CONCLUSION: Our data shows that less than 11/12 circumferential rectal resection never causes stricture. Only more than 11/12 circumferential rectal resection has a risk of developing stricture after ESD, however, it could be treated by the combination of steroid therapy and EBD, or EBD alone. Because ESD is less invasive and can preserve anal function compared to surgical resection, indication of ESD for large rectal neoplasms which needs more than three-quarter circumferential resection could be effective and beneficial.

P1321 EVALUATION FOR THE DIAGNOSTIC PERFORMANCE OF TRADITIONAL SERRATED ADENOMA USING MAGNIFYING CHROMOENDOSCOPY

Y. Sato[1,*], T. Sakamoto[1], H. Sasaki[1], Y. Matusyama[1], T. Yokota[1], J. Nakamura[1], H. Takamaru[1], M. Yamada[1], Y. Otake[1], T. Nakajima[1], T. Matsuda[1], Y. Saito[1]
[1]*Endoscopy division, National Cancer Center Hospital, tokyo, Japan*

INTRODUCTION: Serrated neoplastic pathway has been proposed in recent years as a new oncogenic pathway for development of colorectal carcinoma. Traditional serrated adenoma (TSA) is focused of attention as one type of precursor lesion. We use magnifying chromoendoscopy for diagnosis about colorectal lesions, Type III H pit-pattern (fernlike pit-pattern) and IV H pit-pattern (pinecone pit-pattern) are used for diagnosis of TSA.
AIMS & METHODS: The aim of this investigation was to evaluate the diagnostic performance using magnifying chromoendoscopy (MCE) in identifying TSA. We analyzed a total of 50 histologically proven TSA and a total of 150 non TSA lesions that underwent endoscopic resection at a single tertiary hospital between January 2007 and June 2013. For each lesion images taken by conventional white light endoscopy and magnified indigo carmine spraying were reviewed by five experienced and five non-experienced colonoscopists. A diagnosis of TSA or non-TSA was made on a six-point scale of confidence. Diagnostic performance was evaluated using Receiver Operating Characteristic (ROC) analysis based on calculation of the Area Under the Curve (AUC).
RESULTS: AUC was 0.91 for correctly diagnosis TSA or non TSA with MCE for all reviewers. AUC was 0.95 in experienced group and 0.85 in non-experienced group, respectively ($P < 0.001$). The lesions was diagnosed correctly with high confidence in 89% of the experienced group and in 57% of the non-experienced group ($P < 0.001$). AUC was 0.95 which diagnosed with high confidence versus 0.75 which diagnosed with low confidence in experienced group, and 0.87 versus 0.67 in non-experienced group. In both groups, diagnostic performance was significantly higher when diagnosed with high confidence ($P < 0.001$). Interobserver agreement for diagnosis of TSA was 0.72 (kappa value) in experienced group and 0.42 (kappa value) in non-experienced group.
CONCLUSION: The performance of MCE for diagnosis of TSA was highly accurate when the experienced group diagnosed with high confidence. Interobserver agreement was good results in experienced group. In non-experienced group, the diagnostic performance was still high. With education and experience in recognizing the typical findings of TSA a high diagnostic accuracy can be achieved.

P1322 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR COLORECTAL TUMOR BECAME SAFE AND CURATIVE PROCEDURE AS COMPARED WITH EMR AND PIECEMEAL EMR

Y. Tamegai[1,*], T. Kishihara[1], H. Ishikawa[1], K. Okamoto[1], A. Chino[1], M. Igarashi[1]
[1]*Endoscopy Division, Cancer Institute Hospital, Tokyo, Japan*
Contact E-mail Address: *yoshiro.tamegai@jfcr.or.jp*

INTRODUCTION: Endoscopic submucosal dissection (ESD) technique has made it possible to perform one-piece resection of colorectal tumors regardless of lesion size and location. However, ESD has been regarded as a procedure with the high risk complication than endoscopic mucosal resection (EMR) and piecemeal EMR. In this study, we compared the safety and curability between these endoscopic treatments.
AIMS & METHODS: ESD was performed for 766 cases of tumor in 760 patients (male: female = 449:311; mean age, 65.7 years) including 8 withdrawal cases. In same periods, we experienced 4.870 EMR cases and 507 cases with piecemeal EMR. We compared the incidence of perforation and residual/local recurrence between ESD, EMR, and piecemeal EMR.

RESULTS: We completed ESD procedure on 758 of 766 colorectal tumors (84 lesions in the caecum, 129 in the ascending colon, 142 in the transverse colon, 33 in the descending colon, 180 in the sigmoid colon and 190 in the rectum), and other 8 cases were abandoned endoscopic treatment due to severe degree fibrosis relating deep SM cancer invasion and screen-like fibrosis. The average lesion size was 34.0mm (range: 5-170 mm), and 11 lesions were larger than 100 mm in diameter. The average operation time was 74.2 minutes (range, 7-480 min).
The incidence of perforation was 0.25% (12/4.870) with EMR, 0.59% (3/507) with EPMR, and 0.13% (1/766) with ESD including 8 withdrawal cases. This result revealed that ESD has become a very safe procedure than the EMR and piecemeal EMR technique. The incidence of residual/local recurrence was 0.49% (24/4.870) with EMR, 5.33% (27/507) with piecemeal EMR, and 0.13% (1/758) with ESD excluding 8 withdrawal cases. Thus, although there is no significant difference in the incidence of perforation between these endoscopic procedures, the rate of residual/local recurrence after piecemeal EMR was significantly higher ($p < 0.001$) than after EMR and ESD. The possibility to completing ESD for colorectal tumor sometime depends on the existence of fibrosis in submucosal layer rather than the size and location. Among 766 ESD cases, 190 cases were accompanied by SM fibrosis. Among 190 cases with SM fibrosis, of which 59 cases were considered related to cancer invasion and 131 cases were unrelated. En bloc resection rate of the tumor without fibrosis was 97.6% (562/576), and the tumor was accompanied with fibrosis in 84.7% (161/190). We experienced only one case of perforation (0.13%), which was accompanied by fibrosis. From the view point of safety and curability, use of the ESD procedure is thought to be limited for this group at high risk of perforation and recurrence. For the above mentioned reasons, we have developed laparoscopy endoscopy cooperative surgery (LECS) in order to perform an one-piece resection of tumor, which was difficult to complete ESD due to firm fibrosis in submucosal layer. And we have achieved one-piece resection for 4 cases by using LECS procedure successfully.
CONCLUSION: ESD for colorectal tumors became safe and curative procedure owing to the progress of endoscopic technique and devices as compared with EMR and piecemeal EMR. And we have established LECS procedure in order to overcome the limitation (high risk of perforation due to wide and firm fibrosis in SM layer) of ESD procedure.

P1323 COMPARISON OF EFFICACY BETWEEN COLONIC SELF-EXPANDING METALLIC STENTS AND TRANSANAL TUBE FOR PALLIATION OR AS A BRIDGE TO ELECTIVE OPERATION IN MALIGNANT LARGE BOWEL OBSTRUCTION

Y. Ito[1,*], N. Ogasawara[1], H. Noda[1], Y. Tamura[1], A. Shimozato[1], Y. Kondo[1], Y. Hijikata[1], M. Sasaki[1], K. Kasugai[1]
[1]*Aichi Medical University School of Medicine, Nagakute, Japan*

INTRODUCTION: Acute colorectal obstruction often accompanies advanced colorectal cancer and requires urgent surgical treatment. Approximately 30% of patients present with acute obstruction, which represents a surgical emergency associated with mortality and morbidity rates higher than when surgery is performed in elective conditions. To avoid major postoperative complications such as anastomotic leakage with septic multiple organ failure resulting in high morbidity and mortality, most surgeons advocate two-step surgery. However, various methods for performing one-step surgery have been reported including intraoperative colonic lavage, preoperative small bowel and colonic decompression and lavage with a long nasointestinal tube, decompression with self-expandable metal stent (SEMS) and decompression with a transanal drainage tube (TDT). However, each of these methods still presents unsolved problems or difficulties with regard to efficacy, safety and technical aspects. In particular, the efficacy and safety between SEMS and TDT placement as a bridge to elective surgery or definitive palliation is debated. This study aimed to evaluate the outcomes of patients with colorectal obstruction treated using different strategies.
AIMS & METHODS: Fifty eight patients with colorectal obstruction caused by advanced colon cancers were studied between January 2009 and January 2014. Twenty three patients underwent SEMS as a bridge to elective surgery ($n = 11$) or for definitive palliation ($n = 12$). On the other hand 35 patients underwent TDT as a bridge to elective surgery ($n = 33$) or for definitive palliation ($n = 2$). Colonic obstruction was identified as the cause of the mechanical ileus by computed tomography (CT) scan in all patients. The site of the obstruction was the rectum for 27 patients, the sigmoid colon for 25 patients, the descending colon for 5 patients and the transverse colon for 1 patient. The histologic diagnosis was confirmed by endoscopic biopsy at SEMS or TDT placement, or by examination of the operation specimen.
RESULTS: Placement of SEMS was technically successful in 92.3 % and clinically successful in 100 % of the technically successful cases. Placement of TDT was technically successful in 85.7 % and clinically successful in 93.5 % of the technically successful cases. The short-term complication was perforation in 1 patient of SEMS group and 1 patient of TDT group. However, there were no complications such as migration, occlusion, colon bleeding and abdominal pain in both groups. The rates of clinically efficacy and complication were not significantly different between the two groups. The median postoperative hospital stay was 18.8 days in SEMS group versus 38.9 days in TDT group ($P < 0.001$). The in-hospital mortality rates in SEMS group and TDT group were 7.7 % and 11.4%, respectively. The mean procedure time was significantly shorter for SEMS than for TDT (33.9 minutes vs. 46.0 minutes; $P < 0.05$).
CONCLUSION: SEMS achieved a high rate of clinical success and a low rate of complications. In case of colorectal obstruction, SEMS as a bridge to elective operation or definitive palliation should be considered as the treatment for patients given the significant advantages for outcomes compared with TDT.

P1324 PROS AND CONS OF UNSEDATED COLONOSCOPY WITH WATER INFUSION PERFORMED BY EXPERIENCED COLONOSCOPISTS

S. Lee[1], **Y. Yang**[1,*], G. Song[1], A. Jiang[1]
[1]*digestive department, the first affiliated hospital of Harbin medical university, Harbin, China*
Contact E-mail Address: *Dr.yangylin@163.com*

INTRODUCTION: Recently, lots of papers has indicated that colonoscopy with water infusion in lieu of air insufflation can relieve unsedated patients' abdominal pain, facilitate colonoscopic performance and increase the rate of successful cecal intubation, et al, especially for trainees. However, non-difficult colonoscopy performed by experienced colonoscopists is still unclear.
AIMS & METHODS: The aim of this study was to identify if the advantages above could be achieved by our endoscopists with great total experience.
Method:This study was conducted at 1st hospital of Harbin medical University from August 2013 through December 2013. A total of 800 patients were randomized to undergo unsedated colonoscopy with either water infusion or air insufflation. Two experienced colonoscopists who had performed at least 10000 standard air insufflation colonoscopies, attained a 95% completion rate and spent no more than 10min in intubating on average conducted these procedures. Cecal intubation times, intent-to-treat (ITT) cecal intubation rates and abdominal pain scores evaluated by visual analogue scale (VAS) were documented in the water infusion group (WIG) compared with the air insufflation group (AIG).
RESULTS: Cecal intubation time in WIG was significantly longer ((273 ±159s) than that in AIG (246s ±146s). ITT cecal intubation rate in WIG was about 97%, significantly higher when compared with AIG(93%). Median pain scores in WIG and AIG were 3 and 5, respectively ($p < 0.01$).
CONCLUSION: Although colonoscopy with water method seemed time-consuming for experts, it could still increase successful cecal intubation rate, improve colonoscopists'performances and effectively relieve patients' abdominal pain at non-difficult colonoscopy. For unsedated colonoscopy conducted by experienced colonoscopists, it was superior to traditional colonoscopy with air insufflation.

INTRODUCTION: The femle patients with a lower BMI and abdominal-pelvic surgery history always suffer more abdominal pain during unsedated colonoscopy, even effect cecal intubation rate and insertion time. Recently years, some research revealed the water method could reduce abdominal pain during insertion time. But, without research about water method colonoscopy on femle patients with a lower BMI and abdominal-pelvic surgery history (difficult colonoscopy).
AIMS & METHODS: To perform a randomized, controlled trial comparing water infusion in lieu of air insufflation (study method) and air insufflation (conventional method) in unsedated difficult colonoscopy. One hundred outpatients with difficult colonoscopy that were defined as femle, with a lower BMI and abdominal-pelvic surgery history were randomized divided into a water infusion group (water group) and a traditional air insufflation group (air group). The cecal intubation rate, abdominal pain scores, cecal intubation time and the rate of patients refuse to reapt the unsedated colonoscopy were compared between the water group and the air group.
RESULTS: There was no significant difference in the age and body mass index (BMI) between the water group and the air group. The abdominal pain score of the water group was significantly lower than that of the air group ($P < 0.05$). The rate of patients refuse to repeat the unsedated colonoscopy of water group (8.1%) was significantly lower than that of the air group (29.79%, $P < 0.05$). There was no significant difference in the cecal intubation rate and cecal intubation time between the water group and the air group.
CONCLUSION: Water infusion method instead of air insufflation can reduce the abdominal pain and improve the acceptability of unsedated colonoscopy.

INTRODUCTION: Because the invasive procedure of colorectal endoscopic submucosal dissection (ESD) entails a extensive mucosal defect and submucosal exposure, the procedure may have a substantial risk of complications including delayed bleeding, perforation and bacteremia and/or endotoxemia. Therefore, these complications was increasing the duration of hospital day.
AIMS & METHODS: The aim of our study is to investigate whether Surgicel® would be effective in reducing complications after colorectal ESD.
Between 2011 and 2013, 72 consecutive patients who underwent a colorectal ESD by one skilled endoscopists were enrolled. After the colorectal epithelial neoplasm removed, surgicel® was sprayed onto the submucosal surface using the wet type of application in some cases. We evaluated tumor type, location, size, histology, procedure time, hospital stay and associated complications for both the surgicel® groups (Group A) and non- surgicel® groups (Group B). For assessing inflammatory reaction, white blood cells and body temperature were monitored.
RESULTS: Of the 72 patients, two patients with microperforation were excluded. Of the total 70 patients, 35 cases (50.0%) underwent the surgicel® application. During follow-up period, rebleeding occurred in 0 (0% in Group A) patient and 2 (5.7% in Group B) patients. The fever (>37.7) was 1 (2.9%) and 8 (22.9%) patients, respectively ($p=0.028$) and the leukocytosis (>10.000 cells/μL^3) was 5 (14.3%) and 11 (31.4%) patients, respectively ($p=0.088$). The inflammatory reaction (fever or leukocytosis) was 6 (17.1%) and 13 (37.1%), respectively ($p=0.060$). Blood cultures were obtained in five patients with high fever ($>38^{\circ}C$) and were positive in three of these patients (60%). The isolated microorganism was coagulase-negative *Staphylococcus* in two patients, and *Streptococcus* species in one patient. The mean hospitalization period was 5.14 and 5.97 days, respectively ($p=0.016$). The Group (surgicel Vs non-surgicel, $p=0.034$, odds ratio (OR) = 10.074 (1.186–85.570) was identified as independent predictor for fever by multivariated analysis.
CONCLUSION: Surgicel® application after Colorectal ESD may be effective method to reduce complications and mean hospitalization period. Therefore, Surgicel® application may be considered to be a valuable clinical methods.

Contact E-mail Address: *ikuyayimonin@live.jp*

INTRODUCTION: Low-dose aspirin (LDA), which prevents platelet aggregation, is prescribed to pharmacologically prevent cardiovascular disease. Japan Gastroenterological Endoscopy Society guideline recommends non-interruption of LDA perioperatively for patients undergoing endoscopic submucosal dissection (ESD) of colorectal neoplasias (CRNs); however, no studies have confirmed the efficacy of this practice.
AIMS & METHODS: To retrospectively confirm the validity of non-interruption of LDA in patients undergoing ESD for CRN. Four hundred and ninety-four patients with 494 CRNs who were resected by ESD at our institution between August 2008 and December 2013 were included in this study. The patients were classified into three groups: Group A, those in whom LDA use was interrupted perioperatively (11 patients treated between August 2008 and November 2010); Group B, those in whom LDA use was continued perioperatively (24 patients treated between December 2010 and December 2013); and Group C, those who did not take any anti-thrombogenic agents (440 patients treated between August 2008 and December 2013). For each group, we investigated the bleeding rate after ESD and compared the rates among the three groups in location, tumor size, and pathological diagnosis. We defined bleeding after ESD as a hemoglobin level decreased by >2.0 g/dL and identified it in those in whom bleeding points were identified by emergency endoscopy for melena after treatment as previously reported. There was no difference in clinicopathological backgrounds among the three groups.
RESULTS: The bleeding rates after ESD were 18% (2/11) in Group A, 21% (5/24) in Group B, and 8% (34/440) in Group C, respectively. There was no significant difference in bleeding rate between Groups A and B; however, that of Group B was significantly higher than that of Group C ($p < 0.01$). Bleeding after ESD occurred in the colon in 13% (1/8), 18% (3/17), and 4% (12/271) of patients and in the rectum in 33% (1/3), 29% (2/7), and 13% (22/169) of patients in Groups A, B, and C, respectively. Bleeding occurred in 0% (0/2), 33% (1/3), and 11% (6/53) of patients with tumor size <20 mm, and in 22% (2/9), 19% (4/21), and 7% (28/387) of patients with tumor size$\geqq$20 mm in Groups A, B, and C, respectively. Bleeding occurred in 0% (0/5), 0% (0/10), and 8% (14/173) of patients with adenoma, in 33% (1/3), 38% (3/8), and 9% (15/173) of patients with Tis carcinoma, and in 33% (1/3), 18% (2/11), and 5% (5/94) of patients with T1 carcinoma in Groups A, B, and C, respectively. There were no differences in these variables among the three groups. No patients suffered from ischemic events during the perioperative period.
CONCLUSION: Our data indicate that the continued use of LDA increased the risk of bleeding after ESD compared to its non-use; however, outcomes did not differ significantly when LDA use was perioperatively interrupted or continued in patients with LDA use.

P1328 DIAGNOSIS OF COLORECTAL SERRATED POLYPS USING ENDOCYTOSCOPY

Y. Ogawa[1,*], S.-E. Kudo[1], M. Kutsukawa[1], Y. Mori[1], K. Wakamura[1], K. Ichimasa[1], M. Misawa[1], T. Kudo[1], Y. Wada[1], T. Hayashi[1], A. Katagiri[1], H. Miyachi[1], F. Ishida[1], S. Hamatani[1], H. Inoue[2]
[1]*Digestive Disease Center, Showa Univercity Northern Yokohama Hospital, Yokohama,* [2]*Digestive Disease Center, Showa Univercity Koto Toyosu Hospital, Tokyo, Japan*
Contact E-mail Address: *sunny.onet@gmail.com*

INTRODUCTION: Recently, serrated polyps have gathered much interests as the precursor lesions to colorectal cancers which follow the "serrated pathway" different from adenoma carcinoma sequence.
Accurate endoscopic criteria to differentiate the family of serrated polyps including hyperplastic polyps (HPs), sessile serrated adenoma/polyps (SSA/Ps), and traditional serrated adenomas (TSAs) are needed.
AIMS & METHODS: The aim was to investigate the endocytoscopic features of serrated polyps focusing on elements of the shape of lumens and nuclei.
A total of 590 colorectal lesions were observed with Endocytoscopy (EC, XCF-Q260EC1, CF-Y0020I, Olympus, Tokyo, Japan), and resected endoscopically or surgically in our Center from May 2005 to October 2013. Of these, 83 serrated lesions were analyzed. 39 lesions were HPs, 24 lesions were SSA/Ps, and 20 lesions were TSAs.
In the EC images, the shapes of lumens were divided into straight, star-like, oval, serrated and villous, while the shapes of nuclei were classified into small round and fusiform.
The study protocol was approved by the ethics committee of Showa University Northern Yokohama Hospital (No.1302-01). Informed consent was obtained from all patients before collection of the specimens. This study was registered in UMIN Clinical Trials Registry (UMIN000007850).
RESULTS: The results are shown in the table below.

	lumen					nuclei	
	straght	star-like	oval	serrated	villous	fusiform	small round
HP (%)	6 (15.4)	31 (79.5)	2 (5.1)	0	0	37 (94.9)	2 (5.1)
SSA/P(%)	0	6 (15)	18 (85)	0	0	21 (87.5)	3 (12.5)
TSA (%)	0	0	0	7 (35)	13 (65)	0	20 (100)

Presence of oval lumens was for diagnosing SSA/Ps ($p < 0.05$), and presence of star-like lumens was for diagnosing HPs ($p < 0.05$). Presence of fusiform nuclei and serrated or villous lumens were significant elements for diagnosing TSA ($p < 0.05$).
CONCLUSION: Endocytoscopic diagnosis focusing on the shape of lumens and nuclei would be useful for the differentiation of serrated polyps.

P1329 QUANTITATIVE IMAGE ANALYSIS OF THE LUMINAL AREA FOR HYPERPLASTIC POLYPS AND SESSILE SERRATED ADENOMA / POLYPS WITH ENDOCYTOSCOPY

Y. Ogawa[1,*], S.-E. Kudo[1], M. Kutsukawa[1], Y. Mori[1], K. Wakamura[1], K. Ichimasa[1], Y. Kouyama[1], M. Misawa[1], T. Kudo[1], Y. Wada[1], T. Hayashi[1], A. Katagiri[1], H. Miyachi[1], F. Ishida[1], S. Hamatani[1], H. Inoue[2]

INTRODUCTION: Sessile serrated adenoma/polyps (SSA/Ps) are known to be precursors of CRCs. Kimura et al reported that the Type II open pit pattern (Type II-O) was specific to SSA/Ps. [1] Type II-O were wider and more rounded in shape, reflecting dilatation of the crypts. But there are no reports which measured the actual value of the dilatation. Actually we investigated luminal area by using Endocytoscopy (EC).
AIMS & METHODS: The aim was to determine the threshold of the area that differentiate SSA/Ps from Hyperplastic polyps (HPs) using EC.
A total of 247 lesions were observed with a single CCD integrated type Endocytoscopy (CF-Y0020I, Olympus, TOKYO, Japan), and resected endoscopically or surgically in our Center from August 2010 to December 2012. Of these, 19 HPs and 8 SSA/Ps were included. For each lesion we selected one image which showed the widest lumen, then measured the average area of the contiguous three lumens, using Image J software (NIH, Bethesda, MD). We analyzed the specific threshold of the areas.
RESULTS: The average luminal area of SSA/Ps was $9323.3 \pm 4208.1 \mu m2$, while that of HPs was $2565.1 \pm 1556.9 \mu m2$. As assessed by ROC analysis, the luminal area's threshold of $\geqq 6676.3 \mu m2$ was found with moderate accuracy (sensitivity 87.5% and specificity 94.7%, AUC 0.875).
CONCLUSION: This analysis of the luminal area has been revealed to be useful for SSAP's diagnosis.
Endocytoscopy is a promising diagnostic tool not only for neoplastic lesions but also for serrated lesions.
This approach could be adopted to computer-aided diagnosis.

P1330 COMPARISON OF BIPOLAR RADIOFREQUENCY CUTTING AND MONO POLAR CUTTING FOR ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) IN A PORCINE MODEL

Z.P. Tsiamoulos[1,*], P. Sibbons[2], C. Hancock[3], A. Polecina[4], B.P. Saunders[4]
[1]*Wolfson Unit for Endoscopy, St Mark's Hospital/Academic Institute,* [2]*Division of surgical science, Northwick Park Institute for Medical Research, London,* [3]*Department of Physics, University of Bangor, Bangor,* [4]*Wolfson unit for Endoscopy, St Mark's Hospital and Academic Institute, London, United Kingdom*

INTRODUCTION: Current endoscopic knives utilise mono-polar energy (transmitted from the device across the bowel wall to the return plate) to incise the mucosa, dissect the submucosa and coagulate bleeding vessels. Monopolar devices have proven efficacy but remain technically challenging to use with the risk of major complications (perforation/bleeding).
AIMS & METHODS: A new bipolar endoscopic device (energy localised to the device tip) "Speedboat-RS2, Creo Medical Ltd, UK" was compared to a standard mono-polar endoscopic device (Flush-knife-BT, Fujifilm, Japan) for endoscopic submucosal dissection (ESD) in the porcine colon. The Speedboat-RS2 blade delivers bipolar radio frequency (RF-400KHz) cutting and microwave coagulation (5.8GHz) for hemostasis, and contains a retractable needle for submucosal injection/tissue irrigation. It also has an insulated hull to prevent thermal injury to the underlying muscle layer. ESD was performed and video recorded on 5 consecutive 60kg pigs. The following parameters were measured: time taken to complete resection, complications encountered and histological assessment. Two animals were recovered for one week and four animals for four weeks.
RESULTS: Ten consecutive resections were performed in the colorectum (2 per animal), 5 with Speedboat-RS2 and 5 with Flushknife-BT. Median time for Speedboat RS2 to complete a resection was 44 min, range (33-58 min) using RF cutting 30W, voltage circa 300Vrms and for Flushknife-BT was 52min, range (28-67min) using monopolar cutting for mucosal incision (80W) and for submucosal dissection, monopolar forced coagulation 30W. Median flap size (longest diameter) for Speedboat RS2 was 36.8mm, range (30-42mm) and for Flushknife was 43mm, range (35-55mm). Microwave coagulation was applied for either minor bleeding or visible vessels on 25 occasions (mean energy 7.5W) with Speedboad-RS2. Monopolar coagulation was applied 14 times with Flushknife, mean energy 30W. The Hemostatic Coagrasper was used 7 times to control arteriolar bleeding during Speedboat RS2 dissection when microwave was not sufficient and only once during Flushknife-RS2 dissection. Endoclips were placed to treat deep muscle injury in the resection base on 10 occasions in the Flushknife resections (15clips placed) and on 3 occasions (3 clips) for the Speedboat-RS2 resections. There was only one study perforation - Flushknife-BT group, where urgent peritoneal decompression was required and the resection was abandoned. Histology (Speedboat-RS2 resections) showed an intact muscle layer in four resection bases and in one there was slight muscle alteration but muscle cell viability was retained. The muscle layer was absent in two Flushknife-BT resection bases and moderately altered in one.
CONCLUSION: Compared to Flush knife-BT ESD colonic resections (monopolar) the Speedboat-RS2 was associated with less muscle injury and need for endoscopic clipping. However Speedboat-RS2 resections produced more intraprocedural bleeding requiring the haemostatic forceps.

P1331 SINGLE CENTRE PILOT EVALUATING THE USE OF ENDOCUFF-VISION IN SCREENING COLONOSCOPY

Z.P. Tsiamoulos[1,*], K. Patel[1], R. Misra[1], N. Suzuki[1], A. Haycock[1], S. Thomas-Gibson[1], B.P. Saunders[1]
[1]*Wolfson Unit for Endoscopy, St Mark's Hospital/Academic Institute, London, United Kingdom*

INTRODUCTION: Although colonoscopy is considered the optimal procedure for bowel cancer screening, it remains an imperfect tool for cancer prevention, due to missed adenomas and early cancers. Optimal imaging modalities, innovative scopes and accessories (cap-assisted colonoscopy) have attempted to decrease the adenoma miss rate. Adenoma detection rates (ADR) have been shown to be a key performance indicator of quality colonoscopy.
AIMS & METHODS: Endocuff-vision is a simple accessory mounted at the end of the scope with a proximal row of 6mm length soft plastic, finger-like projections. During scope insertion, these projections invert towards the shaft of the tube and during withdrawal they evert to hold back the colonic folds augmenting the forward endoscopic views. ADRs were recorded for screening colonoscopy procedures before and after introduction of Endocuff-vision.
RESULTS: To date, three screening endoscopists (BPS, STG, AH) have used the Endocuff-vision as part of a clinical evaluation process (at the discretion of each endoscopist) from August 2013 until February 2014. From our local Bowel Cancer Screening Program database, the figures of the caecal intubation rate (CIR) and the ADR in 135 screening colonoscopies during April 2013 to July 2013 (BPS-45, STG-42, AH-48) before Endo-cuff were retrieved:
Pre-Endocuff performance:
BPS: CIR-100%/ADR-62%
STG: CIR-97%/ADR-40%
AH: CIR-97%/ADR- 54%
Prior to the introduction of the Endocuff-vision, the mean CIR was 98% and the mean ADR was calculated to be **52%.**
The total number of procedures where Endocuff-vision has been utilized was in 65 occasions (BPS-21, STG-30, AH-14) with similar CIR rates but increased post-Endocuff ADR.
Post-Endocuff performance:
BPS: CIR-100%/ADR-78%
STG: CIR-98%/ADR-74%
AH: CIR-97%/ADR-77%
The mean ADR with the aid of Endocuff was calculated to be **76%.**
On 8 patients the Endocuff-vision was electively removed from the scope due to insertion difficulties through fixed sigmoid colonic segments secondary to severe diverticular disease. There were no adverse events reported during the trial evaluation period.
CONCLUSION: In this small pilot study, use of the Endocuff-vision appeared to improve the average ADR. There were no complications from the use of the cuff although it was electively removed in 8 cases with severe sigmoid colon diverticulosis. Further randomized evaluation of this simple novel device is warranted.

P1332 ENDOSCOPIC SNARE PAPILLECTOMY (ESP) FOR AMPULLARY TUMOURS: SAFETY AND OUTCOMES FROM A SINGLE CENTRE TERTIARY CENTRE

N. Dubale[1,*], A. Bapaye[1], S.K. Davavala[2]
[1] *Department of digestive diseases and Endoscopy, Deenanath Mangeshkar Hospital and Research Centre, Pune, Pune,* [2] *Department of digestive diseases and Endoscopy, Deenanath Mangeshkar Hospital and Research Centre, Pune, Mumbai, India*
Contact E-mail Address: *amolbapaye@gmail.com*

INTRODUCTION: Tumors of duodenal papillae may be malignant or premalignant. Endoscopic snare papillectomy (ESP) may be a minimally invasive solution to treat these lesions. This retrospective single centre study evaluates the safety and outcome of ESP for ampullary tumors.
AIMS & METHODS: Patients with ampullary tumors treated with ESP during 6-years (Feb 2007 to Jan 2013) identified from ERCP database. All underwent pre-ESP EUS and relevant imaging to confirm localized disease and suitability for procedure.
ESP was performed using a diathermy snare followed by biliary and pancreatic stenting - removed at 4 – 6 weeks with base biopsies for residual tumor. Patients with histology adenocarcinoma were counseled for either close follow-up or surgical resection & with benign histology were followed up. Follow up done at 3, 6, 12, 18, and 24 months, yearly thereafter.
RESULTS: 36 patients underwent ESP, mean age 63 years (33 – 83), males – 23. Mean tumor diameter was 18mm (7 – 37). Complications - 2 bleeds (managed endoascopically), one delayed biliary stenosis (underwent stenting) and one fatal pancreatitis after biopsy.
Histopathology: adenocarcinoma – 20 (56%), adenoma – 15 (41%), NET – 1. Margin positive 7 (19.4%) – adenocarcinoma– 4 (20%), adenoma – 3 (20%). Mean follow up 13.6 months (1 – 58).
4 (11%) lost to follow up – 2 each in carcinoma and adenoma group.
Adenoma group – no recurrence at mean 12-month (3 – 36) – 10 (67%), recurrence – 3 (treated by APC), NET 3-month no recurrence.
CONCLUSION: ESP for ampullary tumors is effective and safe. It can be curative for most ampullary adenomas. ESP for localized adenocarcinoma may be potentially curative in > 50% patients and may obviate need for major surgery. Negative resection margin status may be a predictor of improved ESP outcomes.

INTRODUCTION: Secondary biliary stones have been known as a relevant complication after orthotopic liver transplantation (OLT) and may be associated with liver dysfunction. Endoscopic retrograde cholangiopancreatography (ERCP) represents the reference standard for the therapy of biliary stones. Data on the efficacy of ERCP in the treatment of post-OLT biliary stone are scanty.
AIMS & METHODS: To report the rate of secondary biliary stones after OLT, to investigate the possible triggering factors and to describe treatment in our Academic Centre.
From January 2000 to December 2013, 539 patients underwent OLT for HCV (#209) and non-HCV cirrhosis (#330). Among them, 78 OLT-patients (15%) were evaluated for biliary complications (choledoco-choledocal anastomotic stricture, biliary stones, hepatico-jejuno anastomotic stricture, hilary ischemic stricture, biliary leak, sphincter of Oddi dysfunction) on the basis of symptoms, alterations of liver tests (LTs) and non invasive imaging tests (abdominal ultrasound/magnetic resonance cholangiopancreatography). Presence of biliary stones was confirmed by ERCP. Patients with biliary stones during biliary stent exchange to treat anastomotic stricture or leak were excluded.
Comparison between OLT patients with or without biliary stones was done (using Chi-square test) in the view of etiology of cirrhosis (HCV vs non HCV), age, immunosuppressive therapy, use of ursodeoxycholic acid and associated ABS.
RESULTS: Overall 11 patients (10 male, 42-62 y.o.) on 539 (2%) post-OLT patients with secondary biliary stones were found. They had undergone OLT

for HCV, HCV and ETOH, HBV and Wilson's disease associated cirrhosis (# 5, 2, 3 and one respectively). Median timing from OLT was 31 (3-182) mos. Alteration of LTs and symptoms were present in all patients (jaundice in five, abdominal pain in four or both in other two). Median stone diameter was 10 (5-25) mm. In eight patients (73%) stones were multiple and in nine (82%) found above the anastomosis. De novo ABS was found in four patients and recurrence of ABS was found in five at a median time of 20 mos after the end of endotherapy.
In this series 32 ERCPs (1-7/patient) were performed to treat biliary stones. Three patients required multistenting to progressively dilate a recurrent ABS and to access stones above it. Seven perendoscopic, six extracorporeal shock waves and two percutaneous laser lithotripsies were used in four patients, all of them presenting with multiple and large biliary stones associated with recurrent ABS. One patient underwent hepatico-jejuno anastomosis to treat tight and angulated ABS and biliary stones as well. Overall, successful removal of biliary stones was achieved in 9 patients (82%) and ongoing in the remaining two. The presence of secondary biliary stones was significantly associated with the presence of ABS ($p<0.001$) and not associated to the other factors analyzed.
CONCLUSION: Symptomatic secondary biliary stones have been found in 2% of all OLT patients which represents 14% of biliary complications in our series. Recurrence of ABS could play a role as marker of presence of multiple and large biliary stones. Successful treatment of this condition needs a multidisciplinary approach, including multisession endotherapies.

INTRODUCTION: Cannulation with a sphincterotome is an efficient technique to gain biliary access in endoscopic retrograde cholangiopancreatography (ERCP). Contrast injection and two-operator guidewire cannulation technique requires experience and precise coordination between the operators. The short-wire system allowed the endoscopist to manage the guidewire and the endoscope independently (single-operator technique).
AIMS & METHODS: We compared single-operator cannulation technique with two-operator technique collecting data of all consecutive naïve patients (pts) that underwent ERCP in 3 referral centres (2 used the single-operator technique and 1 the two-operator technique). Data on demographics, final diagnosis, cannulation, non-intentionally pancreatic cannulation, stents placement and complications were evaluated.
RESULTS: 80 pts (male 46 [58%], mean age 69.9±16.4 yrs) were evaluated retrospectively in a 1 to 3 ratio (1 from two-operator group vs. 3 from single-operator group). Indications for ERCP were: choledocholithiasis in 46 pts (57.5%), pancreatic carcinoma in 15 (18.7%), cholangiocarcinoma in 12 (15%), oddi dysfunction in 3 (3.8%), benign strictures in 2 (2.5%), ampulloma in 1 (1.4%), biliary leakage in (1.4%). Successful biliary cannulation was achieved in 69/80 pts (86%) without difference between the two groups (81 vs. 75%, p = ns). Cannulation time was 2.81±1.71 min. (2.72 vs. 3.11, p = ns). In biliary cannulation failure: 9/11 achieved a complete biliary drainage after precut papillotomy and 2/11 after EUS-rendez-vous. Non-intentionally guidewire pancreatic cannulation was 7 vs. 30% in the single and two-operator group respectively (p = 0.006; OR 0.16, 95%CI 0.04-0.67) without difference of post-ERCP pancreatitis. Peri/intradiverticular papilla was reported in 14% of pts without difference in terms of cannulation failure or complications between the two groups. No differences concerning plastic or metallic stents placement were observed. Ten/80 pts (13%) experienced a complication (12% in single and 15% in two-operator group, p = ns): 5 pancreatitis/hyperamylasemia, 4 bleeding, 1 perforation. All complications resolved after medical or endoscopic therapy.
CONCLUSION: Our study shows that the single-operator cannulation technique offers the same efficacy and safety compared to the two-operator technique but with lower risk of non-intentionally pancreatic cannulation.

INTRODUCTION: Biliary anastomotic stricture (BAS) represents the most frequent biliary complication following liver transplantation (LT).
AIMS & METHODS: The aim of the study was to identify epidemiological, clinical and endoscopic factors influencing appearance and resolution of BAS in patients undergoing ERCP. We included 171 consecutive liver transplanted recipients recruited in University Hospital of Udine, Italy from 2004 to 2010 with at least one year of follow-up. All patients with clinical or radiologic suspicion of obstructive jaundice and cholestasis underwent ERCP. The ERCP treatment implied biliary sphyncterotomy followed by stricture dilation and placement of at least one plastic stent, exchangeable every 3-6 months until the final stricture resolution.
RESULTS: During post-operative follow-up 40 patients developed BAS. They underwent median number of 3 ERCP per patient. The median number of 1 stents was inserted per procedure and median period until stricture resolution was 9 months. Stricture resolution was obtained in 83%. The use of Kehr T tube (12/23 Vs 28/148, $p<0.01$) and use of cyclosporine as immunosuppressive therapy (18/54 Vs 22/117, $p<0.05$) were significantly more frequent among patients who developed BAS. We identified use of Kehr T tube (O. R. 5.46, $p<0.01$) and male gender of donor (O. R. 2.61, $p<0.01$) as an independent predictors of BAS development. The elevated number of repeated ERCP (OR 0.659; 95% CI 0.522-0.832; p = 0.000), combined stenting with dilation (OR 0.197; 95% CI 0.074-0.525; p = 0.001), increasing number of inserted stents per procedure (OR 0.896; 95% CI 0.782-1.026; p = 0.112) and longer period of warm ischemia (OR 0.966; 95% CI 0.938-0.995; p = 0.023) were associated with successful endoscopic treatment. On the contrary, longer period of stent in place (OR 1.034; 95% CI 1.005-1.064; p = 0.021), elevated MELD score (OR 1.104; 95% CI 1.035-1.178; p = 0.003), elevated Child-Pugh score (OR 1.679; 95% CI 1.089-2.591; p = 0.019) and high pre-transplantation bilirubin values (OR 1.104; 95% CI 1.007-1.210; p = 0.035) were associated with endoscopic treatment failure.
CONCLUSION: Detailed clinical assessment and skilled endoscopic team is necessary in order to achieve the successful endoscopic treatment of BAS. Understanding clinical and endoscopic risk factors may help in predicting of more appropriate regimen of treatment of patients undergoing ERCP for BAS post-LT.

P1336 MANAGEMENT AND OUTCOMES OF ERCP-RELATED PERFORATIONS: EXPERIENCE OF THE LAST 6 YEARS IN THE SINGLE INSTITUTION

S. Budzinskiy[1,*], S. Shapovaliantc[1], E. Fedorov[1], G. Konuhov[1]
[1]*Moscow University Hospital №31, Russian National Research Medical University n/a N. I. Pirogov, Moscow, Russian Federation*
Contact E-mail Address: *konuhov_gv@rambler.ru*

INTRODUCTION: Endoscopic retrograde cholangiopancreatography (ERCP) and endoscopic papillotomy (EPT), being relatively minimally invasive, nevertheless have their own morbidity, the most feared of which is periduodenal perforation, and mortality. The management of ERCP-related perforations remains controversial: some patients requiring immediate surgery, some endoscopy treatment and others only conservative management.
AIMS & METHODS: The aim of the study was to determine the incidence, predisposing factors, management approaches and clinical outcomes of ERCP-related perforations. Patients were evaluated according to ERCP indication, clinical presentation, diagnostic methods, time to diagnosis and treatment, type of injury, management, length of hospital stay, and clinical outcome.
RESULTS: In our hospital ERCP&EPT have been launched in 1977 and at the moment experience equals 13937 cases. For the last 6 years - from 01.2008 till 04.2014 - a total 2788 ERCPs were performed in our department. Perforations were diagnosed in 13 (0.48%) patients. There were 3 males and 10 females. The age ranged from 55 to 83, mean age 62.7±10.3 years. Perforation developed after EPT in 11 pts.; after catheterization with a guide wire in 1; after insertion of an endoscope in 1 pt. Perforation was confirmed immediately during endoscopy in 7 pts.; per ERCP – in 3 pts.; using plain abdominal X-ray or upper abdominal CT scan in 3 pts. Conservative management was employed in 3 (23%) pts., which was successful in all of them. Surgical treatment was carried out in 4 (31%) pts.; 3 of them received surgery within 2 to 5 hours after perforation, the rest one was operated at 8 days after perforation. Two pts. from surgical group died from intra-abdominal abscess and multiple organ failure (mortality rate 50%). Six pts. were managed by endoscopic interventions: by endoclipping - 3, by endoclipping and plastic biliary stenting - 2, by inserting full-covered metal stent and endoclipping - 1. Five pts. recovered without additional complications and their post-operative period was uneventful. One pt. died (16.6%) from abdominal sepsis and multiple organ failure after salvage surgery due to failed endoscopic treatment (biliary stenting with plastic prosthesis and clipping of the perforation). The lengths of hospital stay in conservative, endoscopic and surgical groups were 12.2; 12.3 and 31.6 days, respectively. The overall mortality rate after ERCP-related perforations was 23.1% (3 of 13 pts.).
CONCLUSION: Although rare, ERCP-related perforations are serious complications that may end fatally. Early recognition and appropriate intervention is the only way to avert a fatal outcome. Early diagnosis can be established by prompt intraoperative identification using endoscopic visualization, ERCP, abdominal X-ray and postoperative CT scan. The choice of the management approach should be individualized, depending on endoscopic and radiological findings, the features of perforation type and the clinical picture. Endoscopic clips and biliary stenting should be considered aside from surgical intervention. Based on our experience delay in intervention, surgery treatment and salvage surgery after failed endoscopic management contributed to a longer hospital stay and bad outcomes.
Disclosure of Interest: None declared

P1337 COMPLICATIONS ARISING AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPY PLASTIC STENT INSERTION

S. Chetcuti Zammit[1,*], D. Muscat[2], J. Ellul Pirotta[2], V. Said Pullicino[2], J. Pocock[1]
[1]*Gastroenterology,* [2]*Medicine, Mater Dei Hospital, Msida, Malta*
Contact E-mail Address: *stf_che@yahoo.com*

INTRODUCTION: This is a retrospective study looking at possible complications arising after plastic biliary stenting at Endoscopic Retrograde Cholangiopancreatograpy (ERCP). Biliary stenting is performed to relieve biliary obstruction in patients with benign or malignant biliary strictures and in patients with choledocholithiasis if complete common bile duct (CBD) stone clearance is not achieved at ERCP. More than 90% of stents used were 12 cm 10 Fr plastic stents. Patients with cholelithiasis and benign strictures usually undergo elective stent change at 3-4 months while patients stented for malignancy undergo re-stenting after onset of complications.
For the purposes of the study, biliary sepsis was defined as: fever, right upper quadrant pain and jaundice requiring intravenous antibiotics and hospitalization. Stent failure was defined as recurrent obstructive jaundice with biliary hypertension confirmed on CT scan or MRCP but without signs of sepsis.
AIMS & METHODS: All patients who underwent an ERCP between 2009 and 2012 at our hospital were included in this study. Patients were then followed up until 2013 to determine complication rates.
RESULTS: 552 ERCPs were carried out in 420 patients as 96 patients (22.9%) underwent an ERCP more than once. Of these 229 (n = 552 41.4%) patients had a stent inserted, and another 63 (n = 552 11.4%) patients underwent a change of stent. 148 patients (n = 292; 50.7%) underwent stent insertion due to a malignant stricture. 24 of these patients underwent a change of stent. Stents were inserted in 35 patients (n = 292; 12.0%) with underlying benign strictures. 109 patients (n = 292; 37.3%) had a stent inserted due to incomplete CBD stone clearance.
On follow up 62 patients (n = 292; 21.2%) required hospitalization after undergoing their first stent insertion or a change of stent due to biliary sepsis or stent failure. The average time span between stent insertion and readmission due to complications was 232 days. Complications related to sepsis and stent failure were commonest beyond 6 months across all groups. None of the patients experienced problems related to stent migration. Complication rates were similar in all 3 groups.

