardelle[2], S. Lopatriello[2], L. Peraro[1], D. Caroli[1], L. Scribano[1], F. De Lazzari[1], S. Lobello[1], V. Baldo[2]

[1]*Dpt of Specialized Medicine, Gastroenterology Unit, St Anthony Hospital,*
[2]*Department of Molecular Medicine, Laboratory of Public Health and Population Studies, Padua University, Padua, Italy*

INTRODUCTION: Chronic hepatitis B virus (HBV) infection is a serious health problem affecting 350 million to 400 million people worldwide. Although HBV infection occurs everywhere in the world, nationality is strongly associated with the prevalence of HBV infection. The epidemiology of hepatitis B in Europe is changing, with migration causing significant increases in prevalence rates. Immigration to Italy is a relatively new phenomenon that became relevant only at the end of the 1990s. As of January 2013, there were 4,387,721 foreign nationals resident in Italy.[ISTAT (2013). Statistiche report, 26 Luglio 2013. Rome, Italian National Institute of Statistics]. This amounted to 7,4% of the country's population, mainly concentrated in the northern part of the country. Veneto region is one of the main immigration destination areas. With about 500.000 foreign people staying in its territory, Veneto is the third Italian region for the number of immigrants and the fourth one if you consider the immigration rate on the overall population (10.2%). These influxes involve a considerable proportion of citizens from countries where hepatitis B is highly (> 8%) endemic, such as eastern Europe (Moldovans, Romanians and Ukrainians), from Africa (especially Ghana and Morocco), Balkan states (especially Albania, Montenegro and Serbia) and China, compared with less than 1 % of overall Italian population. Systematic screening and early treatment of migrants for chronic hepatitis B virus infection may have a large impact on liver-related health outcomes and is likely to be cost-effective. In four cost-effectiveness analyses, the estimated average cost per life-year gained of screening ranged from € 8966 to € 46260 per QALY gained. A cost-consequence analysis (CCA) provides an estimation of the costs as well as the expected health outcomes in terms of liver disease progression and mortality. Cost-consequence analyses play an essential part in the comprehensive economic assessment of a health care intervention.

AIMS & METHODS: We used the Markow model to examine the cost-consequence of screening and treatment vs a no screening strategy in a cohort of 348,991 adult migrants resident in the Veneto Region. The rate of adherence to the HBV screening program was judged to be 40%. The prevalence of HBV infection and the chance of having active CHB was based on our recent screening campaign in Padua involving 465 migrants (Tab.) Likelihood of HBV-related events were obtained from literature.

RESULTS:

POPULATION	AGE GROUP > 20 y	HBsAg+ N° (%)	ACTIVE CHB N° (%)	Rate of adherence to screening program n° (%)
465322	348991	21048 (6)	6314 (30)	2525 (40)

The screening-treatment strategy prevented 273 cases of cirrhosis, 18 decompensated cirrhosis, 28 HCC, and 54 CHB related deaths, over a period of 5 years. The incremental cost of the screening strategy totaled 51.597.980 € in five years (0,1% of the Veneto annual health budget).

CONCLUSION: This study provides information useful mainly to policy makers, who need to establish whether the cost generated by a screening strategy is affordable when set against the better health outcomes for resident immigrants.

Disclosure of Interest: None declared

P0652 HEPATITIS VIRUSES IN HEALTHY IMMIGRANTS: TO SCREEN OR NOT TO SCREEN?

E. Rosa-Rizzotto[1,*], L. Peraro[1], D. Caroli[1], L. Scribano[1], S. Gallo[1], C. Magro[1], F. De Lazzari[1], D. Martines[1], S. Lobello[1]

[1]*Dpt of Specialized Medicine, Gastroenterology Unit, St Anthony Hospital, Padua, Italy*

INTRODUCTION: Over the past four decades international migrations have increased up to an unprecedented rate. New migrants come from countries at low hepatitis B prevalence [hepatitis B surface antigen (HBsAg) seroprevalence <2 per cent], intermediate (HBsAg seroprevalence between 2 per cent–7 per cent) or high hepatitis B prevalence (HBsAg seroprevalence ≥8 per cent). Over this period both chronic HBV infection and HCC prevalence are increased in North America and Western Europe, also because migrants have higher incidence of chronic HBV infection and an increased mortality for cirrhosis and HCC compared to host populations. Hepatitis viruses screening is a form of secondary prevention to find early diseases amenable to antiviral treatments in order to prevent liver diseases. Moreover the screening helps to vaccinate the people cohabiting with HBsAg +ve subjects. Worldwide HCV prevalence is generally low and only in few countries it is over 3.5 per cent. Immigrants in Italy come mainly from Eastern Europe, Asia and Africa. In all these areas HCV prevalence is lower than HBV.