Reason for stent insertion	Number of months after stent insertion						
	1	2	3	4	5	6	>6
Benign stricture	0	2 (5.71%)	0	2 (5.71%)	0	2 (5.71%)	3 (8.57%)
Choledocholithiasis	4 (3.66%)	4 (3.66%)	3 (2.75%)	0	2 (1.83%)	1 (0.92%)	9 (8.26%)
Malignant stricture	6 (4.06%)	3 (2.03%)	2 (1.35%)	3 (2.03%)	6 (4.06%)	0	10 (6.76%)

Table 1: Number of patients admitted with complications within months from ERCP stenting.
CONCLUSION: Leaving a plastic stent for 6 months appears to be safe and does not seem to result in a disproportionate increase in the rate of biliary sepsis or stent failure.
Disclosure of Interest: None declared

P1338 SERUM LIPASE LEVEL THRESHOLD < 10N AT H4 PREDICTS THE ABSENCE OF POST-ERCP PANCREATITIS OCCURRENCE AND ALLOWS EARLY ORAL REFEEDING

R. Alhameedi[1], A. Di Fiore[1], M. Antonietti[1], I. Iwanicki-Caron[1], A. Gangloff[1], P. Michel[1], P. Ducrotté[1], **S. Lecleire**[1,*]
[1]*Gastroenterology, University Hospital of Rouen, Rouen, France*
Contact E-mail Address: *stephane.lecleire@chu-rouen.fr*

INTRODUCTION: Acute pancreatitis is a common complication of endoscopic retrograde cholangio-pancréatography (ERCP), varying from 2 to 20 % in the literature. Although several predictors of post-ERCP pancreatitis (PEP) have been described, there is to date no reliable method for predicting its occurrence with a good accuracy. Besides, post-ERCP early refeeding remains discussed among physician endoscopists.
AIMS & METHODS: The aim of the study was to test whether the serum lipase level at H4 after ERCP would: 1) predict the occurrence of PEP; 2) allow an early refeeding.
Patients and Methods. All patients who underwent ERCP between January 2013 and January 2014 were included in this prospective study, with the exception of patients who had acute pancreatitis before ERCP. Serum lipase level was routinely controlled after the endoscopic procedure at H4, to define patients at low risk of pancreatitis (< 10N), and patients at high risk of pancreatitis (> 10N). Threshold of lipasemia upper 10N at H4 was chosen in order to determine the prediction of post- ERCP pancreatitis. This threshold was strongly suggested to be relevant for the prediction of PEP in a previous prospective study of 272 patients (1). When lipase was < 10N and in the absence of abdominal pain, the patients received an oral feeding on the evening of the same day with a calory intake of less than 800 Cal. Patients with lipase > 10N with or without abdominal pain remained fasting overnight. The sensitivity (Se), specificity (Sp) and positive (PPV) and negative predictive values (NPV) of the lipase for predicting a PEP at H4 were calculated. The occurrence of abdominal pain occurring after early refeefing was noted.
RESULTS: Among the 175 consecutive patients, five patients were excluded because they had pancreatitis before ERCP. Data from 170 patients were analyzed. The average age of patients was 70 years, 92 women and 78 men. ERCP was performed for gallstones in the common bile duct (n = 103) or a tumor compressing the CBD (n = 67). The rate of PEP was 10.6%. There was a significant correlation between the value of the serum lipase level at H4 and the occurrence of PEP ($p < 0.0001$, Fisher's exact test). PEP were mild on CT scan (Balthazar stages A to C) except from one severe acute pancreatitis (Balthazar D, 0.6%). The Se, Sp, PPV and NPV of serum lipase level at for predicting PEP were respectively 100 %, 95%, 77% and 100 %. No patient who underwent early post-ERCP oral refeeding showed any pain nor complications. The mortality was 0%. Patients who benefited from early oral refeeding did not show any sign of pancreatitis in postprandial peroid.
CONCLUSION: The dosage of serum lipase level at H4 is a simple, fast and effective method for predicting the occurrence of PEP and identifying patients who may benefit from early oral refeeding after ERCP and early discharge after procedure. None of the patients with a serum lipae level < 10N at H4 developed PEP. Early oral refeeding in patients with serum lipase level < 10 N at H4 did not induce PEP.

Contact E-mail Address: *medi01@naver.com*

INTRODUCTION: In patients with Billroth II gastrectomy, ERCP has often been performed using a cap-fitted forward-viewing endoscope because of technical difficulty and risk of adverse events in the use of duodenoscope. This study was aimed to investigate the outcomes and the risk factors of adverse events of ERCP using a cap-fitted forward-viewing endoscope in patients with Billroth II gastrectomy as a multicenter study.
AIMS & METHODS: Between August 2008 and May 2013, we retrospectively reviewed the data on the ERCP using a cap-fitted forward-viewing endoscope in patients who had undergone Billroth II gastrectomy. During the study periods, 123 patients were enrolled at five tertiary referral centers in South Korea.
RESULTS: The indications of ERCP were common bile duct (CBD) stone in 80.5% (99/123), CBD stricture in 9.8% (12/123), CBD cancer in 1.6% (2/123) and others in 8.1% (10/123). Successful ERCP could be achieved in 82.1% (101/123). The reasons of failed ERCP were failure of entry to ampulla in 13 patients, failure of cannulation in five patients and the others in four patients. Mean size and number of CBD stones was 10.8±3.9mm and 1.78±1.1, respectively. For the complete removal of CBD stones, mechanical lithotripsy was required in 17.8% (15/84) of patients. Endoscopic papillary balloon dilatation was performed in 68.2 % (84/123) of patients. In these patients, the mean CBD diameter was 15.2±3.9mm and the mean balloon size and mean ballooning time was 10.1±1.4mm and 63.4±27.4sec. Adverse events occurred in 24.3% (30/123), including asymptomatic hyperamylasemia in 15.4% (19/123), post-ERCP pancreatitis in 7.3% (9/123), bowel perforation in 1.6% (2/123). The large stone more than 20mm was the significant risk factors for adverse events (odds ratio 15.5).
CONCLUSION: In patients with Billroth II gastrectomy, the ERCP using a cap-fitted forward-viewing endoscope may be a useful method. Nevertheless, the significant rate of adverse events cannot be ignored, suggesting the need for taking precautions.

P1340 EFFICACY AND SAFETY OF ENDOSCOPIC PAPILLARY LARGE BALLOON DILATION FOR DIFFICULT STONES IN HIGH ELDERLY PATIENTS

T. Tsuchiya[1,*], T. Itoi[1], A. Sofuni[1], F. Itokawa[1], S. Tsuji[1], K. Ishii[1], I. Nobuhito[1], K. Kamada[1], J. Umeda[1], R. Tanaka[1], R. Tonozuka[1], M. Honjyo[1], S. Mukai[1], M. Fujita[1], F. Moriyasu[1]

INTRODUCTION: Minimally invasive interventions for choledocholithiasis are preferable in elderly patients because they tend to have multiple underlying disorders or a decreased activity of daily living. Endoscopic sphincterotomy and endoscopic papillary balloon dilation have been recognized as first-line treatments for choledocholithiasis excluding difficult cases such as large stones or multiple stones. Recently, the safety and efficacy of endoscopic papillary large balloon dilation (EPLBD) for difficult choledocholithiasis cases have been reported. However, there was a few reports for elderly patients.
AIMS & METHODS: To investigate whether EPLBD can be safety and effectively performed in high elderly patients. The medical records of 204 patients who

underwent EPLBD from November 2006 to August 2013 were analyzed retrospectively. The patients were divided into 2 groups: Group A (≥85 years); Group B (<85 years). The criteria of EPLBD was the patients with large or multiple CBD stones; 13 mm or more in the shortest dimension (i.e., the shortest dimension of the largest stone) or multiple (≥3) bile duct stones with the smallest stone >10 mm in the shortest dimension.
RESULTS: Number of patients are 57 and 147 in Group A and B. The average age are 89.9 (85-102) and 73.2 (31-84) years old in Group A and B, respectively. The patients in Group A had more prevalence of periampullary diverticulum than those in Group B (54.4% vs 36.7 %, p = 0.02). However, there was no significant difference in the success rates in the first session (96.5 vs 95.3 %, p = 0.99) and in the final success rates (100 % in both groups) between Group A and Group B. The adverse event rates (3.5 vs 3.4 %, p = 0.70) and recurrence rates of choledocholithiasis (12.3 vs 10.2 %, p = 0.67) were not significantly different. Post-EPLBD pancreatitis (moderate) was observed in 1 patient in Group A. Perforation developed in 1 patient in Group A and none in Group B. In Group B, mild hemorrhage without a transfusion developed in 4 patient, and acute cholangitis in 1 patients.
CONCLUSION: This study suggested that EPLBD procedure for high elderly patients was safe and effective for difficult stones.

INTRODUCTION: Patients with chronic pancreatitis often present with severe abdominal pain, resistant to common analgesics. There is no etiological therapy for chronic pancreatitis. The goal of the endoscopic treatment of painful chronic pancreatitis is to drain the pancreatic duct, reduce the frequency and severity of pain and resolve local complications of the disease. Few data are available on the long term efficacy of endoscopic treatement.
AIMS & METHODS: The aim: to evaluate the endoscopic treatment efficacy and the prognostic factors of long-term response treatment in patients with painful chronic pancreatitis. All the patients with painful chronic pancreatitis who underwent ERCP or endoscopic treatment in the last 5 years at a single tertiary referral endoscopy center were retrospectively identified from the hospital database. The inclusion criteria were: the pancreatic pain and dilated pancreatic duct. Demographics data regarding the clinical history, the endoscopic procedures and the patients follow-up were collected from the medical charts and analyzed. All the patients were called to obtain updated clinical informations.
RESULTS: We included 132 patients (109M,23F, mean age 52, predominant etiology ethanolic). At enrollment, the pancreatography showed:minimal changes of the pancreatic ducts in 10 patients, pancreatic duct stones in 30 patients, pancreatic pseudocyst in 24 patients and 29 patients had chronic pancreatitis related biliary strictures. A total of 375 procedure were performed (mean3/patient). In 25 patients the sphincterotomy was the only procedure required. 2 patients needed ESWL. Pancreatic stone extractions were performed in 39 patients. Pancreatic plastic stenting were performed in 49 patients among which 34 patients required many long term stenting. The pseudocyst have been drained transpapillary (11 patients), transmural (9 patients) and EUS (4 patients). During the follow-up, a part of patients (10 patients) developed a biliary stricture. The biliary decompression was performed by CBD plastic stenting (22 patients), multiple plastic stents (8 patients), SEMS (2 patients). In 90.16% cases the procedures was successful, in 9.8% failed and the patients underwent surgical drainage. Mean follow up after treatment is 24 months. About 90% of patients had substantial improvement of symptoms after endoscopical treatment, including frequency and severity of pain attack. Pain disappeared completely in 56% patients during follow-up. The pseudocysts was successfully drained and did not reappeared during follow-up in 95% cases. The hospitalization admission rate in patients with severe chronic pancreatitis was higher (mean5/patient) compared to those patients with minimal pancreatic changes (mean3.6/patient). No differences were found regarding the number of hospital admission between the patients with pancreatic stones and the patients without pancreatic duct stones. Success of endotherapy in chronic pancreatitis with minimal changes was 94.12% vs. 89.8% in patients with pancreatic duct strictures. None of the patients younger than 40 years required surgical drainage and the success rate in patients older than 40 years was 87%.
CONCLUSION: We consider that in painful chronic pancreatitis the minimal endoscopic treatment is sufficient. Due to the increased risk of complications and higher costs, additional endoscopic treatment and surgical intervention should be reserved for cases with no response to the minimal endoscopic treatment.

P1342 ASSESSING ENDOSCOPIC SKILLS DURING ERCP TRAINING – A ROMANIAN TERTIARY CENTER EXPERIENCE

T.A. Pop[1,2,*], M. Tantau[1,2]
[1]*Gastroenterology, Regional Institute for Gastroenterology and Hepatology "Prof. Dr. O. Fodor"*, [2]*Gastroenterology, UNIVERSITY OF MEDICINE AND PHARMACY I. HATIEGANU, Cluj-Napoca, Romania*

INTRODUCTION: The current Romanian endoscopy teaching system confronts with several problems including lack of targeted courses for practical skills development. Also, clear criteria for assessing ERCP procedures and the ability to develop and carry out patient management plans are not defined.
AIMS & METHODS: Our aim was to analyze the ERCP learning curve and to assess the development of endoscopic competence.
From January 2011 - May 2013, 4 trainees in our center entered the ERCP training program. The training consisted of modules of 100 cases each. The CBD cannulation in patients with non-altered anatomy and the rate of complications were prospectively recorded for every trainee after every module fulfillment. Trainee success rates were compared to those of the trainer.
RESULTS: Trainees performed 1041 examinations. Each did an average of 251 examinations (range, 109 to 396). The CBD median cannulation rate improved significantly from first module (100 procedures - 54.57%) to 2nd module (200 procedure) (79.33%, P < .048). The 3rd module was completed only by 2 trainees who reached a 82.5 CBD cannulation rate. The rate of complications decreased form 14.67% (first 100 ERCPs) to 8.72% (200 ERCPs) and 6.01% (300 ERCPs), respectively.
CONCLUSION: The success rate for deep biliary cannulation should be assessed in every ERCP trainee. A success rate of at least 80% for deep biliary cannulation should become a threshold for ERCP competence programs.

P1343 RISK FACTORS FOR BLEEDING AFTER ENDOSCOPIC SPHINCTEROTOMY IN COMPARISON WITH ENDOSCOPIC PAPILLARY BALLOON DILATION FOR THE PATIENTS WITH ANTIPLATELET THERAPY

T. Arizumi[1,*], N. Toda[1], K. Saito[2], T. Yamada[1], M. Yamagami[1], K. Kojima[1], T. Ohki[1], M. Seki[1], K. Tagawa[1]
[1]*Gastroenterology, Mitsui Memorial Hospital,* [2]*Department of Gastoenterology, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan*
Contact E-mail Address: *arizut-tky@umin.ac.jp*

INTRODUCTION: In Japan, endoscopic papillary balloon dilation (EPBD) is classified as low risk procedure of bleeding, and considered endoscopic sphincterotomy (EST) as high risk. EPBD can be performed for the patient with antiplatelet therapy. But Japan Gastroenterological Endoscopy Soaciety Guideline do not recommend to perform EST for the patient with antiplatelet therapy, except for the patient with aspirin monotherapy. This study aimed to evaluate risk factors of bleeding after such endoscopic procedures for the patient with antiplatelet therapy.
AIMS & METHODS: Consecutive patients received EST or EPBD with antiplatelet therapy were retrospectively studied. A total of 118 patients (EST 85, EPBD 33) who were received such endoscopic procedure (Jan 2009 to Dec.2013) were enrolled. Univariate and multivariate analyses to identify risk factors for bleeding were performed using a proportional hazards model.
RESULTS: In EST group (25 female, 60 male, mean age 77.0), the number of patients taking with aspirin, ticlopidine, clopidogrel, other antiplatelet agent, dual agents were 70, 9, 16, 12, 21, respectively. In EPBD group (7 female, 26 male, mean age 76.8), the number of patients were 25, 3, 4, 5, 4, respectively. Perforation did not occur in both groups. Pancreatitis was significantly frequent in EPBD group (EST 2/85 2.4% vs EPBD 4/33 12.1%, p = 0.042). Bleeding occurred with 3 patients in EST group (3.5%), but did not occurred in EPBD group. There was not significant change. The details of patients with bleeding were 2 patients taking with aspirin and ticlopidine, 1 patient with clopidgrel monotherapy. All patient with bleeding took thienopyridine compound. Univariate analysis revealed that ticlopidine therapy (2/9 p = 0.0163), tienopyridine compound therapy (3/25 p = 0.0058), and dual antiplatelet therapy (2/21 p = 0.0031) were risk factors of bleeding after EST for patient with antiplatelet therapy. But by multivariate analysis, none of them were significant.
CONCLUSION: In this study, taking tienopyridine compound and taking ticlopidine, dual antiplatelet therapy were proved to be not statistically significant risk factors for bleeding after EST, but showed increase trend. EPBD may be considered alternative procedure to EST instead of the high incidence of pancreatitis associated with EPBD.

P1344 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN BILLROTH II PATIENTS – A SINGLE CENTRE EXPERIENCE

V. Costa Santos[1,*], N. Nunes[1], F. Ávila[1], P. Massinha[1], R. Liberal[1], A.C. Rego[1], J.R. Pereira[1], N. Paz[1], M.A. Duarte[1]
[1]*Gastrenterologia, Hospital do Divino Espírito Santo de Ponta Delgada, Ponta Delgada, Portugal*
Contact E-mail Address: *vera@multi.pt*

INTRODUCTION: Endoscopic retrograde cholangiopancreatography (ERCP) in patients submitted to a previously gastrectomy with a Billroth II reconstruction is technically challenging, with success rates ranging from 50 to 90 %.
AIMS & METHODS: In this study we aimed to analyse ERCPs performed in Billroth II patients, addressing techniques and accessories used, difficulties found, success rate and complications.
Medical and endoscopic records of Billroth II patients submitted to ERCP between January 2011 and December 2013 at our institution were retrospectively reviewed.
RESULTS: A total of 15 ERCPs performed in 12 patients (9 male and 3 female, mean age 71 years, range 51-88 years) were included in the analysis.
A duodenoscope was used in 12 procedures (3 of which with a guidewire previously placed in the afferent loop), a paediatric colonoscope in 2 and an endoscope in 1 procedure.
Afferent loop intubation was achieved in all patients. In one patient, papilla was not reached due to duodenal stenosis. Precut was used for biliary cannulation in 9 ERCPs (60%). Of these, 3 were performed in a previously placed Wirsung stent, and 2 were followed by dilation without sphincterotomy.

ERCP was successful at first attempt in 9 procedures. Inability to perform selective cannulation in 5 cases and the presence of a duodenal stenosis in 1 prevented the completion of ERCP in the remaining cases. A second ERCP was performed in 3 patients, successful in all of them. The overall success rate was 80%.
One ERCP was interrupted due to patient hemodynamic instability and in another patient there was a self-limited papilla bleeding after dilation. No perforation was recorded.
CONCLUSION: ERCP is effective and safe in Billroth II patients. The choice of the most appropriate technique in each case seems to be the best way to increase the success rate in these patients and to avoid complications.
Disclosure of Interest: None declared

P1345 PROSPECTIVE EVALUATION OF ERCP PERFORMANCE – RESULTS OF A NATIONWIDE QUALITY REGISTRY

V.E. Ekkelenkamp[1,*], R.A. de Man[1], F. ter Borg[2], P.C. J. ter Borg[3], M.J. Bruno[1], M.J. M. Groenen[4], A.J. P. van Tilburg[5], E.A. J. Rauws[6], A.D. Koch[1]
[1]Gastroenterology and Hepatology, Erasmus MC University Medical Center, Rotterdam, [2]Gastroenterology and Hepatology, Deventer Hospital, Deventer, [3]Gastroenterology and Hepatology, Ikazia Hospital, Rotterdam, [4]Gastroenterology and Hepatology, Rijnstate Hospital, Arnhem, [5]Gastroenterology and Hepatology, Sint Franciscus Gasthuis, Rotterdam, [6]Gastroenterology and Hepatology, Academic Medical Center, Amsterdam, Netherlands

INTRODUCTION: Despite significant interest by health authorities, patient organizations and insurance companies, data on procedural outcome and quality of ERCP in general and academic practice are sparse. The aim of this study was to assess procedural outcome of ERCP within a large prospective registry in the Netherlands and to evaluate associations between endoscopist-related factors and procedural outcome.
AIMS & METHODS: All endoscopists performing ERCP in the Netherlands were invited to register their ERCPs over a one-year period using the Rotterdam Assessment Form for ERCP (RAF-E). Primary outcome measure was procedural success. A priori difficulty level of the procedure was classified according to Schutz. Baseline characteristics of the endoscopist, e.g. previous experience, were recorded at study entry. Regression analysis was performed to identify predictors of procedural outcome.
RESULTS: A total of 8575 ERCPs was registered by 171 endoscopists from 61 centers. This entails about 50% of all ERCPs performed in that period nationwide. Overall procedural success was 85.8%. An intact papillary anatomy was present in 5106 patients (59.5%): procedural success in this subset of patients was 83.4% versus 89.4% after sphincterotomy ($p < 0.001$). Regression analysis through Generalized Estimating Equations identified "degree of difficulty" ($p < 0.001$), "intact papillary anatomy" ($p < 0.001$), and "previous ERCP failure" ($p < 0.001$) to be independently associated with procedural failure. "Yearly volume of ERCPs" ($p < 0.01$) and "trainee involvement" ($p < 0.05$) were independently associated with success.
CONCLUSION: Our nationwide prospective RAF-E registry proved to be a valuable tool to gain insight in procedural outcome of ERCPs. The overall procedural success rate for ERCP was 85.8%. Factors predictive of outcome include Schutz classification (degree of difficulty), papillary anatomy, previous ERCP failure, ERCP volume, and trainee involvement.

P1346 HIGH RATE OF DEEP SEDATION WITH A COMBINATION OF MIDAZOLAM AND FENTANIL IN A CONSECUTIVE SERIES OF PATIENTS UNDERGOING UPPER EUS

N. Pagano[1,*], L.H. Eusebi[1], C. Luigiano[2], G. Rando[3], R.M. Zagari[1], F. Bazzoli[1]
[1]Gastroenterology and Endoscopy Unit, Policlinico S. Orsola, University of Bologna, Bologna, [2]Gastroenterology Unit, ARNAS Garibaldi, Catania, [3]UOC Chirurgia e diagnostica endoscopica, Az. ospedaliera S. Salvatore, L'Aquila, Italy

INTRODUCTION: A good level of sedation increases outcomes and safety in interventional endoscopic procedures. With benzodiazepines and morphinic based protocols a high frequency of deep sedation has been reported. This is our experience with a midazolam/fentanil based protocol of sedation in patients undergoing upper digestive endoscopic ultrasonography (EUS) with particular attention to the level of sedation.
AIMS & METHODS: We retrospectively analyzed data on sedation in all patients undergoing EUS, collected prospectively from March to October 2013. Demographic data, indication, type of procedure, data on technique, ASA score, dosage of drugs, outcomes and complications were collected. Patients were sedated with a combination of 1-2 mcg/Kg of fentanil and 0.05 mg/Kg of midazolam as initial bolus. Repeated boluses of 1 mg of midazolam every 5 minutes were then administered based on patient's response. Sp02, blood pressure, heart rate and respiratory movements were continuously monitorized during the procedure. OASS score was calculated every 5 minutes. Patients were discharged when the score was > 5. We evaluated patients and endoscopist satisfation on a scale from 0 to 10 after the procedure.
RESULTS: During the observation period, 320 upper EUS procedures were performed. 178 patients were males, mean age was 65 (range 25-89), 280 outpatients (88%). There were 22 ASA IV patients (7%), 98 ASA III patients (31%) and 200 ASA I and II patients (62%). In 96 cases a FNA was performed (30%). The mean duration of procedures was 25 minutes (range 5-45). The mean dose of midazolam was 8.5 mg (range 2-15) and the mean dose of fentanil was 95 mcg (range 0-200). In 125 procedures (39%) the mean OASS was < 2 (deep sedation), in 149 (46%) was between 2 and 4 (moderate sedation), in 46 (15%) > 4 (mild sedation). We reported 20 minor desaturation events (Sp02 $<90\%$ but $> 85\%$ for more than 10 seconds) that responded promptly to increase in oxygen flux. One patient required bag-mask ventilation for 2 minutes. In this case the procedure was completed after rescue maneuvers. The mean recovery time was 65 minutes (range 45 to 90). The patients and endoscopist mean statisfation was 8.5 (range 6-10) and 7.3 (range 6-9).
CONCLUSION: In our series, midazolam and fentanil based sedation allowed the execution of all upper EUS with a good safety profile. The doses needed to obtain a good compliance resulted in a consistent rate of deep sedation in our experience.
Disclosure of Interest: None declared

P1347 HIGHER CA 19-9 LEVELS ARE RELATED WITH HIGHER DIAGNOSTIC YIELD OF EUS-FNA IN PANCREATIC ADENOCARCINOMA

R. Barosa[1,*], P.P. Marques[2], L.R. Ramos[2], P. Figueiredo[2], T. Meira[2], J. Freitas[2]
[1]Gastroenterology, [2]Hospital Garcia de Orta, Almada, Portugal
Contact E-mail Address: *a.rita.b@gmail.com*

INTRODUCTION: Endoscopic ultrasonography guided fine needle aspiration (EUS-FNA) sensitivity and accuracy described in literature is 60-90% and 60-95%, respectively. Size and type of needle, multiple passes and on-site cytopathology assessment increases diagnostic accuracy. Serologic CA 19-9 correlates with pancreatic adenocarcinoma stage.
AIMS & METHODS: To assess the relationship between CA 19-9 and diagnostic yield of EUS-FNA. Retrospective analysis of 293 patients with pancreatic mass diagnosed between January 2009 and May 2013. A total of 87 patients underwenting first EUS-FNA were included. Two groups were analyzed: cytology diagnostic of adenocarcinoma (group 1) and inconclusive cytology (group 2). Median expression of CA 19-9 was compared and CA19-9 was analyzed as dichotomous variable (≥ 1000 or < 1000 U/L). Mann-Whitney and Qui-square tests were used for groups comparison.
RESULTS: FNA was suggestive of adenocarcinoma in 69 patients (mean age 70 years, 49% male) and inconclusive in 18 patients (mean age 67 years, 56% male). EUS-FNA sensitivity for adenocarcinoma diagnosis was 73%. The median CA 19-9 in group 1 was 1000 U/L (range 0-48462 U/L) and in group 2 was 196 U/L (range 0-7685 U/L), $p = 0.04$. In the subgroup with CA 19-9 ≥ 1000 U/L, 7.9% of all EUS-FNA were inconclusive vs. 30.6% when CA 19-9 < 1000 U/L ($p = 0.009$).
CONCLUSION: To the best of our knowledge this is the first study assessing the relationship between CA 19-9 levels and EUS-FNA diagnostic yield. Patients with first EUS-FNA diagnostic for adenocarcinoma have higher levels of CA 19-9. When using a cut- off ≥ 1000 U/L cytology is less often inconclusive.
Disclosure of Interest: None declared

P1348 A PROSPECTIVE COMPARISON OF 22-GAUGE FLEXIBLE NEEDLE AND SIDE PORT NEEDLE IN EUS-FNA FOR PANCREATIC MASSES

S. Koyama[1,*], H. Imazu[1], H. Arakawa[1], S. Koido[2], K. Kanazawa[1], N. Mori[1], M. Chiba[1], H. Toyoizumi[1], N. Shimamoto[1], T.L. Ang[3], H. Tajiri[2]
[1]Department of Endoscopy, [2]Division of Gastroenterology and Hepatology, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan, [3]Department of Gastroenterology and Hepatology, Changi General Hospital, Singapore, Singapore
Contact E-mail Address: *himazu21@aol.com*

INTRODUCTION: Two different needles; a cobalt chromium needle with an end port alone to enhance flexibility (Expect™: flexible needle, Boston Scientific) and a stainless steel needle with both side and end ports (EzShot2: side port needle, Olympus Medical Systems), have been developed to improve the diagnostic yield of EUS-FNA.
AIMS & METHODS: The aim of this study was to compare the performance of the 22-gauge flexible needle and side port needle in EUS-FNA for pancreatic masses. Fifty-two consecutive patients who underwent EUS-FNA for pancreatic masses were prospectively enrolled in this study from January 2013. EUS-FNA was performed for each mass using both with randomization of puncture sequence. Then, differences of diagnostic accuracy was evaluated, as well as, the score of adequateness of obtained specimens for cytological evaluation, needle visibility and ease of puncture (0: poor, 1: good, 2: excellent) 1).
RESULTS: A total of 86 punctures (43 with the flexible needle and 43 with the side port needle) were analyzed in 42 patients with pancreatic masses. The final diagnosis based on results of EUS-FNA, surgery and clinical course were pancreatic carcinoma in 32 patients, chronic pancreatitis in 6 and autoimmune pancreatitis in 5. The pancreatic mass was located in the head of pancreas in 25 patients, the body in 11, and the tail in 7. Sensitivity, specificity and accuracy with the overall, flexible needle and side port needle for detecting pancreatic carcinoma were 93.5/100/95.2%, 83.9/100/88.1%, and 77.4/100/83.3%, respectively (N. S). Although the score of visibility of both needles was similar (1.9 vs. 1.86, $p = 0.4$), the score of adequateness of specimens of flexible needle was significantly higher than that of side port needle (1.88 vs. 1.69, $p = 0.039$). In addition, there was no significant difference in the score of adequateness of specimens obtained from masses of the pancreatic head and body/tail with the flexible needle (1.87 vs. 1.89), while the score of adequateness for specimens obtained from pancreatic head masses with the side port needle was significantly lower than that for pancreatic body/tail masses (1.57 vs. 1.83, $p = 0.02$). The score of ease of puncture of flexible needle was significantly higher than that of side port needle (1.88 vs. 1.38, $p < 0.001$).
CONCLUSION: The flexible and side port needles have similar overall diagnostic yield, when EUS-FNA is performed for pancreatic masses. However, the flexible needle was superior in the adequateness of obtained specimens, especially from pancreatic head lesions, because puncture is significantly easier. Therefore,

the exploitation of new needle should probably be focused on enhancement of puncture performance.

P1349 REVIEW OF 114 ENDOSCOPIC ULTRASOUND-GUIDED CYSTGASTROTOMIES FOR PANCREATIC PSEUDOCYST IN TWO LONDON TEACHING HOSPITALS

S.F. Sze[1,*], M.G. Keane[1], S. Murray[1], G.J. Johnson[1], M.H. Chapman[1], G.J. Webster[1], D. Thorburn[2], S.P. Pereira[1]
[1]*Division of GI Services, University College London Hospital,* [2]*Royal Free Hospital, London, United Kingdom*
Contact E-mail Address: *alexsze@yahoo.com*

INTRODUCTION: With the advancement of interventional endoscopic ultrasound (EUS), EUS-guided cystgastrostomy is now regarded as a good alternative to surgical or percutaneous drainage in the management of pancreatic fluid collections. This procedure was performed in University College London Hospital (UCLH) since 1998 and was started in Royal Free Hospital (RFH), London from 2009 when the two services were combined.

AIMS & METHODS: This is a retrospective review of all EUS-guided cystgastrostomies performed in UCLH from 1998 to 2013 (16-year period) and RFH from 2009 to 2013 (5-year period). Case details including demographics, indications, procedure method and outcome were retreived from patient record database and endoscopy reporting tool, which were then reviewed and analyzed.

RESULTS: A total of 114 EUS-guided cystgastrostomies were identified, with 80 performed at UCLH and 34 at RFH. The male-to-female ratio was 1.5:1 and the median age was 55 years (range 23-85). The median onset of pancreatitis before drainage was 6 months (range 1-120). The most common causes of pancreatitis were gallstones (44.7%), idiopathic (23.7%), alcohol (20.2%), and post-ERCP (3.5%). The pseudocyst was usually located over the pancreatic body (45.6%) or head (14.9%). Indications for drainage included abdominal pain (40.4%), increasing pseudocyst size (35.1%), both pain and increasing size (3.51%), infected pseudocyst (14%) or luminal or biliary obstruction (5.3%). 87.7% of patients had only one pseudocyst. The median maximum diameter of the pseudocyst was 97.5mm (range 42-200). Nine patients had received previous percutaneous drainage while one patient had previous surgical drainage.

Bulge sign was reported in 28 cases (24.6%). The routes of puncture were via body (64%), antrum (13.2%), fundus (7.9%) and duodenum (6.1%). A cystotome was used in 71.1% of cases. The median length of follow-up was 13 months (range 1-138). The procedure was technically successful in 86% (98/114); drainage failed in fourteen cases (12.3%) and in two cases the pseudocyst was aspirated to dryness without stent insertion. Among those technically successful cases, a pseudocyst recurred in 13.3% (13/98) cases and one pseudocyst persisted despite drainage. Those with recurrence were managed conservatively (7/13), by repeat EUS-guided cystgastrostomy (3/13), by surgical drainage (2/13) or percutaneous drainage (1/13). Complications occured in 8.8% (10/114) including three cases of pneumoperitoneum which required laparotomy, one oesophageal perforation, four gastrointestinal bleeding (two required blood transfusion), one pneumothorax and one aspiration pneumonia. The median length of hospital stay was 7 days (range 0-174). The 30-day mortality was zero.

CONCLUSION: EUS-guided cystgastrostomy is increasingly employed in the management of pancreatic fluid collections. This large series demonstrated comparable rates of technical success, recurrence and reintervention to those reported by other groups. In comparison to surgical cystgastrostomy, rates of technical success appear to be similar but with lower complication rates and shorter hospital stays. Further studies are needed to define clear pathways for use of interventional EUS in the management of pancreatic fluid collections.

P1350 A NEW NEEDLE PLATFORM FOR EUS-GUIDED FNA: A PROSPECTIVE RANDOMIZED CLINICAL TRIAL COMPARING THE 22G NEEDLE AND THE 25G NEEDLE

S. Carrara[1,*], M. Jovani[1], A. Anderloni[1], D. Rahal[2], L. Di Tomasso[2], D. Federico[2], A. Repici[1]
[1]*Endoscopy Unit; Department of Gastroenterology,* [2]*Pathology Unit, Humanitas Research Hospital, Milan, Italy*

INTRODUCTION: EUS-FNA is safe and effective in obtaining samples from the GI masses and lymphnodes. Available needles include 25G, 22G and 19G. A recently developed needle platform allows for interchangeability of all needle sizes through a universal delivery system (BNX system, Beacon Endoscopic, Newton, MA).

AIMS & METHODS: The primary endpoint of this prospective, randomized, trial was to compare the performance of 25G and 22G needle by evaluating the adequacy of the aspirated obtained from solid lesions. Secondary aims were the ease of needle pass, needle malfunctions, n° of passes, n° of crossovers to the other needle size, major complications.

Consecutive patients referred for EUS-FNA for solid masses were randomized to the 25G or to the 22G needle arm. Inclusion criteria: EUS appearance of a solid lesions, age >18 yrs, informed consent. Crossover to the other size of needle was allowed when the endoscopist experienced difficulties in puncturing the mass, or when the material was not adequate after 3 passes.

RESULTS: Eighty-two patients were enrolled from Aug 2013 to Apr 2014 (50 M, 32F), mean age 67 years (range 29-87). Sixty pancreatic masses, 17 lymphnodes and 5 parietal lesions were biopsied. Forty-one patients were randomized to the 25G needle arm: in 8 cases (19.5%) a crossover to the 22G was asked by the pathologist in order to obtain more material for immunohistochemistry (neuroendocrine tumors or lymph-nodes). Forty patients were randomized to the 22G needle arm: in 9 cases (22%) a crossover to the 25G was done because of the hardness of the tumor. The mean of needle passes was 2.2 (±1.08 SD) per lesion. In 37 cases the aspirate was both smeared for cytological examination and put into formalin for histology. Final diagnosis was confirmed by surgical resection or radiological follow up. Overall adequacy was 86%. In 11 cases the aspirated was inadequate: 1 adenocarcinoma, 3 lymphnodes (1 sarcoidosis, 2 colliquative nodes), 1 GIST, 1 pseudosolid pancreatic mass, 1 suspected groove pancreatitis, 1 IPMN, 1 tumor involving the hepatic hylum, 2 hypervascularized pancreatic lesions. In patients with adequate specimen the sensitivity and accuracy were 95% and 91% for the 22G needle and 97% and 97% for the 25G needle, respectively. In 5 cases a resistance to 22G needle advance was felt by the endosonographer. No major complications were observed.

CONCLUSION: The BNX-platform is accurate for the diagnosis of solid masses, with results comparable to those of the literature and with no significant difference between the performance of the 22G and 25G needle. Nearly one fourth of all procedures may require crossover with a higher adequacy rate.

INTRODUCTION: Computed tomography (CT) is the commonest imaging modality used to detect fluid collections in acute pancreatitis. However CT poorly differentiates solid necrotic debris from liquid component, which plays an important role in planning intervention and predicting outcome.

AIMS & METHODS: To evaluate the role of CT and EUS in defining the morphological characteristics of pancreatic fluid collections along with quantification of the solid debris and evaluate their predictability for intervention and outcome.

Consecutive patients of acute pancreatitis with fluid collections detected on CECT, between January-October, 2013 were evaluated further by EUS using Pentax and Olympus linear echoendoscopes. Morphological characteristics of fluid collections (based on revised Atlanta) i.e. nature of collection, location, size and the amount of solid debris, were correlated for need of intervention and final outcome using CT and EUS. The amount of solid debris was graded as minimal (<10%), moderate (10-50%) and profound (>50%) and compared between various types of collections. CECT images were analysed by 2 experienced radiologists and EUS images were analysed by 2 independent endosonologists.

RESULTS: 50 patients (mean age-41.84±11.7 years, 44% males) of acute pancreatitis with fluid collections were analysed. 61 fluid collections were detected in these 50 patients, 11 of which were distant collections and could be demonstrable only on CT and remaining 50 were pancreatic/peri-pancreatic collections which could be analysed using both on CT & EUS. 18 (36%) had acute necrotic collections (ANC), 29 (58%) had walled off necrosis (WON) and 3 (6%) had pseudocysts. The mean size of fluid collections on CT was significantly more than on EUS (9.3 vs. 7.7 cm, $p<0.001$). Solid debris was detected in 46 (92%) patients using EUS while only 16 (32%) patients could be identified with CT ($p<0.001$). On EUS, minimal solid debris was noted in 11 (22%), moderate solid debris in 23 (46%) and profound solid debris in 16 (32%). 72% of ANC's labelled on CT had profound solid debris and 30% of pseudocysts labelled on CT had moderate solid debris, all of whom were managed conservatively. Amongst WON's labelled on CT, 8 (27.5%) had minimal solid debris who could be managed conservatively; 18 (62%) had moderate solid debris, 7 (38%) of whom required intervention (4-percutaneous; 3-endoscopic drainage) and 3 (10.3%) had profound solid debris, all (100%) of whom required intervention (2-endoscopic necrosectomy; 1-percutaneous drainage) ($p<0.001$).

CONCLUSION: EUS is a better modality than CT in detecting solid debris in pancreatic fluid collections. As the fluid collections evolve from ANC into WON the solid debris decreases making EUS the preferred modality for follow up of fluid collections. EUS quantification of solid debris can be used as a guide for selecting the treatment modality.

INTRODUCTION: Endoscopic ultrasonograpy (EUS) is thought to be the most reliable preoperative method for evaluation of depth of invasion. Findings on endoscopy can also predict the depth of tumor invasion.

AIMS & METHODS: The aim of this study was to evaluate the accuracy of EUS for depth of invasion and to compare the accuracy of EUS with that of conventional endoscopy (CE) to predict suitable candidates for endoscopic submucosal dissection (ESD) according to standard and expanded indication.

Between May 2009 and May 2013, 300 patients were underwent EUS and curative treatment for early gastric cancer (EGC). We reviewed the medical and compared preoperative CE and EUS staging with the pathological staging results.
RESULTS: The overall accuracy of CE and EUS to evaluate the invasion depth of EGC were 73.3% versus 76.5% ($p=0.209$). Large size, submucosal invasion, radial EUS were associated with accuracy of EUS. The accuracy of CE and EUS to identify proper candidate of ESD were 98.8%, 89.9 ($p=0.568$) in standard indication and 60.0%, 71.8% in EUS ($p=0.0064$). Undifferentiated histology (100% and 66.7%, $p=0.007$) or invasion depth confined to the mucosa (80.3% and 63.6%, $p=0.033$) were associated with higher accuracy of EUS to select the proper candidates according to expanded ESD indication compared with CE.
CONCLUSION: EUS staging could be helpful to decide the optimal treatment according to expanded indication. Especially, lesion with undifferentiated histology should be carefully considered prior to ESD by pretreatment EUS staging.

INTRODUCTION: Endoscopic ultrasonography (EUS)-guided drainage has recently been shown to be useful for treating walled-off pancreatic necrosis (WOPN), a late complication of necrotizing pancreatitis that consists of loculated fluid collections with necrotic material. With this development in mind, we became interested in determining if EUS-guided drainage is also useful for treating postoperative pancreatic fistula (POPF). Hence, the objective of this study was to examine the usefulness and safety of EUS-guided drainage for POPF.
AIMS & METHODS: A total of 37 patients who had undergone EUS-guided drainage for treatment of POPF or WOPN between December 2002 and March 2013 were enrolled in this retrospective study. We reviewed the success rates of the procedures, rates of lesion size reduction, treatment success rates, and complication rates associated with EUS-guided drainage. By comparing the resultant data for EUS-guided drainage of the two conditions (POPF and WOPN), we were able to determine the usefulness and safety of EUS-guided drainage for POPF.
RESULTS: EUS-guided drainage was performed in 14 patients with POPF and in 23 patients with WOPN. There were no significant differences in the clinical characteristics—including sex, age, and lesion size—of the patients in the POPF and WOPN groups who underwent EUS-guided drainage. The procedures required for EUS-guided drainage included aspiration in three cases, an external fistula in one case, internal fistulas in four cases, and external and internal fistulas in six cases in the POPF group, but no endoscopic necrosectomy. The corresponding numbers for the WOPN group were aspiration in five cases, external fistulas in three cases, internal fistulas in three cases, external and internal fistulas in seven cases, and endoscopic necrosectomy in three cases. The successful procedures, reduced lesion size, and successful treatment rates were 100 %, 100 %, and 93 %, respectively, in the POPF group and 91.3 %, 78.2 %, and 71.4 %, respectively, in the WOPN group. The reduced lesion size and treatment success rates were significantly higher in the POPF group than in the WOPN group. No complications occurred in the POPF group, whereas four patients in the WOPN group suffered such complications as perforative peritonitis and procedure-related bleeding. In all, 26 (13 POPF, 13 WOPN) of 37 patients were followed up for a mean of 22 ± 4.2 months. There were no recurrences in the POPF group, whereas three patients in the WOPN group did have a recurrence.
CONCLUSION: EUS-guided drainage is a useful treatment not only for WOPN but also for POPF. Comparing the usefulness and safety of EUS-guided drainage in patients with POPF using the same parameters as those used to assess its use in those with WOPN indicated that EUS-guided transmural drainage can be a good option for treating POPF.

INTRODUCTION: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is an accurate technique to biopsy lymph nodes and masses for cytological analysis. Residual material, being residue aspirate or an extra aspiration after preparation of cytological smears or residual tissue, can be used for liquid-based or cell block preparation, which may be useful when smears are inadequate and/or immunohistochemistry is required. For liquid-based preparation, residual material is placed in hemolytic solution and then placed on a slide, resulting in a thin layer of cells. For cell block preparation, residual material is clustered, embedded in a fixative and then cut, enabling analysis of tissue particles that are too thick to be analysed with cytological smears. The diagnostic value of these additional tests is unclear. We hypothesised that analysis of residual material is a valuable addition to EUS-FNA.
AIMS & METHODS: The aim of this study was to evaluate the additional diagnostic yield of liquid-based or cell block prepared residual material after routine cytological smear analysis in EUS-FNA procedures. EUS-FNA procedures between 2002 and 2013 were identified using a single center endoscopy database. Diagnostic yield and accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of cytological smears and smears combined with residual material were calculated and compared using one-sided testing. Diagnostic yield was defined as the proportion in which the pathologist could make a diagnosis. Diagnostic accuracy was defined as the proportion in which the diagnosis of the pathologist was in line with the final diagnosis based on a histologal biopsy, surgical resection or clinical outcome.
RESULTS: In total, 510 cases were identified. EUS-FNA was successful in 482 cases (95%), on-site evaluation was available in 448 (93%). A total of 580 sites were targeted, a lymph node was targeted 444 times (77%) and a mass 136 times (23%). The most frequently aspirated sites were the subcarina ($n=264$, 46%), pancreas ($n=64$, 11%) and aortopulmonary window ($n=64$, 11%). Residual material was available in 216 cases (45%), which directly benefited the diagnosis in 30 cases (14%). In 11 cases (37%), it led to the diagnosis, in 4 cases (13%) it enabled differentiation in origin of the tumour and in 15 cases (50%) immunohistochemistry was useful to determine the origin of the tumour. In cases with residual material available and using the cytological smears only for analysis vs. combining this with analysis of residual material, the diagnostic yield was 88% vs. 88% ($p=0.5$), diagnostic accuracy 82% vs. 92% ($p=0.01$), sensitivity 79% vs. 90% ($p=0.01$), specificity 97% vs. 97% ($p=0.5$), PPV 99% vs. 99% (0.44) and NPV 55% vs. 72% ($p=0.03$). Number needed to test with regard to residual material was 7.2.
CONCLUSION: Additional analysis of liquid-based or cell block prepared residual material after analysis of cytological smears benefits diagnostic accuracy, sensitivity and NPV in EUS-FNA procedures. Future studies are warranted to establish whether adding the analysis of residual material is indeed cost-effective.

INTRODUCTION: Assessing the role of endoscopic ultrasound (EUS) examination in the diagnosis of non-typical or malignancy suspected stomach lesions found in conventional upper endoscopy.
AIMS & METHODS: Twenty eight patients (64.3% male, 35.7% female) at mean age 55±18 years with endoscopy findings of stomach ulcers (25%), polyps (21.4%), polypoid mucosal changes (35.7%) or enlarged folds (17.9%) were evaluated by linear EUS in our centre following conventional forceps biopsies. According to the endosonographic features of the lesions: homogeneity, thickening or loss of wall stratification, lesion margins, presence of necrotic areas and lymph nodes, they were classified as EUS benign and EUS malignant. Biopsy results were also subdivided into two groups – benign (gastritis, adenoma, hyperplastic and fundic gland polyp) or malignant (carcinoma, lymphoma) and compared to EUS groups. All lesions signed as malignant were further evaluated by computer tomography, second look biopsies and/or laparoscopy/laparotomy.
RESULTS: Patients' evaluation resulted in the following groups: EUS benign – 42.9%, EUS malignant – 57.1%; biopsy benign 67.9%, biopsy malignant 32.1%. When comparing EUS and biopsy groups we found that EUS features of malignancy were present in 7 cases (43.8%) with benign histology results, while all EUS benign lesions corresponded to benign histology ($p=0.002$). The mismatch cases were further evaluated resulting in change of diagnosis in all patients of this group from benign to malignant. In the malignant EUS groups, the predominant EUS features were: presence of lymph nodes (87.5% vs. 12.5%, $p=0.005$), loss of wall stratification (93.8% vs. 6.3%, $p<0.001$) and lesion heterogeneity (87.5% vs. 12.5%, $p<0.001$).
CONCLUSION: Endosonography of stomach lesions is a reliable method for neoplasm detection. Even in patients with negative conventional biopsy histology result certain EUS features are indicative for malignancy and can lead to the final diagnosis.

INTRODUCTION: Contrast-enhanced endoscopic ultrasonography (CE-EUS) is a new imaging modality for detecting intratumoral vessels in real time.
AIMS & METHODS: The aim of this study was to elucidate the histological and clinical implications of detection on CE-EUS of intratumoral vessels in gastrointestinal stromal tumors (GISTs). A total of 13 patients, each having a GIST, and all of whom were referred for surgery, underwent presurgical CE-EUS. Final diagnoses were made by pathologic examination of resected specimens. The GIST malignancy potential, assessed according to the modified Fletcher risk classification system, and the histological degree of angiogenesis were compared to the presence or absence of intratumoral vessels on CE-EUS.

RESULTS: Intratumoral vessels were observed on CE-EUS in 6 patients, but not in the remaining 7. Of the 6 tumors with intratumoral vessels, 5 (83%) were intermediate- or high-risk GISTs, and all negative cases were categorized as very low risk or low risk. Presence of intratumoral vessels on CE-EUS was significantly correlated with a higher-risk classification (according to the modified Fletcher classification system) ($P = 0.005$). All GISTs with the visualized vessels with CE-EUS incorporated vessels more than 500 μm in histology. The large intratumoral vessels of the 5 intermediate- or high-risk GISTs lacked elastic fibers, suggesting that they were neovascular in nature. These higher-risk tumors were also found, by immunohistochemical analysis, to have high expression of vascular endothelial growth factor.
CONCLUSION: Intratumoral vessels observed in GISTs on CE-EUS are large vessels, by histological examination, and are correlated with higher malignant potential.

INTRODUCTION: According to TNM classification of esophageal cancer, the T1 stage is subdivided into mucosa (T1m) and submucosa (T1sm). Endoscopic submucosal dissection (ESD) is a newly developed skill to complete resection gastrointestinal (GI) tract early cancer. The limitation of ESD is cancer invasion to submucosal layer and increasing the risk of lymph node metastasis (20-28%), therefore, the accurate T1 stage subdivision of esophageal cancer prior to ESD is essential.
Endoscopic ultrasound (EUS) is a useful examination for detecting the T stage of GI tract cancer, the reported accuracy of different T stage are around 70-90%, however, there are few published data on the detail discrimination of EUS among each subdivision T1m or T1sm of esophageal cancer. The aim of this study is to evaluate the accuracy of T1 stage subdivision of esophageal cancer by higher frequency EUS probe.
AIMS & METHODS: From April 2009 to March 2014, there are 1125 patients diagnosed with esophageal cancer, further stage with EUS, computered tomography and PET-CT. The EUS examination is performed with miniprobe (UM-2R, 12 MHz, UM-3R, 20 MHz; Olympus Optical Co. Ltd., Tokyo, Japan) and water immersion method.
The enrolled criteria of this study: 1. esophageal squamous cell carcinoma was proved by biopsy result. 2. T1m or T1sm stage diagnosed by EUS. 3. Further treatment with ESD or radical surgery. All EUS-T stage results were correlated with final pathological T stage.
RESULTS: There were 134 patients with T1 stage of esophageal squamous cell carcinoma by EUS, and 73 patients received further ESD (33) or surgical esophagectomy (40). All lesions were confirmed as T1 on pathology, EUS stage of T1m in 55 patients and 45 (82%) were confirmed as T1m on pathology; of the 18 T1sm on EUS and12 (67%) were confirmed as T1sm. Positive predictive value of EUS for T1m was 82%, negative predictive value was 67%, sensitivity 88%, specificity 55%.
CONCLUSION: EUS demonstrated median degree of accuracy for distinguishing between stages T1m and T1sm of esophageal squamous cell carcinoma. Even with high frequency miniprobe, peritumoral inflammation or submucosal fibrosis causes some difficulties in differentiating mucosal from submucosal lesions, and develops more advanced EUS device is needed. EUS remains a valuable tool when endoscopic treatment is considered.

P1358 EUS GUIDED CARDIAC APRROACH-EUS GUIDED TRANSESOPHAGEAL PERICARDIOCENTESIS

Y. Hashimoto[1,*], I. Kazuaki[2]
[1]*Gastrointestinal Oncology/Endosocpy, National Cancer Research Center East Hospital, Kashiwa,* [2]*Gastroenterology, Showa Univeristy Fujigaoka Hospital, Yokohama, Japan*
Contact E-mail Address: *yusuke.h914@gmail.com*

INTRODUCTION: EUS-guided intervention has been established for diagnostic and therapeutic procedures in gastroenterology. Echocardiographic-guided pericardiocentesis is the preferred initial procedure for the diagnosis and treatment of pericardial effusion. Pericardial effusion is rarely located in the posterior side of pericardial sac, which makes it difficult for cardiologist to perform Echocardiographic-guided pericardiocentesis through the subxiphoid route. Cardiac intervention using EUS- guided transesophageal approach might be anatomically practical but has still been experimental.
AIMS & METHODS: AIM: These clinical cases are to show our experience of EUS guided-transesophageal pericardiocentesis successfully and safely. METHODS: Three patients who failed echo-cardiography guided diagnostic pericardiocentesis were offered EUS-guided approach. Informed consent was obtained. Diagnostic EUS-pericardiocentesis was performed with sedation of meperidine and midazolam. EUS guided transesophageal puncture using 22G needle was performed into the pericardial effusion. The fluid was fully aspirated for evaluation of tumor makers, cytology and culture. Patients were carefully monitored during and after the procedure and given third generation cephalosporins.
RESULTS: EUS-guided pericardiocentesis performed in 3 patients in hemodynamic stable condition (Male = 2, Average 69 year old). The puncture was via lower portion of the esophagus. The average procedure time is 10minutes. The median fluid amount was 15ml. EUS guided aspiration confirmed non-diagnostic in 2 patients and tubeculosis in 1 patients. No early or late complications: no infection, arrythmia, heart failure and/or bleeding.
CONCLUSION: EUS guided transesophageal approach to pericardiocentesis was successful in the limited cases. The cases must be applied to the procedure only if echocardiographic pericardiocentesis fails.

P1359 GUIDE-WIRE ASSISTED INSERTION OF AN ULTRATHIN ENDOSCOPE INTO THE PROXIMAL JEJUNUM: A NOVEL TECHNIQUE

A. Mori[1], **T. Yumura**[1,*], H. Hachiya[1], S. Ito[1], S. Hayashi[1], N. Ohashi[1]
[1]*Ichinomiya Nishi Hospital Gastroenterology, Ichinomiya, Japan*
Contact E-mail Address: *a-mori@anzu.or.jp*

INTRODUCTION: Insertion into the proximal jejunum with conventional esophagogastroduodenoscopy (EGD) by push technique is difficult. The reasons for difficulty are that an endoscope bends in the stomach and the distal end of an endoscope has less flexibility for advancement. Although the flexible ultrathin endoscope (UTE) has the drawback of easily bending in the stomach, when inserting the stiff guide-wire through the biopsy channel, the bending of the UTE in the stomach is avoided. Using these characteristics of the UTE, we made it possible to insert the UTE assisting with a balloon and a super stiff guide-wire into the common bile duct (Endoscopy 2012; 44). Recently, we have developed a novel technique which inserts the UTE assisting with only a super stiff guide-wire into the proximal jejunum. We report here the method and the feasibility of this technique.
AIMS & METHODS: 20 consecutive patients were evaluated in a preliminary prospective feasibility study. 16 patients were suspected of the distal duodenal and proximal jejunum diseases (7 strictures, 4 obscure gastrointestinal bleedings, 2 tumors and 3 others) and 4 patients needed injection of enteral feeding from the distal duodenal and proximal jejunum. All unsedated patients underwent this procedure via transnasal route. After observing the upper gastrointestinal tract with the UTE (EG580NW, FujiFilm, Tokyo, Japan), we inserted a guide wire (Amplatz superstiff 0.035) using the biopsy channel of the UTE until about 20 cm distal end of the UTE to maintain the stiffness of the UTE to avoid the bending in the stomach. This facilitated insertion of the UTE into the proximal jejunum and made it possible to perform not only EGD but also jejunoscopy at the same time (ultrathin esophagogastroduodenojejunoscopy: UT-EGDJ). We assessed the success rate, procedure time and usefulness in diagnosis. Successful UT-EGDJ was defined as the fluoroscopically-confirmed advancement of the UTE beyond the duodeno-jejunal angle.
RESULTS: UT-EGDJ was performed successfully in 19/20 patients (95%). We failed to complete UT-EGDJ in only one patient who had a huge abdominal aortic aneurysma placed the stent graft in. The median (interquartile range) time to reach the proximal jejunum was 300 (240-327) seconds. This procedure revealed 3 SMA syndromes, one small intestinal adenoma with bleeding and one lupus enteritis. No significant clinical complications related to UT-EGDJ.
CONCLUSION: UT-EGDJ appears to be sufficiently feasible and may be available for a screening of the deep duodenum and proximal jejunum as a bridge to balloon small intestinal endoscopy.

P1360 EFFECTIVENESS OF ENDOSCOPIC ULTRASONOGRAPHY DURING DOUBLE BALLOON ENTEROSCOPY FOR SUSPECTED SMALL BOWEL TUMORS

A. Murino[1,*], M. Nakamura[1], T. Yamamura [2], A. Nagura [2], T. Yoshimura [1], A. Nakano [1], H. Oshima [1], J. Sato[1], K. Furukawa [1], K. Funasaka [2], E. Ohno [1], R. Miyahara [1], H. Kawashima [1], O. Watanabe [1], Y. Hirooka [2], T. Ando[1], H. Goto[1]
[1]*Department of Gastroenterology and Hepatology, Nagoya University Graduate School of Medicine,* [2]*Department of Endoscopy, Nagoya University Hospital, Nagoya, Japan*
Contact E-mail Address: *albertomurino@yahoo.it*

INTRODUCTION: Endoscopic Ultrasonography (EUS) performed during Double Balloon Enteroscopy (DBE) was firstly reported in 2006. The combination of these two techniques allows the endoscopists to evaluate extraluminal small bowel (SB) lesions previously considered inaccessible. Despite appearing a promising diagnostic technique, his employment is still limited and his usefulness is not widely assessed.
AIMS & METHODS: The aim of this retrospective study was to evaluate the diagnostic rate of EUS during DBE for suspected small bowel tumors (SBT) and its usefulness for characterization of sub mucosal tumors (SMT) in a large cohort of patients. The secondary endpoint was to compare, for the first time, DBE and EUS with computerised tomography (CT) and small bowel capsule endoscopy (SBCE).
Patients with a suspected SBT, who underwent EUS-DBE in our Institution between 2007 and December 2013, were retrospectively reviewed. Demographic datas, clinical, endoscopic and radiological findings, therapeutical management, final diagnosis and follow-up were considered. DBE, EUS, SBCE and CT diagnostic rate and concordance among the 4 procedures analysed.
RESULTS: Sixty-one patients with suspected SBT were included in the study (38 male, 54 years old). DBE and EUS were performed in all patients, CE in 29 and CT in 56. SBT were diagnosed in 46 patients, 30 were SMT while the remnant 16 SBT involved the mucosa. DBE and EUS diagnosed SBT in 44 (96%) and 43 (93%) patients respectively. In particular a correct characterization of SMT was obtained by DBE and EUS in 8 (27%) and 20 (67%) patients respectively ($p = 0.0014$). GIST (8), carcinoid (1), metastasis (3), haemangioma (3) were successfully diagnosed in all case by EUS while the characterization of SB pancreatic

rest (3/8), lymphangioma (1/4) and lipoma (0/2) was limited. In addition CE detected 10 SB tumors out of 19 (53%) and CT 34 out of 44 (77%). SBT diagnosis concordance rates among the procedures were the following: DBE-EUS 91% (42/46), DBE-CE 53% (10/19), DBE-CT 73% (32/44), EUS-CE 47% (9/19) EUS-CT 68% (30/44), CE-CT 42% (8/19).
CONCLUSION: Our results suggest that EUS performed during DBE is a useful technique for SBT diagnosis and in particular for SMT characterization. Therefore we recommend integrating EUS to DBE practice to establish a certain diagnosis, in order to provide the most appropriate medical management.

[1]*Gastroenterology, C. HOSPITALAR VILA NOVA GAIA, V N Gaia, Portugal*

INTRODUCTION: After positive findings in capsule enteroscopy, device-assisted enteroscopy route is not always evident. Gay *et al*[1] developed an index to predict the correct route for device-assisted enteroscopy after a positive capsule enteroscopy (if transit time until the finding > 0.75 of orocecal time – anal route). Recently, Li *et al.*[2] proposed another índex (if transit time between pylorus and the finding >0.6 of small bowel transit – anal route).
AIMS & METHODS: To evaluate Gay index ability to predict the correct route for single balloon enteroscopy after positive findings in capsule enteroscopy. To compare Gay index with Li index.
A single-center retrospective study evaluated patients with positive findings on capsule enteroscopy that were subsequently submitted to a single balloon enteroscopy. Considered the period between January 2010 and September 2013. Single balloon enteroscopy route selected accordingly to Gay index. Comparison with Li index.
RESULTS: 49 patients (female gender 57.1%; mean age 66.7 years) were evaluated. Angioectasias (n:20) and bleeding without an identified source (n:17) were the most important capsule enteroscopy positive findings. Accordingly to Gay index, oral route was selected in 69.4% (n:34) of the cases. The single-ballon enteroscopy goal was not fulfilled in 12.2% (n:6). Nevertheless, in 5 cases the goal was not achieved for reasons not related to the distance (fixed angulation: 3; technical issues 1; stenotic ileo-colic anastomosis: 1). In one case it was attempted the alternative route, without success. Gay index and Li index were concordant in 98% (n:48) of the cases.
CONCLUSION: In our study 1) the single-balloon enteroscopy goal was achieved in most of the patients; 2) Gay index revealed a good ability to predict the single-balloon enteroscopy route; 3) Li index and Gay index revealed a similar ability to predict the correct insertion route.

P1362 CELIAC DISEASE AND DOUBLE-BALLOON ENTEROSCOPY: WHAT CAN WE ACHIEVE? THE EXPERIENCE OF TWO EUROPEAN TERTIARY REFERRAL CENTERS

C. Tomba[1,2,*], L. Elli[2], R. Sidhu[3], F. Branchi[1], M. Locatelli[1], L. Roncoroni[2], D. Conte[1,2], M.T. Bardella[2], P. Mooney[3], D. Sanders[3]

Contact E-mail Address: *tomba.carolina@gmail.com*

INTRODUCTION: The indications for and efficacy of device-assisted enteroscopy is not standardised in celiac disease (CD).
AIMS & METHODS: We present the largest study to date to evaluate the clinical role of double-balloon enteroscopy (DBE) in complicated CD. DBE findings in CD patients with suspected small bowel complications were retrospectively evaluated in two tertiary referral centers (Milan and Sheffield). Demographic data of the studied cohort were compared with a database of 1000 non complicated CD patients.
RESULTS: Findings from 14 oral and seven anal DBE in 19 CD cases (11 males p = 0.003 vs control database) were reviewed. Mean age at CD diagnosis (39±19 vs 27±18) and at small bowel evaluation (49±15 vs 38±13) was significantly higher in the DBE group compared to controls (p < 0.001). Indications for DBE were the follow up of known refractory coeliac disease (RCD) (#7), suspicion of small bowel complications due to gastrointestinal symptoms (#4), severe iron deficiency anemia (#6) and long standing poor dietary adherence (#2). All DBE were performed after small bowel capsule endoscopy, except for one case. Three patients from the known RCD group had evidence of TCR gamma monoclonality on biopsy (type 2 RCD). One of these patients had jejunal ulceration whilst the other 2 cases had areas with small white raised patches. A further RCD case had evidence of jejunal ulceration however biopsies didn't show any evidence of TCR gamma monoclonality. Patchy small bowel atrophy was observed in all the non adherent patients and in 2 patients with persistent gastrointestinal symptoms who had only been on a gluten free diet for a short time. Two jejunal adenocarcinomas and an ileal neuroendocrine tumour were detected. All 3 of these patients presented with iron deficiency anaemia. A therapeutical approach was planned in 30% of patients after DBE. No events were detected at follow up (18 months; 5-55).
CONCLUSION: This is the largest international DBE outcomes study in CD patients. DBE could be useful in selected CD cases to exclude/confirm malignant or premalignant conditions, possibly associated even with minor mucosal lesions. Evaluation of non-responsive/refractory symptoms by DBE was associated with older patients and a higher proportion of males than an uncomplicated CD population. Studies are needed to understand the clinical relevance of the small bowel endoscopic features and to optimise DBE indications.

INTRODUCTION: Diagnosis of small bowel tumor can be a very challenging. Videocapsule endoscopy (VCE) and balloon-assisted enteroscopy (BAE) have their own specific limitations.
AIMS & METHODS: To estimate the benefits of combined use of VCE and BAE in diagnosis and treatment of small bowel tumors. From II. 2007 until IV.2014 VCE followed by BAE were performed in 43 pts. (m-18, f-25, mean age 45±13.9 yrs., range 18-73) with strongly suspected small bowel neoplasia. Small bowel tumors have been detected in 31 (72.0%) pts. (m-14, f -17, mean age 42±14.5 yrs., range 18-70). Obscure GI bleeding was an indication for VCE in 19 (61.3%) of them. The insertion route for BAE was determined according to the site of the suspected lesions detected by VCE. For precise diagnosis and tumor evaluation we performed sonde-EUS through the enteroscope in 13 (41.9%) pts. with intestinal neoplasia.
RESULTS: According to VCE data tumor was suspected in 30 (96.7%) pts. while BAE detected the neoplastic lesions in 29 (93.5%) pts. (plus in 2 pts. with negative BAE we've performed laparoscopy and revealed tumors with extra-organic growth). BAE-EUS in 13 pts. provided detailed and useful information about the echogenicity, its echo-structure and the layer of origin of the tumor that helped to determine the treatment policy and method of tumor removal. Histologically the tumors were defined as neuroendocrine tumors in 6 (19.3%) pts., GIST in 4 (12.9%) pts., adenocarcinoma in 2 (6.4%) pts., lymphoma in 1 (3.2%) pt., Peutz-Jeghers hamartomas in 8 (25.8%) pts., hyperplastic polyps in 4 (12.9%) pts., tubular adenoma in 2 (6.4%) pts., cavernous haemangioma in 2 (6.4%), angiofibrolipoma in 1 (3.2%), lymphangioma in 1 (3.2%) pt. Intestinal tumors mainly localized in jejunum in 16 (51.6%) pts. and in ileum 8 (25.8%) pts. and in 7 (22.6%) pts. with Peutz-Jeghers syndrome (5) and neuroendocrine tumors (2) the lesions extended segmental in jejunum and ileum. Conservative specific treatment was applied in 1 (3.2%) patient with B-cell lymphoma as well as endoscopic haemostasis by APC during BAE because of tumor bleeding. Endoscopic treatment (polyp removal) was performed in 11 (35.5%) pts.: EMR (1) and polypectomy (10). Surgery was performed in 18 (58.1%) pts.

Diagnostic accuracy	VCE	BAE	VCE+BAE
Sensitivity	**96.6%**	**93.3%**	**100%**
Specificity	**77.0%**	**92.3%**	**92.3%**

CONCLUSION: Complex enteroscopy (VCE+BAE) provides all the benefits of gradual, proper and accurate diagnosis of small bowel tumors as well as possibilities of conservative/endoscopic treatment through the endoscope in 38.7% patients. Combination of VCE and BAE demonstrates a higher effectiveness in the diagnosis of small bowel neoplasia than its separate usage.

P1364 A PROSPECTIVE COHORT STUDY EVALUATING NAVIAID AB - A NOVEL PLATFORM FOR DEEP SMALL BOWEL ENTEROSCOPY

H. Neumann[1,*], K. Mönkemüller[2], G.E. Tontini[1,3], M. Grauer[1,4], M. Vieth[5], L.C. Fry[2], M.F. Neurath[1]
[1]*UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen, Germany,* [2]*University of Alabama at Birmingham, Birmingham, United States,* [3]*IRCCS Policlinico San Donato, San Donato Milanese, Italy,* [4]*Klinikum Neumarkt, Neumarkt,* [5]*Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: Endoscopic visualization of the small-bowel is facilitated by device-assisted enteroscopy. Deep small-bowel intubation mostly requires a significant amount of time, involved a prolonged learning curve, and coopers often two assistance. Notable, it has been shown that more than 75% of lesions within the small bowel are located in the proximal jejunum.

AIMS & METHODS: To evaluate the feasibility, usability, and safety of a novel platform for deep small bowel enteroscopy featuring the very recently introduced NaviAid AB device. This was a prospective, single-center pilot and feasibility study. Patients underwent deep small bowel enteroscopy featuring the newly introduced NaviAid AB device for evaluation of obscure gastrointestinal bleeding, suspicious small-bowel Crohn's disease, celiac disease, familial adenomatous polyposis or abdominal pain. Study end points included successful deep small bowel enteroscopy, time to evaluate the small bowel, success of therapeutic interventions, adverse events, and endoscopists' subjective evaluation of NaviAid AB.
RESULTS: Overall, 23 patients, aged 19 - 77 years were prospectively included. Enteroscopy was feasible in all cases. Mean time to prepare the system was 2 minutes (Range 2-5 minutes). The estimated small bowel intubation depth was 200 cm (Range 90-280 cm) past the ligament of Treitz. Average time of the procedure was measured as 14 minutes (Range 13-18 minutes). Findings included small bowel Crohn's disease, small bowel diverticulosis, NSAID enteropathy, celiac disease, small bowel polyps and angiovascular malformations. No procedure related complications occurred.
CONCLUSION: The newly introduced NaviAid AB device allows safe and fast on demand deep enteroscopy. Approaching the deep jejunum could be achieved within only 14 minutes. The device allows stable positioning of the scope for therapeutic interventions. Therefore, the new NaviAid AB device could become an additional device to explore the small bowel. Future studies should now focus on the learning curve and if even total enteroscopy is feasible.

P1365 UTILITY OF DOUBLE BALLOON ENTEROSCOPY IN PATIENTS WITH SURGICALLY ALTERED BOWEL ANATOMY AFTER OBESITY SURGERY

J. Velazquez[1,2,*], M. Skinner[2], S. Peter[2], K. Monkemuller[2]
[1]*ENDOSCOPY, UNIVERSIDAD NACIONAL AUTÓNOMA DE MÉXICO, MEXICO, Mexico,* [2]*ENDOSCOPY, UNIVERSITY OF ALABAMA, Birmingham, United States*
Contact E-mail Address: *jacovelazquez@gmail.com*

INTRODUCTION: Endoscopic investigation of the gastrointestinal (GI) luminal and pancreatobiliary tracts in patients with surgically-altered GI anatomy after bariatric surgery is challenging and often impossible. The advent of balloon-assisted enteroscopy (BAE) has increased our ability to navigate through the surgically altered bowel. Despite the existence of BAE since more than a decade there is few data available on it potential utility for evaluation post-obesity-surgery patients.
AIMS & METHODS: To evaluate the diagnostic yield, success and complications rates of double-balloon enteroscopy (DBE) in consecutive patients with GI problems necessitating endoscopic evaluation.
Materials and Methods: Single-center, observational, cohort study of consecutive patients with post-obesity-surgery undergoing DBE during a 12-months period. Patients' demographics, procedure indications, findings, endoscopic interventions, and post-procedural recovery data were recorded.
RESULTS: A total of 265 DBE were performed at our institution during the 12-months study period. Thirty-three patients (12.1%) with post-obesity surgery were evaluated using DBE. The most common indication for DBE was obscure GI bleeding (OGIB) (n = 12), followed by DBE-ERCP (n = 11), and evaluation of and abdominal pain (n = 10). The excluded stomach could be reached in 90% of patients. The overall diagnostic yield of DBE-ERCP was 65% (stones, n = 4, sphincter stenosis, n = 3, bile leak, n = 2, bile duct stricture, n = 1). The yield of DBE for abdominal pain was 20% (n = 2: gastric erosions, gastro-gastric fistula) and DBE for OGIB 75%. Of the 12 patients with OGIB, 9 had active bleeding at the time of DBE. In all but one case, the bleeding was occurring at the site of the anastomosis, whether that be hepaticojejunal, jejunojejunal, or gastrojejunal. Of these patients 5 patients had arteriovenous malformations at the anastomotic site, 5 had ulcers or erosions, and 2 were bleeding secondary to Dieulafoy's lesions. A total of one complication (3%) was observed (small bowel perforation after application of argon plasma coagulation to the jejunojejunal anastomosis).
CONCLUSION: DBE is a feasible and relatively safe technique to evaluate the small intestines, stomach and biliary tract and associated with reasonably high diagnostic yield in patients with surgically altered bowel anatomy in the setting of bariatric surgery.

INTRODUCTION: The causal mechanism of acute pancreatitis after oral double balloon enteroscopy (DBE) is still uncertain. The most probable cause seems to be a mechanical straining of the endoscope with an over-tube on the pancreas. Hyperamylasemia and hyperlipasemia after DBE are frequent and usually asymptomatic. They do not represent the immediate risk factor of acute pancreatitis. The aim of this prospective study was to investigate several laboratory markers to predict patients in a higher risk of hyperamylasemia and hyperlipasemia and/or possible DBE-associated acute pancreatitis.
AIMS & METHODS: A total 38 patients (18 men and 20 women, mean age 51 years) with 44 DBEs and 30 matched healthy controls with no endoscopy entered the study. Following laboratory markers were investigated before, 4 hours and 24 hours after DBE and once in controls: serum hs-CRP, prokalcitonin, total S100 protein, cathepsin B, SPINK1, lactoferrin, E-selectin, alfa-1-antitrypsin, malondialdehyde, amylase and lipase. The mean time of DBE was 80 min. (range 20 – 210 min.), the mean number of push-and-pull cycles was 14 (range 1 – 41). We have not recorded any DBE-associated acute pancreatitis in this series.
RESULTS: Serum amylase and lipase rose significantly with the maximum 4 hours after DBE, with increased abnormal values in 31/44 (70%) of serum amylase and 29/44 (66%) of serum lipase ($p < 0.001$ and $p < 0.001$). Serum cathepsin and procalcitonin decreased significantly 4 hours after DBE compared to healthy controls and patients' values before DBE ($p = 0.018$ and $p = 0.031$). There was a statistically significant, but clinically irrelevant, difference in malondialdehyde between males and females 4 hours after DBE (0.33±0.20 vs. 0.20±0.13 μmol/L; $p = 0.012$). No other gender-associated difference was recorded. There was a trend for an association between number of push-and-pull cycles in DBE and procalcitonin ($r = -0.384$; $p = 0.011$) and urine amylase ($r = 0.313$; $p = 0.043$) 4 hours after DBE; between procalcitonin and alfa-1-antitrypsin ($r = 0.358$; $p = 0.021$), cathepsin ($r = 0.362$; $p = 0.020$) and hs-CRP ($r = 0.358$; $p = 0.021$); and between E-selectin and malondialdehyde ($r = 0.364$; $p = 0.019$) 4 hours after DBE. Either serum amylase or lipase 4 hours after DBE did not correlate with any markers before DBE.
CONCLUSION: Our current results support our previous hypothesis that endoscope-induced mechanical straining during DBE is the most important factor responsible for the increase of amylase and lipase or even for progression to acute pancreatitis. We found no laboratory predictive markers that would identify in advance those patients in a higher risk.

P1367 EFFICACY OF SINGLE-BALLOON ENTEROSCOPY FOR TREATMENT OF THE STENOSIS IN SMALL INTESTINE

N. Ogata[1,*], K. Ohtsuka[1,2], S. Hayashi[1], K. Kodama[1], S.-E. Kudo[1]
[1]*Digestive Disease Center, SHOWA UNIVERSITY NORTHERN YOKOHAMA HOSPITAL, Yokohama,* [2]*Endoscopy unit, TOKYO MEDICAL and DENTAL UNIVERSITY HOSPITAL, Tokyo, Japan*
Contact E-mail Address: *n.ogata@hotmail.co.jp*

INTRODUCTION: Before the progress of balloon-assisted enteroscopy (BAE) and wireless capsule endoscopy, the stenoses of the small intestine were detected by CT or radiological enteroclysis. They were often difficult to diagnose, and surgery was selected for diagnostic therapy. BAE has enabled to make diagnosis and treat small intestinal lesions. We evaluated the efficacy of single-balloon enteroscopy (SBE) for treatment of small intestinal stenosis.
AIMS & METHODS: A total of 632 cases of SBE were performed between September 2005 and December 2013 at our center, and 62 stenotic cases of the small intestine detected by SBE were enrolled in the study. Stenosis was defined as difficulty in penetrating the enteroscope or sliding tube. Endoscopic balloon dilation (EBD) was performed to the suitable cases of benign stenosis. The indications of EBD were as follows: ①benign stenoses with the length being less than or equal to 5cm, ②strictures without deep ulcers, fistulas, or abscesses, and ③stenoses without sharp angle. Adopted cases were divided into two groups: 'CD' group with stenoses caused by Crohn's disease, and 'non CD' group with benign stenoses caused by other factors. We assessed the first EBD success rate, restenotic rate, duration until restenosis, cumulative surgical free rate and occurrence of complications.
RESULTS: The causes of the stenosis cases included 23 Crohn's disease (CD, 37.1%), 4 postoperative stenosis (6.5%), 4 ischemic enteritis (6.5%), 6 adenocarcinoma (9.7%), 4 cases of invasion of small intestine from other carcinoma (6.5%), 6 malignant lymphoma (9.7%), 5 other cases (8.1%), and 10 cases of unknown etiology (16.1%). Of the 62 cases, 24 were suitable for EBD therapy, and 15 cases were included in the 'CD' group while 9 cases (2 ischemic enteritis, 2 postsurgical stenoses, and 5 others) were in the 'non CD' group. The first EBD successful rate was 100% for each. Eight of the 15 CD cases had restenosis, while restenosis occurred in one of nine non CD cases. The two groups had a significantly different restenotic rate ($P < 0.05$). Duration until occurrence of restenosis was 10.9±1.9 months on average. The cumulative surgical free rate after EBD was 87.5% (21/24), and the observation period was almost 4 years. One case had a post-EBD bleeding, but perforation or other complications did not occur.
CONCLUSION: EBD was performed safely in most cases. The result suggests it is necessary to consider periodical SBE for stenotic lesions in the small intestine, especially in CD cases. There is a possibility that surgery can be avoided by doing EBD in cases of small intestinal stenoses.

P1368 USEFULNESS OF CAPSULE ENDOSCOPY IN THE DIAGNOSIS OF OVERT OBSCURE GASTROINTESTINAL BLEEDING COMPARED WITH BALLOON-ASSISTED ENTEROSCOPY

R. Sawada[1,*], T. Kato2[2], D. Ide[1], E. Hayashi[1], T. Iwasaki[1], N. Komoike[1], M. Saruta[1], S. Arihiro[1], N. Tamai[2], M. Matsuoka[1], S. Saito[2], H. Tajiri[1]
[1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine,* [2]*Department of Endoscopy, The Jikei University School of Medicine, Tokyo, Japan*

INTRODUCTION: Although overt obscure gastrointestinal bleeding (OGIB) is difficult to diagnose, capsule endoscopy (CE) and balloon-assisted enteroscopy (BAE) are very effective approaches that are essential to the control of small intestinal bleeding. CE in particular is a very simple and convenient technique for overt OGIB. Despite great progress, few cases could not be detected using CE. Here we checked the detection and lack of detection rates of CE and BAE.
AIMS & METHODS: Between April 2005 and June 2013, a total of 364 patients had both CE and BAE (239 men, 125 women; mean age, 60 years) in our institute; of these, 155 had overt OGIB. When the diagnosis of overt OGIB using CE (Pillcam SB2; Given Imaging) was first made, BAE (single-balloon enteroscopy; Olympus Medical Systems) was checked for the diagnosis and treatment. If lesions were suspected in the small intestine by another modality, BAE was used despite negative CE findings. CE was checked independently by at least two doctors. BAE was performed using an oral or anal approach according to the CE results. Prior to checking small intestinal lesions with CE and BAE, esophagogastroduodenoscopy and total colonoscopy were both performed to confirm a lack of gastrointestinal bleeding except in the small intestine.
RESULTS: CE findings of 155 overt OGIB cases included: angiectasia, 30%; erosion/ulcer, 28%; carcinoma, 7%; and Crohn's disease, 1%. Active bleeding was observed in 47 of 155 patients (30%) using CE, and all cases were confirmed using BAE. A total of 39 (83%) of 47 cases were diagnosed by BAE, and some cases such as angiectasia were simultaneously treated with BAE. However, 17 (17%) of the 47 cases could not be diagnosed using BAE. Of the 155 cases of overt OGIB, 108 (70%) could not be detected by bleeding points using CE, but five (3.2%) cases were diagnosed using another modality such as scintigraphy or BAE. They were three cases of Meckel's diverticulum, one case of jejunal sarcoma, and one case of angiectasia of the ileum. CE images of these patients were not consistent with lesions, so the diagnoses could not be made by CE only.
CONCLUSION: CE is very useful for the detection and diagnosis of overt OGIB. However, some cases could not be detected in the present study. Therefore, even if bleeding points cannot be detected by CE and bleeding occurs repeatedly, another modality such as BAE should be applied.

P1369 FACTORS INFLUENCING CECAL INTUBATION TIME DURING RETROGRADE SINGLE-BALLOON ENTEROSCOPY: IS IT THE SAME AS THAT DURING COLONOSCOPY?

T.-M. Ou[1], P.-J. Chen[1], W.-K. Chang[1], T.-Y. Hsieh[1], **T.-Y. Huang**[1,*]
[1]*Internal Medicine, TRI-SERVICE GENERAL HOSPITAL, Taipei, Taiwan, Province of China*

INTRODUCTION: The retrograde technique for single-balloon enteroscopy (SBE) seems to be more difficult than the antegrade technique because of the need to pass through the colon. The predisposing factors for prolonged cecal intubation time (CIT) during colonoscopy have been well identified. However, the factors influencing CIT during retrograde SBE have not been addressed.
AIMS & METHODS: The aim of this study was to determine the factors influencing CIT during retrograde SBE. We investigated patients who underwent retrograde SBE at a medical center from January 2011 to March 2014. The medical charts and SBE reports were reviewed. The patients' characteristics and procedure-associated data were recorded: age, sex, body mass index (BMI), indication, history of surgery, bowel preparation, CIT, total procedure time, endoscopic findings, and endoscopic interventions. These data were analyzed with univariate analysis as well as multivariate logistic regression analysis to identify the possible predisposing factors.
RESULTS: The median CIT was 17.4 minutes. With univariate analysis, there was no statistical difference in age, sex, BMI, or history of abdominal surgery, except for bowel preparation ($P = 0.022$). Multivariate logistic regression analysis showed that bowel preparation (odds ratio 7.80, 95% confidence interval 2.76–22.02; $P < 0.001$) and previous history of pelvic surgery (odds ratio 0.26, 95% confidence interval 0.70–0.97; $P = 0.045$) were the independent predisposing factors for prolonged CIT during retrograde SBE.
CONCLUSION: Bowel preparation and previous history of pelvic surgery were the independent predisposing factors for prolonged CIT during retrograde SBE.

P1370 SMALL BOWEL AND COLONIC MUCOSAL HEALING IN CROHN'S DISEASE - A PILOT STUDY WITH PILLCAM COLON 2 FOR ENTIRE GASTROINTESTINAL CAPSULE ENDOSCOPY

P. Boal Carvalho[1,2,*], B. Rosa[1,2], F. Dias de Castro[1,2], M.J. Moreira[1,2], J. Cotter[1,2]
[1]*Life and Health Sciences Research Institute (ICVS), School of Health Sciences, University of Minho,* [2]*Gastrenterology, Centro Hospitalar do Alto Ave, Guimaraes, Portugal*

INTRODUCTION: In Crohn's Disease (CD), both small bowel and colonic mucosa are affected in almost half the patients. PillCam COLON2 Capsule (PCC2) allows for the non-invasive evaluation of the entire gastrointestinal tract.
AIMS & METHODS: Our aim was to evaluate mucosal healing in patients with both small bowel and colon distribution of CD using PCC2.
We included patients with non-stricturing non-penetrating small bowel *plus* colonic CD in corticosteroid-free remission (Harvey-Bradshaw Index < 5); patients had been submitted to ileocolonoscopy (identifying active CD lesions such as ulcers, erosions and spontaneous bleeding) and small bowel capsule endoscopy (with Lewis Score assessment) at diagnosis.
After $\geq$ 1 year of follow-up, patients underwent entire gastrointestinal tract evaluation with PCC2, which was reviewed by an independent researcher, blinded to both the initial endoscopic results and current CD therapy. Primary endpoint: to assess mucosal healing in small bowel and colon mucosa, defined as a Lewis Score (LS) < 135 and no active CD lesions in the colon.
RESULTS: Twelve patients were included, 7 male; mean age was 32 (18-50) years, mean follow-up was 38 (12-62) months. At diagnosis, most patients ($n = 8$, 66.7%) presented with segmental CD lesions in ileocolonoscopy; moderate to severe activity (LS$\geq$790) was observed during SBCE in 7 patients (58.3%), while 5 (41.7%) presented with mild activity (LS 135-790). Two patients were treated with combination immunossupression therapy (anti-TNFα and azathioprine), 8 with azathioprine in monotherapy and 2 with messalazine. We are currently recalling patients for PCC2.
Six patients already completed the procedure: the entire gastrointestinal tract was observed in all of them. Small bowel mucosal healing (LS$<$135) occurred in 3 patients (50%) patients - 2 of them, with a LS$\geq$790 at diagnosis, treated with azathioprine in monotherapy, and the other one, with previous LS 135-790, was treated with messalazine. Two patients maintained moderate to severe activity in the small bowel despite treatment with azathioprine, and another one, also under azathioprine monotherapy, was shown to have intensified inflammatory activity (mild activity at diagnosis and moderate to severe activity in the small bowel observed with PCC2).
Mucosal healing of the colonic mucosa was observed in 3 patients (50%), two of them treated with azathioprine, and the remainder with messalazine; 2 patients maintained a segmental pattern of colon CD, and in one patient, treated with azathioprine, CD lesions throughout the entire colonic mucosa persisted during follow-up.
CONCLUSION: With this pilot study, in a population of patients with both small bowel and colonic Crohn's Disease, we have shown that endoscopy of the entire gastrointestinal tract with PCC2 is feasible and safe, allowing for mucosal inflammatory activity assessment in patients in clinical remission, evaluating mucosal healing as a surrogate of treatment efficacy.

P1371 VIRTUAL CHROMOENDOSCOPY IMPROVES THE DIAGNOSTIC YIELD OF SMALL BOWEL CAPSULE ENDOSCOPY IN OBSCURE GASTROINTESTINAL BLEEDING

P. Boal Carvalho[1,*], J. Magalhães[1], F. Dias de Castro[1], T. Cúrdia Goncalves[1], B. Rosa[1], M.J. Moreira[1], J. Cotter[1,2]

INTRODUCTION: Small bowel capsule endoscopy (SBCE) represents the initial form of investigation for obscure gastrointestinal bleeding (OGIB). FICE mode is a virtual chromoendoscopy technique designed to enhance focal lesions during endoscopic procedures.
AIMS & METHODS: Our objective was to compare and analyze the differences in diagnostic yield using both FICE 1 and conventional SBCE imaging.
Included 60 consecutive patients referred to SBCE for OGIB. Every SBCE exam was independently reviewed by four researchers using conventional imaging and FICE 1, and afterwards compared by an independent researcher for consensus report.
Diagnostic yield was defined as the presence of at least one small bowel lesion with high bleeding potential (P2), such as angioectasia, ulcer or tumor, after the exclusion of false positive results.
Statistical analysis of the data was performed with SPSS v21.0, using the McNemar test for categorical variables and paired-samples T-test for continuous variables.
RESULTS: SBCE diagnostic yield using FICE 1 was significantly higher than conventional imaging (58.3 vs 41.7 %, $p = 0.021$). Using FICE 1 we additionally found a superior number of P2 lesions (74 vs 44, $p = 0.003$), particularly angioectasias (54 vs 26, $p = 0.002$). No differences were observed regarding the number of ulcers (17 vs 15, $p = 0.568$) or tumors (3 vs 3, $p = 1.000$) when comparing FICE 1 with conventional imaging.
CONCLUSION: FICE 1 viewing during small bowel capsule endoscopy for obscure gastrointestinal bleeding was significantly superior to conventional imaging, resulting in a 16% improvement in diagnostic yield. Potentially bleeding lesions were more often observed when using FICE 1, in particular angioectasias. Our results support the generalization of this technique while reviewing small bowel capsule endoscopy for obscure gastrointestinal bleeding.

P1372 ACTIVE SMALL BOWEL BLEEDING: EARLIER DETECTION, EARLIER REACTION

P. Boal Carvalho[1,*], B. Rosa[1], J. Cotter[1,2]
[1]*Gastrenterology, Centro Hospitalar do Alto Ave,* [2]*Life and Health Sciences Research Institute (ICVS), School of Health Sciences, University of Minho, Guimaraes, Portugal*
Contact E-mail Address: *Pedro.n.carvalho@gmail.com*

INTRODUCTION: Obscure gastrointestinal bleeding (OGIB) is the leading indication for small bowel capsule endoscopy (SBCE). Despite being present in only a minority of patients undergoing SBCE, early detection of active bleeding allows for treatment adjustments and prognostic improvement.
AIMS & METHODS: We aimed to ascertain whether some clinical and analytical patient characteristics would correlate with active bleeding in the small bowel observed during capsule endoscopy.
Unicentric retrospective study comprising all patients submitted to SBCE for OGIB over 6 years. The following variables were analyzed: age, gender, comorbidities (hypertension, chronic kidney disease, diabetes mellitus, ischemic heart disease), antiplatelet and anticoagulant drug use, and the need for hospital admission. Both active bleeding and potentially bleeding lesions in the small bowel were assessed during SBCE. Statistical analysis was performed with SPSS 21.0, and a p value < 0.05 was considered significant.
RESULTS: Among the 244 patient included, potentially bleeding lesions were found in 65 (26.6%), while active bleeding on SBCE was observed in 21 patients (8.6%). Small bowel hemorrhage was significantly more frequent among patients presenting with visible gastrointestinal bleeding (19 *versus* 7%, $p = 0.008$). Elder patients (72 *versus* 60 years $p = 0.003$), hospitalized patients (17 *versus* 7%, $p = 0.034$) and those with ischemic heart disease (16 *versus* 5%, $p = 0.007$) displayed significantly more often small bowel active bleeding. Only 1% of the patients with no comorbidities was found to have active bleeding during SBCE, compared to 14% among patients with 2 or more comorbidities ($p = 0.007$). Antithrombotic drugs were not associated with an increased risk for small bowel active bleeding.
CONCLUSION: Small bowel active bleeding was significantly more frequent in patients presenting with visible OGIB. Advanced age, the need for hospital admission and comorbidities, particularly ischemic heart disease, were associated with an increased prevalence of active bleeding during SBCE. In such patients, carrying out small bowel capsule endoscopy early on is of prime importance as to swiftly detect and treat the observed lesions.

P1373 DELIVERING A CAPSULE ENDOSCOPY SERVICE TO A WIDE GEOGRAPHICAL AREA – THE SOUTH TYNESIDE EXPERIENCE

R. Bevan[1,2,*], C. Davison[1,2], S. Dunn[1,2], F. Butt[1], S. Panter[1,2]
[1]*SOUTH TYNESIDE DISTRICT HOSPITAL, South Shields,* [2]*NREG, Newcastle, United Kingdom*

INTRODUCTION: Video capsule endoscopy (VCE) is an increasingly utilised small bowel investigation. Not all hospital sites offer it; patients may need to travel to have the procedure performed. It involves several appointments; assessment prior to the procedure, patency capsule (PC) procedure, follow up radiology, & the VCE procedure itself.
In the Northern region of England, 2 centres offer an established VCE service, with a 3rd service recently commissioned. Despite efforts to develop services in the most appropriate localities, the referral area to these centres is large with potential journey times of over 2 hours.
South Tyneside District Hospital (STDH) started performing VCE in 2006, and began a telephone assessment service in 2010. Referrals are received from across the Northern region, frequently extending as far as Cumbria, North Yorkshire and South Teeside, and occasionally from further afield (Scotland, the Midlands). Prior to the telephone service, patients were admitted for assessment, PC (if appropriate, based on clinical information and patient informed choice), bowel prep, and VCE procedure – equating on average 1-3 nights in hospital.
AIMS & METHODS: We describe the patient pathways before and after the telephone service began, and evaluate the service up to January 2014. Average patient stay was calculated, bed days saved and cost differences described using NHS costings for elective stays in hospital.
RESULTS: The telephone service started in August 2010. Two 30-minute slots are allocated each week to the service, and are reserved for patients from outside the local area.
A nurse consultant conducts the telephone consultation. Those requiring PC are sent the device to their home to take unsupervised, or may attend their local hospital to be observed. They attend STDH the following day for a scan +/- AXR/localised CT abdomen. They either stay locally overnight for VCE the following day, or return home with a future plan for VCE. Alternatively, they are admitted to STDH, and VCE administered the following day. If not requiring PC, bowel preparation, consent forms and instructions are sent to the patient, with the patient attending STDH for VCE to be delivered. Patients can be admitted to STDH for inpatient preparation if required.
1164 VCE procedures have been performed at STDH. From 525 referrals from outside STDH, 205 telephone assessment appointments have been utilised.
The highest number of telephone assessments have come from hospitals in Cumbria: 77 referrals from Carlisle, and 52 from Whitehaven; 73 and 111 miles from STDH respectively. Saving each patient one return journey by using the telephone service has reduced patient journeys by almost 23,000 miles. An elective inpatient bed costs £225 per night. A telephone service appointment is charged at £23.69. PC device and VCE device costs are the same in both pathways. Therefore, making a conservative estimate of cost savings (assuming all telephone service patients have reduced their inpatient stay by one night), £38,000 has been saved by this service in 4 years.
CONCLUSION: A telephone assessment clinic for patients distant to the VCE centre has been well utilised at STDH. This has reduced the inpatient stay required for VCE investigation, reducing costs, the impact on the gastroenterology inpatient service, and travel burden on patients.

P1374 CAPSULE ENDOSCOPY: DIAGNOSTIC ACCURACY OF LEWIS SCORE IN PATIENTS WITH SUSPECTED CROHN'S DISEASE

S. Monteiro[1,*], P. Boal Carvalho [1], F. Dias de Castro [1], J. Magalhães [1], J. Firmino Machado[2], M.J. Moreira[1], B. Rosa[1], J. Cotter[1,3]
[1]*Gastroenterology,* [2]*Centro Hospitalar do Alto Ave, Guimarães,* [3]*Instituto de Investigação em Ciências da Vida e da Saúde, Universidade do Minho, Braga/ Guimarães, Portugal*
Contact E-mail Address: *sara.s.o.monteiro@gmail.com*

INTRODUCTION: Small bowel capsule endoscopy (SBCE) has assumed an increasing importance in the diagnosis of Crohn's Disease (CD). The Lewis Score (LS) aims to standardize the quantification of inflammatory activity detected in the small bowel mucosa.
AIMS & METHODS: The aim of this study was to evaluate the diagnostic accuracy of the LS in patients undergoing SBCE for suspected CD. We performed a retrospective single-center study including 95 patients who underwent SBCE for suspected CD between September 2006 and February 2013, with at least 12 months of follow-up after the capsule. Patients were divided in 2 groups according to the criteria of the *International Conference on Capsule Endoscopy* (ICCE) for the definition of suspected CD. Group 1: 37 patients not fulfilling ICCE criteria; Group 2: 58 patients with ≥ 2 ICCE criteria. Inflammatory activity on SBCE was objectively assessed by determining the LS. The diagnosis of CD during follow-up was based on a combination of clinical, analytical, endoscopic, histological and imaging elements.
RESULTS: SBCE detected significant inflammatory activity (LS $\geq$ 135) in 46 patients (48.4%), 7 patients from group 1 (18.9%) and 39 patients from group 2 (67.2%) ($p < 0.001$).
The diagnosis of CD was established in 38 patients (40%): 8 patients (21.6%) from Group 1, 30 patients from Group 2 (51.7%) ($p = 0.003$), 34 patients with LS $\geq$ 135 (73.9%) and 4 patients with LS $<$ 135 (8.2%) ($p < 0.001$). The LS $\geq$ 135 had an overall diagnostic accuracy of 83.2 %. The LS Sensitivity, Specificity, Positive Predictive Value and Negative Predictive Value for the diagnosis of CD were 89.5%, 78.9%, 73.9% and 91.8%, respectively.
CONCLUSION: The application of LS $\geq$ 135 as the cut-off value for the presence of significant inflammatory activity in patients undergoing SBCE for suspected CD may be useful to establish the diagnosis. In patients with LS $<$ 135, the probability of having CD confirmed on follow-up is low.