AIMS & METHODS: Regular healthy immigrants were sent to our clinic by community leaders from March 2013 to October 2013, questioned about their socio-demographic characteristics, tested for HBcAb and, when positive, for HBsAg. HBsAg+ve subjects were studied for HBVDNA levels and enrolled for clinic controls of liver disease. This population was also tested for HCV-Ab. HCV-Ab+ve subjects were tested also for HCV-RNA and HCV genotype.

RESULTS: 450 (264- M 58,7% - and 185 - F 41,3%) immigrants were screened. 39% were from Eastern Europe, 23% from Asia, 36% from Africa, and 2% from other areas. This distribution is comparable with immigrants residing in Padua. 144 (32%) were anti-HBcAg +ve, 31 (7%) HBsAg +ve, 4 (1%) HBeAg +ve. HBVDNA levels were over 2000 IU/ml in 11/31 (35.5%). The prevalence of HBsAg +ve in the Eastern European group was 11.4%, 7.9% in the Asiatic group and 1,2% in the African group. Eight immigrants resulted positive for HCV (1.8%), but only 6 were HCV-Rna positive, all were Moldavian (8.4%).

CONCLUSION: The seroprevalence of chronic HBV infection in migrants is similar to that of their countries of origin: high among migrants from East Asia and Eastern Europe, where 32% were found to be anti-HBcAg+ve. Hepatitis B virus screening on healthy migrants in our area is effective to identify HBsAg+ve subjects and it seems useful to define the amount of patients with HBV related liver disease. Targeted screening and vaccination of international migrants can become an important aspect of HBV disease control efforts in immigrant-receiving countries, thus changing the natural history of HBV chronic infection. The prevalence of HCV in Padua immigrants seems to be very low unlike HBV. HCV screening for immigrants does not appear useful to detect Hepatitis C virus affected subjects. The HCV screening strategy could be effective only in special populations of immigrants with higher HCV prevalence (i.e. East Europe).

P0653 METABOLIC PHENOTYPING OF BILE ACIDS - STANDARDIZED QUANTITATIVE BILE ACIDS ANALYSIS IN HUMAN PLASMA/SERUM AND MOUSE PLASMA ON DIFFERENT LIQUID CHROMATOGRAPHY TANDEM MASS SPECTROMETRY PLATFORMS

INTRODUCTION: Bile acids are considered not only as endogenous markers for liver cell functions, but also as signaling molecules regulating triglycerides, cholesterol and glucose metabolism as well as inflammatory processes and apoptosis. Accurate determination of individual bile acids and their conjugates is very important in assessing liver damage as well as hepatic and biliary tract diseases, colon cancer, atherosclerosis and type 2 diabetes. Therefore, bile acid analysis could provide a powerful tool for applications in precision medicine, toxicology, and clinical biomarker research. We have developed and validated a standardized (U)HPLC-ESI-MSMS assay for the analysis of ca. 20 bile acids from only 10 µL human plasma/serum or mouse plasma samples. The panel consists of cholic acid, deoxycholic acid, chenodeoxycholic acid, ursodeoxycholic acid, hyodeoxycholic acid, muricholic acids and their glycine as well as taurine conjugates.

AIMS & METHODS: 10 µL sample and 10 µL IS mixture are pipetted onto the paper filter spot suspended in a 96-well filter plate. After a short drying under nitrogen stream, bile acids are extracted with 100 µL methanol. The methanolic extract is filtered through the plate into the 96- deep well receiving plate, under light centrifugation. 60 µL water is added to the extract before injecting into the (U)HPLC-ESI-MSMS for analysis. The analysis runtime for UHPLC and HPLC is 5 and 11 min, respectively. Bile acids detection is performed using MRM in negative ESI mode. 7-points calibration curves are used for quantitation. The assay has been rigorously validated according to the EMA guideline.

RESULTS: Due to the special arrangement of the paper filter spot, proteins which have been precipitated are largely captured by the filter, while allowing the target metabolites to be extracted and filtered through. Only 3 steps are needed to complete the sample preparation. Seven calibrators levels and three quality control levels are used to guarantee the accuracy and precision of the measurements. This new assay in kit format has been validated for different LC-MS/MS platforms from AB Sciex, Waters, and Thermo Scientific. In general an

LLOQ of 0.01 to 0.02 μM have been achieved for all target bile acids. Among the tested LC-MS/MS platforms, increasing sensitivity for bile acids analysis can be graded as follows: Xevo TQ MS < TSQ Vantage < 400QTRAP< QTRAP5500.
CONCLUSION: With the help of the very simple and robust bile acids kit, the analysis of several human plasma/serum samples and mouse plasma samples reveals that the bile acid profile of mice is quite different from that of human. While taurine conjugates of bile acids are prevalent and glycin conjugates are amost absent in mouse plasma, the situation is reversed in human plasma/serum. Moreover, the male/female differences found in mouse plasma is much more profound than that found in human samples.