P1375 IS IT WORTH REPEATING PREVIOUSLY UNREMARKABLE SB2 CAPSULES WITH THE NEW SB3?

S. Dunn[1,*], R. Bevan[1], L. Neilson[1], **R. Dunn**[1], C. Davison[1], F. Butt[1], S. Panter[1]
[1]*South Tyneside NHS Foundation Trust, South Shields, United Kingdom*

INTRODUCTION: Small bowel capsule endoscopy (SBCE) has become a valuable tool for investigating the small bowel and technology is rapidly advancing. One of the most recent devices available for capsule endoscopy (Pillcam® SB3, Given Imaging) has improved image resolution and a variable frame rate. The aim of this work is to address whether these innovations lead to increased mucosal visualisation and diagnostic yield in clinical practice and therefore whether a repeat SB3 capsule should be considered in those patients with an equivocal SB2 result.
AIMS & METHODS: A review was undertaken of the last 100 Pillcam® SB2 capsules and the first 100 Pillcam® SB3 capsules to be performed at South Tyneside District Hospital (14/01/13 - 13/03/14). Visualisation of the ampulla was used as a surrogate marker of mucosal visualisation and diagnostic yield was assessed by reviewing the reports. Statistical significance was calculated using Fisher's exact test.
RESULTS: Results are summarised in the table below. The ampulla was visualised in 14% of SB2 capsules and 14% of SB3 capsules ($p > 0.05$). 44% of SB2 capsules were abnormal and SB3 capsules were abnormal in 60% of cases ($p < 0.05$)

Capsule type	Number	Ampulla seen (%)	Pathology found (%)
SB2	100	14 (14%)	44 (44%)
SB3	100	14 (14%)	60 (60%)
p value		1.0000	0.0335

CONCLUSION: It is recognised that the views obtained by SBCE can be compromised in the duodenum due to "rapid transit" and variable frame rates hope to address this by capturing more images when the capsule is moving quicker. We showed no statistically significant difference in ampullary visualisation between the SB2 and SB3 capsules. However the overall yield of pathology from SB3 capsules was significantly higher than that in SB2 capsules. Given the overall

increased yield of pathology it may be beneficial to repeat an SB3 capsule in someone with a previously equivocal SB2 result.

P1376 IS THERE A ROLE FOR URGENT SMALL BOWEL VIDEO CAPSULE ENDOSCOPY?

S. Dunn[1,*], F. Butt[1], R. Bevan[1], C. Davison[1], S. Panter[1]
[1]*South Tyneside NHS Foundation Trust, South Shields, United Kingdom*
Contact E-mail Address: *simon.panter@stft.nhs.uk*

INTRODUCTION: Capsule endoscopy has become a valuable modality for imaging the small bowel and has been suggested as a useful diagnostic tool in the emergency diagnosis of overt occult GI bleeding when used in the appropriate context[1]. Diagnostic yield (DY) is known to be greatest if the study is performed as soon as possible after the bleeding episode[2]. This is not possible in centres without a capsule endoscopy service who therefore refer for urgent studies. Presently the DY of urgent small bowel video capsule endoscopy (SBCVE) is unclear. This work aims to assess the DY of urgent SBVCE in a district general hospital acting as a tertiary referral centre for SBVCE.

AIMS & METHODS: All referral letters since 2008 were reviewed. Referrals were classified as urgent if the referrer had indicated a degree of urgency or if the team at South Tyneside felt the SBVCE should be done urgently. DY was assessed by reviewing the capsule endoscopy reports and then relating the findings to the indication. Considered as positive findings were active bleeding, angiodysplasias, ulcers, strictures, tumours, villous atrophy and polyps.

RESULTS: 127 studies were identified from reviewing the referral letters (1164). Of these 60 were requested as urgent, 24 were expedited and 43 were changed to urgent by the capsule endoscopy team. 57 of the 127 capsules had a significant finding (45%). The table below summarises the results. Active bleeding was defined as patients having melaena or ongoing transfusion requirements. Abnormal imaging was defined as a CT or MRI showing potentially abnormal small bowel. Diarrhoea only and weight loss only were indications where the referrer was not querying the possibility of Crohn's disease.

Indication	Number	%	Significant?	%
?Active bleeding	47	37.01%	25	53.19%
?Crohn's disease	12	9.45%	3	25.00%
Abnormal imaging	14	11.02%	5	35.71%
Anaemia	27	21.26%	16	59.26%
Crohn's assessment	5	3.94%	2	40.00%
Diarrhoea only	3	2.36%	1	33.33%
Weight loss only	11	8.66%	3	27.27%
Other	8	6.30%	2	25.00%
Total	**127**	**100.00%**	**57**	

CONCLUSION: The most common indication for an urgent capsule was the suspicion of active bleeding and more than half of these SBVCEs showed a bleeding point. Urgent investigations for anaemia also had a high yield of positive findings. Other indications with more than 10 urgent studies performed did not show an appreciable yield. Our data adds weight to the argument that capsule endoscopy may be a useful test in active occult GI bleeding while also suggesting it may play a role in the assessment of severe anaemia in the absence of overt GI bleeding. Such patients should be referred for urgent assessment to maximise diagnostic yield.

P1377 MAJOR PREDICTORS OF PORTAL HYPERTENSIVE ENTEROPATHY IN PATIENTS WITH LIVER CIRRHOSIS

T. Aoyama[1,*], S. Oka[2], H. Aikata[1], A. Igawa[1], M. Nakano[1], N. Naeshiro[1], S. Yoshida[2], S. Tanaka[2], K. Chayama[1]
[1]*Department of Gastroenterology and Metabolism, Graduate School of Biomedical Sciences, Hiroshima University,* [2]*Department of Endoscopy, Hiroshima University Hospital, Hiroshima, Japan*

INTRODUCTION: Since portal hypertensive enteropathy (PHE) has been acknowledged as a source of bleeding, predicting its presence has become more important. However, few previously published reports discuss factors that predict its presence in the context of portosystemic shunts (PSs).

AIMS & METHODS: We aimed to assess PHE in patients with liver cirrhosis (LC) using capsule endoscopy (CE) and investigated factors that may predict its presence, including PSs.

One hundred and thirty-four consecutive patients with LC (78 males and 56 females), with a mean age of 66.7 years (range: 27–88 years) who underwent CE at our hospital between February 2009 and September 2013, comprised the study population. All had undergone dynamic computed tomography (CT) and esophagogastroduodenoscopy before CE examination. The frequencies and types of PHE lesions were investigated. The distribution of the lesions was also determined. Moreover, the relationships between PHE and the patients' clinical characteristics, which included age, sex, liver function, etiology of cirrhosis, PSs, ascites, hepatocellular carcinoma, splenomegaly, portal thrombosis, esophageal varices (EVs), gastric varices, and portal hypertensive gastropathy (PHG), were examined. PSs were evaluated using dynamic CT during the portal venous phase and coronal CT imagery. Left gastric veins, short gastric veins, posterior gastric veins, paraesophageal veins, splenorenal shunts, and paraumbilical veins with diameters greater than 3 mm were defined as PSs. Comparisons were performed using Student's t-test for quantitative data and the chi-square test for categorical data. All tests were 2-sided, and a P value < 0.05 was considered statistically significant. The impacts of the clinical variables on PHE were estimated by calculating the odds ratios (OR) and the 95% confidence intervals (95% CI) using logistic regression analyses.

RESULTS: PHE was found in 91 (68%) patients, and 70 (52%) patients had erythema, 25 (19%) had erosions, 24 (18%) had angioectasia, 18 (13%) had villous edema, and 10 (7%) had varices. Most lesions were located in the jejunum. The clinical characteristics associated with the presence of PHE were a Child-Pugh grade of B or C ($P = 0.0058$), and the presence of PSs ($P < 0.0001$), ascites ($P = 0.0017$), portal thrombosis ($P = 0.016$), EVs ($P = 0.0017$), and PHG ($P = 0.0029$). The other factors had no significant relation with the presence of PHE. Subsequent multivariate analysis determined that the presence of PSs was an independent predictor of PHE (OR: 3.15; 95% CI: 1.27–7.95). The shunt types significantly associated with PHE on univariate analysis were the left gastric vein ($P = 0.00068$), the paraesophageal vein ($P = 0.029$), and splenorenal shunts ($P = 0.03$). Subsequent multivariate analysis determined that left gastric vein (OR: 5.31; 95% CI: 1.97–17.0) and splenorenal shunts (OR: 4.26; 95% CI: 1.29–19.4) were independent predictors of PHE.

CONCLUSION: PSs appear to reliably predict the presence of PHE. Furthermore, CE should be considered in patients with LC accompanied by PSs, especially left gastric vein and splenorenal shunts.

INTRODUCTION: Capsule endoscopy (CE) is currently recommended as first-line study in the evaluation of obscure gastrointestinal bleeding (OGIB), some consider small bowel computed tomography (SBCT) as a complementary test to CE

AIMS & METHODS: AIMS: This study evaluated the factors of improvement the diagnostic yield of CE in patients with OGIB and negative SBCT.

METHODS: We reviewed the medical records related to forty one patients with OGIB who was performed SBCT and CE from July 2007 to February 2013, focusing our attention with negative SBCT. SBCT is defined including enteral phase with or without neutral enteric contrast material. We evaluated forty one patients with negative SBCT and analyzed the detection rate of CE obscure bleeding focus. Cases were divided into two groups; first group who had diagnostic finding of CE ($n = 26$) and second group who had non-diagnostic finding of CE ($n = 15$). The two groups were compared retrospectively.

RESULTS: Twenty six of 41 (63.4%) CE studies had diagnostic results. Mucosal lesions (75.6%) were the most common findings, followed by nonspecific findings (17.1%) and tumorous lesions (2.4%). In comparison between patients with and without diagnostic CE finding, mucosal lesion (Odds 21.660, CI 2.269-206.755; $p = 0.008$) and using of neutral enteric contrast material before SBCT (Odds 15.828, CI 1.005-249.350; $p = 0.050$) were significant factor for diagnostic CE finding.

CONCLUSION: In the patients with OGIB and negative SBCT, using of neutral enteric contrast material before SBCT is possible to improve the diagnostic yield of the CE

P1379 SELF-EXPANDABLE METAL STENTS IN THE MANAGEMENT OF BENIGN ESOPHAGEAL DISEASES

P. Magalhães-Costa[1,*], T. Bana[1], D. Serra[1], L. Matos[1], C. Chagas[1]
[1]*Gastrenterology, Hospital Egas Moniz - Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal*
Contact E-mail Address: *pmagalhaescosta@gmail.com*

INTRODUCTION: The use of self-expandable metal stents in the esophagus for the management of benign disease has grown immensely over the last decade. Fully covered self-expandable metal stents (FCSEMS) are considered a viable alternative to serial bougienage and endoscopic dilation in the management of

refractory benign esophageal strictures. The use of SEMS, particulary partially covered (PCSEMS), in the treatment of anastomotic esophageal leaks or fistulas is a valid and efficacious resource in order to restore the gastrointestinal function, resume oral nutrition and avoiding a, potencially costly, surgical re-intervention.
AIMS & METHODS: The primary aim of this retrospective study was to determine the efficacy and safety, in our institution (Jan 2008 - Feb 2013), of FCSEMS for refractory benign esophageal strictures and SEMS (mainly PCSEMS) in the management of anastomotic esophageal leaks/fistulas.
RESULTS: A total of 14 patients underwent SEMS placement for benign esophageal conditions. 8 patients for refractory esophageal stricture and 6 for post-surgery leak/fistula. In the stricture group, 19 FCSEMS were used (patient/stent ratio: 2.4) and in the post-surgery group, 13 SEMS were needed (patient/stent ratio: 2.0). Regarding the etiology, stricture group: post-surgery (n = 3), radiation-induced (n = 2), caustic (n = 1) and peptic (n = 1). In the anastomotic esophageal leak/fistula group, the most common procedure was a laparoscopic gastric sleeve (n = 4) and gastric bypass (n = 2). In 50% of the cases, 2 stents were deployed in the same session. In the stricture group, the preferred stents were the Wallflex@ Boston Scientific (n = 11) and the Hanarostent@ M. I. Tech (n = 5). The stent body diameter ranged from 18 and 23mm. In the post-surgery group, the preferred stent was the partially covered Ultraflex@ Boston Scientific (n = 5), Wallflex@ Boston Scientific (n = 4) and Evolution@ Cook Medical (n = 3). In this group, the use of PCSEMS dominated (n = 10; 77%). The mean stent body diameter was 25mm and length 125mm. The technical immediate success rate was 79% (15/19) and 100% (6/6) for the stricture and post-surgery groups, respectively. Global stent migration rate, for the stricture group, was 63% (12/19). No migration events were reported in the post-surgery group. Stent occlusion by tissue hyperplasia occurred more in the stricture group (3 events vs 1 event). All the stents were removed successfully, including those who migrated, and no procedure nor stent-related complications were reported. Clinically, at the end of the study, in the stricture group, 3 out of 8 patients (38%) remain symptom-free and their stricture was deemed solved, another 3 out of 8 patients (38%) had a temporary clinical benefit but remain dependent of endoscopic dilation and 2 cases (25%) demanded an invasive procedure. In the leak/fistula group, complete resolution was achieved in 83% (5/6).
CONCLUSION: Althought far from being the perfect solution for refractory benign esophageal strictures, FCSEMS appear to be a valid and safe option in their management. Their clinical success is moderate (38%) but migration rates seem to remain a frequent issue (63%). On the other hand, the use of PCSEMS in the management of anastomotic esophageal leaks or fistulas seems to hold a high clinical success rate (83%) without complications or migration events.

P1380 GASTRIC OUTLET OBSTRUCTION TREATMENT WITH ENDOSCOPIC PLACEMENT OF SELF-EXPANDING METAL STENT: DATA FROM A LARGE SERIES OF PATIENTS TREATED IN A TERTIARY REFERRAL HOSPITAL FOR PALLIATIVE CARE

R. Di Mitri[1,*], F. Mocciaro[1], G.M. Pecoraro[1]
[1]*Gastroenterology and EndoscopyUnit, A. R. N. A. S. Civico-Di Cristina-BenfratelliHospital, Palermo, Italy*
Contact E-mail Address: *fmocciaro@gmail.com*

INTRODUCTION: Gastric outlet obstruction (GOO) can occur in several different GI malignant conditions (intrinsic or extrinsic) that can be treated with endoscopic placement of self-expanding metal stents (SEMS). In non operable patients SEMS placement ensure a prompt oral intake with less morbidity and shorter hospital stay compared to surgical jejunostomy. Clinical success rate is similar between surgical and endoscopic treatment (around 90%).
AIMS & METHODS: The aims of this study are to evaluate the efficacy and safety of SEMS placement in a large consecutive series of patients with malignant inoperable gastroduodenal obstruction. From March 2007 to March 2014 we collected data on all consecutive patients treated with SEMS placement (Wallflex Enteral by Boston Scientific) due to malignant GOO. Baseline gastric outlet obstruction scoring system (GOOSS) score was recorded (0 = no oral intake; 1 = liquid diet; 2 = soft solid diet; 3 = low residue or normal diet). Stents were deployed under fluoroscopic and endoscopic guidance after traversing the stricture with a catheter/guidewire. If needed, balloon dilation was performed before stent placement. Technical and clinical success, and adverse events were recorded.
RESULTS: 63 patients (42 male [67%]), with a mean age of 69.6±12.7 year, were treated: 34 had pancreatic head cancer (54%), 13 antro-bulbar cancer (21%), 7 gallbladder cancer/cholangiocarcinoma (11%), 4 retroperitoneal sarcoma (6%), 3 peritoneal carcinomatosis (5%), 2 duodenal obstruction due to colon cancer (3%). Thirty-one of these patients had biliary involvement too (49%) treated with biliary SEMS placement. Baseline GOOS score was: 0 in 27 patients (43%), 1 in 23 (36%), 2 in 10 (16%), 3 in 3 (5%). Technical success was achieved in all patients with a satisfactory oral feeding after 24-42 hours. Median lenght of SEMS was 9 cm (range 6-12). At 1 month the median GOOSS score improved from 1 [range 0 -3] to 2 [range 2-3]. In patients with both biliary and duodenal obstruction the double stenting allowed significant improvement in oral feeding and bilirubin levels reduction (at least 50% of the baseline value). None complications related to the SEMS placement were recorded. Stent occlusion due to ingrowth occurred in 3 patients (5%). The median hospital stay was 4 days (range 3-8) with a median survival time of 7 months (range 3-9). All deaths were due to the natural course of underlying malignancy.
CONCLUSION: Endoscopic management of gastroduodenal obstruction with SEMS placement is the treatment of choice in advanced unresectable gastroenteric neoplasm. It is a safe procedure and it enhances patients quality of life. In advanced diseases or in frail patients palliative surgery should be considered only in case of endoscopic failure.

P1381 EFFICACY OF THE 'OVER-THE-SCOPE CLIP' (OTSC) IN THE MANAGEMENT OF IATROGENIC GASTROINTESTINAL PERFORATIONS

S. Khater[1,*], G. Rahmi[1], E. Samaha[1], L. Abbes[1], M. Barret[1], M. Georgia[1], C. Cellier[1]

INTRODUCTION: Perforation is a rare but serious complication of endoscopic procedures. The over-the-scope clip (OTSC, Ovesco®, Tuebingen, Germany) is a novel endoscopic tool used in the non surgical management of gastrointestinal perforations. However, data from clinical use are still limited.
AIMS & METHODS: The aim of this study is to evaluate the efficacy and safety of this clip in closure of iatrogenic perforations occurring during diagnostic and therapeutic endoscopies. We conducted a monocentric retrospective study. From June 2011 to September 2013, eight consecutive patients (mean age: 72 years [43-93], 7 women) had an acute iatrogenic perforation treated with an OTSC.
RESULTS: The perforation was located in the sigmoid in five patients, the duodenum in two patients and the cardia in one patient. The mean size of the perforation was 11.8 mm [10-20]. Endoscopic repair was performed by using a single OTSC. The twin grasper was used in 50% of the cases to approximate the edges of perforation. Complete sealing of the perforation was achieved with OTSC in all patients. An exsufflation of the pneumoperitoneum using an 18-gauge needle was performed in two patients. An abdominal CT scanner was done in the following 48 hours in five patients and showed a pneumoperitoneum without leakage. The overall clinical success rate was 75% (6/8 patients). One patient required surgical intervention although the clip had completely sealed the perforation because of the presence of a localized peritonitis with fever and abdominal pain. An adverse event occurred in one patient in whom the OTSC placement in the sigmoid was complicated by right ureteral obstruction; this patient had to undergo surgery in order to perform a ureteral resection and anastomosis and remove the clip.
CONCLUSION: OTSC is effective for endoluminal closure of iatrogenic gastrointestinal perforations, with a complete sealing of the perforation in 100% of cases. Complications can occur but are exceptional.

INTRODUCTION: Laparoscopic sleeve gastrectomy is gaining popularity as a treatment for obesity. This procedure is prone to some complications, including staple line leak, sleeve stricture and bleeding. Several therapeutic approaches have been suggested for leaks but limited data is available regarding the safety and efficacy of each technique.
AIMS & METHODS: Describe a single tertiary center experience using bariatric designed, self-expandable metallic stents (BSEMS) for the treatment of post-operative leaks.
We reviewed the medical records and imaging studies of consecutive patients diagnosed with staple line leakage between June 2012 and December 2013 and treated with BSEMS.
Either the Hanaro stent (MI-Tech, Seoul, Korea) with a length of 18-24cm or the Niti-S stent (Teawoong, Seoul, Korea) with a length of 18 or 23 cm were used.
RESULTS: Twenty six patients were referred to our clinic and treated with BSEMS. The average treatment duration was 28 days. Success, defined as avoiding further surgical intervention, removal of external drain tubes, weaning off TPN and resuming oral diet was achieved in 65%. A higher rate of 81% was reached when excluding 5 patients in which the stent was removed less than 2 weeks after insertion.
In 8 patients endoscopic fistule closure was achieved and in 7 patients reposition was needed due to migration.
Severe adverse event were noted in 5 patients that mandated early removal: 4 patients with severe intolerance and 1 patient with severe upper gastrointestinal bleeding. Minor AE were universal, including discomfort and ulceration.
CONCLUSION: BSEMS is a safe and effective treatment for staple line leak following LSG.

P1383 EFFICACY OF A WALLFLEX ENTERAL STENT FOR MALIGNANT GASTRIC OUTLET OBSTRUCTION DURING CHEMOTHERAPY

T. Yoshii[1,*], M. Asayama[1], H. Hara[1], K. Yamaguchi[1]
[1]*Gastroenterology, Saitama Cancer Center, Kitaadachi-gun, Japan*
Contact E-mail Address: *takako_y@cancer-c.pref.saitama.jp*

INTRODUCTION: Gastric outlet obstruction (GOO) occurs due to different gastroenteral malignancy. It causes nausea, deficient oral intake, resulting in a low quality of life. The newly available enteral WallFlex stent (Boston Scentific) has been reported to be useful to improvement of these troublesome symptoms. It might benefit survival, improving not only nutrition but also the compliance to

the chemotherapy of the patients. To date, this matter has not been fully evaluated.
AIMS & METHODS: The aim of this study is to investigate the efficacy of enteral WallFlex stent for malignant gastric outlet obstruction (GOO) during chemotherapy of unresectable gastroenteral malignancy. Twenty-one consecutive patients with symptomatic malignant GOO who were treated with a WallFlex stent between September 2011 and January 2014 at our hospital were analyzed retrospectively. All the patients gave the written informed consent. We evaluated the following clinical outcomes: the improvement of oral intake, the timing of stent insertion during the cancer treatment progress, and the survival after stent insertion. A four-point GOO scoring system (0-3) was used to estimate oral intake. We also analyzed the complications. The statistical analysis was performed by Kaplan-Meier method in April 2014.
RESULTS: Among 21 patients, median age was 69 years (43-77), and 15 were male. Sixteen patients had pyloric stenosis, 3 had stenosis of bulbs, and 2 had stenosis of more anal side of duodenum. Seventeen patients had stenosis due to primary tumor, and others due to extraductal compression by the pancreatic or biliary cancer. Sixteen patients had gastric cancer, 1 had duodenal cancer, and 4 had pancreatic or biliary cancer. Almost all patients had the GOO score of 0 before insertion. Of them, improved score of more than 2 points was achieved in 16 patients (76%). The improvement was achieved within 2 days after treatment on average. Seven patients were released from the total parenteral nutrition. Median survival time after the stent insertion was 96 days (95%CI, 96-155). Seven patients underwent the treatment as the initial step of clinical course, and 14 as the sequential course among the chemotherapy. Fifteen patients could continue the chemotherapy after the insertion (71%). The survival time was not significantly different with or without the therapy before the insertion [initial insertion vs after chemotherapy: 82 days (95%CI, 46-117) vs. 96 days (95%CI, 22-169), $p = 0.85$]. However, the survival time of the patients who could continue the chemotherapy after stent insertion was significantly longer compared with the other group [150 days (95%CI, 59-240) vs 40 days (12-67),$p = 0.0022$]. Although there was no statistical significance, the patients who could continue the chemotherapy showed the trend wherein GOO score after the treatment was improved. Five patients experienced tumor in-growth and were successfully treated by stent in stent. In these cases, median time to tumor in-growth was 116 days (95%CI, 96-135). No life-threatening complication or treatment-related death occurred within 30 days.
CONCLUSION: Placement of enteral WallFlex stent for malignant GOO could benefit survival other than improvement of oral intake, supporting the compliance of chemotherapy. Further research should be continued.

P1384 COMPLICATIONS OF ENDOSCOPIC DILATATION FOR ESOPHAGEAL STENOSIS AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL ESOPHAGEAL CANCER

Y. Kishida[1,*], N. Kakushima[1], M. Tanaka[1], K. Takizawa[1], N. Kawata[1], Y. Tanaka[1], K. Igarashi[1], S. Sugimoto[1], M. Yoshida[1], K. Shinjo[1], K. Imai[1], K. Hotta[1], H. Matsubayashi[1], H. Ono[1]
[1]*Endoscopy, Shizuoka Cancer Center, Shizuoka, Japan*
Contact E-mail Address: *y.kishida@scchr.jp*

INTRODUCTION: Esophageal stenosis is a major problem after performing endoscopic submucosal dissection (ESD) for large superficial esophageal cancer. Endoscopic dilatation (ED) is useful for benign strictures caused by reflux esophagitis or anastomotic stenosis after esophagectomy. However, little is known about the incidence of complications of ED for stenosis caused by esophageal ESD.
AIMS & METHODS: Between September 2002 and December 2012, a total of 111 patients underwent ED for stenosis after esophageal ESD. Among these patients, we retrospectively assessed the following factors; age, sex, use of antithrombotics, location of lesion, circumferential extent of mucosal defect after ESD, diameter of the specimen resected by ESD, number of ED sessions, period from ESD to starting ED, treatment duration of ED, and complications. Since ED is considered as a high-risk procedure for bleeding in the Japanese guideline [1], antithrombotics were generally discontinued a minimum days before ED.
RESULTS: The patient population included 90 men and 21 women. The median age was 69 years old. Among them, 19 patients (17%) had daily usage of antithrombotics. The major location of the lesions was the middle or lower thoracic esophagus (81/111, 73%). The mucosal defect was larger than 3/4 circumferential extent in 75 patients (68%), and the median diameter of the resected specimen was 50 mm (range 23-106mm). A total of 1250 ED sessions were performed, and the median number of ED sessions per patient was 17 (range 1-70). The first ED session was performed a median of 13 days (range 1-154 days) after ESD, and the median treatment duration was 86 days (range 1-1079 days).
The incidence of bleeding was 0.9% (1/111) per patient, 0.1% (1/1250) per session. The only case of bleeding occurred in the middle thoracic esophagus with a mucosal defect less than 1/2 of circumference. This patient did not take daily antithrombotics. Bleeding occurred at the first time of ED session which was performed 23 days after ESD. The bleeding was stopped endoscopically without the need of blood transfusion. The incidence of perforation was 4.5% (5/111) per patient, 0.4% (5/1250) per procedure.
The location of the lesion among these five patients was upper/middle/lower/abdominal esophagus 1/2/1/1, respectively. The mucosal defect was 1/2-3/4 / 3/4-semicircular / whole circumference 1/2/2, respectively. Perforation occurred at a median of second time of ED session (range 2-9), and a median of 18 days (range 8-29) after ESD The median treatment duration of ED among these five patients was 190 days which was longer compared to that of the whole population. Four patients recovered by conservative treatment but there was one fatal case that developed pyogenic spondylitis after 26 times of ED.
CONCLUSION: The incidence of bleeding caused by ED for esophageal stenosis after ESD was small. Relevant risk of perforation should be considered for patients requiring multiple sessions of ED.

INTRODUCTION: Gastric stenosis is a major problem after performing endoscopic submucosal dissection (ESD) for large superficial gastric cancer. Endoscopic dilatation (ED) is a safe and useful treatment for benign strictures caused by postoperative anastomotic stenosis or peptic ulcer disease. However, little is known about the incidence of bleeding and perforation caused by ED for gastric stenosis after ESD.
AIMS & METHODS: Between September 2002 and December 2012, a total of 64 patients underwent ED using a wire-guided balloon dilator for stenosis after gastric ESD. Among these patients, we retrospectively assessed the following factors; age, sex, use of antithrombotics, location of the lesion, circumferential extent of mucosal defect after ESD, diameter of the specimen resected by ESD, number of ED sessions, period from ESD to starting ED, treatment duration of ED, and complications of bleeding and perforation. Since ED is considered as a high-risk procedure for bleeding in the Japanese guideline [1], antithrombotics were generally discontinued a minimum days before ED.
RESULTS: The patient population included 48 men and 18 women. The median age was 75 years old. Among them, 19 patients (30%) had daily usage of antithrombotics. Lesions were located in the upper part of the stomach in 38% (24/64), lower part in 58% (37/64). The mucosal defect was larger than 3/4 circumferential extent in 46 patients (72%), the median diameter of the resected specimen was 66 mm (range 27-147 mm). A total of 341 ED sessions were performed, and the median number of ED sessions per patient was four (range 1-25). The first ED session was performed a median of 28 days (range 9-90) after ESD, and the median treatment duration was 30 days [1-282].
The incidence of bleeding was 3% (2/64) per patient, 0.6% (2/341) per session. One patient who continued taking antithrombotics because of concomitant disease required blood transfusion. The incidence of perforation was 8% (5/64) per patient, 1.5% (5/341) per procedure. All five cases of perforation occured in the lower stomach, and the mucosal defects were larger than 3/4 circumference. Among them, two patients underwent surgery.
There was no significant increase in the incidence of complication among patients taking antithrombotics when they were discontinued before ED.
CONCLUSION: The incidence of bleeding and perforation caused by ED for gastric stenosis after ESD was small.

P1386 COMPARISON OF ENDOSCOPIC COLORECTAL STENT AS A BRIDGE TO SURGERY AND CURATIVE SURGERY ONLY IN THE MANAGEMENT OF ACUTE MALIGNANT OBSTRUCTION

Y.Y. Choi[1,*], D.H. Kang[1], H.W. Kim[1], **C.W. Choi**[1], S.J. Kim[1], S.B. Park[1], B.J. Song[1], Y.S. Shin[1], D.K. Kang[1], H.K. Lim[1], J.J. Goo[1]

Contact E-mail Address: *shadam@naver.com*

INTRODUCTION: Recently, the use of endoscopic colorectal stenting for palliation or as a bridge to surgery in acute malignant colorectal obstruction has increased. However, there are many questions whether endoscopic colorectal stenting as a brige to surgery is really useful for obstructive colorectal cancer, according to the results of recently pulblished studies.
AIMS & METHODS: The aim of this study was to compare the outcomes between operation after colorectal stenting and surgery only for curative purpose in patients with colorectal obstruction.
100 patients who were treated for obstructive colorectal cancer between May 2009 and May 2013 were enrolled. We reviewed the medical records retrospectively. 37 patients underwent endoscopic colorectal stent as a bridge to curative surgery (stent group). 40 patients underwent a curative operation without colorectal stent (surgery only group). Primary outcomes included the stoma rate and the length of hospital stay after surgery, postoperative complication including in-hospital mortality and the emergency and open surgery rate. Secondary outcomes included the technical success rate of stent insertion and symptom improvement rate after stenting, complication during procedure.
RESULTS: The stoma rate was 27.0% (10/37) in stent group versus 45.0% (18/40) in surgery only group ($p = 0.10$). The median postoperative hospital stay was 12.3±5.8 versus 12.2±7.4 days ($p = 0.92$). The postoperative complication rate was 8.1% (3/37) versus 10.0% (4/40) ($p = 1.00$). In-hospital death happened two case (5.4%, 2/37) in stent group and one case in surgery only group ($p = 0.60$). 7

patients (18.9%) in stent group and 11 patient (27.5%) in surgery group underwent emergency surgery ($p = 0.37$). Open surgery rate was 32.4% (12/37) versus 40.0% (16/40), respectively ($p = 0.49$). Subgroup analysis showed that emergency surgery rate of stent group who had successful stent insertion was significantly lower compared to surgery only group (6.7%, $p < 0.01$). The overall success rate of colorectal stent insertion for malignant colorectal obstruction was 88.7% (77/86). The success rate of stent as a bridge to curative surgery was 81.1% (30/37). Failure of the guidewire passage through lesions occurred in 5 patients (13.5%). Perforation during procedure occurred in 2 patients (5.4%). All patients who were performed stent insertion successfully, achieved symptom improvement.
CONCLUSION: The role of endoscopic colorectal stenting for bridging procedure before surgery is limited in the management of acute malignant obstruction. When the patients have high risks of complications of emergency surgery, stent can be considered as alternative approach to emergency surgery.

P1387 OUTCOMES OF STENT-IN-STENT TECHNIQUE FOR PRIMARY-FAILURE AND RECURRENCE OF SYMPTOMS IN MALIGNANT COLORECTAL OBSTRUCTION CASES WITH SELF-EXPANDABLE METALLIC STENTS

Y. Ota[1,*], S. Yoshida[2], H. Isayama[1], T. Sasaki[1], A. Narita[1], T. Shimpoh[1], T. Hamada[1], A. Yamada[1], N. Takahara[1], H. Kogure[1], N. Yamamoto[1], Y. Nakai[1], Y. Hirata[1], K. Koike[1]

Contact E-mail Address: *u_mix0042008@hotmail.co.jp*

INTRODUCTION: Self-expandable metallic stents (SEMS) placement was widely accepted procedure for malignant colorectal obstruction (MCRO), however, we sometimes encounter the primary failure or recurrence of colorectal obstruction (RCRO) after SEMS placement. In these cases, additional SEMS insertion through the previous SEMS, so-called stent-in-stent (SIS) technique, was effective, but was not well reported.
AIMS & METHODS: To estimate the safety and efficacy of SIS technique for MCRO, we retrospectively reviewed the clinical records. Between Mar. 2006 to Apr. 2014, 104 patients underwent endoscopic SEMS placement for MCRO. Primary SEMS failure was defined as un-resolved symptom of MCRO and RCRO as the recurrence of colorectal obstructive symptoms after SEMS placement. Technical success was defined as deployment of the stent across the entire length of the stricture on the first attempt. Clinical success was defined as a resolution of symptoms and radiological relief of the obstruction within 24 h, confirmed by radiographic observation. To pass the stricture in the previous SEMS, a hydrophilic biliary guidewire was promoted in a J-turn shaped by way of prevention for passing through the SEMS's mesh. We excluded the obstruction at the different locations.
RESULTS: Primary stent failure and RCRO occurred in 2 and 21 patients, retrospectively. The causes of primary stent failure were insufficient expansion (0) and remaining stricture with too-short SEMS because of underestimation of stricture length (2). Those of RCRO were kinking at the stent edge (8), tumor in/overgrowth (10) and stool impaction (3). Four patients underwent surgical intervention (bypass operation = 1, colostomy = 3), stent-in-stent placements were performed for 15 patients. We used covered (5) and uncovered (10) stents. The obstructions were located at rectum (5), sigmoid colon (4), splenic flexure (3), descending colon (1), and transverse colon (1) and cecum (1). Six patients had colorectal cancer. The remaining 9 patients had extra-colonic obstruction by following malignancies; pancreatic cancer (4), stomach cancer (2), ovarian cancer (2) and gallbladder cancer (1). Technical success was 100%, and clinical success was 86.7% (13/15). The median duration of secondary stent patency and survival was 161 (1-234) days and 122 (24-487) days, respectively. There was no severe adverse event. Long-term clinical failure occurred in 9 of 15 patients, attributed to re-occlusion of SEMS. Of these patients, tertiary SEMS placements were attempted for 4 patients, technical success was 100%, and clinical success was 50% (2/4). One patient underwent colostomy because of immediate perforation at 1 day after last stent insertion. Of the remaining 6 patients without tertiary stent insertion, four patients received palliative surgery and 2 patients were managed with total parenteral nutrition through a central venous catheter.
CONCLUSION: Stent-in-stent placement for primary failure and RCRO showed high technical and clinical success rate without any serious complications for both colonic and extra-colonic obstruction. We should carefully assess effectiveness of tertiary SEMS placement.

P1388 THE USEFULNESS OF A CLOSURE OF ULCER FOR THE PREVENTION OF DELAYED PERFORATION AND BLEEDING AFTER DUODENAL ESD

A. Takahashi[1,*], T. Oyama[1]
[1]*Endoscopy, Saku Central Hospital Advanced Care Center, Nagano, Japan*
Contact E-mail Address: *aurevoireurope@yahoo.co.jp*

INTRODUCTION: Duodenal ESD is difficult, because of narrow cavity, thin wall and poor maneuverability. And complication rate such as delayed bleeding and perforation is higher than that of gastric ESD. We tried the closure of ESD ulcer by clip for the prevention of delayed perforation and bleeding.
AIMS & METHODS: The aim of this study is to investigate the usefulness of a closure of ESD ulcer by clip for the prevention of delayed perforation and bleeding after duodenal ESD.
68 patients who had duodenal tubular adenoma or adenocarcinoma treated by ESD from May 2001 to December 2013 were enrolled into this retrospective study. The patients were divided into 2 groups, one was followed up without closure (non-closure group), the other was closure group. EZ clip made by Olympus (HX-610-090L) was used for the closure. Second look endoscopy was performed on 2 to 5 days after ESD to check delayed bleeding and perforation. Characteristics of the lesions were as follows. Bulbs / 2nd portion / 3rd portion was 1/3/0 in non-closure group and 0/57/7 in closure group. The median diameter of resected specimen was 25 (23 - 30) mm and 17 (10 - 44) mm, respectively (P: 0.0239). The median diameter of lesion was 17 (13 - 22) mm and 9 (2 - 34) mm, respectively (P: 0.018). The oral intake of anticoagulant drug and under artificial dialysis were 0, 5 and 0, 2, respectively.
RESULTS: 1. The delayed bleeding rate was 50% (2/4) in non-closure group and 5% (3/64) in closure group. There was significant difference (P :0.0248). Three patients who had the delayed bleeding in closure group had risk of bleeding such as oral intake of anticoagulant drug, hemodialysis and diabetes mellitus.
2. The delayed perforation rate was 25% (1/4) in non-closure group and 0% (0/64) in closure group (P: 0.06).
3. The successful rate of the closure was 98% (63/64). The mean number of clips was 8.7 (range 4 to 17). The ESD ulcer of only one patient could not be closed by clips. Therefore, ENPD and ENBD was performed to prevent complications. And, the patient was fine without any complications such as delayed perforation and bleeding.
CONCLUSION: The incidence of delayed bleeding or perforation after duodenal ESD is high. However, the closure of ESD ulcer by clip is useful for the prevention of delayed perforation and bleeding after duodenal ESD.

P1389 TRANSORAL DIVERTICULO-ESOPHAGOSTOMY AS TREATMENT OF ZENKER DIVERTICULUM

A. Melis[1,*], M. Ceolin[2], U. Fumagalli[2], L. Barbieri[2], U. Elmore[1], R. Rosati[1]
[1]*Chirurgia Gastroenterologica, Ospedale San Raffaele, Milano,* [2]*Chirurgia Generale e Mini-Invasiva, Humanitas Research Hospital, Rozzano (MI), Italy*
Contact E-mail Address: *melis.alessandra@hsr.it*

INTRODUCTION: Transoral diverticulo-esophagostomy (TDE) is a modern treatment for Zenker diverticula (ZD) with low morbidity rate and high rate of symptom improvement. Residual or recurrent symptoms may impair patient's QoL and may request retreatment. Aim of this study is to analyze mode of presentation, diagnosis and treatment details of patients (pts) submitted to TDE who needed retreatment.
AIMS & METHODS: From March 1998 to September 2013, 96 out of 101 candidates, pts were submitted to TDE. TDE was performed with linear stapler with modified anvil (Endo GIA 30, 3.5) in all patients and, since 2009 (44 cases), with placement of two stay sutures on the septum to increase the length of section. All patients underwent FU at 1 month with barium swallow, whenever symptoms occurred by endoscopy and manometry, and at the time of this analysis.
RESULTS: Oropharyngeal dysphagia occurred in 83/96 pts; regurgitation, inhalation, throat lump were also recorded. Complications were: 4 dental lesions, 2 perforation treated conservatively, 1 bleeding. Two bleeding from the stapled line required endoscopic hemostasis. Twenty pts complained persistent symptoms due to residual spur or recurrent diverticulum: in 3/20 stay sutures were used; 15/20 pts (with a residual spur < 2 cm) were treated with flexible endoscopy with further treatment required in 2 cases; in 5/20 pts with a spur longer than 2 cm second TDE (4 pts) or open diverticulectomy (1 pt) were performed. Mean interval between TDE and retreatment was 7 months. After retreatment 4/20 patients complained mild symptoms. At a median FU of 42 months symptoms disappeared globally in 94% of patients.
CONCLUSION: Transoral treatment of ZD shows good results in terms of symptom reduction and patients' satisfaction. In few cases results were optimized by complementary treatment. The use of stay sutures allows to obtain better results.

P1390 TUMOR STROMA RATIO (TSR) IN ESOPHAGEAL ADENOCARCINOMA BIOPSIES IN THE PREDICTION OF RESPONSE TO NEOADJUVANT THERAPY AND OVERALL SURVIVAL

C. Hetterschijt[1], S. Lagarde[1], R. Blom[1], **M. Anderegg**[1,*], H.van Laarhoven[2], S. Meijer[3], S. Gisbertz[1], M.van Berge Henegouwen[1]

Contact E-mail Address: *s.m.lagarde@amc.uva.nl*

INTRODUCTION: The incidence of esophageal carcinoma has been rising over the past decades. Surgical resection remains an important part of curative treatment. Several studies have demonstrated a survival benefit for patients receiving neoadjuvant therapy compared to patients that underwent surgical resection alone. Identification of non responders at an early stage could prevent patients from the toxicity of neoadjuvant therapy and avoid a possible fatal delay in the performance of potentially curative surgery. Tumor stroma ratio (TSR) in primary tumor biopsies taken before neoadjuvant therapy and surgery proved to be a prognostic factor for patient's survival. The aim of this study was to evaluate the prognostic value of the TSR in biopsies of esophageal adenocarcinomas taken before neoadjuvant therapy and surgery, in correlation to the response to neoadjuvant therapy prior to esophagectomy. In addition the correlation of the tumor stroma ratio with overall survival was evaluated.

AIMS & METHODS: In a retrospective study, we selected 141 patients with esophageal adenocarcinoma who underwent neoadjuvant chemoradiotherapy prior to esophageal resection between 2004 and 2011. The haematoxylin-eosin (H&E) stained sections of the tumor biopsies were reanalysed. TSR was scored as TSR low (< 50% carcinoma) or TSR high (> 50% carcinoma). Response to neoadjuvant therapy was determined in the resected specimen based on the tumor regression grade (TRG). The chi-square and Fisher's exact tests were used to evaluate the correlation of TSR with TRG. Survival was calculated from the date of surgery using the Kaplan–Meier method.
RESULTS: 141 patients were analysed. 55 (39%) patients were defined as responders (TRG 1 and 2) and 86 (61%) as non-responders (TRG 3 and 4). Estimation of the TSR was performed successfully in all the tumors (100%). 104 (74%) patients were classified as TSR high and 37 (26%) patients as TSR low. The correlation of TSR with TRG was not significant ($p = 0.537$). The correlation of TSR with overall survival was not significant ($p = 0.793$).
CONCLUSION: Our results suggest that the TSR in biopsies of esophageal adenocarcinomas does not have a prognostic value in correlation to the response to neoadjuvant therapy prior to esophagectomy. Moreover, according to our results TSR is not a prognostic characteristic for overall survival.

INTRODUCTION: In the last decade, work participation of cancer survivors has received growing attention worldwide and cancer survivors are at risk for job loss, unemployment and social and work disability. Cancer survivors who are unable to resume a former job face the risk of a financial loss.
AIMS & METHODS: The purpose of the current study was to evaluate the impact of esophagectomy for cancer on patients' occupation. We also evaluated the association between the job condition and perceived quality of life at one year after esophagectomy.
We retrospectively evaluated all consecutive patients referring to our department between 2009 and 2012 for esophageal cancer. Inclusion criteria was esophagectomy for cancer. Patients not suitable for work (due to psychiatric disease or tetraplegia) and patients with missing information about their job were excluded. Working condition at diagnosis, at one month before surgery and at one year after surgery was collected. Patient's and tumor characteristics – along with therapeutic strategies – were also collected. Quality of life was evaluated at diagnosis and at one year after surgery using Financial Difficulties (FI), Social Functioning (SF), Role Functioning (RF) and Global health status (QL2) scores of EORTC QLQ-C30 questionnaire.
RESULTS: Fifty-one active workers and 29 retirees underwent surgical resection for esophageal cancer.
At diagnosis, retirees had slightly lower FI score than active workers (9.0±15.1 vs. 18.9±27.8, $p = 0.07$), whereas self-employed subjects had slightly higher RF (93.6±12.8 vs. 78.5±31.3, $p = 0.05$) and QL2 (80.1±17.2 vs. 65.6±23.6, $p = 0.06$) than employees.
At one year after surgery, 64% active workers were still in labor force whereas 36% quit their job; SF score (92.9±13.1 vs. 86.7±17.3, $p = 0.34$), FI score (14.3±26.2 vs. 22.7±26.7, $p = 0.47$), RF score (71.4±28.4 vs. 86.7±22.6, $p = 0.15$) and QL2 score (67.9±18.3 vs. 73.0±22.1, $p = 0.58$) were similar between the two groups.
CONCLUSION: Retirees reported less financial concerns than active workers at cancer diagnosis. A considerable number of patients quit their job after esophagectomy for cancer. Adequate welfare strategy should be implemented for esophageal cancer survivors.

P1392 OMENTECTOMY IN GASTRIC CANCER SURGERY: A PROSPECTIVE COHORT STUDY IN 100 PATIENTS

E.J. Jongerius[1], D. Boerma[2], K.A. Seldenrijk[3], S.L. Meijer[4], J.J. Scheepers[5], F. Smedts[6], S.M. Lagarde[1], O. Balague Pons[7], M. I.van Berge Henegouwen[1], J.W. van Sandick[8], **S.S. Gisbertz**[1,*]

INTRODUCTION: There is no evidence for a complete omentectomy as part of a radical gastrectomy with a modified D2 lymphadenectomy in potentially curative gastric cancer. In this study we prospectively evaluated the presence of metastases in the greater omentum in potentially curative radical gastrectomy for gastric cancer patients.
AIMS & METHODS: In this multicenter prospective cohort trial 100 consecutive patients with gastric cancer underwent a (sub) total gastrectomy with complete en-bloc omentectomy and a modified D2 lymphadenectomy. After resection of the specimen, the omentum was separated from the stomach distal to the gastro-epiploic vessels and separately sent for pathological examination. The primary endpoint was the presence of metastases in the greater omentum.
RESULTS: In 5 of 100 patients (5.0%) metastases were detected in the greater omentum (2 patients with omental lymph node metastases, 3 patients with omental tumor deposits). These patients had pT4N1M1, pT4N1M0, ypT4N1M0, ypT3N0M1, ypT3N3M0 disease. In all 5 patients with omental metastases, the resection was irradical (R1) at the proximal ($n = 3$) or distal ($n = 2$) resection margin. Two patients were operated for linitis plastica and 3 had a proximal gastric tumor. In 3 patients the tumor expanded in the esophagus, in 2 in the duodenum.
CONCLUSION: Metastases in the greater omentum are infrequent. It seems that there are factors demonstrable that coincide with the presence of metastases in the greater omentum. In all patients with omental metastases an irradical resection was performed. This study suggests that omentectomy could possibly be omitted in some gastrectomy for gastric cancer patients. However, identification of these patients, safety and true benefit of omentum preservation needs further investigation in a randomized controlled trial.

INTRODUCTION: The most important part of advanced gastric cancer surgical treatment consists of either open surgery or minimally invasive surgical procedures, both techniques being under current evaluation for the clinical impact and prognosis of each patient. According to various parameters which can be revealed by pre-procedure imaging and endoscopy, the minimally invasive surgery is generally preferred. However, there are certain cases in the evolution of advanced gastric cancer when the results indicate the necessity to switch to open surgery due to safety and better outcome reasons.
AIMS & METHODS: We retrospectively evaluated 187 patients known with advanced gastric cancer, whom were operated on between 2008 and 2014 in the Surgery Department of Clinical Institute Fundeni. The patients were divided into 2 groups according to the type of surgery performed: either open or minimally invasive surgery. We analysed the following parameters obtained by upper endoscopy: location of cancer, aspect, extension, involvement of pylorus and cardia, presence of haemorrhage; and tomographic imaging: metastasis, peritoneal carcinomatosis, lymph node involvement, surpassing the gastric wall, invasion of cardia, pylorus, duodenum and great vessels, presence of ascites. The obtained data were processed in Prism5 programme for statistical analysis using chi-square test.
RESULTS: Following statistical analysis we retain that 66% were male patients; 73% were operated by open surgery. A statistical significant p value (< 0.05) was obtained for Bormann classification type 2 relevant for a clear indication of open surgery ($p = 0.0091$), while type 3 could be managed by minimally invasive techniques ($p = 0.0003$). Non-involvement of cardia and pylorus was an indicator for the minimally invasive surgery with a p-value of 0.0037 and 0.00259, respectively (endoscopic parameters). Regarding the results from computer-tomography, minimally invasive surgery was used in the absence of the following parameters: great intra-abdominal vessel involvement ($p = 0.0177$), cardia invasion ($p = 0.0067$), surpassing of gastric wall ($p = 0.019$) and the presence of metastasis ($p = 0.05$).
CONCLUSION: The minimally invasive surgery of gastric cancer has gained increased interest among surgeons. It should be considered in the majority of cases, except when there is a sum of indicators such as local invasion (cardia, pylorus, great vessels, gastric wall), metastatic disease, lymph nodes involvement and Borrmann 2 lesions in which open surgery is rather recommended. Type 1 and 4 Borrmann lesions and active haemorrhage did not show a precise correlation.

Contact E-mail Address: *luca.saadeh@gmail.com*

INTRODUCTION: The esophagectomy for cancer is still burdened by many complications. Simple, easy-to-use clinical predictors of cardiopulmonary complications may help in preventing and managing these events.

AIMS & METHODS: This study aimed at identify predictive factors of cardiac and pulmonary post-operative complications before patients undergo surgery in order to improve the outcome and shorten the hospital stay. Every patients underwent a cardiologic evaluation with echocardiography, ECG with further stress-test when required and pulmonary evaluation with function tests. The cardiologic parameters considered were the QT corrected interval, the E/A ratio, the diastolic volume of the left ventricle, the presence of mitral and/or tricuspid valves insufficiency, the ejection fraction and the evidence of myocardial asynergy at the cardiac US. The pulmonary function tests considered the observed/theoretical ratio in vital capacity (VC), forced expiratory volume in one second (FEV1), total lung capacity (TLC), transfer coefficient for carbon monoxide (KCO), FEV1/VC, RV/TLC. Logistic regression analysis was used.
RESULTS: In our center, 212 patients underwent esophagectomy for cancer from 2008 to 2013. Cardiologic complications were reported in 14 patients (6.6%): 7 arrhythmias with no hemodynamic instability (3.3%), 1 cardiac tamponade (0.5%), 4 myocardial infarctions (1.9%). Pulmonary complications were observed in 20 patients (9.4%): 19 pleural effusion (9%) and one acute respiratory distress syndrome (0.5%). Overall cardiac complications were predicted only by the presence of myocardial asynergy at cardiac US [OR 6.41 (95% CI = 1.84-22.36), p = 0.003] that also predicted cardiac arrhythmias [OR 6.08 (95% CI = 1.07-34.32), p = 0.041]. Pulmonary complications were predicted by the presence of myocardial asynergy at the cardiac US (p = 0.018), male sex (p = 0.046), reduced observed/theoretical ratio in: TLC (p = 0.019), KCO (p = 0.039) RV/TLC (p = 0.007), VC (p = 0.008). At the multivariate analysis the reduced observed/theoretical ratio in KCO resulted to be the only independent predictor of pulmonary complication [OR 0.94 (95% CI = 0.91-0.98), p = 0.009].
CONCLUSION: Cardiac and pulmonary complications after esophagectomy can be predicted by simple, repeatable and low cost tests. Therefore, studying every patient with cardiac US and pulmonary function tests should become part of the path to esophagectomy in order to adopt preventive medical therapy before and/or after surgery, to improve the outcome and to reduce the hospital stay with a cost-effectiveness benefit.

P1396 DINAMICS OF ENDOSCOPIC AND HISTOPATHOLOGICAL CHANGES OF THE MUCOUS AND SMOOTH ESOPHAGEAL MUSCLE AFTER SURGICAL TREATMENT ACHALASIA

P.D. Fomin[1,*], A. Kurbanov[1]
[1]*Surgery, National medical university named after A. A. Bogomoletz, Kiev, Ukraine*
Contact E-mail Address: *peter_fomin@mail.ru*

INTRODUCTION: Achalasia is associated with functional esophageal obstruction. Food stasis can predispose for esophagitis. For surgical treatment of achalasia there is important to study and compare in the dynamics in the long term of the endoscopic data with structural and morphological changes of the mucous membrane and smooth muscle of the esophagus and the incidence of esophagitis.
AIMS & METHODS: To investigate the correlation between endoscopic data and morphological changes of the mucous, incidence and severity of esophagitis in achalasia patients after surgical treatment with Heller-Dor or Heller-Toupet procedures. Before surgery on endoscopy biopsy specimens of mucous were sampled just above and at the zone of gastro-esophageal junction and the pieces of smooth esophageal muscle were taken above esophageal incision and at the zone of gastro-esophageal junction after myotomy. We performed routine histological sections and electron-microscopic studies of muscle biopsies. The macroscopic esophagitis graded according the Los Angeles classification (grades A–D) and histology was graded into grade 1-3. In the long term after surgery patients were seen in 1, 2, 4, 7, 10 and 17 years with upper GI endoscopy and inspection of the presence macroscopic esophagitis, three to four biopsy specimens were sampled just above and at the zone of gastro-esophageal junction for investigation.
RESULTS: Before surgical treatment 51 patients with achalasia had according radiological examination stage I - 3, stage II -5, stage III – 32 and stage IV – 11 pts. Endoscopic sings of esophagitis A – 22 (43, 2%), B – 15 (29, 4%), C – 9 (17, 6%), D – 5 (9, 8%) and histology grade I –27 (52, 9%), II – 18 (35, 3%) and III - 6 (11, 8%). The association between endoscopic food stasis and histological inflammation was significant. The ultrastructural alterations in the smooth muscle of all patients included muscle filament disarray, mottling of the fibre density in myocytes, thick and long cytoplasmic dense bodies, long dense plaques, and relatively few nexus junctions. In achalasia, the smooth muscle cells exhibited nuclear and cytoplasmic inclusions. The changes are most commonly seen between the narrowed and dilated segment of the esophagus but at the narrowed area of gastro-esophageal junction there was a striking loss of small nerve fibres and reduced numbers of granules in the remaining fibres. All patients were followed for mean values of 9.4 years (range: 1–22). The average number of endoscopies with biopsy sample sets per patient was 5 (range: 1–17). 19 (37, 3%) patients had no histological signs of esophagitis throughout follow-up, 32 (62, 7%) had esophagitis grade I – 29 (90, 6%) and grade II – 3 (9, 4%). Specialized intestinal metaplasia was found in 5 patients. The association between endoscopic food stasis and histological inflammation was significant. The association between the severity of clinical signs evaluated by a modified symptom score as the sum of the scores for dysphagia, regurgitation and chest pain with endoscopic signs of esophagitis and histological inflammation was poor.
CONCLUSION: Results of our studies evidence that in the long term after surgical treatment of esophageal achalasia with antiflux fundoplication is a considerable improvement of clinical symptoms, endoscopic sings and histological evidence of esophagitis. The dynamics of improvement depends on the duration and disease stage.

P1397 THE IMPACT OF LYMPH NODE METASTASIS NEAR THE CELIAC TRUNK IN PATIENTS WITH CANCER OF THE DISTAL ESOPHAGUS OR GASTRO-ESOPHAGEAL JUNCTION

S. Lagarde[1], **M. Anderegg**[1,*], S. Gisbertz[1], S. Meijer[2], M. Hulshof[3], J. Bergman[4], H.van Laarhoven[5], M.van Berge Henegouwen[1]

Contact E-mail Address: *s.m.lagarde@amc.uva.nl*

INTRODUCTION: The present TNM staging system (7th edition, 2010) does not take into account the location of truncal nodes metastasis after neoadjuvant therapy. Therefore the aim of the present study is to identify the incidence and prognostic significance of celiac trunk metastasis in patients who underwent neoadjuvant chemo (radiation) therapy followed by an esophagectomy.
AIMS & METHODS: Between March 1994 and September 2013 a total of 462 consecutive patients with cancer of the mid-to-distal esophagus or gastroesophageal junction (GEJ) who underwent potentially curative esophageal resection after neoadjuvant chemotherapy (N = 88, 19%) or chemoradiotherapy (N = 374 (81%) were included.
RESULTS: 71 (15.4%) patients had positive truncal nodes in the resection specimen. Metastases to these nodes occurred more frequent in male patients with adenocarcinoma and in GEJ tumors. Pretreatment staging was significantly more advanced. While the number of resected nodes was comparable, a worse Mandard score, a higher yT and yN stage and a worse grade of differentiation were significantly related to truncal node metastases. Patients with positive truncal nodes had a worse median disease free survival (11months vs 65 months). In multivariate analysis, yN stage as well as positive truncal nodes were independently associated with a worse survival. Only 22 (31%) of 71 patients with positive truncal nodes were identified preoperatively with EUS or CT. 37 patients had suspicious truncal nodes on EUS or CT, but metastases in the pathology specimen were absent.
CONCLUSION: In the present study, it is demonstrated that positive truncal nodes are associated with advanced tumor stages and are an independent factor for worse survival. It seems that celiac nodal involvement is a "marker" for widespread microscopic disease that may later become evident, since patients with positive truncal nodes in the resection specimen have a dismal prognosis. Future studies need to investigate to what extent truncal node status should influence surgical decision making.

P1398 RELATIONSHIP BETWEEN RIGHT GASTROEPIPLOIC ARTERY LYMPH NODE DISSECTION AND PYLORUS-PRESERVING GASTRECTOMY BASED ON THE SENTINEL LYMPH NODE BASIN THEORY

T. Ono[1,*], H. Takeuchi[1], R. Nakamura[1], T. Takahashi[1], N. Wada[1], H. Kawakubo[1], Y. Saikawa[1], T. Omori[1], Y. Kitagawa[1]
[1]*digestive surgery, Keio University, shinjuku ku, Japan*

INTRODUCTION: Pylorus preservation decreases weight, prevents the dumping syndrome, and prevents bile reflux and gallstone formation.
Postoperative quality of life (QOL) is often the most important concern for patients with early gastric cancer; therefore, pylorus-preserving surgery has an important clinical significance.
In the present study, we identified the involvement of certain lymph nodes as sentinel nodes (SNs) using the Sentinel Lymph Node Basin theory to ensure appropriate lymph node dissection during pylorus-preserving gastrectomy (PPG) in patients with middle-third early gastric cancer.
AIMS & METHODS: Totally, 283 patients with middle-third gastric cancer who underwent PPG from 2002 to 2013 were included. The inclusion criteria were as follows: no previous treatment, tumor size < 4 cm, single tumor, cT1N0 disease. Informed consent was obtained from all patients.
We evaluated the lymphatic flow in all patients to identify the involvement of lymph nodes 4d and 6 as sentinel nodes (SNs). PPG was then performed on the basis of this detection.
RESULTS: Lymph node 6 was identified as an SN in 27 of the 283 patients, with a detection rate of 7.1%, 5.9%, 22%, and 7.1% in the lesser curvature, greater curvature, anterior wall, and posterior wall, respectively, while the detection rate for lymph nodes 6 and 4d as SNs was 16%, 84%, 72%, and 44%, respectively, in these regions.
Our findings showed that lymph nodes 6 and 4d were less frequently involved as SNs in patients with lesser curvature lesions, with lymph node 6 being directly involved without the involvement of lymph node 4d.
On the other hand, the frequency of detection of lymph node 6 as an SN was high in patients with greater curvature lesions; furthermore, it was always associated with the involvement of lymph node 4d.
Anterior wall lesions exhibited the highest frequency of lymph node 6 involvement as an SN.
CONCLUSION: The probability of lymph node 6 involvement as an SN was 9.5% in patients with middle-third early gastric cancer. Therefore, lymph node 6 dissection should be mandatory during PPG in these patients.

P1399 THE USEFULNESS OF SEDATION USING A COMBINATION OF PROPOFOL AND DEXMEDETOMIDINE HYDROCHLORIDE UNDER THE CONTINUOUS AIRWAY TONE MONITORING WITH A PROPRIETARY MICROPHONE IN THE ESOPHAGEAL ESD

T. Nonaka[1,*], M. Matsuura[1], K. Kanoshima[1], Y. Inoh[1], H. Iida[1], M. Inamori[2], A. Nakajima[1]
[1]*Department of Gastroenterology and Hepatology, Yokohama City University School of Medicine,* [2]*Office of Postgraduate Medical Education, Yokohama City University Hospital, Yokohama, Japan*

INTRODUCTION: The esophageal endoscopic submucosal dissection (ESD) is known to be technically more difficult and riskier about intraoperative complication than gastric ESD due to the narrow space and the thin wall of the esophagus. Although proper sedation is essential for successful esophageal ESD, it is sometimes difficult to achieve stable sedation with midazolam or other benzodiazepines alone. Recently, introduction of new sedatives such as propofol and dexmedetomidine hydrochloride on ESD are expected to be useful agents. There are few reports investigating the effects of such sedatives on ESD performance and complications.
AIMS & METHODS: Objective: We started new sedation using a combination of propofol and dexmetomidine under the continuous airway tone monitoring with a proprietary microphone in the esophageal ESD since August 2013. The study was conducted to investigate the safety and efficacy of our new sedation. Subjects: The present study included consecutive 35 patients undergone esophageal ESD before and after introducing the new sedation on August 2013, in which 20 patients were sedated either with midazolam or other benzodiazepines alone (Conventional group) just before introducing the new sedation between July 2012 and August 2013, and 15 patients were sedated with a combination of propofol and dexmetomidine (New group) between August 2013 and April 2014. Outcome Measurements: The clinical characteristics (age, sex, body mass index, alcohol consumption and underlying disease) was collected. Minimum value of systolic blood pressure (sBP), minimum value of blood oxygen saturation (SpO_2), and the degree of body movement leading to the interruption of maneuver during ESD were compared between the groups. The clinical characteristics (age, gender, body mass index, alcohol consumption and underlying disease) was collected. We consequently compared the following outcome of ESD between the groups: procedural time, en block resection rate, resected lesion size and incidence of complications (massive bleeding or perforation).
RESULTS: There was no significant difference between the two groups in the clinical characteristics. Minimum value of sBP (mmHg) in the New group was lower than in the Conventional group (82.27 ± 16.77 vs 102.10 ± 19.30, $p = 0.002$). Minimum value of SpO_2 (%) in the New group was higher than in the Conventional group (97.13 ± 2.07 vs 94.15 ± 2.41, $p = 0.001$). Regarding ESD performance, there was no statistically significant difference in en block resection rate, maximum diameter of specimen and incidence of complications during ESD between the two groups. However, the mean procedural time (min) in the New group was significantly shorter than in the Conventional group (105.13 ± 43.48 vs 134.95 ± 45.58, $p = 0.013$).
CONCLUSION: The continuous airway tone monitoring with a proprietary microphone may provide the prevention of respiratory suppression by earlier detection of apnea, glossoptosis and laryngeal spasm. Sedation using a combination of propofol and dexmedetomidine hydrochloride under the continuous airway tone monitoring with a proprietary microphone can improve procedural time without respiratory suppression in the esophageal ESD.

P1400 NEW METHOD OF LAPAROSCOPY ASSISTED ENDOSCOPIC FULL-THICKNESS RESECTION WITH SILICON AND POLYGLYCOLIC ACID SHEETS IN PORCINE MODEL

T. Itoh[1,*], H. Kitakata[1], S. Kinami[2], K. Kawaura[1], K. Hamada[1], S. Azukisawa[1], **R. Itoh**[1], **T. Kosaka**[1]
[1]*Dept. of Gastroenterological Endoscopy,* [2]*Dept. Surgical Oncology, KANAZAWA MEDICAL UNIVERSITY, Uchinada, Japan*

INTRODUCTION: It is reported that the sentinel node concept is valid in cases of early gastric cancer using lymphatic basin dissection method. It means that dissection of the lymph nodes outside the basins may be avoided when the sentinel nodes were negative for metastasis. We have previously shown the safety and benefits of endoscopic full-thickness resection (EFTR) in *in vivo* porcine models. Furthermore, we initiated a clinical study of EFTR in patients with submucosal invasive gastric cancer who were diagnosed as negative for lymph node metastasis by laparoscopic sentinel lymph node biopsy. With this technique, the lesion can be resected with an appropriate surgical margin, since the resection is performed while confirming the lesion. On the other hand, it has some disadvantages, such as loss of endoscopic view caused by collapse of the stomach and intra-peritoneal infection by outflow of gastric juice. Thus, we tried new method of covering the serosa of stomach with silicon sheet and polyglycolic acid felt to prevent collapse of the stomach and outflow of gastric juice.
AIMS & METHODS: Three domestic pigs were used for LA-EFTR. Under general anesthesia, virtual lesions measuring 2 to 3 cm in diameter were set in various positions of the stomach. Silicon sheet and polyglycolic acid (PGA) felt (Neoveil ®) were put on the serosa of the virtual lesion and pasted with fibrinogen, thrombin solution. Then, full-thickness incision was performed by IT knife.
RESULTS: By covering the serosa with PGA felt, endoscopic view was kept during EFTR without collapse of the stomach. The felt was detached from the stomach by laparoscopic forceps after EFTR and removed through oral cavity.
CONCLUSION: This method prevents the collapse of the stomach and enables endoscopic resection with stable endoscopic view. EFTR may be a useful surgical treatment as the extent of resection is limited to the minimum necessary and the remnant gastric volume is preserved.

P1401 MODIFIED INTRODUCER METHOD FOR PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) DOES NOT NEED ADMINISTRATION OF SYSTEMIC PROPHYLACTIC ANTIBIOTICS - A PROSPECTIVE, RANDOMISED, DOUBLE-BLIND STUDY

Y. Adachi[1,*], K. Akino[1], H. Mita[1], T. Kikuchi[1], K. Yamashita[2], Y. Arimura[2], T. Endo[1]
[1]*Sapporo Shirakaba-dai Hospital,* [2]*First Department of Internal Medicine, Sapporo Medical University, Sapporo, Japan*

INTRODUCTION: Percutaneous endoscopic gastrostomy (PEG) is the most common method of enteral nutrition in patients who require long-term tube feeding. According meta-analysis, administration of systemic prophylactic antibiotics for PEG tube placement reduces peristomal infection. However, several recent developments of its procedure and instruments, the risk of infection having been reduced. We want to assess necessity of systemic antibiotic prophylaxis for a new modified introducer method PEG.
AIMS & METHODS: A prospective, randomised, double-blind trial. A total of 278 patients undergoing PEG were assessed for inclusion. Ninety-one patients with an indication for PEG who gave informed consent to participate were randomized. Forty-six patients received prophylactic ampicillin (sulbactam sodium/ampicillin sodium) and 45 patients received a placebo. Introducer method for PEG using Kangaroo-II Seldinger PEG kit was performed. Primary outcome was the occurrence of clinically evident wound infection within 3 and 7 days after insertion of the PEG catheter. Secondary outcomes were fever and any infection within 3 and 7 days after PEG.
RESULTS: There were not significant difference between 2 groups in all parameters, including wound infection within 3 and 7 days, any fever within 3 and 7 days, any infection witin 3 and 7 days, and successive rate of finising antibiotics.
CONCLUSION: The new modified introducer method PEG might not needed for systemic antibiotic prophylaxis.

Contact E-mail Address: *mjacobse@online.no*

INTRODUCTION: Biopsy tissue has advantages over animal- and single cell models as both the original disease mechanisms and the cell-matrix interactions are maintained. Several authors have developed chip-based model for tissue culture (1,2),
AIMS & METHODS: The chip was produced in-house of glass and PDMS with a $2mm^3$ biopsy chamber. Microfluidic channels ($200\mu m$) flushed the biopsy with DMEM in separate flows to the epithelial and the basolateral surface. A syringe pump established the flow ($120\mu lmin\text{-}1$) and the effluents from both sides were collected for analyses. The use of microfluidic channels ensured spatial and temporal regulation of solute concentration essential for the control of biomimetic processes To ensure that the epithelial and the basolateral flow did not mix, phenol red was added to the fluid on the epithelial side and the effluents examined with a photometer.
With proper consent from the ethics boards (UK) and after written patients consent, biopsies were taken from patient with IBD. To investigate tissue survival, the tissue was processed for histology (HE) at start, at 24, 48 and 72 hours. Furthermore, the biopsies were treated with Triton-X 100 at the same time-points and the release of LDH was measured. The acute phase protein SA-100 was measured in the effluent from tissue with macroscopic, inflammatory changes and compared to normal looking tissue.
RESULTS: Photometry of the effluents demonstrated that the media did not mix. Histology (HE) demonstrated that the epithelial layer was intact after 72 hours. Application of the Triton-X buffer sharply increased the LDH in the effluent on both sides. S-100A was significantly higher in IBD than in effluents from the non-IBD biopsies. This relationship was maintained up to 50 hours. Staining with Ki-67 demonstrated proliferating cells in the crypts even at 50hours.
CONCLUSION: We have established a dual channel, chip method for tissue culture that ensure tissue viability and maintain inflammatory characteristics for more than 50 hours.
Three-dimensional culture models with intact cell-cell and cell-matrix connections have several advantages over single cell models. Our goal is to develop this model to study individual disease mechanisms and therapy responses in IBD. Our dual flow model may enable us to study the influence of luminal metabolites on the colonic mucosa.

P1403 THE EFFECT OF THE ANTI-TNFA ADALIMUMAB ON THE LEVELS OF ANGIOGENIC FACTORS IN MUCOSAL CULTURES FROM PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD)

P.M. Linares[1,*], M.E. Fernández Contreras[1], A. Algaba[2], M. Chaparro[1], I. Guerra[2], F. Bermejo[2], J.P. Gisbert[1]
[1]*Gastroenterology, Hospital Universitario de La Princesa, IP and CIBEREHD,* [2]*Gastroenterology, Hospital Universitario de Fuenlabrada, Madrid, Spain*

INTRODUCTION: Effectiveness of adalimumab (ADA) treatment could be related to the modification of different angiogenic proteins, including VEGF, Ang1, Ang2 and their receptor Tie2.
AIMS & METHODS: The aim of this study was to compare the concentrations of several angiogenic factors in colonic mucosa culture supernatant (MCS) in patients with IBD and matched controls and to analyze their modifications with the *in vitro* ADA addition to the culture.
Prospective study in patients with IBD and non-IBD controls that underwent endoscopy. Duplicates of colonic mucosa samples from affected and non-affected mucosa from each IBD patient were obtained for comparison. Both were washed and then cultured at 37°C in 5% CO_2 medium under shaking for 24hours. In one duplicate, ADA was added up to a final concentration of 10μg/mL prior to culture. MCS levels in AP were determined by ELISA. Endoscopic ulcerative colitis (UC) and Crohn's disease (CD) activity was ascertained by Mayo subscore and SES-CD indexes, respectively.
RESULTS: 28 patients with IBD (16 UC, 12 CD) and 21 controls were included. Mean age was 41±16 years, and 61% were women. The mean disease duration was 7±7 years. According to endoscopic activity, 36% of patient had quiescent, 32% mild, 28% moderate, and 4% severe activity. All angiogenic factors mean levels in MCS were higher in affected than in non-affected MCS; VEGFA (19.1±18.7 vs. 8.7±10.5 pg/mL/mg) and Ang2 (21.3±15.7 vs 11.8±8.9 pg/mL/mg) ($p<0.05$). There were no differences in MCS depending on endoscopic activity. Levels of VEGFA, Ang1 and Ang2 from the affected, and VEGFA and Tie2 from the non-affected mucosa, were lower when cultured with ADA than without it (table 1). In UC patients, VEGFA and Ang1, and all angiogenic factors MCS mean levels were lower in the affected-mucosa and non-affected mucosa, and in the non-affected mucosa when cultured with ADA, respectively. In contrast, in CD patients, there were no differences in MCS angiogenic factors levels and the addition of ADA to the culture.
Table 1. Levels of angiogenic factors in MCS from IBD patients after culture.

	Affected mucosa	Affected mucosa + ADA	p-value
VEGFA	19.1±18.7	14.6±14.5	0.003
Ang1	15.7±8.8	12.2±6.2	0.021
Ang2	21.3±15.7	19.4±13.1	0.021
Tie2	12.0±5.5	12.4±16.1	0.911

Concentrations are expressed in pg/mL per mg of tissue.
CONCLUSION: ADA might downregulate the production of angiogenic factors in MCS. ADA addition to mucosal cultures affects angiogenic factors levels in samples from patients with UC differently than in patients from CD.

INTRODUCTION: Chondroitin sulphate, a glycosaminoglycan that modulates NF-κB, might modulate several pro-inflammatory proteins involved in the pathogenesis of IBD.
AIMS & METHODS: The aim of our study was to evaluate the incidence rate of relapse in patients with IBD under chondroitin sulphate treatment and its effect on the concentrations of diverse pro-inflammatory mediators in serum and urine. Prospective observational 12-month (m) follow-up study in patients with IBD in remission for at least 6 m, starting chondroitin sulphate treatment (Condrosan®, CS Bio-Active™, Bioibérica S. A., Barcelona, Spain) for osteoarthritis (OA) (dose: 800 mg o.d.). Visits were as follows: Baseline, 3rd, 6th, 9th and 12th m. CDAI and modified Truelove-Witts clinical indexes were calculated for Crohn's disease (CD) and ulcerative colitis (UC) respectively. C-reactive protein (CRP), orosomucoid, and erythrocyte sedimentation rate (ESR) were also determined. Levels of VEGFA, VEGFC, FGF2, HGF, Ang1, Ang2, TGFβ, TNFα, IL1β, -6, -12, -17, -23, ICAM1, VCAM1, MMP3 and PGE2 were quantified by ELISA. OA joint pain was evaluated by a visual analogue scale (VAS).
RESULTS: 37 patients with IBD (19 UC, 18 CD) were included. Mean age was 59.8 years, and 70% were women. The mean disease duration was 12.7 years. 62% of patients were under mesalazine, 5% with sulfasalazine, 22% with thiopurines, and 3% with methotrexate. There was only one patient (with UC) that had a flare during follow-up (6th m visit). The incidence rate of relapse was 3.4% per patient-year of follow-up. That figure is lower than the relapse rate previously reported for IBD patients. 12 UC and 11 CD patients completed the 12 m follow-up. In all patients with IBD, mean serum VEGFA levels were higher after 12 months of CS treatment (799 pg/mL) as compared to baseline (492 pg/mL) ($P<0.05$). Further differences regarding the other studied pro-inflammatory markers were not found. At 12th m, the OA joint pain had improved in all but four patients (from 5.9 to 3.0) ($P<0.01$). 43% of patients suffered adverse events, but only 5% were related to the drug.
CONCLUSION: The incidence of IBD relapse in patients under chondroitin sulphate treatment was lower than the generally reported. This treatment might modulate VEGFA serum levels, but it is not associated with modifications in the concentrations of the other studied pro-inflammatory mediators. Chondroitin sulphate decreases pain related to OA in patients with IBD.

INTRODUCTION: Interleukin (IL)-17A, which is up-regulated in inflammatory bowel disease (IBD) mucosal lesions, and IL-17F are normally present as IL-17AA and IL-17FF homodimers and may occasionally form IL-17A/F heterodimers. The role of each IL-17 dimer in IBD is currently unknown.
AIMS & METHODS: Here we studied the effects of IL-17AA, IL-17FF and IL-17-A/F in ulcerative colitis (UC) and Crohn's disease (CD) mucosa. Inflamed colonic biopsies from 17 IBD patients (6 UC and 11 CD) were cultured *ex vivo* for 24 hours with IL-17AA, IL-17FF or IL-17A/F (1 ng/ml). Mucosal myofibroblasts isolated from the inflamed colon of 4 CD and 4 UC patients were cultured for 24 hours with tumor necrosis factor (TNF)-alpha 20 ng/ml or with increasing concentrations (1-100 ng/ml) of IL-17AA, IL-17FF or IL-17A/F. IL-6 and IL-8 were measured in culture supernatants by ELISA.
RESULTS: IL-17AA, but not IL-17FF, significantly reduced both IL-6 and IL-8 production by inflamed IBD biopsies cultured *ex vivo*, whereas IL-17A/F decreased IL-8 release by IBD mucosa. No difference was observed between CD and UC. Neither IL-17AA, nor IL-17FF, nor IL-17A/F exerted any effect on IL-6 and IL-8 production by IBD myofibroblasts. As expected, TNF-alpha stimulation significantly increased IL-6 and IL-8 production by both CD and UC myofibroblasts *in vitro*. No difference was observed between CD and UC myofibroblasts.
CONCLUSION: IL-17AA exerts an anti-inflammatory action on inflamed IBD biopsies cultured *ex vivo*. The action of IL-17AA is not mediated by myofibroblasts, therefore further studies are underway to ascertain which cell type is the main target of IL-17AA in IBD mucosa.

INTRODUCTION: Reactive oxygen species (ROS) induced oxidative stress is one of most important etiological factor involved in the inflammation [1-2]. The key producers of ROS in the cells are NADPH oxidase enzymes. Several studies have shown that epithelial NADPH oxidase might be responsible for normal immune response to antigens in the gut [1,3]. On the other hand, little is known about the molecular pathways controlling ROS production via NADPH oxidase enzymes in the primary intestinal epithelial cells during inflammation.
AIMS & METHODS: AIM: To investigate the role of NADPH oxidase in colon epithelial cells in pathogenesis of acute and chronic colon inflammation using mice dextran sulphate sodium (DSS) colitis model.
METHODS: BALB/c mice were divided into three groups: 8 mice with acute DSS colitis (3.5% DSS solution; 7 days), 8 mice with chronic DSS colitis (3.5 % DSS solution for 5 days + water for 6 days; 4 cycles; total: 44 days) and 12 mice without DSS supplementation as control group. The primary colonic epithelial cells were isolated using chelation method. The cells were cultivated in the presence of mediators (lipopolysaccharide (LPS), apocynin or diphenyleneiodonium). Viability of cells was assessed by fluorescent microscopy. Production of reactive oxygen species (ROS) by the cells was measured fluorimetrically using

Amplex Red. Production of tumour necrosis factor- *alpha* (TNF- α) by the colonic epithelial cells was analysed by ELISA. *Nox1* gene expression was assessed by real-time (RT) PCR.
RESULTS: Our study showed that TNF-α level was increased in unstimulated primary colonic cells both in the acute and chronic DSS colitis groups, whereas decreased viability, increased ROS production, and expression of *Nox1* was characteristic only for chronic DSS colitis mice when compared to the controls. The stimulation by LPS increased ROS generation via NADPH oxidase and decreased cell viability in mice with acute DSS colitis. Treatment with NADPH oxidase inhibitors increased cell viability decreased the levels of ROS and TNF- α in the LPS-treated cells isolated from mice of both acute and chronic DSS colitis groups.
CONCLUSION: Our study revealed the importance of NADPH oxidase in pathogenesis of acute and chronic colon inflammation. Moreover, the treatment with NADPH oxidase inhibitors had a protective effect against pro-inflammatory action of LPS in mice colonic epithelium cells during DSS colitis.

INTRODUCTION: The adenosine system is emerging as a pathway involved in the regulation of balance between tissue repair and fibrosis. However, the role of adenosine in the pathophysiology of gut fibrotic remodelling has been scarcely investigated.
AIMS & METHODS: This study evaluated the role of adenosine A2B receptors on inflammation, pro-fibrotic TGF-beta/SMAD signalling and motility in experimental colitis. Colitis was induced in rats by intrarectal 2,4-dinitrobenzenesulfonic acid (DNBS). After 6 days, systemic [body and spleen weight] and tissue inflammatory parameters [macroscopic and microscopic damage, myeloperoxidase (MPO)] were assessed. Three days before colitis assessment, animals were treated daily with BAY606583 (BAY, A2B agonist, 2 mg/kg) or MRS1754 (MRS, A2B antagonist, 1 mg/kg) by i.p. route. At sacrifice, molecular factors involved in fibrosis (collagen I and III, fibronectin, TGF-beta, phosphorylated SMAD2) were analyzed by western blot. Collagen fibers (Sirius red) and elastic fibers (orcein) were examined by histochemistry. Colonic longitudinal muscle strips were suspended in organ baths (Krebs solution with NK 1, 2 and 3 receptor antagonists, guanethidine, L-NAME) to record atropine-sensitive cholinergic motor activity. Contractions were evoked either by electrical stimulation or by carbachol in the presence of tetrodotoxin.
RESULTS: DNBS-induced inflammation was associated with a decrease in body weight and increase in spleen weight, tissue MPO as well as macroscopic and microscopic alterations. Western blot revealed an increased expression of collagen I and III, fibronectin, TGF-beta and pSMAD2, as compared with controls. Histochemistry confirmed an increment of collagen deposition and a loss of elastic fibers. In functional assays, both electrically-evoked and carbachol-induced contractions were reduced, as compared with controls. In the setting of colitis, treatment with MRS counteracted the inflammatory indexes, while not affecting the molecular parameters related with fibrotic remodelling. By contrast, the administration of BAY failed to modify both systemic and tissue inflammatory indexes. However, BAY increased the expression of collagen I and fibronectin, while downregulating the TGF-beta/pSMAD2 pathway. With regard for motility, the altered motor patterns associated with colitis were not affected by BAY, while they were partly normalized by MRS.
CONCLUSION: DNBS-induced colitis is associated with colonic fibrotic remodelling and altered excitatory motility. In this setting, the pharmacological activation of A2B receptors did not modify the inflammatory indexes and abnormal patterns of cholinergic motility, while it increased the fibrotic remodelling through molecular pathways independent of TGF-beta signalling. By contrast, the pharmacological blockade of A2B receptors counteracted bowel inflammation and improved colonic dysmotility, without affecting fibrotic remodelling. Overall, these findings suggest a marginal role of endogenously activated A2B adenosine receptors in the pathogenesis of fibrosis associated with bowel inflammation.

INTRODUCTION: Antimicrobial mucosal barrier dysfunction, including the reduction of Human alpha-Defensin (HD) 5, is one of the most crucial pathogenesis of Crohn's disease (CD). Human Paneth cells produce two α-defensin peptides, which called HD5 and HD6. Recently, it has been reported that HD6 promotes mucosal innate immunity through self-assembled peptide ''nanonets'' whereas HD5 has the antimicrobial activity. The transcriptional regulation of HD6 has not been elucidated. Moreover the association of HD6 expression with CD also remains unknown.
AIMS & METHODS: We therefore aimed to elucidate the transcriptional regulation of HD6 and the pathogenesis of CD by HD6 expression.
For the analysis of the transcriptional regulation of HD6, We transgened Atoh1 into colon cancer cell line; SW480 by lentivirus infection. The expression of HD6 was assessed by quantitative RT-PCR and immunofluorescence. The transcriptional activity of HD6 promoter was assessed by the luciferase reporter assay. For the analysis of the HD6 expression in CD, non-inflamed jejunum biopsy specimens of 8 CD patients and 9 healthy controls using double balloon enteroscopy (DBE) were assessed.
RESULTS: HD6 was significantly increased by Atoh1 expression in SW480 whereas other antimicrobial peptides such as HD5, Lysozyme and phospholipase A2 were not changed. Atoh1 also enhanced the transcriptional activity of HD6 promoter. We found that HD6 promoter within 200-bp from ATG contains a transcription factor (TCF) binding site and four E-box binding site. The deletion of each binding sites revealed that not only TCF4/β-catenin protein complex but also Atoh1 is indispensable for HD6 expression. Moreover, ChIP assay showed that Atoh1 directly binds to the promoter region of HD6.
Finally, we assessed the pathogenesis of CD by HD6 expression. The microarray using mapping biopsy of whole small intestine in CD patient showed that almost inflammatory related genes were not shown in jejunum, suggesting that the pathogenesis before the onset of CD might remain in jejunum. The expression of Atoh1 and secretory cell markers (HD5, HD6, MUC2 and CgA) in jejunum of CD patients were significantly lower than that of healthy controls. Moreover, HD6 positive Paneth cells of CD patients were significantly lower than that of healthy controls.
CONCLUSION: Both TCF4/β-catenin protein and Atoh1 are essential to express HD6 in different from HD5. The decrease of HD6 in small intestine might cause mucosal barrier dysfunction suggesting that HD6 might be one of the pathogenesis of CD.

P1409 DIVERSITY OF ADHERED MICROBIAL COMMUNITIES IN COLON MUCOSAL BIOPSIES OF CROHN PATIENTS BY 16S RRNA GENE PYROSEQUENCING, EVIDENCES FOR TWO MAIN DISTINCT GROUPS

D. Ginard[1], **S. Khorrami**[1,*], R. Vidal[2], M. Mora[3], R. Muñoz[3], M. Hermoso[2], S. Díaz[3], A. Cifuentes[3], A. Orfila[3], R. Roselló-Móra[3]
[1]*Gastroenterology. Palma Health Research Institute, Son Espases Hospital, Palma de Mallorca, Spain,* [2]*Institute of Biomedical Sciences, Faculty of Medicine, Universidad de Chile, Santiago de Chile, Chile,* [3]*Department of Ecology and Marine Resources, Institut Mediterrani d'Estudis Avançats (IMEDEA; CSIC-UIB), Esporles, Spain*

INTRODUCTION: The human gut microbiota participates actively in the host homeostasis and plays an important role in Crohn's disease (CD) pathogenesis. Microbial diversity measures based on environmental 16S rRNA genes had permitted the recognition of the vast diversity of yet uncultured microorganisms in environmental samples. Next Generation Sequencing (NSG) techniques produce thousands of sequences, and had been thoroughly used to reveal diversity in environmental samples with identifications based on clustering sequences into Operational Phylogenetic Units (OPUs).
AIMS & METHODS: We aimed to study the microbiota adhered in the gut mucosa of CD patients and compare with healthy controls by means of a high-throughput NGS approach. Mucosal biopsies of 13 CD and 7 healthy controls submitted to colonoscopy for medical indications were recruited between Augost 2011 and March 2012. Demographics and clinical characteristics (disease localization, inflammatory activity, behavior, medication and surgical history) were also collected. Biopsies were immediately placed in sterile tubes and stored at -80°C for DNA/RNA extraction. The mucosal adhered microbiota was studied by high quality deep-sequencing of 16S rRNA gene amplicons. High quality sequences (mean 500 nuc) were applied to OPUs identification approach based on clustering sequences. The Balearic Islands' Ethical committee approved the study.
RESULTS: CD samples showed a mean of 83 ($\pm$16) OPUs, whereas HC samples showed a mean of 101 ($\pm$19). Two major groups of CD patients with different mirobiomes could be discriminated. Both groups presented a common trend mainly exhibited as depletion in members of the class *Clostridia*. In addition, CD1 showed enhanced presence of co-colonizing *Bacteroidetes* as a result of the disappearance of *Firmicutes*; whereas CD2 seemed to exhibit an opportunistic colonization of the mucosa by members of *Proteobacteria*.
CONCLUSION: CD patients exhibited consistently lower microbiota diversity than controls. CD may include different pathological disorders resulting in different adhered microbial profiles with a similar inflammatory end process. Simple amplification tests checking the presence or absence of *F. prausnitzii*

and the relative abundances of *Firmicutes*, *Bacteroidetes* and *Proteobacteria* could serve as diagnosis of both major CD groups found here and may help in the recognition of the genetic or metabolic disorders that conduct to the CD phenotypes.

P1410 THE ROLE FOR THE CYTOKINES INTERLEUKIN-22 AND INTERLEUKIN-17A AND PATHOGEN-ASSOCIATED MOLECULAR PATTERNS DURING THE PATHOGENESIS OF CROHN'S DISEASE ASSOCIATED PERIANAL FISTULAS

S.M. Frei[1,*], A. Fürst[2], E. Jehle[3], M. Fried[1,4], G. Rogler[1,4], M. Scharl[1,4]

Contact E-mail Address: *sandra.frei@usz.ch*

INTRODUCTION: Intestinal and perianal fistulas represent an important complication of Crohn's disease (CD). Therapeutic outcome using conventional drugs such as antibiotics, immunosuppressive agents and biologics is poor and surgical intervention is often required. Chronic inflammation, failure of the intestinal barrier function and a bacterial imbalance may contribute to the induction of epithelial-mesenchymal transition (EMT) and the consequent formation of fistula tracts. Tumor necrosis factor alpha (TNF-α), transforming growth factor beta (TGF-β) and interleukin (IL)-13 synergistically contribute to the migration and invasiveness of intestinal epithelial cells (IECs). The underlying extracellular matrix is broken down to enable IECs to invade.

AIMS & METHODS: Human perianal fistula tissue was investigated for the IL-22 receptor subtype RA1 and IL-17A using immunohistochemical procedures. Multicellular three-dimensional HT-29 IEC constructs were exposed to MDP (100 ng/ml) or IL-22 (50 ng/ml) for one, five and seven days and assessed microscopically as well as on a molecular level. Monolayer IECs were challenged to IL-22, IL-17A (100 ng/ml), TGF-β (100 ng/ml) or a combination of IL-22 plus TGF-β or IL-17A plus TGF-β.

Here, we investigated the impact of the Th17 and/or innate lymphoid cell derived cytokines interleukin (IL)-22 and IL-17A and pathogen-associated molecular patters (PAMPs) such as muramyldipeptide (MDP) on the induction of EMT.

RESULTS: After exposure to MDP for seven days, the spheroids lost the well-defined globular shape and the epithelial cells separated indicating the onset of EMT. This was not seen in untreated control spheroids. In accordance with these microscopic findings, MDP treated spheroids up-regulated mRNA levels of EMT-related genes, including *SNAIL1* ($p < 0.05$), *TGF-β* ($p < 0.05$) and *IL-13* ($p < 0.05$) after treatment for seven days. In contrast to MDP, IL-22 did not induce EMT in spheroids. When IECs were co-treated with IL-22 and TGF-β, the effects of TGF-β were abrogated, but a further enhanced mRNA expression of *β6-Integrin* ($p < 0.001$) was observed. A similar pattern was found for the co-treatment with IL-17A and TGF-β; TGF-β induced up-regulation of *SNAIL1* ($p < 0.05$) and *IL-13* ($p < 0.01$) *was* abolished and the reduced *E-Cadherin* ($p < 0.05$) levels were restored. Interestingly, we observed a strong staining signal for IL-22RA1 and IL-17A in fistula tissue of non-smoking CD patients whereas smokers revealed almost no expression of the indicated proteins.

CONCLUSION: Here, we demonstrate that PAMPs might contribute to the onset of EMT and therefore to the development of CD fistulas. The observed effects for the cytokines are indicative for an antagonistic effect of IL-22 and IL-17A on TGF-b. We therefore hypothesize that IL-22 and IL-17A might exert protective effects in the pathogenesis of CD-associated fistulas. There are some tremendous differences in the protein expression between smokers and non-smokers, indicating an altered immune response during fistula pathogenesis. In summary, our data suggest that bacterial pathogens likely impact the pathogenesis of CD-associated fistulas and the nicotine status might impact the response to fistula development.

INTRODUCTION: Malnutrition leads to intestinal inflammation and diarrhoea. In recent studies we have identified ACE2 as a key regulator of dietary amino acid homeostasis, innate immunity, gut microbial ecology, and transmissible susceptibility to colitis which can be directly regulated by the dietary amino acid tryptophan (TRP) (1). Moreover, B0AT1, the colonic TRP transporter, is downregulated in IBD mucosa (1). In an ongoing study we have investigated the role of TRP in a consecutive series of patients with IBD (n = 445, UC.n = 165, CD:n = 280) and controls (healthy controls and disease specificity controls = 125). More than 200 patients were seen twice and are not included in the basic statistics.

AIMS & METHODS: Patients with IBD were recruited consecutively from an outpatient setting, controls comprise healthy blood donors and disease specificity controls (patients with suspected IBD, in whom the diagnosis of IBD was not confirmed). A serum sample was prospectively obtained during a three months, ongoing sampling campaign to assess TRP levels. Patients were clinically characterized and TRP levels were related in an exploratory analysis to clinically characteristics, age, severity of disease, gender, BMI, smoking status CRP and duration of disease. A forward and backward logistic regression was performed.

RESULTS: TRP levels in patients with IBD were significantly lower ($P < 0.00001$) than in controls (UC: $p = 0.028$, CD: $p < 10E\text{-}8$) (Fig.1). Levels were lower in CD patients lower than in UC ($P < 0.0001$). In a first analysis of 258 patients a clear relationship of low TRP levels was seen with high disease activity ($p = 0.0077$ for UC and $p = 0.0070$ in CD). Female individuals had lower TRP levels than male individuals, both in controls ($p = 0.0097$) and patients ($p = 0.0006$). TRP levels were correlated with BMI ($p = 0.015$ in controls and $P < 0.0001$ in patients). The examination of TRP and smoking status was heavily confounded by the uneven distribution of smokers (n = 8 (10.3%) in UC, n = 67 (36-5%) in CD, $P < 0.0001$). No correlation of TRP levels and age or duration of disease could be found.

CONCLUSION: Tryptophane deficiency appears to be an important, novel mechanism in IBD. It appears likely that low TRP levels in serum reflect a reduced availability of TRP metabolites on the mucosal surface or an increased local consumption through the inflammatory process. In analogy to murine models TRP deficiency could cause the microbial changes seen in IBD and promote the rise of a colitogenic flora. While it high TRP exposure is poorly tolerated in the GI tract, a controlled delivery formulation of TRP derivatives with low toxicity is under clinical development for the use in IBD.

P1412 THE EXPRESSION OF MYOSIN LIGHT CHAIN KINASE INDUCED BY NK-KB ACTIVATION IS INVOLVED IN THE DEVELOPMENT OF COLITIS-ASSOCIATED CANCER

N. Jose[1,*], T. Nagaishi[1], T. Watabe[1], A. Tokai[1], M. Suzuki[1], M. Yamazaki[2], M. Watanabe[1]
[1]*Gastroenterology, Tokyo Medical and Dental University,* [2]*Obstetrics and Gynecology, Nihon University School of Medicine, Tokyo, Japan*

INTRODUCTION: It has been suggested that prolonged inflammatory bowel disease may promote carcinogenesis in the epithelia. Myosin light chain kinase (MLCK) has been reported to be essential to the permeability of epithelial barrier in the context of colitis, however its role in the development of colitis-associated cancer (CAC) is still unknown.

AIMS & METHODS: The aim of this study was to examine the effects of NF-kB activation and MLCK expression in the setting of CAC. Wild type C57BL/6 mice were pre-treated with azoxymethane and then three times with dextran sodium sulfate to induce a model of CAC.

RESULTS: Semi-quantitative polymerase chain reaction (qPCR) revealed that inflammatory cytokines such as IL-1b, IL-6 and MIP-2, which are known to be associated with tumor growth, were up-regulated in the inflamed colonic lamina propria. Western blotting (WB) showed slight up-regulation of MLCK in the colonic epithelia in association with the phosphorylation of IkBa and p65. NF-kB and MLCK were further up-regulated in the tumor tissues compared to the non-tumor areas, as well as up-regulation of the specific receptor for tumor necrosis factor (TNF) assessed by qPCR and WB. Immunohistochemistry (IHC) and transmission electron microscopy (TEM) showed that MLCK inhibitor, ML-7, treatment prevented the disruption of epithelial tight junctions. IHC and TEM also showed that anti-TNF mAb, MP6-XT22, treatment restored the disrupted tight junctions and suppressed tumor development.

CONCLUSION: Our studies suggest that permeability of epithelial layer in the inflamed tissues is associated with MLCK up-regulation and susceptibility to inflammatory cytokines that potentially promote CAC growth.

P1413 SERUM REG3ALPHA LEVELS IN CROHN'S DISEASE PATIENTS UNDERGOING IMMUNOABLATION AND AUTOLOGOUS HEMOPOETIC STEM CELL TRANSPLANTATION IN THE ASTIC TRIAL

T. Greuter[1,*], S. Lang[1], C.J. Hawkey[2], G. Rogler[1], L. Biedermann[1] on behalf of the ASTIC Trial group
[1]*Division of Gastroenterology and Hepatology, University Hospital Zurich, Zurich, Switzerland,* [2]*Nottingham Digestive Diseases Centre, Nottingham, United Kingdom*
Contact E-mail Address: *thomas.greuter@usz.ch*

INTRODUCTION: Regenerating islet-derived 3-alpha (REG3α) has been shown to be a promising biomarker with remarkable specificity for lower gastrointestinal Graft versus Host Disease (GvHD) after allogeneic stem cell transplantation, allowing better risk stratification of patients and the prediction of non-relapse mortality (1). GvHD shares many similarities (histological features and genetic risk factors) with Crohn's disease (CD). We aimed to investigate the role of serum REG3α as a diagnostic and prognostic biomarker in CD patients undergoing autologous hemopoetic stem cell transplantation (HSCT) in the multicenter ASTIC trial.

AIMS & METHODS: Stored serum samples from the ASTIC trial were analyzed using a commercially available ELISA-kit to measure serum REG3α levels (Ab-

Match Assembly Human PAP1 kit, MBL International Cooperation, Catalog Number 5323). Clinical, laboratory and endoscopic data was available from the ASTIC trial. Serum REG3α levels were correlated with clinical (Crohn's disease activity index (CDAI), harvey bradshaw index (HBI)) and endoscopic disease activity (CDEIS) as well as overall outcome 1 year after HSCT, which was assessed by changes in CDAI and CDEIS, and by clinical (CDAI≤150) or endoscopic remission (CDEIS < 4), respectively.
RESULTS: As of January 2014, 132 serum samples were available from 37 of the 45 ASTIC trial participants. Mean concentration of serum REG3α was 101.8 ng/ml (95% CI 22.6-258.3). No significant elevation of serum REG3α levels was found among patients with moderate or severe symptoms compared to patients in clinical remission (106.3 vs. 91.4, p = 0.289) and no correlation of REG3α to CDAI was identified within the group of symptomatic patients. Nonetheless, patients with moderate to severe endoscopic disease activity (CDEIS > 9) showed slightly although not significantly elevated REG3α levels compared to patients in endoscopic remission (95.4 vs. 52.4, p = 0.052). Baseline REG3α of patients without clinical or endoscopic remission 1 year after HSCT was not elevated compared to patients in remission after HSCT (63.1 vs. 66.9, p = 0.947, and 68.4 vs. 59.2, p = 0.796, respectively). Changes in CDAI or CDEIS after HSCT did not show any correlation with REG3α levels at study enrolment.
CONCLUSION: We did not observe a correlation of serum REG3α levels with Crohn's disease activity except for a trend regarding endoscopic disease activity scores. In contrast to the findings in GvHD after allogeneic HSCT baseline REG3alpha did not have any prognostic value for clinical and endoscopic outcome 1 year after HSCT. Given the divergent findings compared to GvHD (1), we conclude that REG3α is not a promising diagnostic and predictive biomarker in CD patients undergoing autologous HSCT.

INTRODUCTION: Eotaxin-1 is a potent eosinophil chemoatractant which is considered a major contributor to tissue eosinophilia. Elevated tissue Eotaxin-1 has been previously reported in Ulcerative colitis (UC) patients. Simultaneous serum and tissue sampling from intestinal biopsies can be used to demonstrate the effect of tissue vs. serum Eotaxin-1 levels on tissue eosinophila in patients with UC or Crohn's disease (CD).
AIMS & METHODS: To evaluate serum and tissue levels of Eotaxin-1 in patients with Crohn's disease (CD) and Ulcerative colitis (UC) compared with healthy controls.
METHODS: Serum samples and intestinal biopsies were obtained from consenting patients with known CD or UC or healthy individuals undergoing screening colonoscopy. Biopsies were used for quantitative assessment of tissue Eotaxin-1 levels and for histological evaluation of tissue eosinophlia as measured by average eosinophil count per high power field (HPF), by a blinded pathologist. These parameters were than compared between the patients, which were sub-grouped according to diagnosis and disease activity.
RESULTS: Intestinal biopsies were obtained from 60 patients (10 controls, 15 active UC, 10 UC in remission, 16 CD active and 9 CD in remission). Mean tissue Eotaxin-1 levels were 34.02 pg/mg protein in control group compared to159.79 and 219.62 pg/mg protein in active UC and active CD respectively (p < 0.001 for both) and compared to 106.13 and 97.78 pg/mg protein in UC and CD in remission (p = 0.06 and 0.07 respectively). Tissue Eotaxin-1 levels in active CD were significantly elevated compared with non active CD patients (p < 0.05).
No significant difference was noted in serum Eotaxin-1 levels in neither CD nor UC patients, regardless of disease activity.
In healthy control, a strong correlation was found between tissue and serum eotaxin-1 levels (r = 0.75, p = 0.01). A weak correlation was found in CD and UC patients.
Tissue but not serum eotaxin-1 levels correlated tissue eosinophilia in active UC patients only (r = 0.63, p = 0.01).
CONCLUSION: This study demonstrates elevated tissue Eotaxin-1 levels as a hallmark of both UC and CD, especially in active disease. The increase in tissue but not in serum eotaxin-1 levels suggests its importance as a local mediator of mucosal inflammation.
The correlation between tissue eotaxin-1 and tissue eosinophila in active disease, marks its central role in mediating local inflammation, and also suggests that its role in the pathogenesis of CD is not restricted to eosinophils recruitment.

INTRODUCTION: Ileal lesions of 36.4% of Crohn's disease (CD) patients are colonized by pathogenic adherent-invasive *Escherichia coli* (AIEC), able to highly replicate in mature phagolysosomes within cultured macrophages. The aim of this study was to assess whether macrophages from CD patients showed impaired ability to control intracellular bacteria replication and pro-inflammatory cytokine expression in response to pathogenic AIEC or non-pathogenic *E. coli* infection.
AIMS & METHODS: Human peripheral blood monocyte-derived macrophages were obtained from CD patients, ulcerative colitis (UC) patients and controls. All patients and controls were genotyped for the main coding mutations in *NOD2* and for *ATG16L1*. Following in vitro infection with AIEC reference strain LF82 or non-pathogenic *E. coli* K-12 levels of intracellular bacteria at 1h and 10 h post-infection was assessed by using gentamicin protection assay. IL-6, IL-8, and tumour necrosis factor alpha (TNF-α) cytokine levels were evaluated at 10h post-infection by ELISA. The effect of neutralization of TNF-α on the number of intracellular AIEC LF82 bacteria were analysed in CD macrophages untreated or not with Infliximab at 1 μg/ml.
RESULTS: A higher number of AIEC bacteria than non-pathogenic *E. coli* is internalized within macrophages whatever cell origin. The intracellular AIEC replicate rate was the highest in macrophages from CD patients. This was not observed when macrophages were infected with non-pathogenic *E. coli*. In our cohort of CD patients, only macrophages heterozygous for a NOD2 polymorphism were found and they did not show significant difference in their ability to control AIEC intracellular replication. Concerning ATG16L1 polymorphism, high levels of intracellular AIEC bacteria were observed in AIEC-infected macrophages homozygous for ATG16L1 (T300A). AIEC infection of macrophages induced the secretion of IL-6, IL-8 and TNF-α at levels higher than infection with the non-pathogenic *E. coli* whatever cell origin. The levels of IL-6 cytokine secreted were higher with AIEC-infected macrophages from CD patients. A positive correlation was observed between the number of intracellular AIEC bacteria at 10 h post-infection and the level of TNF-α secreted by infected CD macrophages. In contrast no significant difference in TNF-α or IL-6 secretion was observed between non-pathogenic *E. coli*-infected macrophages from CD and UC patients or from controls. Infliximab have not effect on the control of intracellular bacterial replication within macrophages.
CONCLUSION: Human peripheral blood monocyte-derived macrophages from CD patients compared to those of UC patients or controls showed specific characteristics in response to AIEC infection but not to non-pathogenic *E. coli* challenge including load of intracellular bacteria and secretion of pro-inflammatory TNF-α and IL-6 cytokines.

P1416 A PROSPECTIVE STUDY OF CIGARETTE SMOKING AND THE RISK OF CROHNS DISEASE

V. Andersen[1,2,*] on behalf of EPIC-IBD Study Investigators
[1]*Organ Center, SHS Aabenraa, Aabenraa,* [2]*Institute of Regional Health Research, University of Southern Denmark, Odense, Denmark*

INTRODUCTION: Prospective studies on smoking and the risk of Crohn's disease (CD) in the general population are limited.
AIMS & METHODS: We aimed to conduct a cohort study of both men and women investigating smoking and the development of CD in the " EPIC-IBD Study". In total 401,326 participants, aged 30-74 years, were recruited from 12 regions in 8 countries in Europe between 1991 and 1998. Baseline questionnaires recorded data on smoking status and the number of cigarettes. The cohort was monitored until at least June 2004 to identify participants who developed CD. Each case was matched with four controls (age at recruitment, gender, centre and recruitment date) and odds ratios (ORs) calculated using conditional logistic regression.
RESULTS: In total, 110 participants developed incident CD (73% women, mean age at diagnosis = 55.7, SD = 11.1 years) after a median follow-up of 5.4 years (range 1.5-14.3 years). Current smoking at recruitment was associated with an increased odds of CD (OR = 1.95, 95% CI = 1.14-3.34) compared to non-smoking, but not former smoking (1.23, 95% CI = 0.71-2.12). There was some evidence of a dose-response with an increasing number of cigarettes (P trend = 1.28, 95% CI = 0.96-1.63, p = 0.05), with for those smoking >20/day reporting an OR = 2.34 (95% CI = 0.90-6.12, p = 0.08). Similarly also for a duration effect with an association with current smoking at the time of recruitment for those diagnoses more than 5 years after recruitment (OR = 2.13, 95% CI = 1.09-4.17), but none for those diagnosed within 5 years of recruitment. Ileal disease only was associated with smoking (OR = 3.02 95% CI = 1.11-8.20), but not colonic involvement only (OR = 1.02, 95% CI = 0.35-2.98).
CONCLUSION: The positive associations with smoking help to confer a causal link with CD due to the prospective collection of data and some evidence of a dose response. Further work should elucidate the biological mechanisms for these associations.

INTRODUCTION: Phosphatidylcholine (PC) in intestinal mucus establishes a hydrophobic barrier against the colonic microbiota. In ulcerative colitis (UC) intrinsic low mucus PC concentration may result from disturbed PC translocation into mucus.
AIMS & METHODS: Elucidation of the mechanism of PC translocation across the mucosa and its disturbance in UC. Apical PC translocation was examined in CaCo2 cells plated on transwell tissue culture dishes under various conditions. Mucus PC recovery was also evaluated in genetic UC mice models with intestinal deletion of kindlin1 and 2 as well as in mucosa specimens of patients with UC, Crohn's disease and controls.
RESULTS: In intestinal mucosa derived CaCo2 cells we demonstrate that out of various phospholipids only PC translocates via paracellular movement across lateral tight junctions (TJ) to the apical (mucus) compartment driven by stepwise negative charge generation from TJ to mucins. Driving force is CFTR mediated HCO_3 secretion and binding to membrane localized mucin3. The efficacy of apical PC movement increases from 4.7 ± 0.6 % to 8.0 ± 0.9 % in presence of mucin1 or 2. PC is basally presented as complex with apolipoprotein which itself is not apically translocated. In in vivo mouse models with disrupted TJ (intestinally deleted kindlin1 and 2), apical PC secretion into the ileal lumen is by >70 % reduced with consequent low mucus PC concentration. It preceded the development of ulcerative colitis. This was prevented by therapeutic supplementation of orally applied PC. Finally, mucosa specimens of patients with ulcerative colitis revealed disturbed TJ with suppression of paracellular luminal PC movement determined by immunofluorescence microscopy.
CONCLUSION: Disturbance of the TJ barrier results in impaired apical PC secretion and, thus, loss of hydrophobic protection which is of pathogenetic relevance for development of ulcerative colitis.

INTRODUCTION: Helper T cells (Th) and their related cytokines have validated roles in mediating gut inflammation in inflammatory bowel diseases such as ulcerative colitis (UC). Although anti-TNF therapy has been shown highly effective in a subset of patients with UC, specific anti-cytokine therapy according to tissue cytokine expression may still be warranted. Efforts to date to examine the relation between mucosal expression of immune mediators and disease severity in UC have yielded inconsistent and inconclusive results, possibly partly due to the common practice of single-marker analyses that are insensitive to the interaction of different molecules and are susceptible to large between-sample variation. We hypothesized that joint expression of important immune molecules, which is unidentifiable by univariate analysis, may significantly correlate with disease severity, as we have previously reported a similar method for differentiating UC from Crohn's disease (reference 1).
AIMS & METHODS: 47 patients with UC underwent colonoscopy and were assessed with Rachmilewitz endoscopic index (REI), which quantifies mucosal damage. Biopsy samples were obtained from inflamed (REI = 3-12, n = 40) and noninflamed (REI < 3, n = 47) colonic mucosae and examined for mRNA expression of cytokines and transcription factors related to Th1 (IFN-γ, IL-12p35, IL-12p40, T-bet, and TNF-α), Th2 (IL-4, IL-13, IL-33, and GATA3), Th17 (IL-17A, IL-17F, IL-23p19, IL-21, IL-22, IL-6, and RORC) and regulatory T cells (TGF-β and Foxp3) by quantitative PCR. Univariate and multivariate analyses were performed to identify expression pattern that paralleled the endoscopic severity.
RESULTS: Although 16 of 18 targets were upregulated in inflamed mucosae compared with noninflamed mucosae, none of the targets examined was univariately correlated with REI in the inflamed mucosae, which showed large expression variation between samples. Multiple regression analysis with stepwise selection, however, identified a significant expression pattern predictive of REI ($p = 0.0009$, $RSq = 0.443$, $RMSE = 2.0104$), consisting of IL-17A, IL-17F, IL-21, IL-22 and Foxp3. In this model IL-17A (positive, $p = 0.0002$) and IL-17F (negative, $P < 0.0001$) were the most influential parameters in predicting REI, where IL-21 (negative, $p = 0.0139$) and IL-22 (positive, $p = 0.0105$) were also significant parameters. A simplified version of this model, IL17A/IL-17F ratio, substantially correlated with REI ($\rho = 0.5186$, $p = 0.0006$). Markers such as IL-13, IFN-γ, TNF-α and etc. did not serve as significant parameters in any useful REI-predictive model.
CONCLUSION: IL-17A/IL-17F expression ratio in inflamed mucosae significantly paralleled the endoscopic severity in UC. Our findings indicate that IL-17A and IL-17F might have different roles in mucosal inflammation and that they might be of equal or even higher importance to other key inflammatory mediators in exacerbation of UC.

INTRODUCTION: Limited data are available on the hospitalization rates in population-based studies.
AIMS & METHODS: Since this is a very important outcome measure, the aim of this study was to analyze prospectively if early hospitalization is associated with the later disease course as well as to determine the prevalence and predictors of hospitalization and re-hospitalization in a population based inception cohort in the Veszprem province database between 2000 and 2012. Data of 304 incident CD patients diagnosed between January 1, 2000 and December 31, 2010 were analyzed (mean age at diagnosis: 32.2; SD: 15.4 years). Both in- and outpatient records were collected and comprehensively reviewed.
RESULTS: Probabilities of first hospitalization and first re-hospitalization were 54.9%, 72% 76% and 22.8%, 34%, 52.3% after 1, 2 and 5 years of follow-up in Kaplan-Meier analysis. Main reasons for hospitalization in the first year were diagnostic procedures (48.5%), IBD related surgery (29.9%) and disease activity (14.3%). Non-inflammatory disease behavior at diagnosis (HR: 1.41, 95%CI: 1.41-1.89, $p = 0.02$) was the only factor significantly associated with time to hospitalization while both non-inflammatory disease behavior at diagnosis (HR: 1.92, 95%CI: 1.35-2.74, $p < 0.001$) and disease behavior change (HR: 1.89, 95%CI: 1.27-2.81, $p = 0.002$) were associated with time to first re-hospitalization in multiple Cox-regression analysis. Early hospitalization (within the year of diagnosis) was associated with age at onset ($p = 0.002$), non-inflammatory disease behavior at diagnosis (OR: 2.67, $p < 0.001$), internal fistulizing disease (OR: 2.02, $p = 0.04$) and it was predictive for need for immunosuppressives (OR: 1.74, $p = 0.018$) and need for surgery/multiple surgeries (OR: 2.63, $p = 0.018$ and OR: 2.54, $p = 0.005$) during the disease course.
CONCLUSION: Early hospitalization was associated with clinically significant outcomes (need for immunosuppressives and surgery). Hospitalization and re-hospitalization rates are still high in this population-based cohort. Non-inflammatory disease behavior at diagnosis was identified as the pivotal predictive factors for both hospitalization and re-hospitalization.
Disclosure of Interest: None declared

P1420 HOSPITALIZATION RATE BEFORE AND AFTER ANTI-TNF THERAPY: HOSPITALIZATION RATES ARE ASSOCIATED WITH TIME TO ANTI-TNF THERAPY

P.A. Golovics[1,*], A. Bálint[2], M. Mandel[1], Z. Végh[1], A. Mohás[1], B. Szilágyi[1], Á. Szabó[1], Z. Kürti[1], L.S. Kiss[1], K.B. Gecse[1], B.D. Lovász[1], K. Farkas[2], T. Molnár[2], P.L. Lakatos[1]

INTRODUCTION: Hospitalization is an important outcome measure and a major driver of costs in patients with IBD.
AIMS & METHODS: Our aim was to analyze prospectively the prevalence and predictors of hospitalization and re-hospitalization before and after anti-TNF therapy. Data of 194 consecutive IBD (152 CD, 42 UC) patients were analyzed (male/female: 88/106, median age at diagnosis: 24.0, IQR: 19-30 years, duration: 8, IQR: 8-12.5 years) in whom anti-TNF therapy was started after January 1, 2009. Total follow-up was 1874 patient-years and 474 patient-years with anti-TNF exposure. Both in- and outpatient records were collected and comprehensively reviewed.
RESULTS: The hospitalization rate in the 2 years preceding anti-TNF therapy was significantly higher compared to the hospitalization rate during anti-TNF therapy (61.6/100 patient-years vs. 43.2/100 anti-TNF exposed patient-years, OR: 0.64, 95%CI 0.43-0.95, $p = 0.03$). The risk for hospitalization decreased only in CD (OR: 0.57, 95%CI 0.36-0.90, $p = 0.02$), but not UC In addition, there was an association with disease duration, the risk of hospitalization decreased in CD patients with early (within 3-years from diagnosis, $p < 0.001$), but late anti-TNFs exposure. In a logistic regression analysis complicated disease behavior ($p = 0.03$) concomitant AZA ($p = 0.02$) use but not anti-TNF type, gender, perianal disease or previous surgeries were associated with the risk of hospitalization during anti-TNF therapy.
CONCLUSION: Hospitalization rate decreased significantly in this referral CD but not UC cohort after the introduction of anti-TNF therapy and it was

associated to time to anti-TNF therapy. Complicated disease phenotype and concomitant AZA use were additional factors defining the risk of hospitalization.

P1421 PREVALENCE OF DYSLIPIDEMIA IN INFLAMMATORY BOWEL DISEASE

S.R. Fernandes[1,*], P. Sousa[1], M. Moura[1], L.A. Correia[1], P. Moura Santos[1], A. Valente[1], A.R. Gonçalves[1], C. Baldaia[1], J. Velosa[1]
[1]*Gastrenterologia e Hepatologia, Hospital Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa, Portugal*
Contact E-mail Address: *Samuelrmfernandes@gmail.com*

INTRODUCTION: The risk of venous thromboembolic events in inflammatory bowel disease (IBD) is increased (relative risk 2.5). However, the incidence of cardiovascular and cerebrovascular events is only modestly elevated (relative risk 1.19). In this subgroup, a disorder of lipid metabolism mediated by pro-inflammatory cytokines may trigger an accelerated atherogenic process.
AIMS & METHODS: To determine the prevalence of dyslipidemia in IBD. We retrospectively analysed patients with Crohn's disease (CD) and Ulcerative Colitis (UC) and determined the lipid profile [total cholesterol (TC), triglycerides (Tg), LDL-cholesterol (LDL) and HDL cholesterol (HDL)], endoscopic activity and comorbidities [chronic kidney disease (CKD) and alteration of glucose metabolism (AGM)]. Dyslipidemia was defined by TC > 190 mg/dl, Tg > 160 mg/dl, LDL > 115 mg/dL and HDL < 40/45 mg/dl (men/women) and CKD and AGM by 2 consecutive values of creatinine > 1.0 mg/dl and/or glucose > 100 mg/dl. We used samples from several portuguese Dyslipidemia prevalence studies (VALSIM, BECEL and ALTO-MAR - 34522 individuals) as a control group.
RESULTS: We evaluated 478 patients, 282 women (59 %), mean age 44.0 years±16.2 years with CD (67.6 %) and UC (32.4 %). The prevalence of CKD and AGM was 23.4% and 23.7%. We assessed mean levels of TC (176.4 ± 41.8 mg/dl), Tg (111.1 ± 58.0 mg/dl), LDL (97.9 ± 35.3 mg/dL) and HDL (54.6 ± 18.3 mg/dl). In UC, TC and LDL were higher and Tg were lower compared to CD ($p < 0.02$). The overall prevalence of dyslipidemia among patients was 58.6% (61.9% in UC and 57.0% in CD). Endoscopic activity was associated with higher Tg and lower LDL levels. Only HDL levels were significantly lower compared to the control group (27.3 % versus 12.8%).
CONCLUSION: In our series, despite a high prevalence of dyslipidemia, levels did not reach the high values reported in the control group. However, the prevalence of HDL-dyslipidaemia was significantly higher. In IBD the pro-inflammatory state is associated with increased phospholipase A2 and decreased lipoprotein lipase activity, both implicated in decreased levels of HDL. Given the recognized anti-inflammatory and anti-atherogenic role of HDL, their compromise may have na influence on the progression of IBD.

P1422 INCREASE OF INFLAMMATORY BOWEL DISEASE INCIDENCE IN TEENAGERS IN A PROSPECTIVE POPULATION-BASED STUDY DURING A 21-YEAR PERIOD (1988-2008)

S. Ghione[1,*], H. Sarter[2], L. Armengol-Debeir[3], M. Fumery[4], G. Savoye[3], D. Ley[1], C. Spyckerelle[5], O. Mouterde[6], D. Djeddi[7], L. Dauchet[2], J.-F. Colombel[8], L. Peyrin-Biroulet[9], D. Turck[1], C. Gower-Rousseau[2,2] on behalf of Epimad Group

INTRODUCTION: Few data are available on recent temporal trends in the incidence of paediatric-onset inflammatory bowel disease (IBD) in industrialized countries.
AIMS & METHODS: The aim of this study was to assess the change in incidence and location at diagnosis of paediatric-onset IBD during a 21-year period.
Patients & Methods: Paediatric-onset IBD was defined by an age at diagnosis ≤ 17 years. Data at diagnosis were extracted from the population-based IBD study in Northern France (Epimad Registry) between 1988 and 2008. Age groups and digestive location at IBD diagnosis were defined according to the Paris (1) classification with age: <10 yrs or ≥ 10 yrs and location as follows: 1) for CD: pure small bowel involvement (L1); pure colonic involvement (L2) or ileocolonic involvement (L3); 2) for UC: proctitis (E1); left sided colitis (E2); extensive colitis (E3); pancolitis (E4).
RESULTS: During this 21-year period, 1147 incident paediatric-onset IBD cases were recorded (8% of all IBD) including 846 CD, 271 UC and 30 IBD unclassified (IBDU) cases. Median age at diagnosis was not significantly different in CD (14.5 years [Q1 = 11.9-Q3 = 16.1]) and UC (14.1 years [11.0-16.0]) and did not change over time. There was significantly more males in CD than in UC (53.4% *vs* 45.0%; $p = 0.02$). Median time between onset of symptoms and IBD diagnosis was stable over time at 3 months [1-6]. Mean incidence was $4.0/10^5$ for IBD as a whole (3.0 for CD, 0.9 for UC and 0.1 for IBDU). During this 21-year period a dramatic increase of both CD and UC incidences was observed in teenagers [10-16 years]: for CD from 4.3 in 1988-90 to $9.6/10^5$ in 2006-2008 (+123%; $p < 10^{-3}$) and for UC, from 1.6 to $2.9/10^5$ (+81%; $p < 10^{-3}$) in both genders. Digestive location did not change over time in both CD and UC; for CD L1 = 12.2%, L2 = 14.5% and L3 = 73.3% and for UC E1 = 31.1%, E2 = 25.4%, E3 = 10.5% and E4 = 33%.
CONCLUSION: In this large population-based study the incidence of both CD and UC dramatically increased in teenagers during a 21-year period without modification of neither age, location at diagnosis nor time between onset of symptoms and diagnosis. This suggests that a strong environmental factor predisposing to IBD is at work in this population.

INTRODUCTION: Despite the widespread perception of Crohn's disease (CD) as a wasting disorder there is a well-recognised sub-population of obese patients with the disease (1). Notwithstanding the possibility of a pathogenic link, obesity may influence the severity and phenotype of CD.
AIMS & METHODS: We conducted a retrospective analysis of our Institution's electronic patient record to stratify and compare CD patients by body mass index (BMI) at diagnosis, with regard to their disease characteristics, medication use and outcomes. Smoking status recorded on the hospital database was validated by survey with general practitioners. All statistical analysis was conducted using GraphPad Prism 6.0. Mann-Whitney U test and Kruskal-Wallis with Dunn post-test were used when the data was not normally distributed. Fisher-exact test was used for contigency tables, one way ANOVA and t-test if the data was normally distributed.
RESULTS: Reliable data was available for 282 patients with CD (130 female, age 43.6 ± 14.3y). At diagnosis, BMI ≥35 was recorded in n = 20 (7.09%), ≥30 in 43 (15.2%), 25-29.9 in 68 (24.1%), 24.9-18 in 144 (51.06%) and <18 in 7 (2.4%). The proportion of smokers did not differ significantly in each group. Patients with BMI > 30 were older ($p < 0.0001$) compared to the other groups. Rates of operative intervention per patient year were slightly higher in BMI≥30 group compared to the normal BMI group (0.08 vs 0.04, $p = 0.007$). The median time to surgery was significantly shorter in BMI≥35 (11.5 months) and BMI ≥30 (18months) compared to the other groups ($p = 0.053$). The median time to anti- TNF therapy in the morbidly obese group and the obese groups were 11.5 and 14 months respectively compared to 48 months in BMI 29.9-25.36 months in the normal BMI, and 12 months in BMI < 18 group respectively ($p = 0.008$). Other comparators are shown in the table below.
Table: Disease characteristics across different BMI groups.

Disease Characteristics	BMI≥ 35	BMI≥30	BMI 29.9-25	Normal BMI 24.9-18	BMI <18	P value
Average age	49.2±12.1	51.4±13.1	47.6±13.1	39.7±13.1	42.2±21.1	<0.0001
Female: Male	14:6	23:20	35:33	82:62	5:2	0.001
Ileal disease	8/20	10/63	28/66	37/128	2/7	0.08
Colonic disease	3/20	32/63	16/66	29/128	2/7	
Ileo colonic disease	9/20	21/63	23/66	62/128	3/7	
B1 inflammatory	11/18	7/60	40/68	72/128	3/6	0.61
B2 stricturing	6/18	32/60	18/68	33/128	3/6	
B3 fistulizing	1/18	21/60	10/68	23/128	0/6	

CONCLUSION: Obesity is a common phenomenon in this representative cohort of patients with CD with 22.3% having BMI > 30 – nearing the national average of 26%. Obesity is associated with slightly increased operative intervention per patient year. Our data also imply a more aggressive inflammatory phenotype in terms of requiring surgery and biologic therapy significantly earlier in the natural history of disease.

P1424 VITAMIN D INFLUENCES HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

T. Hlavaty[1,*], A. Krajčovičová[1], T. Koller[1], J. Toth[1], M. Nevidanska[1], M. Huorka[1], J. Payer[2]
[1]*Dept. Gastroenterology and Hepatology,* [2]*University hospital Bratislava, Bratislava, Slovakia*

INTRODUCTION: Several lines of evidence indicate that vitamin D (VD) plays an important role in the pathogenesis of inflammatory bowel diseases (IBD).
AIMS & METHODS: We investigated the effect of VD concentrations and VD supplementation on health related quality of life in Crohn's disease (CD) and ulcerative colitis (UC) patients. A cohort of 220 IBD patients (141 CD and 79 UC) was followed-up at a tertiary IBD centre. A subgroup of the cohort (n = 26)

took VD supplements for >3 months. Health related quality of life was assessed using the short IBD questionnaire (sIBDQ). VD serum concentration and sIBDQ score were assessed during summer/autumn period and winter/spring period.
RESULTS: During summer/autumn and winter/spring period, 28% and 42% of IBD patients were VD-deficient (<20 ng/ml), respectively. In winter/spring period, there was a significant correlation between sIBDQ score and VD serum concentration in UC patients ($r = 0.35$, $p = 0.02$), with a trend towards significance in CD patients ($r = 0.17$, $p = 0.06$). In winter/spring period, VD-insufficient patients (<30 ng/ml) had a significantly lower mean sIBDQ score than VD-sufficient patients; this was true of both UC (48.3±2.3 vs. 56.7±3.4, $p = 0.04$) and CD (55.7±1.25 vs. 60.8±2.14, $p = 0.04$) patients. In all analysed scenarios (UC/CD, summer/autumn period and winter/spring period), health related quality of life was the highest in patients with VD serum concentrations of 50–59 ng/ml. Supplementation with a median of 800 IU/day VD day did not influence VD serum concentration nor the sIBDQ score.
CONCLUSION: VD serum concentration correlated with health related quality of life in UC and CD patients during winter/spring period. Supplementation with currently recommended doses of VD did not influence health related quality of life.

INTRODUCTION: The pathogenesis of inflammatory bowel disease (IBD) is unclear. Environmental factors in combination with genetic predisposition may play a role. The aim of this study was to analyse prenatal risk factors for IBD in a well described birth cohort from Northern Finland.
AIMS & METHODS: The prospectively collected Northern Finland Birth Cohort 1966 (NFBC 1966) is a longitudinal research program to promote health and well-being of the population (http://www.oulu.fi/nfbc/). The population is comprised of mothers living in the two northernmost provinces of Finland, Oulu and Lapland with expected dates of delivery between Jan 1st - Dec 31st, 1966 (12 068 mothers, 12 231 children, 96.3% of all births during 1966 in that area). Information about family history, social relationships, environment, mother's health habits and clinical parameters were collected from antenatal clinics, hospital registers and by postal questionnaires. Between years 2012 and 2014, at the age of 46 years, a large health examination was performed including both questionnaires and clinical examination, including questions about physician's diagnosis of IBD. 6852 subjects (66%) answered for the postal questionnaires. Data were analyzed by chi square test, Fishers exact test and counting relative risks (RR).
RESULTS: Data were available from 6685 individuals, of whom 175 (2.6%) reported physician's diagnosis of IBD, 88/2957 male and 87/3553 women. Maternal age, gestation age, gestation weight, maternal comorbidities, parity, number of siblings, household farm animals or pets, living in an urban area and social class were not associated with IBD of children until 46 years of age. However, consumption of antibiotics during pregnancy [(23/549 vs. 140/5375) RR 1.6 (1.0-2.4), $p = 0.041$], smoking during pregnancy [continued, 37/892 RR 1.7 (1.2-2.5) vs. stopped, 8/406 RR 0.7 (0.4-1.5) vs. never smoked 128/5247 RR 0.7 (0.5-1.0), $p = 0.0033$] and living in the most northern part of Finland [above the Arctic Circle 19/419 RR 1.7 (1.1-2.8) vs. southern Lapland 45/1943 RR 0.8 (0.6-1.1) vs. Oulu district 111/4148 RR 1.0 (0.7-1.3), $p = 0.0188$] were associated with IBD.
CONCLUSION: Smoking and consumption of antibiotics during pregnancy and mothers' living above the Arctic Circle were risk factors for IBD until the age of 46.

P1426 CLINICAL AND ENDOSCOPIC FEATURES OF RESPONDERS AND NON-RESPONDERS TO THERAPEUTIC DEPLETION OF MYELOID LINEAGE LEUCOCYTES IN PATIENTS WITH ULCERATIVE COLITIS: WHY THIS NON-PHARMACOLOGICAL TREATMENT OPTION IS FAVOURED BY PATIENTS?

T. Tanaka[1,1,*], S. Sugiyama[1], H. Goishi [1], T. Kajihara[1], M. Akagi [1], T. Miura[1]
[1]*Department of Gastroenterology, Akitsu Prefectural Hospital, Hiroshima, Japan*

INTRODUCTION: Patients with active inflammatory bowel disease have elevated and activated myeloid lineage leucocytes, notably the CD14 (+)CD16 (+) monocyte phenotype, which is a major source of tumour necrosis factor-α (Belge KU, et al. J Immunol 2002). Hence selective depletion of these leucocytes by granulocyte/monocyte adsorption (GMA) with an Adacolumn is expected to alleviate inflammation and promote remission or at least enhance drug efficacy. However, studies in ulcerative colitis (UC) reported contrasting efficacy outcomes, from an 85% (Cohen RD. Gastroenterology 2005) to a statistically insignificant level (Sands, et al. Gastroenterology 2008). Patients' demographic variables in the aforementioned studies were very different.
AIMS & METHODS: In 143 consecutive UC patients, we were interested to identify clinical and endoscopic features, which could mark a patient as a responder or otherwise as a non-responder to GMA. Seventy-three patients were steroid naive, and 70 were steroid dependent. Patients received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated according to Rachmilewitz, allowing each patient to serve as her or his own control. Clinical activity index (CAI) ≤4 at week 12 was defined as response to GMA. Additionally, biopsies from colonoscopically detectable inflamed mucosa were processed to see the impact of GMA on leucocytes within the mucosa.
RESULTS: At entry the average CAI was 12.8, range 10-17. Ninety-two of the 143 patients (64.3%) responded to GMA, 52 of 73 steroid naïve patients (71.2%) and 40 of 70 steroid dependent patients (57.1%). On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent cohort. Upon relapse, the majority of patients responded well to a second course of GMA. Over 1200 biopsies were processed. Infiltrating leucocytes were overwhelmingly neutrophils and monocytes/macrophages. GMA was associated with a marked reduction of infiltrating leucocytes. Patients who had extensive deep UC lesions together with near total loss of the mucosal tissue at the affected sites were identified as non-responders. Patients with the first UC episode were identified as the best responders (100%) followed by steroid naive patients. Additionally, a short duration of active UC prior to GMA marked a patient as a likely responder. No GMA related serious adverse event was observed.
CONCLUSION: Depleting elevated myeloid lineage leucocytes by GMA should have significant efficacy in patients with UC, but before the disease has become very severe with deep ulcers and extensive loss of the mucosal tissue, and when the disease does not respond well to pharmacological interventions. Most notably, first episode and steroid naïve cases respond well to GMA and attain a favourable future clinical course by avoiding medications like corticosteroids from the start. Likewise, GMA should be applied immediately after a relapse. Generally, GMA is very much favoured by patients for its safety profile and for being a non-drug therapeutic intervention. Accordingly, patient compliance is always good.

INTRODUCTION: Treatment of inflammatory bowel disease (IBD) with immunosuppressive medications has been associated with an increased risk of developing melanoma and non-melanoma skin cancer.
AIMS & METHODS: The aim of this study was to evaluate the risk of melanoma and non-melanoma skin cancer (NMSC) associated with immunomodulator and anti-TNF-α medications in IBD patients. Using provincial health insurance databases (RAMQ/MedECHO), a nested-case control analysis was conducted within a cohort of patients diagnosed with IBD (Crohn's disease [CD] or ulcerative colitis [UC]) between 1996 and 2009. Cohort entry was defined as the date when patients met a strict IBD definition (i.e. at least one hospitalization with a primary diagnosis of Crohn's disease (CD) or ulcerative colitis (UC) or four physician claims with the CD or UC diagnosis within a two-year period). Patients were excluded if they had a diagnosis of any cancer prior to cohort entry or within the first year from the inclusion, and if they had less than 1 year of prescription coverage prior to inclusion in the cohort. Cases were patients newly-diagnosed with melanoma and NMSC during follow-up. For each case, up to 10 controls were randomly selected and matched on age, sex, and duration of disease. Conditional logistic regression was used to estimate odds ratios (ORs) with 95% confidence intervals (CIs) of melanoma and NMSC associated with ever use of immunomodulators and anti-TNF-alpha-α medications. Secondary analyses considered duration of exposure and stratification by IBD type (CD vs UC). The models were adjusted for history of IBD-related hospitalizations.
RESULTS: A total of 41,176 IBD patients were identified in the RAMQ/MedECHO database; 19582 patients were eligible for inclusion in the study. The mean age at inclusion was 42.5 ± 19.3 years and 45.4% of the patients were male. The mean duration of follow-up was 5.6±3.3 years and CD was the primary diagnosis in 60.2% of the cases. Immunomodulators were utilized in 25.4%, and anti-TNF-α medications in 2% of the patients. A total of 102 cases of melanoma were identified in the cohort. Neither immunomodulators (OR: 1.38, 95% CI- 0.82-2.31), nor anti-TNF- α medications (OR: 6.28, 95% CI-0.59-60.79) were associated with an increased risk of melanoma. A total of 474 cases of NSMC were identified. Treatment with immunomodulators for ≥ 3 years was associated with a significantly increased risk of NSMC (OR: 1.78, 95% CI- 1.25-2.54) and this increased risk was seen in both CD and UC patients. No cases of NMSC occurred in patients exclusively exposed to anti-TNF-α medications.
CONCLUSION: In a large provincial IBD cohort, treatment with immunomodulators for ≥3 years was associated with an increased risk of non-melanoma skin cancer. No association was demonstrated between the risk of melanoma and immunomodulator medications. Although no association between melanoma and NMSC with anti-TNF-α medications was identified, no firm conclusions can be made given the small number of patients on these medications in the cohort.

INTRODUCTION: The aim of the present study was to validate the IBD (inflammatory bowel diseases) incidence reported in the 2010 ECCO-EpiCom (European Crohn's and Colitis Organization - Epidemiological Committee) inception cohort[1] by including a second independent inception cohort from participating centers in 2011 and an Australian centre to investigate whether there is a difference in the incidence of IBD between Eastern and Western European countries and Australia.

AIMS & METHODS: Fourteen centers from 5 Eastern and 9 Western European countries and one center from Australia participated in the ECCO-EpiCom 2011 inception cohort. Patients' data regarding disease type, socio-demographic factors, extraintestinal manifestations and therapy were entered into the web-based EpiCom database, www.ecco-epicom.eu.

RESULTS: A total of 711 adult patients were diagnosed during the inclusion year 2011, 178 (25%) from Eastern, 461 (65%) from Western Europe and 72 (10%) from Australia; 259 (37%) patients were diagnosed with Crohn's disease, 380 (53%) with ulcerative colitis and 72 (10%) with IBD unclassified. The mean annual incidence rate for IBD was 11.3/100,000 in Eastern Europe, 14.0/100,000 in Western Europe and 30.3/100,000 in Australia. Significantly more patients were diagnosed with complicated disease at diagnosis in Eastern Europe compared to Western Europe (51% vs. 37%, $p = 0.03$).

CONCLUSION: Incidence rates, disease phenotype and initial treatment characteristics in the 2011 ECCO-EpiCom cohort were not significantly different from that reported in the 2010 cohort.

Contact E-mail Address: *oykutayfur78@yahoo.com*

INTRODUCTION: Electrocardiographic (ECG) abnormalities have been described in inflammatory bowel disease (IBD) patients. Underlying chronic inflammation, medicines used, nutritional deficiencies can cause many rhythm disorders. Most commonly encountered rhythm disorders are atrial fibrillation than less commonly supraventricular tachycardia, ventricular tachycardia and atrioventricular block. Previous studies mostly used 12 lead normal surface ECG and many rhythm disorders that can be detected only by holter ECG were probably missed. This may caused underestimation of the prevalence of arrhythmia in inflammatory disease patients.

AIMS & METHODS: 67 IBD patients aging between 18-65 years referring to gastroenterology clinic between October 2013-March 2014 were included in this study. Patients with previous history of coronary heart disease, patients with heart failure or cardiac valve disease were excluded. Patients with thyroid hormone abnormalities were also excluded from the study. Physical examination and baseline echocardiography were performed to search for evidence of organic heart disease in cardiology clinic. Patients who do not have evidence of organic heart disease were monitored by Holter ECG for 24 hours and results were analyzed by using special computer software programs.

RESULTS: Of 67 patients 64.2 % were male. Mean age was 42.67 ±12.8 years; mean body mass index was 25.1±4.39 kg /m2. 14 patients (20.9%) had Crohn's disease. 53 patients suffered from ulcerative colitis. Mean time from disease diagnosis was 3.57±3.43 years. Only 12% of the patients had hypertension while 17.9 % had diabetes. 35.8 % of the patients had active bowel disease at the time of evaluation. Mean heart rate of the patients were 75.8±9.3beats/ min. Arrhythmia was detected in 55.1 % of the patients. Mean number of supraventricular extrasystoles were 47.4±217 and mean number of ventricular extrasystoles was 17.4±47.6. Patients with active IBD had higher minimum heart rate ($p = 0.03$) and significantly lower SD5, AVG, SDTF and SDVLF values. These values are parameters used to calculate heart rate variability by the help of special computer software programs. (p values: 0.01, 0.02, 0.03, 0.03 respectively). Comparison of holter parameters between ulcerative colitis and Crohn's disease patients were also performed. SDANN5 (standard deviation of 5 min mean values of RR) was found significantly lower in ulcerative colitis patients (120.3 ±38.4 vs 145.3 ±41.3, p:0.04)

CONCLUSION: Heart rate variability (HRV) was found to be significantly decreased and minimum heart rate was found to be significantly increased in active inflammatory bowel disease patients. Furthermore HRV was found to be significantly lower in ulcerative colitis patients than in Crohn's disease patients. Decreases in HRV have been reported in many cardiologic and noncardiologic diseases. In this study active IBD patients and patients with UC were found to have autonomic dysfunction which is known to be associated with increased cardiac morbidity and mortality. Various symptomatic and asymptomatic rhythm disorders were detected by 24-hour holter suggesting that physicians should be cautious about rhythm abnormalities in follow-up of these patients.

INTRODUCTION: Adherence to therapy is critical to achieve and sustain optimal outcomes in patients (pts) with immune-mediated inflammatory disease (IMID). Pts' beliefs about the necessity of treatment and potential adverse effects could strongly influence adherence.

AIMS & METHODS: ALIGN was a multi-country cross-sectional study exploring pts' beliefs, concerns, attitudes and adherence toward TNF inhibitors (TNFi) and conventional therapies used alone or in combination across multiple IMIDs. Adults age ≥18 y with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), Crohn's disease (CD), ulcerative colitis (UC) or psoriasis (PsO), receiving conventional therapy and/or disease-modifying antirheumatic drugs (including TNFi), were recruited. Pts completed validated questionnaires, e.g., the Beliefs about Medicines Questionnaire (BMQ) and short Morisky Medication Adherence Scale (MMAS-4). BMQ scores, MMAS-4 scores and pts' attitudes toward their medications are presented.

RESULTS: 7197 pts in 33 countries met eligibility criteria. Pts had RA (27.5%), AS (11.3%), PsA (8.9%), CD (17.3%), UC (8.8%) or PsO (26.2%). Mean age was 47.5 y (range, CD = 38.0; RA = 54.8). Mean disease duration was 11.7 y (range, UC = 8.1; PsO = 18.7). The largest proportion of pts received conventional therapies (40.3%), followed by TNFi mono- (32.0%) and combination therapy (27.7%). An attitudinal analysis of BMQ necessity and concern scores revealed that most pts were either "accepting" (high necessity/low concern) or "ambivalent" (high necessity/high concern) toward their medication irrespective of disease or treatment. Adherence across diseases was generally higher in pts receiving TNFi with or without conventional therapy (range of mean MMAS-4 scores, 3.4–3.7; 0–1 = low, 2–3 = medium, 4 = high adherence), vs pts receiving conventional mono- (2.6–3.3) or combination therapy (2.8–3.4). Across treatments, high adherence according to MMAS-4 was consistently lower for "ambivalent" pts (46.1%–69.0%) vs "accepting" pts (55.8%–77.6%) according to combined BMQ scores **(Table)**.

Table. N (%) of Patients Accepting and Ambivalent Toward Their Medications Who Were Adherent.

Monotherapy, n (%)				TNFi + Conventional Combination Therapy, n (%)			
Conventional		TNFi		Conventional		TNFi	
Accepting (n = 1347)	*Ambivalent* (n = 1151)	*Accepting* (n = 1251)	*Ambivalent* (n = 834)	*Accepting* (n = 900)	*Ambivalent* (n = 739)	*Accepting* (n = 1031)	*Ambivalent* (n = 786)
751 (55.8)	531 (46.1)	919 (73.5)	504 (60.4)	550 (61.1)	374 (50.6)	800 (77.6)	542 (69.0)
P < 0.0001		*P < 0.0001*		*P < 0.0001*		*P < 0.0001*	

CONCLUSION: Compared with "accepting" pts, "ambivalent" pts appeared to be less often highly adherent (MMAS-4 score = 4), which could negatively affect treatment efficacy. The high percentage of "ambivalent" pts reveals the need to better explore concerns about medication and address erroneous beliefs regarding benefit-risk of treatments.

P1431 THE EFFECT OF INCREASING BODY MASS INDEX ON CLINICAL OUTCOMES IN PATIENTS WITH CROHN'S DISEASE TREATED WITH INFLIXIMAB

P. Brown[1,*], L. Warren[2], T. Clark[2], G. Dowson[2], J. Hamlin[2], V. Subramanian[1]

INTRODUCTION: The incidence of obesity is increasing worldwide and there is growing evidence that obesity is associated with low-grade 'background' intestinal inflammation. The role of obesity in progressive inflammatory conditions needs to be assessed and there is very little known about the effect of obesity on outcomes in severe Crohn's disease. Recent data seems to suggest that obesity is associated with diminished responsiveness to biological agents in patients with IBD (ref).
AIMS & METHODS: We aimed to examine the influence of obesity as measured by BMI on the response to Infliximab in CD. A retrospective analysis was performed on all patients identified from our CD registry, receiving Infliximab for severe Crohn's disease. The main variable of interest was BMI, assessed using categorical and continuous scales. The outcomes of interest were 1) IBD related flare (defined as increase in dose or steroid use or need for IBD related hospitalization or surgery), 2. Any IBD related surgery and 3) IBD related resectional surgery. Kaplan Meier (KM) curves were used to compare survival curves for each outcome of interest stratified according to the BMI strata (WHO criteria). Additionally variables of interest were entered into a stepwise multivariate logistic regression analysis for each outcome of interest.
RESULTS: Overall, 388 (87.8%) patients met our predefined inclusion criteria, with mean BMI of 24.1kg/m^2 (+/- 5.1). 22.2 % were classed overweight (BMI 25-29.9) and 11.9% as obese (BMI >30). 232 (60.6%) patients had an IBD related flare during mean follow-up of 33.5months (+/-30.9). Of these 82 (21.4%) required CD-related surgery, of which 39 (10.2%) required CD-related bowel resection surgery. Being categorised as overweight (BMI: 25.0-29.9kg/m^2) increased the risk of a clinical flare (adjusted HR: 1.7, $p=0.045$) compared to normal BMI (18.5-24.9kg/m^2). However the risk of surgery (both all IBD-related and resection surgery alone) decreased per unit increase of BMI on a continuous scale (adjusted HR: 0.924, $P< 0.001$). Female sex increased the likelihood of CD-related bowel resection surgery (adjusted HR: 3.5, $p=0.001$) as did disease phenotype (adjusted HR structuring or penetrating versus non-stricturing and non-penetrating: 4.0, $P<0.001$). KM curves did not show any differences in rates of any of the outcomes of interest for the different BMI strata (based on the WHO criteria), (log rank test $p<0.05$).
CONCLUSION: In patients with severe CD on Infliximab, being classed as overweight increased the risk of having an IBD related flare. This may however reflect the variability in definition of an IBD related flare as this outcome occurred in 60% of patients. Increasing BMI was associated with a decreased risk of IBD related resectional surgery. The reasons for this could include better nutritional reserve in these patients and physician reluctance to operate on patients with higher BMI. The role of obesity in outcomes in CD needs further validation in large prospective studies.

P1432 PSYCHOMETRIC EVALUATION OF THE SIGNS AND SYMPTOMS MODULES OF THE ULCERATIVE COLITIS PATIENT-REPORTED OUTCOMES MEASURE (UC-PRO/SS)

P.D. Higgins[1,*], G. Harding[2], D.L. Patrick[3], D. Revicki[2], W.-H. Chen[2], G. Globe[4], H.N. Viswanathan[4], K. Fitzgerald[5], S. Trease[5], D. Borie[4], B.G. Ortmeier[4], N.K. Leidy[2]
[1]*University of Michigan Health System School of Public Health, Ann Arbor, MI,* [2]*Evidera, Bethesda, MD,* [3]*University of Washington, Seattle, WA,* [4]*Amgen Inc., Thousand Oaks, CA,* [5]*Genentech Inc., South San Francisco, CA, United States*

INTRODUCTION: The Ulcerative Colitis Patient-Reported Outcomes Signs and Symptoms (UC-PRO/SS) measure was recently developed to evaluate symptom outcomes in clinical trials of ulcerative colitis (UC).
AIMS & METHODS: To examine the structure, reliability and validity of the UC-PRO/SS. An observational study was conducted in adults with UC and included three clinic visits: Day 1 (Visit 1), Day 7 (Visit 2), and Day 28 (Visit 3). Subjects completed the UC-PRO/SS on a daily basis using an electronic device. Descriptive statistics, factor analysis, and Rasch analysis were conducted to determine final structure. Test-retest reliability was assessed among stable subjects, defined as those with "no change" on patient-rated global rating of change in UC severity from Visit 2 to Visit 3, using paired *t*-test and intraclass correlation coefficients (ICCs). Cronbach's coefficient alpha was used to assess internal consistency. Construct validity was examined based on correlations with the Inflammatory Bowel Disease Questionnaire (IBDQ), Partial Mayo Score, and other ancillary measures. Known-groups validity was evaluated by comparing UC-PRO/SS domain scores by groups defined by the Partial Mayo Score, Patient Global Rating of Disease Severity, and Clinician Global Rating of Disease Severity using ANCOVA models adjusted for age and gender.
RESULTS: Of the 200 participants, 117 (59%) were female; mean (SD) age was 46 (14.6) years. The 14-item UC-PRO/SS includes three domains: Bowel Movement (BM) Signs and Symptoms, Abdominal Symptoms, and Systemic Symptoms. Alpha coefficients ranged from 0.66 to 0.80. No significant differences were observed in UC-PRO/SS domain scores between visits for stable subjects, with ICC values of 0.71-0.81. The BM Signs and Symptoms scale was strongly correlated to the Partial Mayo Score (0.79) and moderately to strongly correlated with the IBDQ (0.51 to 0.73). Moderate correlations (0.45-0.65) were observed between Abdominal Symptoms and Partial Mayo Score, IBDQ, and BPI – Worst Pain. Similar correlations were observed for Systemic Symptoms. Findings indicate that UC-PRO/SS domain scores were significantly different ($p<0.0001$) by known groups.
CONCLUSION: Findings from this study support the UC-PRO/SS as a reliable and valid measure for the evaluation of signs and symptoms in UC clinical trials. Future studies conducted within the context of a clinical trial will examine relationships with clinical measures to assess treatment response.

INTRODUCTION: The Ulcerative Colitis Patient-Reported Outcomes (UC-PRO) measure includes five modules that assess the signs, symptoms, and impact of UC. Modules 1 and 2 comprise the UC-PRO Signs and Symptoms measures, while Modules 3-5 assess Coping, Daily Life Impact, and Emotional Impact.
AIMS & METHODS: To examine the structure, reliability and validity of UC-PRO Modules 3-5. An observational study was conducted in adults with UC and included three clinic visits: Day 1 (Visit 1), Day 7 (Visit 2), and Day 28 (Visit 3). Subjects completed Module 3 (Coping) on a daily basis using an electronic device, while Modules 4 and 5 (Daily Life Impact and Emotional Impact) were completed at clinical visits. Descriptive statistics, factor analysis, and Rasch analysis were conducted to determine final structure. Test-retest reliability was assessed among stable subjects, defined as those with "no change" on patient-rated global rating of change in UC severity, using paired *t*-test and intraclass correlation coefficients (ICCs). Internal consistency reliability was assessed using Cronbach's coefficient alpha and the Kruder-Richardson Formula-20 (KR-20). Construct validity was examined based on correlations with the Inflammatory Bowel Disease Questionnaire, Partial Mayo Score, and other ancillary measures. Known-groups validity was evaluated by comparing module scores by groups defined by the Partial Mayo Score, Patient Global Rating of Disease Severity, and the Clinician Global Rating of Disease Severity using ANCOVA models adjusted for age and gender.
RESULTS: Of the 200 participants, 117 (59%) were female; mean (SD) age was 46 (14.6) years. The final UC-PRO Modules 3-5 include Coping (7 items), Daily Life Impact (9 items), and Emotional Impact (8 items). Cronbach's alphas were 0.94 and 0.91 for Daily Life Impact and Emotional Impact, respectively; the KR-20 coefficient was 0.71 for Coping. No significant differences were observed in Daily Life Impact and Emotional Impact between visits for stable subjects, with ICC values of 0.93 and 0.85, respectively. There was a significant difference in scores observed for Coping (p value 0.001), but the ICC value was 0.84, providing support of test-retest reliability. All three modules were moderately to strongly correlated to ancillary measures. Module scores were significantly different ($p<0.0001$) by known-groups.
CONCLUSION: Findings from this study support the reliability and validity of UC-PRO Modules 3-5 to assess the impact of UC on coping strategies, daily life impact, and emotional impact.

P1434 COMPARISON OF BREATH AND URINE VOLATILE ORGANIC MARKERS IN INFLAMMATORY BOWEL DISEASE (IBD)

J. Covington[1], E. Daulton[2], A. Pauza[3], E. Westenbrink[1], N. O'Connell[4], C. Bailey[4], M. McFarland[4], A. Dhaliwal[4], C. Nwokolo[4], K. Bardhan[5], **R. Arasaradnam**[4,*]

Contact E-mail Address: *r.arasaradnam@warwick.ac.uk*

INTRODUCTION: Early diagnosis of inflammatory bowel disease (IBD) remains a challenge. Latterly the role of volatile organic compounds (VOCs) have come to the fore showing distinct patterns in those with Crohn's disease as well as Ulcerative colitis compared with controls. VOC detection reflects the altered gut fermentome which is perturbed in IBD. Moreover its sampling is non-invasive with various compounds being identified from faecal, breath and urine. We and other have previously reported that urine can be used to diagnose IBD and the same can be achieved with breath and stool.
AIMS & METHODS: Aim: The aim of our study was to compare urine and breath VOC sampling using FAIMS (Field asymmetric ion mobility spectroscopy) in patients with IBD.
Methods: 133 subjects were recruited 86 patients with established IBD (formed from both Crohns and Ulcerative Colitis patients) and 46 volunteers for controls. Urine samples were collected and sampled using the FAIMS system. Urine was heated to 40°C and headspace analysed for VOC patterns using an Owlstone Lonestar FAIMS instrument, fitted with an ATLAS sampling system. For breath analysis, a subset of the subjects (11 controls and 20 with established IBD) were tested. End expiratory breath was captured using a Warwick device and captured in a 3L tedlar bag prior to analysis. Linear discriminatory analysis (LDA) was employed in all cases to determine differences between the two sample modalities, with a "leave on out", combined with a K-nearest neighbour reclassification algorithm to calculate sensitivity and specificity.
RESULTS: VOC signature patterns were clearly separable in IBD patients compared with controls using both urine and breath. We achieved a sensitivity of 86% and specificity of 76% with the FAIMS, However, the analysis of the breath samples achieved a sensitivity of 95% and a specificity of 90%.
CONCLUSION: In this pilot study, we have applied FAIMS technology to the analysis of patients with IBD. Here breath samples tested by FAIMS appear to show superior results than urine samples analysed by the same method. Further statistical work is currently being undertaken to distinguish between Crohns disease and Ulcerative Colitis for both urine and breath samples, whilst a larger patient group is being recruited for further breath sample analysis.

Contact E-mail Address: *ramiro.gonzalez@hospitalitaliano.org.ar*

INTRODUCTION: Magnetic resonance imaging (MRI) and Multiple Slice Computed Tomography (CT) have improved the diagnosis and monitoring of patients with inflammatory bowel disease (IBD), particularly in Crohn's disease (CD). In ulcerative colitis (UC) the usefulness of CT enterography (CTE) has been limited to rule out CD during the diagnostic process. No studies to date have evaluated the prognostic value of CTE findings in patients with severe active UC.
AIMS & METHODS: Our main objetive was to evaluate CTE findings associated with poor response to treatment in patients with severe relapse of UC requiring colectomy. We prospectively included adults hospitalized with a severe relapse of UC according to Truelove–Witts criteria in the gastroenterology unit of a university hospital from April 2010 to October 2013. CTE findings, response to treatment and the need of colectomy were evaluated, as well as endoscopic, biochemical and clinical findings. Variables were compared in order to determine factors associated with poor outcome and colectomy using the SPSS 17.0 statistical system.
RESULTS: Seventeen patients hospitalized with severe UC were included, 9 were women, with a median age of 38.4 years (19-81). The mean time since UC diagnosis was 3.9 years (0-19). Of the 17 patients included, 5 had progression of the affected colon extension at the time of the flare. All patients underwent CTE in a mean time of 3.4 days from the hospitalization. Regarding the response to steroid treatment, 10 patients were refractory, 6 dependent and 1 responder. Eight patients received rescue treatment with Infliximab without primary response. When we compared CTE findings of patients requiring colectomy ($n=11$) versus those who did not ($n=6$), free fluid in the abdominal cavity was observed in 64% vs. 0% ($p=0.043$): haustra loss: 100% vs. 50% ($p=0.029$): megacolon (transverse colon diameter greater than 5 cm) 27 % vs. 0 % (NS): extensive involvement: 72% vs. 50% (NS), wall thickening (>5mm): 100% vs. 66% (NS): and ulcers and/or pseudopolyps: 100% vs 66% (NS). None of the patients had clinical or laboratory evidence of complications related to the CTE.
CONCLUSION: In this pilot study, it seems that in patients with severe relapse of UC, CTE is useful to determine the risk of colectomy while allows us to rule out extra-intestinal complications. Although in IBD MRI is usually preferred due to its lack of radiation, in this particular setting of severe UC, CTE is a reasonable option, widely available and fast to implement in the emergency. Prospective studies with large number of patients are required to assess independent factors that would allow us to choose treatment and predict response.

INTRODUCTION: Magnetic resonance imaging (MRI) and rectal ultrasound (RUS) are the two accepted imaging modalities for the evaluation of perianal fistulas and abscesses. Transperineal ultrasound (TPUS) is a new technique, witch easy to learn and can be performed at any time.
AIMS & METHODS: To prospectively compare the diagnostic accuracy of MRI, RUS and TPUS with the surgical findings of CD patients with perianal fistulas and abscesses. All patients underwent MRI, RUS and PUS within a few days before perianal surgery. Fistulas were classified as simple (43.8%) or complex (52.2%). Perianal Disease Activity Index (PDAI) was estimated in every patient.
RESULTS: Twenty-three patients with active perianal CD (12 women, 11 men, mean age: 36.7 years; current therapy: antibiotics in 69.6%, azathioprine in 56.5%, biologicals in 73.9%; frequency of previous surgery 26.1%; proportion of smokers 39.1%) were included in this prospective study. The mean PDAI was 8.43 (4-15). The validity of MRI, RUS and PUS in the diagnosis of perianal fistulas were 82.6%, 82.6% and 100%, respectively. PUS was significantly more sensitive in the diagnosis of the perianal abscesses than MRI and RUS (100%, 58.8% and 92.8%).
CONCLUSION: PUS is a very accurate and easy to perform diagnostic method with an outstanding sensitivity compared to MRI and RUS in the evaluation of complicated perianal CD. Due to its simplicity and low cost, PUS is recommended be the first diagnostic modality in case of complicated CD.

INTRODUCTION: Accurate diagnosis of inflammatory bowel disease (IBD) and classification of its clinical subtypes, namely Crohn's disease (CD) and ulcerative colitis (UC), are of increasing importance in its management and prognosis. However, diagnosis of IBD based on conventional radiological, endoscopic, and histopathological techniques is often inconclusive and invasive. Urinary metabonomics represents an emerging systems biology approach for the identification of noninvasive metabolic biomarkers of IBD. While previous studies have focused on the use of NMR spectroscopy for urinary metabotyping of IBD patients, complementary analytical tools that may broaden the metabolic coverage for biomarker discovery have been underexplored.
AIMS & METHODS: In this study, the role of gas chromatography/mass spectrometry (GC/MS)-guided urinary metabonomics in the noninvasive characterisation of IBD was investigated for the first time. Marker metabolites characterizing specific subtypes of IBD were further elucidated. Urine samples from 9 IBD patients (5 UC and 4 CD patients) with active disease (CDAI $>$ 150 or Truelove & Witt Activity $>$mild activity, without biological immune-modifiers) and 10 matched healthy controls were metabotyped using gas chromatography/time-of-flight mass spectrometry (GC/TOFMS). The acquired data were subjected to multivariate partial least squares discriminant analysis (PLSDA). The PLSDA model was validated using response permutation testing and subjected to receiver operating characteristic (ROC) analysis.
RESULTS: IBD patients were clearly distinguished from healthy controls based on their urinary metabonomic profiles [validated PLSDA, $R^2X=0.264$, $R^2Y=0.669$, Q^2 (cumulative)$=0.519$]. The robustness of the PLSDA model was demonstrated by an area of 0.978 under the ROC curve and a sensitivity of 100% and specificity of 90% in detecting IBD. Marker metabolites that were dysregulated similarly in UC and CD (e.g. elevated xylose), as well as unique metabolites that characterized each subtype (e.g. increased fucose and decreased

nicotinic acid, picolinic acid and valine in UC; reduced hippuric acid in CD) were further revealed ($p<0.05$).
CONCLUSION: While this diagnostic technique requires further evaluation, our work established surprisingly robust proof-of-principle for the ability of a non-invasive GC/TOFMS-based urinary metabonomic approach to identify patients with IBD and uncovered valuable marker metabolites that may aid in the diagnostic distinction between CD and UC.

Contact E-mail Address: *pauloavfreire@gmail.com*

INTRODUCTION: Ulcerative colitis (UC) is associated with an increased risk of colorectal cancer (CRC). Identification of risk factors for CRC is important to enhance surveillance. Risk factors identified so far resulted mainly from retrospective studies carried out in referral centers and involving high-risk patients.
AIMS & METHODS: Aim: To identify risk factors for intraepithelial neoplasia (IN) in patients with longstanding UC and without primary sclerosing cholangitis (PSC) and/or history of IN.
Methods: 150 patients with longstanding (≥8 years) distal/extensive UC and without PSC and/or history of IN, were prospectively screened by colonoscopy with chromoendoscopy-guided endomicroscopy (n = 73) or convencional colonoscopy with random biopsies (n = 77). In the chromoendoscopy group aberrant crypt foci (ACF) were sought at the lower rectum.
RESULTS: IN was detected in 10 patients (6.7%). Patients with IN have a significantly higher number of ACF than patients without IN (4.83±3.13 vs 2.17±2.78, p = 0.029). ACF prevalence was 100% in patients with IN and 56.7% in patients without IN (p = 0.056). Although not reaching statistical significance, there was a trend for association between the risk of IN with older ages (57.90±13.52 vs 49.51±14.26 years, p = 0.070) and longer disease duration (22.40±10.26 vs 16.37±7.73 years, p = 0.059). There is also a trend towards lower prevalence of treatment with oral mesalazine in patients with IN (70% vs 90%, p = 0.054). Age at diagnosis, extent of disease, presence of pseudopolyps, smoking status, family history of CRC and body mass index revealed no significant association with the risk of IN.
CONCLUSION: In longstanding UC patients without PSC and/or history of IN, the following are risk factors for IN: prevalence/number of ACF, older age, longer disease duration and lack of medication with oral mesalazine.
Disclosure of Interest: None declared

P1439 RISK FACTORS FOR ABERRANT CRYPT FOCI IN ULCERATIVE COLITIS

P. Freire[1,*], P. Figueiredo[1,2], R. Cardoso[1], M.M. Donato[2], M. Ferreira[1], S. Mendes[1], M.R. Silva[3], A. Cipriano[3], A.M. Ferreira [1], H. Vasconcelos [4], F. Portela[1], C. Sofia[1,2]

INTRODUCTION: Aberrant crypt foci (ACF) were identified as biomarkers of sporadic colorectal cancer (CRC) and, more recently, of dysplasia/CCR associated with ulcerative colitis (UC). Therefore, it is important to identify risk factors for ACF, which were previously only explored outside the scope of inflammatory bowel disease.
AIMS & METHODS: Aim: To identify risk factors for ACF in UC.
Methods: Seventy six patients with longstanding (≥8 years) distal/extensive UC and without primary sclerosing cholangitis (PSC) and/or history of intraepithelial neoplasia (IN) were prospectively included in the study. ACF were sought at the lower rectum after chromoendoscopy with methylene blue. Demographic and clinical data were obtained with a standardized questionnaire filled out by reviewing the medical charts and a patient interview at the time of enrolment. Associations of various factors with the prevalence and the number of ACF were sought by univariate and multivariate analysis.
RESULTS: ACF were detected in 46 patients (60.5%) with a per patient average number of 2.4±2.8. ACF prevalence was significantly higher in patients with a family history of CRC (100% vs 56.5%, p = 0.038) and it was also found a trend for a positive association with body mass index (BMI) (p = 0.055). The number of ACF was significantly higher in patients aged >40 years (2.8±3.0 vs 1.4±2.0; p = 0.032), family history of CRC (4.1±3.6 vs 2.2±2.7; p = 0.044) and higher BMI (0, 1.9±2.6, 2.6±3.1, 3.7±2.5 for BMI <18.5, 18.5-24.9, 25-29.9 and ≥30 respectively, p = 0.028). In multivariate analysis only the association with BMI remained statistically significant (p = 0.030).
CONCLUSION: In patients with longstanding UC and without PSC and/or history of IN, having family history of CRC or high BMI are risk factors for ACF.
Disclosure of Interest: None declared

P1440 ANTI-TNF THERAPY AND DISEASE PHENOTYPE: DETERMINANTS OF RISK OF RADIATION EXPOSURE IN CROHN'S DISEASE

R. Coelho[1,*], L. Guimarães[2], S. Lopes[1], F. Magro[1], G. Macedo[1]
[1]*Gastrenterology Department,* [2]*Radiology Department, Centro Hospitalar São João, Oporto, Portugal*

INTRODUCTION: Patients with Crohn's Disease (CD) require repetitive imaging of the gastrointestinal tract for diagnosis, assessment of activity and response to therapy. Epidemiological data suggest that a protracted exposure of a dose of 50–100 millisieverts (mSv) is associated with increased risk of cancer.
AIMS & METHODS: Calculate the cumulative dose of radiation (CDR) in patients diagnosed with CD and its correlation with different variables. Cohort of 630 patients diagnosed with CD between January 1990 and December 2013 treated at an Inflammatory Bowel Disease outpatient clinic. The total dose of effective radiation was estimated for each patient collecting the number and type of radiographic imaging studies since the onset of the symptoms. The CDR was determined for each patient according to the value set in the reference table in units of mSv.
RESULTS: 630 patients were included (49.8% male) with CD phenotype according to the Montreal classification: B1 n = 263, B2 n = 54, B3 n = 313. The CDR mean value was 41.45 mSv (0 - 642.49). There was a correlation between the number of abdominal computed tomography exams performed and the CDR. However, the increased duration of the disease was not associated with a higher CDR. Eighty-six patients (13.7 %) were exposed to a CDR > 50 mSv. There was a relationship between higher CDR and CD phenotype: B1: 27.54 mSv; B2: 34.47 mSv; B3: 40.66 mSv. A CDR > 50 mSv was related to the penetrating phenotype (40.66 vs 27.54, p < 0.001), anti-TNF therapy (52.38 vs 33.04, p = 0.003), surgical treatment (49.86 vs 33.87, p = 0.005) and continuous or intermittent course of the disease vs chronic illness with minimum activity after diagnosis (45.56 vs 29.9, p = 0.004). Azathioprine therapy was not associated with greater CDR.
CONCLUSION: Anti-TNF therapy, surgical treatment, penetrating phenotype and continuous or intermittent course of the disease were factors associated with greater amount of CDR.

P1441 CALPROTECTIN PREDICTS RELAPSE OF IBD EVEN IN THE PRESENCE OF A 'NORMAL' COLONOSCOPY

INTRODUCTION: Faecal calprotectin (FCALP) is a sensitive and reliable marker of mucosal inflammation and mucosal healing in IBD. It has always been compared against endoscopic appearance as the presumed gold standard for assessment of disease activity. Several strands of evidence – using magnifying[1] or image-enhanced endoscopy as well as confocal laser endomicroscopy[2] – highlight abnormalities in colonic mucosa reported as 'normal' by standard white light colonoscopy (WLC). This may be compounded by the difficulties in bowel preparation in IBD[3] and the non-widespread use of high definition technology (although the latter has not been specifically studied in relation to IBD). We wished to determine whether an elevated FCALP could predict relapse even in the presence of an ostensibly normal WLC.
AIMS & METHODS: As part of a larger study correlating FCALP to histologic assessment of disease activity, retrospective data was collected for consecutive patients with IBD on stable therapy undergoing colonoscopy for disease assessment. FCALP (Bühlmann ELISA) was collected as close as possible (prior) to the colonoscopy. When the colonoscopic appearances were reported as normal (Mayo endoscopic subscore 0 for ulcerative colitis, UC, and ulceration score equating to SES-CD = 0 for Crohn's disease, CD), patients were followed to determine if they relapsed, with time to relapse (or last recorded follow-up) taken from the date of colonoscopy. For the purposes of this study, relapse was defined generally as "continuous or worsening intestinal symptoms requiring an escalation in therapy". Switching between 5ASA classes was not included in this definition unless the specifically stated to be in response to uncontrolled symptoms.
RESULTS: 46 patients with UC and 37 with CD were identified with the above criteria. Median time between FCALP measurement and colonoscopy was 0.70 (max 2.89) and 0.90 (max 1.5) months respectively. Normal FCALP was detected in 16 patients with UC and 12 with CD.
Median calprotectin in the 'high' group was 377 (229-794) in UC and 192 (118-247) in CD. At 12 months, relapse-free survival proportions were 86% with UC and normal FCALP compared to 34% in those with high FCALP (p < 0.01 in Kaplan-Meier analysis). In CD, these proportions were 50% and 12% respectively (p = 0.02).
CONCLUSION: Elevated levels of FCALP predict relapse even in the presence of a macroscopically normal colonoscopy. This finding is in general agreement with studies of state-of-the-art endoscopic techniques that detect mucosal abnormalities predictive of relapse, when WLC is reported as 'normal'. FCALP may provide a cheaper and acceptable alternative to routine monitoring endoscopy in IBD.

[2]*Gastroenterology, Addenbrooke's Hospital, Cambridge, United Kingdom*
Contact E-mail Address: *swchuah18@gmail.com*

INTRODUCTION: Tumour necrosis factor (TNF)–antagonists are effective treatments for inflammatory bowel disease (IBD), but secondary loss of response (LOR) occurs in 10-15% patients/year. Therapeutic drug monitoring (TDM) has emerged to facilitate decision-making around secondary LOR. In Addenbrooke's Hospital 107 and 41 IBD patients are on infliximab and adalimumab respectively.
AIMS & METHODS: Assess serum infliximab and antibodies to infliximab (ATI) in IBD patients and determine usefulness of TDM in clinical decision-making. Prospective cohort study of IBD patients on infliximab between Aug 2013-Jan 2014. Demographic and clinical data collected. Disease activity assessed using Harvey-Bradshaw index (HBI) for Crohn's disease (CD) and Simple Clinical Colitis Activity Index (SCCAI) for Ulcerative colitis (UC). C-reactive protein and faecal calprotectin were measured. Bloods assayed for trough level of infliximab (TLI)+/-ATI using LISA-TRACKER Premium ELISA kits (Theradiag). ATI only if intermediate or subtherapeutic TLI and positive evidence of inflammatory activity. TLI interpretations:Therapeutic level > 2μg/mL, Intermediate level 1.0–2.0μg/mL and Subtherapeutic level < 1.0μg/mL. ATI analytical range: 10–200ng/mL.
RESULTS: 107 patients (55males,52females) recruited. Mean age 35.9 years (range,18-74 years). Mean disease duration 9.6 years (range,7months-39 years). Mean disease duration before starting infliximab 6.8 years (range,1month-39 years). Diagnoses of CD, UC and IBD-Unspecified were 104, 2 and 1 respectively. Majority 70 (66%) were on 8-weekly regime. Mean duration of infliximab 3.3 years. For TLI results,73 (68.2%),12 (11.2%) and 22 (20.6%) were in the therapeutic, intermediate and subtherapeutic range respectively. For subtherapeutic TLI group,14 (63%) had undetectable ATI,3 (14%) had ATI of 42ng/mL,31ng/mL and 50ng/mL; and 5 (23%) did not have ATI done as they had no evidence of inflammatory activity. For intermediate TLI group,8 (67%) had undetectable ATI,1 (8%) had ATI of 160ng/mL and 3 (25%) did not have ATI done as they had no evidence of inflammatory activity. For therapeutic TLI group,24 (33%) had evidence of inflammatory activity.39 (36%) were not on immunomodulators (IM). Among 68 patients who were on IM,62 (91%) were on thiopurines and 6 (9%) on methotrexate. In thiopurines group,34 (55%) had thiopurine metabolites (6-TGN) done, of which 25 (74%) were within therapeutic range. Among 68 patients who were on IM,51 (75%) achieved therapeutic TLI and 2 (3%) had detectable ATI versus among 39 patients who were not on IM,24 (61%) achieved therapeutic TLI and 2 (5%) had detectable ATI ($p = 0.143$). There was no significant correlation between 6-TGN and TLI levels ($p = 0.324$).
CONCLUSION: 73 (68.2%) achieved therapeutic TLI. With TDM,58 (54.2%) patients may benefit from interventions:a) Potential infliximab discontinuation (Subtherapeutic TLI + remission)8 (7.5%),b) Potential dose intensification to recapture response (Subtherapeutic TLI with no ATI but clinical/biochemical activity)22 (20.6%) and (Subtherapeutic TLI with low ATI)3 (2.8%),c) Potential switch to other anti-TNF agent (Subtherapeutic TLI with high ATI)1 (0.9%) and d) Potential switch to non-anti TNF agent (Therapeutic TLI + activity) 24 (22.4%). 26/58 (44.8%) patients needed ATI for decision making. To save cost, initial test should be TLI with addition of ATI if needed. Concomitant infliximab and IM seemed to be associated with higher rate of therapeutic TLI. However, there was no significant correlation between 6TGN and TLI levels.

INTRODUCTION: The possible role of immunomodulators (IMM) in the development and/or outcome of neoplasia in Inflammatory Bowel Disease IBD) is still debated. Whether IBD patients with a previous diagnosis of neoplasia may be treated with IMM, including anti-TNFs is undefined.
AIMS & METHODS: In a retrospective cohort study, the outcome of IBD patients treated with IMM and/or anti-TNFs after a diagnosis of neoplasia was evaluated. Clinical characteristics of all IBD patients under regular follow up at our tertiary IBD center from 2000 to 2013, with a proven diagnosis of neoplasia were reviewed. Among this subgroup of IBD patients with a history of neoplasia, only patients treated with IMM and/or anti-TNFs after the diagnosis of neoplasia were included. Parameters considered: 1. IBD type (Crohn's Disease, CD vs Ulcerative Colitis, UC); 2. Gender; 3. Age at diagnosis of IBD; 4. Age at diagnosis of neoplasia (yr); 5. IMM (Azathioprine, AZA;6-mercapopurine,6MP) or anti-TNF (Infliximab, IFX, Adalimumab, AD); 6. IBD duration at time of diagnosis of neoplasia; 7. Time interval between diagnosis of neoplasia and IMM use; 8. Follow up duration after the diagnosis of neoplasia; 9. Characteristics of neoplasia. Data were expressed as median (range)
RESULTS: In the 13 yrs follow up, a history of neoplasia was observed in 82 IBD pts. Among these 82 IBD pts, 15 (18.2%) were treated with IMM for IBD after the diagnosis of neoplasia. This group included 12 CD and 3 UC pts. (8M,5F; age at diagnosis of neoplasia 41, range 21-69; age at diagnosis of IBD 27, range 12-66, IBD duration at diagnosis of neoplasia 10, range 1-38). IMM after the diagnosis of cancer included thiopurines in 12 (AZA n = 8; 6MP n = 4), anti-TNFs in 3 (ADA n = .2; IFX n = 1). Among the 15 IBD pts treated with IMM after the diagnosis of neoplasia, neoplasia included: thyroid (n = 4), skin (NMSC n = 2; 1 basal cell carcinoma, 1 spinal cell carcinoma); breast (n = 2), colon (n = 2), prostatic cancer (n = 2) lymphoma (HL n = 1), seminoma (n = 1), carcinoid of the appendix (n = 1). Time interval between the diagnosis of neoplasia and IMM use: 6 yrs (range 1-26). After a 10 yrs follow up from the diagnosis of neoplasia (range 3-30), none of the 15 IBD pts treated with IMM after the diagnosis of neoplasia showed recurrence or new onset of neoplasia. No cancer-related deaths were observed, as only 1/15 pts. had a cirrhosis-related death..
CONCLUSION: In a retrospective study, the use of thiopurines and anti-TNFs did not appear to worsen the outcome of IBD pts with a positive history of neoplasia. Larger prospective longitudinal studies are needed to further address this relevant issue in IBD
Disclosure of Interest: None declared

P1444 PROSTAGLANDIN E-MAJOR URINARY METABOLITE AS A RELIABLE SURROGATE MARKER FOR MUCOSAL INFLAMMATION IN ULCERATIVE COLITIS

INTRODUCTION: A simple, non-invasive biomarker of ulcerative colitis (UC) activity is required. Because prostaglandin-E2 (PGE2) production is associated with colonic inflammation, we evaluated whether prostaglandin E-major urinary metabolite (PGE-MUM) can be used as a biomarker of UC activity by comparing the PGE-MUM levels of volunteers with those of UC patients. PGE is known to be involved in the development of colon cancer as well as inflammation of the large intestine.
AIMS & METHODS: Urine samples were obtained from 408 non-smoking (172 male and 236 female) volunteers who visited the Health Check Department of the Japanese Red Cross Medical Center for general health checkups and from 79 UC (53 male and 26 female) patients at Jikei University Hospital. UC activity was evaluated using the simple clinical colitis activity index (SCCAI), Mayo endoscopic scoring system, and Matts' grading system (histological activity scoring). PGE-MUM levels were measured by using a radioimmunoassay kit.
RESULTS: PGE-MUM levels were associated with UC activity ($P < 0.01$). The PGE-MUM levels in the active phase were significantly higher in UC patients than in healthy volunteers. The main advantage of PGE-MUM appears to be the differentiation of colonoscopic or histologic remission from active disease in UC patients. In remission, PGE-MUM levels of UC patients were close to those of healthy volunteers.
CONCLUSION: Because PGE-MUM can be estimated using a simple, quick, and non-invasive method and is associated with UC activity, it appears to be a useful biomarker of UC activity. PGE-MUM levels are low in remission in UC patients owing to successful treatment. PGE production in the colon is a risk factor for colon cancer along with cyclooxygenase-2. By keeping PGE-MUM levels low in the long term, it is possible to reduce UC recurrence and the incidence of colorectal cancer.

P1445 POOR RECOGNITION AND MANAGEMENT OF IRON DEFICIENCY ANAEMIA IN INFLAMMATORY BOWEL DISEASE: A MISSED OPPORTUNITY

S. Subramaniam[1,*], K. Besherdas[1]
[1]*Department of Gastroenterology, Barnet & Chase Farm Hospitals NHS Trust, London, United Kingdom*
Contact E-mail Address: *sharmila.subramaniam@nhs.net*

INTRODUCTION: Iron deficiency anaemia (IDA) is a common complication of inflammatory bowel disease (IBD) that has an impact on the patient's quality of life. IDA is caused by inadequate dietary intake, malabsorption of iron and iron loss through intestinal bleeding. Current guidelines recommend that all patients with IBD should be assessed for IDA and that iron supplementation be given as indicated.[1]
AIMS & METHODS: The aim of this study was to ascertain the prevalence of IDA in our IBD cohort, to look at whether iron replacement therapy (and in what form) was given and to assess treatment response.
A single centre, retrospective analysis of IBD patients from a large district general NHS trust in North London was performed. The database of patients was collated by the IBD Clinical Nurse Specialist. Electronic patient records (blood results and outpatient clinic letters) were used to collect data on patient demographics, diagnosis, screening parameters for IDA (Hb, Ferritin/transferrin saturation, CRP) and iron replacement therapy. The WHO definitions of anaemia were used (Hb < 13g/dL in men and Hb < 12g/dL in non pregnant women). Iron deficiency was diagnosed if ferritin < 30 ug/L in quiescent IBD or < 100ug/L in active IBD (CRP elevated) or transferrin saturation < 16%.

RESULTS: 333 IBD patients were identified in the database. 3 patients were excluded because of insufficient data as their care was transferred. 293/330 (88.8%) were checked for IDA using the screening parameters. 146/293 (49.8%) of this group were found to be anaemic. 101/146 (69.2%) had evidence of iron deficiency. 61/101 (60.4%) were treated using oral and/or intravenous (IV) iron preparations or blood transfusions. Most patients (50/61) received oral iron while 10 patients had IV iron (4 had failed oral therapy) and 6 had a transfusion. The recurrence rate of IDA was 21/50 with oral iron, 4/10 with IV iron and 4/6 with transfusions. We also noted that there were 39/184 patients (21.2%) with iron deficiency in the absence of anaemia. Only 3 of these patients were treated for iron deficiency.
CONCLUSION: The prevalence of IDA in our IBD group was close to 50%. Current practice in our trust does not comply with guidelines as only 60.4% of IDA patients were treated. Iron replacement therapy was mostly administered in the oral form. Recurrence of IDA was similar (about 40%) with both oral and IV iron therapy. There is little guidance on management of iron deficiency in the absence of anaemia and supplementation was not widespread in this group. Barriers to appropriate recognition of IDA including lack of routine monitoring and knowledge on iron data interpretation will need to be addressed to improve practice.

INTRODUCTION: Rapid and accurate diagnosis of Crohn's disease (CD) is essential for early intervention, however, a gold standard is not available. Lennard-Jones et al. defined widely adopted macroscopic and histological criteria for CD diagnosis, but these await validation.
AIMS & METHODS: To develop an alternative diagnostic model for CD based on the criteria by Lennard-Jones.
Included were patients from 3 tertiary centres (Nancy, Barcelona and Vienna) with long-standing CD whose records from up to 6 months after initial diagnosis were reviewed. Cases were then re-classified according to Lennard-Jones criteria (LJC). CD was rated as "established" (granuloma + one minor criterion or 3 minor criteria, which include macroscopic discontinuity, transmural inflammation, fibrosis, lymphoid aggregates or discontinuous inflammation on histology), "probable" (2 minor criteria without granulomas) or "non CD". Sensitivity, specificity and balanced accuracy were calculated for the overall sample and for each center separately including patients with ulcerative colitis (UC) as controls. The prognostic value of the 6 variables was modelled by logistic regression. Variables which proved highly significant ($p<0.0001$) in the first model were included in the final model. One hundred 10-fold cross-validations were conducted. ROC-curves were calculated and the value with the best Youden-Index was taken as the optimal cut-off for the diagnosis of CD.
RESULTS: Overall, 328 patients with CD and 170 patients with UC were assessed. At time of diagnosis nearly half of all patients were diagnosed as "non CD" (see Table 1).
Table 1 Diagnosis of CD according to LJC:

	Established CD, n (%)	Sensi/ Speci*	Probable CD, n (%)	Sensi/ Speci**	Non CD, n (%)
Barcelona	49/101 (48%)	0.49/1.00	18/101 (18%)	0.66/0.98	34/101 (34%)
Nancy	19/94 (20%)	0.20/1.00	21/94 (22%)	0.43/0.90	54/94 (58%)
Vienna	44/133 (33%)	0.33/0.99	15/133 (11%)	0.44/0.97	74/133 (56%)

Logistic regression of all 6 variables showed high significance by the 4 factors, granuloma, fibrosis, transmural inflammation, and macroscopic discontinuity with parameter estimates of 4.6, 4.4, 2.3 and 2.3, respectively. A cut-off score value of $\geq$2.28 was associated with highest balanced accuracy (0.82), a sensitivity of 0.8 and a specificity of 0.85 and reflecting a diagnosis of "probable CD". A cut-off value of $\geq$4.4 for "established CD" would be associated with a specificity of 1, but a sensitivity of 0.45.
CONCLUSION: In nearly half of patients managed as long-standing CD at 3 referral centres the LJC would not provide the diagnosis of CD from initial examinations. We elaborated an alternative simple score for the diagnosis of CD resulting in higher sensitivity and specificity by subjecting the criteria by Lennard-Jones to logistic regression modelling.

P1447 CHEMERIN, VISFATIN AND VASPIN SERUM LEVELS IN RELATION TO FAT MASS AND BONE MINERAL DENSITY IN IBD

S.P. terzoudis[1,*], N. Malliaraki[1], J. Damilakis[1], J. Neratzoulakis[1], C. Georgousaki[1], V. Tzimourtos[1], E. Kouroumalis[1], I. Koutroubakis[1]

INTRODUCTION: It has been suggested that the bone and fat interface is implicated in the pathogenesis of osteoporosis. Several studies have shown a strong correlation between fat mass (FM) and bone mineral density (BMD) in patients with IBD, but data including the action of adipokines on this association are limited. The aim of this study was to investigate the role of the adipokines chemerin, visfatin and vaspin in patients with ulcerative colitis (UC) and Crohn Disease (CD) in relation to FM and BMD
AIMS & METHODS: 115 patients with IBD (67 CD, 48 UC) and 98 matched healthy controls (HC) were enrolled in this study. All patients underwent bone densitometry by dual energy x-ray absorptiometry at the femoral neck and lumbar spine, and evaluation of body mass composition with GE-Lunar Prodigy along with host software Encore. Chemerin, visfatin and vaspin serum levels were measured in IBD patients and HC using commercially available enzyme linked immunosorbent assays (ELISA)
RESULTS: Osteopenia was observed in 75 patients with IBD (65.2%, 59 CD and 26 UC) and osteoporosis in 23 patients (20%,19 CD,4 UC). Osteoporotic patients had a significant lower total fat mass (19501.3±8085.2gr) than osteopenic patients (23089.2±9939.9 gr) and the patients with normal BMD (28410±10692 gr)($p=0.01$). Mean (±standard deviation) serum chemerin levels were 14.1±6.6ng/ml in CD patients, 13.5±3.3ng/ml in UC patients and 7.8±2.7ng/ml in HC ($P<0.0001$). No differences between males and females or between UC and CD were observed. Subgroup analysis of correlation of chemerin levels with clinical characteristics showed significant association only with indices of osteoporosis. Chemerin serum levels were found significantly correlated with T score both at the femoral neck and lumbar spine ($r=0.25$ $p=0.007$ and $r=0.19$, $p=0.03$ respectively). There was no significant correlation of chemerin levels with BMI, CRP and fat distribution. No significant correlations between visfatin or vaspin and any of the examined parameters (including disease type or characteristics, FM and BMD) were observed.
CONCLUSION: Fat mass seems to play an important role in the development of osteoporosis in IBD patients. Serum chemerin levels are significantly increased in patients with IBD compared to HC and significantly correlated with the development of osteoporosis.

INTRODUCTION: Histologic healing has been shown to be associated with favorable outcomes in patients with ulcerative colitis (UC). Although mucosal healing (MH) is reported to be an important goal, MH is not always an accurate indicator of histologic healing because microscopic evidence of inflammation is common even in patients with clinically and colonoscopically quiescent colitis.
AIMS & METHODS: We prospectively investigated the usefulness of a high-resolution video-magnifying colonoscope with chromoscopy for UC patients diagnosed with MH by routine colonoscopy to predict exacerbations over a long period (15 years). Magnifying colonoscopy was performed in 25 UC patients in remission who had been found to have MH by routine colonoscopy. Pit patterns in the rectal mucosa were classified into three magnifying-colonoscopy (MCS) grades on the basis of size, shape, and arrangement. Mucosal macrophage inflammatory protein (MIP)-1a activity in biopsy specimens of rectal mucosa was measured and the specimens were microscopically graded according to the system of Riley. The patients were followed until relapse or for 15 years. Multivariate survival analysis was performed to determine independent predictors of clinical relapse.
RESULTS: Of the 25 patients, 4 were MCS grade 1, 10 were grade 2, and 11 were grade 3. A positive correlation was identified among MCS grade, histological grade and mucosal MIP-1a activity. Follow-up for 15 years after the start of the study was possible in all patients. During the study 8 patients (grade 1: 0%, grade 2: 0%, grade 3: 73%), 20 patients (grade 1: 50%, grade 2: 80%, grade 3: 91%), 21 patients (grade 1: 50%, grade 2: 90%, grade 3: 91%), and 22 patients (grade 1: 75%, grade 2: 90%, grade 3: 91%) relapsed within 1, 5, 10, and 15 years, respectively. After magnifying colonoscopy, patients with MCS grade 1 relapsed later than 2 years and those with MCS grade 3 relapsed within 2 years. Multivariate proportional hazards model analysis showed that MCS grade was a significant predictor of relapse. Kaplan-Meier estimates of relapse during the 15-year follow-up increased with increasing MCS grade ($P=0.01$).
CONCLUSION: MCS grading is associated with the degree of histological inflammation and mucosal MIP-1a activity in quiescent UC patients, and may predict the probability of subsequent disease relapse in UC patients in remission over a long period.

Contact E-mail Address: *molnar.tamas@med.u-szeged.hu*

INTRODUCTION: Fecal calprotectin (CP) is a promising activity marker in the differentiation of inflammatory bowel diseases (IBD) vs. functional gastrointestinal diseases. Non-invasive activity markers are extremely important in conditions, like pregnancy, when endoscopy is not recommended to be performed. No data is available on the alteration of fecal CP concentration during pregnancy.
AIMS & METHODS: The **aim** of this study was to determine fecal CP concentrations in healthy non-pregnant and pregnant women and in patients with IBD. Healthy women planning pregnancy (waiting for in vitro fertilisation (IVF) treatment), pregnant women and patients with active and inactive IBD were prospectively enrolled in the study. Demographic and clinical parameters, clinical disease activity scores in case of patients with IBD were recorded. Blood and stool samples were obtained from every patient to determine C-reactive protein (CRP) and fecal CP levels. Fecal CP concentration was quantified by use of enzyme-linked immunosorbent assay.
RESULTS: One hundred and three subjects were enrolled in the study (19 women planning pregnancy, 21 healthy pregnant females, 40 patients with active and 23 patients with inactive IBD). Mean fecal CP and CRP levels were 32.4 μg/g and 6.5 mg/l in pregnant women. Fecal CP concentration was significantly higher in both active and inactive IBD compared to pregnant women ($p<0.001$, $p=0.001$) and also to those waiting for IVF ($p<0.001$, $p=0.001$). No significant difference was detected in CRP levels between the groups. No difference could be detected in the fecal CP concentrations between pregnant and non-pregnant healthy women.
CONCLUSION: Since fecal CP levels did not change during pregnancy, it seems to be useful noninvasive diagnostic tool in pregnancy and maybe beneficial in the future for monitoring disease activity in pregnant patients suffering from IBD. Further studies are necessary to confirm these results.

P1450 HEALTH CARE RESOURCE UTILIZATION AMONG MODERATE TO SEVERE ULCERATIVE COLITIS PATIENTS TREATED WITH CONVENTIONAL THERAPIES IN EUROPE: THE UC CARES (ULCERATIVE COLITIS CONDITION, ATTITUDE, RESOURCES AND EDUCATIONAL STUDY)

G. Van Assche[1], L. Peyrin-Biroulet[2], **T. Fan**[3,*], Q. Ding[4], N. Lara[5], M. Lynam[5], S. Rojas-Farreras[5]
[1]*University Hospitals Leuven, Leuven, Belgium,* [2]*Nancy University Hospital, Vandoeuvre-lès-Nancy, France,* [3]*Merck & Co., Inc, Whitehouse Station,* [4]*Temple University, Philadelphia, United States,* [5]*IMS Health, Barcelona, Spain*

INTRODUCTION: Ulcerative colitis (UC) is a chronic inflammatory disorder of the gastrointestinal tract and can interfere with patient's ability to have full personal and professional lives. Thiopurine immunomodulators are recommended for moderate to severe UC patients. Little data exists on health care resource utilization among UC patients treated with conventional therapies.
AIMS & METHODS: This study is to describe the health care resource utilization among moderate to severe UC patients who were biologics naïve and treated with conventional therapies (5-ASA, steroids and/or thiopurines).
Biologic naïve patients with moderate to severe UC (Mayo score $\geq$6), $\geq$18 years who received conventional therapies during the previous year were recruited in Belgium, France, Germany, Greece, Italy, the Netherlands, Spain, Sweden, Switzerland, Turkey, and the United Kingdom. Patients who underwent colectomy or ileo-anal J-pouch reconstruction were excluded. Medical charts for the 12 months prior to enrollment were reviewed to collect clinical data. Health resource utilization included the tests (imaging, diagnostics, and laboratory) and health care professional visits such as ambulatory hospitalization, emergency room visits and inpatient hospitalization. Descriptive analyses of the health resource utilization during the 12 months prior to enrollment were conducted in this post-hoc analysis.
RESULTS: A total of 250 patients were included in the analysis. Patients' mean (SD) age was 46.6 years (16.3) and 59% were male. The median duration of UC was 6.9 years (IQR 2.3-14.4). Extent of UC included 21.6% proctitis, 28.4% left-sided, and 49.6% extensive colitis. At the enrollment date, the percentages of patients receiving thiopurines, aminosalicylates, corticosteroids and other types of immunosuppressants were 63.2%, 75.2%, 23.6% and 3.6%, respectively.
During the 12 months prior to the enrollment date, only 19 (7.6%) patients had an abdominal X-Ray. In terms of diagnostic tests the most frequently reported tests were colonoscopy (18.4% of patients), flexible sigmoidoscopy (9.2%), and abdominal ultrasound (6.0%). Laboratory tests were performed on half the patients with 51.2% reporting at least one blood chemistry test and 52% at least one hematology test. Most imaging and diagnostic tests were performed once on each patient. The abdominal ultrasound and colorectal biopsy which were performed a mean (SD) of 2.27 (1.92) and 2.40 (1.15) times on each patient. Only 2.4% of patients included in the study had at least one ambulatory hospitalization, 5.6% reported at least one emergency room visit, and 4.4% at least one inpatient hospitalization. The median number of inpatient hospitalization days was 7 days (IQR 4-9).
CONCLUSION: Overall, during 12 months prior to the enrollment date, less than 20% of the patients had imaging or diagnostic tests and half of the patients had laboratory tests. Only 2-5% of the patients had at least one health resource utilization including ambulatory hospitalization, emergency room visit and inpatient hospitalization.

INTRODUCTION: Colitis-associated cancer or dysplasia (CC/D) is a very important complication that is encountered during clinical management of patients with long-standing ulcerative colitis (UC). However, it is very difficult to detect CC/D with conventional colonoscopy (CE) and image-enhanced endoscopy (IEE). The use of many endoscopic procedures such as chromoendoscopy and target biopsy has been suggested for more efficient detection of CC/D lesions, but the reliability of endoscopic detection methods remains uncertain. Recently, photodynamic diagnosis (PDD) has been utilized clinically to detect the extent of the neoplasms, especially in neurosurgical and urologic procedures. The 5-aminolevulinic acid (5-ALA) is converted intracellularly into the sensitizer protoporphyrin IX (PpIX), which accumulates selectively in neoplastic tissue, allowing the detection of its signal. As there are very few reports regarding this use of 5-ALA for UC surveillance, its effectiveness is unclear and controversial.
AIMS & METHODS: This pilot study aimed to evaluate the efficacy of PDD for endoscopic detection of dysplasia in patients with UC by visualization, using autofluorescent endoscopy (AFE), following orally administered 5-ALA sensitization. Eleven patients with a >10-year history of pancolitis were enrolled at the Jikei University Hospital from October 2010 to September 2012. Prior to this study, we confirmed that the 5-ALA metabolite PpIX was detected *in vitro* as strong fluorescence signals, using AFE (CF-FH260AZI, Olympus Medical Systems, Tokyo, Japan). The 5-ALA (20 mg/kg BW; SBI-Pharma, Tokyo, Japan) was administered orally, and conventional colon lavage was undertaken. Endoscopic examination was performed 5 h after oral 5-ALA administration. Each segment of the large intestine was first examined by CE including chromoendoscopy and then reexamined by AFE.
RESULTS: No adverse side effects of 5-ALA were observed. On examination with CE, 81 lesions were suspected and biopsied, and 18 of these were pathologically diagnosed as CC/D. During subsequent AFE, 22 lesions with strong fluorescence signals of a characteristic shape were detected and biopsied, and 14 lesions were diagnosed as CC/D on pathological examination. Positive (PPV) and negative predictive values (NPV) of CE were 22% and 71%, respectively. On the other hand, those of AFE were 68% and 91%, respectively. Among the LGD lesions, CE detected 13 of 81, and AFE detected 10 of 22 suspected lesions. The PPV and NPV of CE were 16% and 71%, and those of AFE were 45% and 92%, respectively. Although the number of HGD/cancer lesions was limited, the accuracy of CE was 13.6% and that of AFE was 78.4%.
CONCLUSION: AFE after 5-ALA sensitization offers the possibility of detecting CC/D lesions by their characteristic shape and color enhancement. Although the number of patients enrolled in this study was small, our experience indicates that AFE is a promising method for detecting CC/D lesions during UC surveillance.

INTRODUCTION: Patients with ulcerative colitis (UC) have an excess risk of cardiovascular (CVD) morbidity due to accelerated atherosclerosis. Markers identifying individuals with subclinical atherosclerosis as measured by carotid intima-medial thickness (IMT) and ankle-brachial index (ABI) may allow for attenuation of CVD risk [1]. The aim of the study was to find the possible correlations between inflammation and subclinical atherosclerosis; also, another purpose was the one to establish possible correlations between ulcerative colitis disease activity index (UCDAI), inflammation and atherosclerosis.
AIMS & METHODS: The study included 108 patients with UC (female: male 52:56, mean age 38.3 $\pm$ 12.8 years, mean disease duration 10.97 $\pm$ 1.04 years). The control group consisted of 112 healthy controls (female: male 54:58 mean age 35.4 $\pm$ 11.6). In order to detect subclinical atherosclerosis, we measured carotid IMT and ABI. The results were correlated with markers of lipid spectrum (total cholesterol, HDL, VLDL, triglycerides, and calculated LDL (using the Friedewald equation), hs CRP, homocysteine, IL-6 and fibrinogen. Clinical disease activity was evaluated by UCDAI score. Lifestyle and other important factors were examined per protocol and by questionnaire.
RESULTS: A significant difference of carotid IMT (0.843 ± 0.11 mm vs 0.625 ± 0.09 mm, $p \leq 0.01$) and ABI (0.97 ± 0.12 vs 1.1 ± 0.16, $p \leq 0.04$) were found

between the UC patients and sex-age adjusted healthy controls. A significant correlation between carotid IMT, ABI and disease duration, age, UCDAI, use of corticosteroids were found. Conventional lipids, systolic blood pressure, fibrinogen and smoking were not significantly correlated to carotid IMT and ABI. However, the correlation between carotid IMT and hsCRP was different regarding the cardiovascular risk: there was a significant positive correlation in patients with hsCRP > 3mg/l (r = 0.58; CI 95% 0.513 – 0.644) and a inverse correlation in patients with values between 1 and 3mg/l (r = – 0.27; CI 95% –0.205–0.321; p = 0.14), correlated with IL – 6 (r = 0.36; CI 95% 0.108 – 0.559), statistically significant (p = 0.03) and with homocysteine (r = 0.19; CI 95% 0.103 – 0.287 p < 0.05). A stepwise logistic regression analysis was conducted with ABI as the dependent variable and lipid spectrum, hs CRP, homocysteine, IL-6 and treatment with statins as independent variables. Following adjustment for age and gender, only the hs CRP and IL-6 remained significantly associated with ABI.
CONCLUSION: Carotid IMT and ABI measurements could be used as a clinical predictor of risk of accelerated atherosclerosis in UC patients. The association of arterial stiffening with circulating levels of hsCRP and IL-6 implicates chronic inflammation as important mediator of this process.

P1454 DIAGNOSIS OF IRON DEFICIENCY IN INFLAMMATORY BOWEL DISEASE BY TRANSFERRIN RECEPTOR-FERRITIN INDEX

V. Abitbol[1,*], D. Borderie[2], V. Polin[1], F. Maksimovic[1], A. Esch[1], M. Dhooge[1], T. Tabouret[1], J. Dreanic[1], G. Perkins[1], S. Chaussade[1]
[1]*Gastroenterology,* [2]*Biochemistry, Hôpital Cochin AP-AP, Paris, France*

INTRODUCTION: Iron deficiency (ID) is common in patients with inflammatory bowel disease (IBD) but can be difficult to diagnose in the presence of inflammation. Serum ferritin level < 30 ng/mL is a diagnostic criterion of ID. Guidelines in IBD [1] consider ferritin level between 30-100 ng/mL associated with inflammation as criteria for ID diagnostic. The sTransferrin receptor-ferritin index (TfR-F) has a high sensitivity for ID diagnosis in chronic diseases [2]. The aim of the study was to assess the added value of TfR-F index to diagnosis of ID in a prospective cohort of IBD patients.
AIMS & METHODS: All consecutive IBD patients seen in our hospital from February 2013 to March 2014 were asked to participate in the study. Exclusion criteria were iron supplementation in the 3 previous months or lack of patient consent. IBD activity was assessed on symptoms and markers of inflammation (CRP, endoscopy, calprotectin). All patients had serum dosages of hemoglobin, hsCRP (N < 2.5 mg/L), ferritin (F), transferrin saturation, vitamin B9 and B12, LDH, haptoglobin. Soluble transferrin receptor (sTfR) was measured by Roche Tina-quant®. TfR-F index was calculated as the ratio sTfR / log10 F. ID was defined by F < 30 ng/mL or TfR-F index > 2 in the presence of inflammation; TfR-F index < 1 excluded ID.
RESULTS: 150 patients aged 38 (16-78) years, 69 males, 105 Crohn's disease (CD), 43 ulcerative colitis (UC) and 2 indeterminate colitis were included. 68 patients (45.3%) had active disease. 42 patients (28%) had anemia (WHO criteria), including 28 CD and 14 UC. 9 patients (6%) had vitamin B12 deficiency and 9 (6%) vitamin B9 deficiency. No one had hemolysis. Mean F level was 80 (9-359) ng/mL and sTfR, 3.7 (1.5-12.8) mg/L. 36 patients (24%) had F < 30 ng/mL, 69 (46%) F between 30-100 ng/mL and 45 (30%) F > 100 ng/mL. 30 patients (20%) had F between 30-100 ng/mL and CRP > 2.5 mg/L: 1 had vitamin B12 deficiency excluding TfR-F analysis, 12/29 patients (41.4%) had TfR-F > 2 and 1 patient (3.5%) TfR-F < 1. Three patients (6.6%) with F > 100 ng/mL had TfR-F > 2. Overall, ID was diagnosed in 48/150 patients (32%), in which 24% on the basis of F < 30 ng/mL and 8% with TfR-F index > 2 in the presence of inflammation.
CONCLUSION: This prospective study in IBD shows that TfR-F index in addition to serum ferritin < 30 ng/mL criterion, increases by 8 % diagnosis rates of ID. Only 41.4% of the patients with ferritin between 30-100 ng/mL and inflammation have ID, suggesting that guidelines [1] overestimate ID in IBD. TfR-F index seems useful to the diagnosis of ID in IBD and prevents from overtreating by iron supplementation.

P1456 SIALIC-ACID-BINDING IG-LIKE LECTINS, POTENTIAL PERIPHERAL MARKERS FOR MUCOSAL DAMAGE OF INFLAMMATORY BOWEL DISEASE

Y. **I. Kawamura**[1,*], C. Maeyashiki[2], T. Hagiwara[1], T. Otsubo[1], J. Akiyama[2], T. Dohi[1]
[1]*National Center for Global Health and Medicine, Chiba,* [2]*National Center for Global Health and Medicine, Tokyo, Japan*

INTRODUCTION: Inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), are characterized by relapsing/remitting nature of the inflammatory process. While some cases with IBD are controllable by means of medical treatment, we encounter many cases with recurrent deterioration of disease which necessitates intensive treatment like high dose of steroid therapy, immunosuppressant or even surgery. In damaged intestinal mucosa of IBD, the mucus layer, which covers intestinal epithelial cell surface with heavily glycosylated mucin, is deteriorated and abnormally glycosylated. Recently, we reported that colonic immune cells express sialic acid-binding Ig-like lectins, siglecs, which recognize cell surface glycans preferentially expressed in normal colonic epithelium. We have speculated that the interaction of siglecs with these glycans might be involved in immune tolerance in the mucosal tissue. However, differential expression of siglecs and its regulation in the peripheral immune cells, as well as the function of siglecs in these cells, has been largely unknown.
AIMS & METHODS: The aim of this study was to investigate whether the siglecs expression of peripheral blood mononuclear cells (PBMCs) may reflect the condition of damaged/unhealed mucosa with abnormal glycosylation, and moreover, predict exacerbation of the disease. IBD patients and disease control (intestinal tuberculosis, Behcet disease (BD), and rheumatoid arthritis (RA)), and healthy volunteers were analyzed. PBMCs were isolated and the expression pattern of siglec-7/-9 was analyzed by flowcytometry.
RESULTS: Flow cytometric analysis revealed that $CD33^+$ macrophage/dendritic cells of healthy PBMCs expressed siglec-9 but not Siglec-7, while $CD33^+$ cells isolated from IBD blood frequently expressed Siglec-7. The frequency of siglec-7^+siglec-9^+ cells in $CD33^+$PBMCs of IBD patients was significantly higher than that of normal control, however; there was no difference between UC and CD. High frequency of siglec-7^+siglec-9^+ $CD33^+$ cells was not observed in intestinal tuberculosis, BD, nor RA blood, even at active stage. In IBD cases, the incidence of siglec-7^+siglec-9^+ cells in $CD33^+$PBMCs correlated with abdominal pain and ESR but not CRP, ALB, Hb, the number of WBC, neutrophils, and platelets, suggesting that inflammation is not essentially parallel to the expression of siglec-7. In fact, some UC patients in clinical remission with high frequency of siglec-7^+siglec-9^+ cells, resulted in aggravated disease several months later.
CONCLUSION: The frequency of siglec-7^+siglec-9^+ cells in $CD33^+$PBMCs of IBD patients, especially at active stage, was significantly higher than those of normal control and patients with non-IBD inflammatory disease, such as intestinal tuberculosis, BD, nor RA. These results suggest that the emergence of siglec-7^+siglec-9^+ cells in the peripheral $CD33^+$PBMCs reflects presence of the mucosal damage in an IBD-specific manner, which may be clinically cryptic without apparent sign of inflammation. Thus, it may predict exacerbation or relapse in IBD patients.

P1457 SAFETY AND EFFICACY OF LOW DOSE AZATHIOPRINE AND ALLOPURINOL CO-THERAPY: A LARGE SINGLE CENTRE EXPERIENCE

P. Stamoulos[1,*], A. Abdul-Rehman[1], C. Bull[1], M. Cowan[1], G. Mackenzie[1], J. Stenner[1], S. Coulthard[2], A. Ansari[1]

INTRODUCTION: The effectiveness of full dose azathioprine (FDA) for inflammatory bowel disease (IBD) has been questioned in recent scientific literature. A popular strategy to improve its outcomes recommends the use of low dose azathioprine with allopurinol co-therapy (LDAA) for patients profiled as "hypermethylators" (30% of non-responders).
AIMS & METHODS: Aims: The aim of this study was to determine the safety and efficacy of LDAA without using thiopurine metabolite (TM) profiling.
Methods: Records of IBD patients treated with LDAA were retrospectively analysed. Patients who had poor response and/or side-effects to FDA were offered LDAA by all consultants whilst a single IBD physician also offered LDAA to thiopurine-naïve patients. Azathioprine dose was reduced to 25% of the thiopurine methyl transferase (TPMT) adjusted dose (0.5mg/kg for wild type and 0.25mg/kg for heterozygotes) followed by conventional haematological monitoring. Non-adherence was assessed by TM measurements. Full response (FR) was defined as steroid free remission (Harvey Bradshaw index ≤3, Truelove-Witts normal) for greater than 3 months after a 3 month induction period for LDAA.
RESULTS: Of 300 LDAA patients, adequate data was available for 295 cases. Group 1 (G1) were treated 1st line (n,105) and Group 2 (G2) were switched from FDA to LDAA (n,190). Overall, for both groups, there were 207 (70%) full responders (FR), 20 partial responders (PR) and 68 non-responders (NR). Full response rate was 78% in G1 and 66% in G2. The commonest indication for switching to LDAA was non-response to FDA (n,118).

	Clinical Response (n)				
Indications for LDAA	**FR**	**PR**	**NR**	**TOTAL**	**Percentage FR**
AZA Naïve					
(LDAA without FDA exposure)	**82**	**7**	**16**	**105**	**78%**
Switched from FDA to LDAA	**125**	**13**	**52**	**190**	**66%**
Reason for switch to LDAA and outcomes					
Poor response	**81**	**10**	**27**	**118**	**69%**
GI intolerance	**16**	**0**	**11**	**27**	**60%**
Hepatotoxicity	**7**	**1**	**3**	**11**	**64%**
Myelotoxicity	**13**	**2**	**1**	**16**	**81%**
"Flu-like" symptoms	**3**	**0**	**1**	**4**	**75%**
Other	**5**	**0**	**9**	**14**	**36%**
Total	**207**	**20**	**68**	**295**	**70%**

Analysis of haematological indices revealed significant changes ($p<0.05$) in erythrocyte sedimentation rate, white cell count and platelet count after therapy induction.
Myelotoxicity occurred in 5 patients (all NR, WCC >2 and <3.5) and 12 patients had asymptomatic hepatotoxicity (ALT range: 100-700) which resolved by increasing allopurinol to 200 mg in 9 patients (all FR).
Time on treatment: 208 patients took LDAA for more than twelve months with a median length of therapy of 24 months.
CONCLUSION: Appropriately dosed LDAA therapy delivers a therapeutically effective dose of azathioprine without the need for dose escalation. It appears to be more effective, better tolerated and safer (less haematological disturbance) than FDA. These results will serve to allay the fear of toxicity of LDAA and question the need for thiopurine metabolite level profiling prior to using this apparently superior therapeutic approach.

Contact E-mail Address: *anapatriciarandrade@gmail.com*

INTRODUCTION: Endoscopic recurrence after surgery for Crohn's disease (CD) is high; 50% of patients require additional surgery. Endoscopic balloon dilation (EBD) is an alternative to surgery, but data on safety and efficacy, as well as factors associated with the need for dilatation are limited.
AIMS & METHODS: The aim of this study was to determine the efficacy and safety of EBD in patients with CD with anastomotic strictures and to evaluate the factors associated with the need for dilatation.
Cross-sectional study of patients with CD who underwent ileocolectomy (stenosis/abscess) proposed for re-evaluation and endoscopic dilation between March/2010 and February/2014. Success of EBD was defined as passage of the scope into the ileum after dilatation.
RESULTS: Endoscopic evaluation of 100 patients (52% female) with a mean age of 44 ± 13 years; median follow-up was 12 months. Thirty-eight percent of patients had anastomotic stricture, of which 34 were dilated (success rate - 89.5%). There were no complications. Thirty-two patients had Rutgeerts score≥2. Twenty patients required a second dilatation, which was performed in median 11 months after the first procedure. The success of dilation avoided the need for surgery after dilatation (3.2% *vs* 50%, $p=0.014$, OR 0.094 [95% CI 0020-0447]). Patients with perianal disease, occlusive symptoms and active smokers required dilatation earlier after the first surgery ($p=0.042$, $p=0.003$ and $p=0.019$, respectively). Patients under treatment with immunomodulators had less dilatations (23.4% *vs* 52.8%, $p=0.003$) and underwent dilatation later (7161 ± 3158 *vs* 4030 ± 648, $p<0.001$).
CONCLUSION: EBD is a safe and effective procedure and avoids the need for surgery in most patients. Perianal disease, active smoking, occlusive symptoms and no therapy with immunomodulators are associated with the need for early dilatation.

P1459 INFLIXIMAB TROUGH LEVELS AND ANTIBODIES: ACADEMIC INTEREST OR USEFULNESS IN CLINICAL PRACTICE?

P. Sousa[1,*], S. Fernandes[1], C.M. Moura[1], C. Baldaia[1], P. Moura dos Santos[1], A.R. Gonçalves[1], A. Valente[1], L. Correia[1], F. Serejo[1], J. Velosa[1]
[1]*Gastrenterologia, Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Lisboa, Portugal*
Contact E-mail Address: *patlizbms@gmail.com*

INTRODUCTION: Infliximab (IFX) has demonstrated effectiveness in inducing and maintaining remission in Crohn's Disease (CD) and Ulcerative Colitis (UC). However, not all patients respond to the therapy and some lose response over time. Low trough levels and high antibodies titers have been associated with loss of response.
AIMS & METHODS: To evaluate the usefulness of trough levels and antibodies against IFX in the clinical management of patients with CD and UC we analyzed this group of patients followed in our IBD department. IFX trough levels and antibodies were performed in patients with clinical activity despite optimal therapy. Tests were performed using ELISA (Theranostic, Lisa-Tracker®).
RESULTS: A total of 109 patients were treated with IFX. 45 patients were included (27 females; mean age 44 + 13.2 years). 39 had CD and 6 UC. Average time of IFX therapy was 48 months. 27 (60%) patients were under combined therapy with azathioprine and 10 had a previous abdominal surgery. Low IFX levels (0.01-1.5 μg/mL) were detected in 15 (33.3%) patients. 11 (24.4%) patients had detectable antibodies against IFX (5-240 UA).
Of the 11 patients with antibodies against IFX: 72.7% were on combined therapy with azathioprine, 7 (64%) had antinuclear antibodies (ANA) and 5 (45%) had anti-dsDNA. All patients presenting with anti-dsDNA (n = 5) had simultaneously antibodies against IFX.
Endoscopic evaluation around the laboratory date was performed in 17 patients and, despite normal IFX level and absence of antibodies, 5 patients didn't show endoscopic remission.
This data led to stopping IFX in 7 (15.5%) patients, dose adjustment in 12 (26.7%) and introduction of methotrexate in 2 (4.4%). Of the 7 who stopped IFX, 6 were started on Adalimumab and one on methotrexate monotheraphy.
CONCLUSION: In our study, infliximab trough levels and antibodies provided important information, leading to optimization of therapy in 47% of patients. It may demonstrate a useful tool in the management of IBD patients, especially in those with clinical or endoscopic activity despite optimized therapy. Our data suggests a link between IFX antibody formation and other antibodies especially anti-dsDNA.

P1460 WEIGHT-BASED MAINTENANCE DOSING OF GOLIMUMAB IN PATIENTS WITH MODERATE TO SEVERE ULCERATIVE COLITIS

P. Rutgeerts[1,*], W. Reinisch[2], B. Feagan[3], W. Sandborn[4], D. Tarabar[5], Z. Habzda[6], H. Weng[7], R. Yao[7], H. Zhang[8], O. Adedokun[9], C. Marano[8], R. Strauss[8]

INTRODUCTION: Given that body weight is the most significant covariate affecting golimumab (GLM) pharmacokinetics, a weight-based approach to dosing was evaluated.
AIMS & METHODS: A posthoc analysis evaluated efficacy in the PURSUIT Maintenance study by body weight (<80kg v ≥80kg; 90 and 100kg cutoffs were also evaluated). Outcomes included clinical response (≥30% and ≥3 points decrease from induction baseline Mayo score, with either a rectal bleeding subscore of 0/ 1 or a decrease of ≥1), clinical remission (Mayo score ≤2 points; no subscore >1), and mucosal healing (endoscopy subscore 0/1). The analysis included patients (pts) with moderately to severely active ulcerative colitis (UC) who were in clinical response to GLM induction therapy and were randomized (1:1:1) to receive placebo (PBO) or subcutaneous GLM 50mg or 100mg every 4 wks through wk 52. *P* values were not adjusted for multiplicity.
RESULTS: 456 pts had clinical response to GLM induction, were randomized, and included in efficacy analyses (8 pts excluded owing to site misconduct); 29% discontinued before wk 52. In the <80kg group, the percentage of pts who maintained clinical response through wk 54, remission at both wk 30 and 54, and mucosal healing at both wk 30 and 54 was generally greater for GLM than PBO; the 2 GLM dose groups had similar magnitudes of response (table). In the ≥80kg group, all outcomes were better for the 100mg dose than the 50mg dose, which had outcomes similar to the PBO group. Similar patterns of efficacy were observed using a 90kg cutoff. A 100kg cutoff was also evaluated, but very few pts had weight >100kg. Given the smaller number of pts ≥90kg or ≥ 100kg, the results should be interpreted with caution. An 80kg cutoff resulted in a greater percentage of patients achieving GLM concentrations favorable for efficacy in UC.
Table. Efficacy Outcomes by Treatment Type and Body Weight.

	Body Weight <80kg			Body Weight ≥80kg		
Outcome, n (%)	PBO n = 105	GLM 50mg n = 108	GLM 100mg n = 100	PBO n = 49	GLM 50mg n = 43	GLM 100mg n = 51
Clinical response through wk 54	31 (29.5)	53 (49.1)[b]	49 (49.0)[a]	17 (34.7)	18 (41.9)[d]	26 (51.0)[c]
Clinical remission at wk 30 and 54	15 (14.3)	28 (25.9)[c]	29 (29.0)[a]	9 (18.4)	7 (16.3)[d]	13 (25.5)[d]
Mucosal healing at wk 30 and 54	27 (25.7)	47 (43.5)[b]	41 (41.0)[a]	14 (28.6)	16 (37.2)[d]	23 (45.1)[d]

CONCLUSION: In patients with UC with body weight ≥80kg, achievement of optimal efficacy outcomes, including sustained remission, with GLM treatment was more likely with a 100mg maintenance dose than a 50mg dose. Overall, the safety profile for GLM in UC was similar to previous reports for GLM in other indications; no new adverse events were identified. P1461 AZATHIOPRINE FOR THE TREATMENT OF PERIANAL CROHN'S DISEASE

R. Meharich[1,*], M. Tahiri[1], S. Oussama[1], A. Bellabah[1], F. Haddad[1], W. Hliwa[1], W. Badre[1]
[1]*Gastroenterology, Ibn Rochd University Hospital, Casablanca, Morocco*

INTRODUCTION: Crohn's disease may be complicated by perianal disease, which can lead to faecal incontinence, abscess formation and stricturing. The management of perianal lesions is complex, with surgery often performed in conjunction with medical therapy. Thiopurines have been employed in the management of perianal Crohn's disease, although evidence of their efficacy is rare.
AIMS & METHODS: The aim of this study was to evaluate whether azathioprine healed perianal Crohn's disease.
Thirty-five patients (20 males and 15 females, mean age: 31 years) with active perianal Crohn's disease were treated with azathioprine for more than 6 months. The evolution of perianal lesions during azathioprine therapy was analyzed retrospectively. Patients who had a clear anatomic improvement (fistula closure, fissure healing, and stricture dilatation) were considered responders regarding their perianal disease.
RESULTS: There were 28 patients (80%) with an anal fistula, 13 patients (37.1%) with anal ulcerations, and five patients (14.3%) with an anal stricture. In 43% of patients, the anal manifestations preceded any evidence of intestinal disease.
Twelve patients (34.2%) required surgical drainage and three patients (8.5%) required anal dilatation.
Response to azathioprine was noted in 28 of the 35 patients (80%), with complete healing in 16 patients (45.7%). Subsequently, five patients (14.3%) relapsed to some degree on azathioprine.
CONCLUSION: Azathioprine is an effective and useful drug in the treatment of perianal Crohn's disease.

Contact E-mail Address: *r.sacco@ao-pisa.toscana.it*

INTRODUCTION: Granulocyte-monocyte-apheresis (GMA) is effective in the treatment of ulcerative colitis (UC). However, all published studies evaluated a low number of patients, with an overall limited follow-up. This observational study investigates the long-term efficacy of GMA in a large number of patients included in the Italian Registry of Therapeutic Apheresis.
AIMS & METHODS: Data of patients with mild/moderate UC treated with a standard protocol of GMA (5 sessions in 5 weeks) were evaluated. All patients had failed to respond to mesalamine or sulphasalazine, and were under steroid treatment. Clinical evaluations were performed at 3, 12 and 24 months since the end of GMA session. The following parameters were assessed: incidence of clinical remission (CAI [Colits Active Index] <4); CAI; erythrocyte sedimentation rate (ESR); c-reactive protein (CRP); white cells blood count (WBC). Endoscopical evaluations were performed at a 3-month follow-up: the incidence of endoscopical remission (EAI [endoscopical activity index] 0/1) was assessed.
RESULTS: Data for 347 patients (214 males, age 46.3 years; CAI 7.47) were available; 288 patients were either steroid-resistant or steroid-dependent. The proportion of patients with remission of disease was 66% at 3 months, 77% at 12 months and 78% at 24 months. At 24 months, all other efficacy parameters had improved from baseline: CAI (7.47 vs 3.47), ESR (35.87 vs 24.1 mm/h), CRP (4.31 vs 2.75 mg/dl) and WBC (8.61 vs 7.19) ($p<0.001$ for all comparisons). Endoscopic data were available for 107 patients. The incidence of mucosal healing was 47% and all patients with mucosal healing presented a clinical remission over the entire follow-up period. No major adverse events were reported during GMA sessions.
CONCLUSION: Data collected on a large sample of steroid-resistant or steroid-refractory patients included in the Italian Registry of Therapeutic Apheresis show that GMA is a safe and effective procedure over a long-term follow-up. Mucosal healing appears strongly associated with clinical remission.

INTRODUCTION: About 60% of Infliximab (IFX)-treated inflammatory bowel disease patients (IBD) develop anti-drug antibodies (ADA) with a sizable population suffering from loss of response (LOR). However, these antibodies were shown to be heterogeneous, some of which have no therapeutic consequences. Defining their neutralizing potential has marked therapeutic significance.
AIMS & METHODS: The aim of the study is to assess the neutralizing capability of infliximab ADA.
A biological assay in which TNF-α induced IL-8 secretion from HT-29 cells followed by application of IFX and control pooled IBD sera, or ADA-containing sera was developed. Thereafter, IL8 amplification ratio was determined for each serum relative to controls. In parallel, an immune test was developed in which the IFX concentration in a standard solution was determined before and after its incubation with ADA positive sera compared to control.
RESULTS: Forty seven infliximab ADA positive patients (43% female, 68% Crohn's disease) were tested. Of those, sera of 41 patients (87%) contained biologically active antibodies that inhibited IFX activity in both the cellular and immune models. No difference in the ability to detect the ADA neutralizing effect was noted between assays. Using the immune assay, the average IFX reduction ratio of 31 serums from patients with clinical LOR was 4.7 ± 3.1 compared to 2.1 ± 1.5 in patients without LOR ($p=0.0003$). Notably, the ADA concentration measured by anti-lambda ELISA of both groups was similar (13.9 and 11.6 μg/ml respectively $p=0.38$). Using a cutoff value of 2.5, the test had sensitivity and specificity of 77% and 72% respectively and positive and negative predictive values of 82% and 65% respectively. Antibody extraction lead to loss of the neutralizing effect in the bioassay pointing to its immune specificity. When early sera from IFX-treated patients with no detected ADA and no IFX (double negatives) obtained from patients without, or with subsequent LOR were compared, the IFX reduction ratios were 0.64 and 1.27 respectively ($p=0.01$). Sera from patients with transient antibodies who maintained clinical remission had no inhibitory effect as well (ratio of 0.55; $p=0.004$ compared to the LOR group).
CONCLUSION: Two assays for detection of neutralizing ADA were developed and compared. No advantage was found for the more complex bioassay. A predictive potential of the test was identified, allowing to identify patients prone to develop immunogenic LOR. These findings may assist in optimizing infliximab therapy in IBD patients.

P1464 5-AMINOSALICYLIC ACID IS EFFECTIVE AS REMISSION INDUCTION THERAPY IN PATIENTS WITH MODERATE TO SEVERE INTESTINAL BEHÇET'S DISEASE

R. Koh[1,*], R. Kunisaki[1], H. Kinoshita[1], H. Kimura[1], S. Maeda[2]
[1]*IBD center, Yokohama City University Medical Center,* [2]*Gastroenterology, Yokohama Citu University Hospital, Yokohama, Japan*
Contact E-mail Address: *ryonhoko@yokohama-cu.ac.jp*

INTRODUCTION: Behçet's disease (BD), the so-called silk road disease is a chronic relapsing-remitting autoimmune disorder with multiple organ system involvement characterized clinically by oral and genital aphthae, cutaneous lesions, ophthalmological, neurological, or gastrointestinal manifestations. Up to 16% of patients with BD have gastrointestinal (GI) involvement, discrete ulcerations are most often seen in the terminal ileum, caecum, and ascending colon, responsible for intestinal complications like severe bleeding and perforation. Various drugs including 5-aminosalicylic acid (5-ASA) preparations, systemic corticosteroids, and immunosuppressive agents have been applied anecdotally to treat intestinal BD. However, the clinical evidence regarding the management of intestinal BD is very limited.
AIMS & METHODS: We were interested to evaluate the efficacy and safety of 5-ASA as a remission induction therapy in patients with intestinal BD, in a retrospective cohort study. Data were obtained using a retrospective chart review of 54 consecutive patients with intestinal BD who were visiting a single centre in Japan between 2004 and 2013. The patients were clinically and endoscopically evaluated before treatment, then assessed after 12 weeks for a clinical response to 5-ASA, defined as a significant improvement of intestinal symptoms, and a reduction in C-reactive protein (CRP) level, as well as the disease activity index for intestinal BD (DAIBD). Clinical remission was defined as complete disappearance of GI symptoms, including abdominal discomfort, GI bleeding and diarrhoea, followed by normalization of serum CRP level. Clinical response was defined as a significant improvement in GI symptoms accompanied by a lower CRP level. To determine factors predictive of clinical response to 5-ASA therapy, we used the chi squared test for nominal variables and the t-test for continuous variables. We also assessed adverse events during 5-ASA therapy.

RESULTS: A total of 13 patients were treated for active intestinal BD with oral 5-ASA as remission induction therapy. Their average age was 26 years at the diagnosis of BD and 34 years at the initiation of 5-ASA therapy. The response rate was 77.0% (remission 30.8%, response 46.2%). Young age, high disease activity at the initiation of 5-ASA therapy, and short disease duration up to the initiation of 5-ASA were predictors for good clinical response to 5-ASA ($P < 0.05$). There was no severe adverse event warranting cessation of 5-ASA therapy.
CONCLUSION: In this study, 5-ASA as remission induction therapy was effective and safe in patients with moderate to severe intestinal BD. Further, use of 5-ASA as first-line medication in this clinical setting is potentially interesting as it spares the patients from exposure to stronger drugs with safety concerns.

INTRODUCTION: Parthenolide (PT), a NF-kB inhibitor, has recently been demonstrated as a promising anticancer agent that promotes apoptosis of cancer cells. We previously showed that PT suppresses tumor growth in a xenograft model of colorectal cancer cells by regulation of Bcl-2 family. Unfortunately, little is known about its role in the process of tumor development in colitis associated colon cancer (CAC).
AIMS & METHODS: Therefore, this study was designed to investigate the effects of PT on an experimental murine CAC model. Experimental CAC was induced by azoxymethane (AOM) and dextran sulfate sodium (DSS). Mice were divided into 3 groups: AOM+DSS, AOM+DSS+2mg/kg PT and AOM+DSS+4mg/kg PT.
RESULTS: We demonstrated that administration of PT significantly reduced the severity of AOM/DSS-induced CAC as assessed by histological analysis, and resulted in downregulation of phospho-NF-κB p65 expression by the blockade of phosphorylation and subsequent degradation of IκB-a. Administration of PT ameliorated the carcinogenesis through the downregulation of antiapoptotic protein Bcl-2 and Bcl-xL mediated by inhibition of NF-kB activation. Moreover, apoptosis and caspase-3 expression also increased markedly in PT administration group.
CONCLUSION: These findings demonstrate that PT downregulates NF-kB resulting in initiation of apoptosis and eventual suppression of CAC development, suggesting that PT exerts beneficial effects in experimental CAC and could therefore be a potential chemopreventive and therapeutic agent of CAC.

INTRODUCTION: Vercirnon (previously called CCX282-B or Traficet-EN) is an oral, specific C-C chemokine receptor 9 inhibitor that has been studied in Crohn's disease (CD). A Phase 2b clinical trial, PROTECT-1, showed evidence of activity of vercirnon in patients with moderate to severe Crohn's disease. A subsequent Phase 3 trial, SHIELD-1, failed to confirm efficacy. The data from the two trials were examined to determine the potential source for the contrasting outcomes.
AIMS & METHODS: Both trials were randomized, double-blind, placebo controlled. SHIELD-1 recruited 608 and PROTECT-1 436 subjects world-wide; the latter excluded the USA. In SHIELD-1, subjects had CDAI 220-450, and endoscopically confirmed disease, or an elevated CRP and fecal calprotectin. Subjects received placebo, 500 mg QD or BID vercirnon for 12 weeks. In PROTECT-1, entry criteria were CDAI 250-450 and CRP $\geq$7.5mg/L. Subjects received placebo or CCX282-B 500 mg QD, 250 mg QD or BID for 12 weeks. Key endpoints: CDAI $\geq$100-point response, CDAI remission, and CDAI $\geq$70-point response.
RESULTS: Areas of differences between the two trials are summarized in the table.
Table to abstract P1466

	PROTECT-1 (N = 436)	SHIELD-1 (N = 608)
Prior TNF inhibitor use	26%	69%
CDAI median (range)	330 (249-471)	317 (123-450)
CRP (mg/L) median (range)	22 (3-200)	14 (0.2-157)
Drop-out rate	16%	25%
Gastrointestinal adverse events	Placebo: 40%, 500 mg QD: 41%	Placebo: 30%, 500 mg QD: 37%, 500 mg BID: 48%
Abdominal pain	Placebo: 13%, 500 mg QD: 12%	Placebo: 7%, 500 mg QD: 9%, 500 mg BID: 11%
Diarrhea	Placebo: 8%, 500 mg QD: 7%	Placebo: 1%, 500 mg QD: 4%, 500 mg BID: 5%
Vomiting	Placebo: 4%, 500 mg QD: 3%	Placebo: 2%, 500 mg QD: 6%, 500 mg BID: 9%

The most significant difference was the higher incidence of prior TNF inhibitor use in SHIELD-1 (69%) compared to PROTECT-1 (26%). Also, PROTECT-1 enrolled patients with more severe disease at baseline (CRP and CDAI higher). Lastly, more GI adverse events were found in SHIELD-1, in particular at the highest dose, 500 mg BID, which was not tested in PROTECT-1.
In the 244 patients from SHIELD-1 who would have met entry criteria for PROTECT-1, i.e., CDAI 250-450 and CRP $\geq$7.5 mg/L, the CDAI $\geq$100-point response at Week 12 was 31%, 45%, and 28% in the placebo, 500 mg QD, and BID groups, respectively. CDAI remission was 13%, 21%, and 9%, respectively, and CDAI $\geq$70-point response was 38%, 56% ($p = 0.02$ vs. placebo), and 39%, respectively. These results suggest activity at the 500 mg QD dose, shown efficacious in PROTECT-1. The higher 500 mg BID dose was associated with a higher incidence of GI AEs (see table), which may increase the CDAI.
CONCLUSION: PROTECT-1 and SHIELD-1 enrolled patient populations that differed mostly in terms of prior TNFI use, disease activity at baseline, and GI AEs. These differences, may at least partly account for the divergent outcomes.

P1467 DISSOLUTION OF COMMERCIALLY AVAILABLE 5-AMINOSALICYLIC ACID (5-ASA) FORMULATIONS AT VARIOUS PH LEVELS

S. tenjarla[1,*]
[1]*Pharmaceutical Sciences, Shire, Wayne, PA, United States*

INTRODUCTION: Ulcerative colitis (UC) is a chronic inflammatory condition that can affect any part of the colon and is characterized by relapsing–remitting gastrointestinal (GI) and systemic symptoms. Treatment with 5-ASA, a topical, locally acting compound that reduces inflammation of the colonic mucosa, is recommended as first-line therapy in patients (pts) with active mild-to-moderate UC. Minimum systemic absorption in the upper GI tract is desired in order to maximize the amount of drug available for local action in the colon. Thus, many 5-ASA formulations employ a pH-dependent release mechanism, designed to dissolve in the more basic environment of the distal small intestine. The pH levels in the GI tract of pts with UC may be lower and more variable than that of unaffected individuals. This in vitro study compared the release of mesalazine from multimatrix mesalazine (Mezavant® XL; Shire Development LLC, USA) and 5 other commercially available 5-ASA formulations.
AIMS & METHODS: The release of 5-ASA from 12 tablets each of multimatrix mesalazine 1.2 g, Mesalazin-Kohlpharma 500 mg (Kohlpharma, Germany), Mesalazin-Eurim 500 mg (Eurimpharm, Germany), Claversal 500 mg (Faes Farma, Spain), Mesalazine EC 500 mg (Actavis, Netherlands), and Mesalazine EC 500 PCH 500 mg (Pharmachemie, Netherlands) was monitored separately at 3 different pH conditions using United States Pharmacopeia dissolution apparatus II, with a paddle speed of 100 rpm. Tablets of each formulation were individually exposed to dissolution medium at pH 1 for 2 h, pH 6.4 for an additional 1 h, and pH 7.2 monitored until complete drug release. After the first 2 h, samples were collected every hour and analyzed by UV spectroscopy at 330 nm. The dissolution percentage was calculated as a mean of 12 units for each formulation.
RESULTS: At pH 1 and pH 6.4, <1% 5-ASA release was observed for each of the 5-ASA formulations. Dissolution profiles for each of the formulations at pH 7.2 (after exposure to pH 1 for 2 h and pH 6.4 for 1 h) are shown in the **Table**. At pH 7.2, 5-ASA was completely released from all generic 5-ASA formulations in about 2 h. Release of 5-ASA from multimatrix mesalazine occurred in a sustained manner over 7 h.

Time at pH 7.2, h	Mesalazin-Kohlpharma 500 mg (% dissolution)	Mesalazin-Eurim 500 mg	Claversal 500 mg	Mesalazine EC 500 mg	Mesalazine EC 500 PCH 500 mg	Multimatrix mesalazine 1.2 g
0	<1	<1	<1	<1	<1	<1
1	36	26	51	102	103	8
2	102	100	101	101	103	26
3	102	101	101	101	103	43
4	102	101	101	101	103	63
5	102	101	101	101	103	84
6	102	101	101	101	102	98
7	102	101	101	101	102	102
8	102	101	101	101	102	102

CONCLUSION: Results of this in vitro study indicate little to no drug release at more acidic pH conditions for all products. At pH 7.2, differences in the respective dissolution profiles suggest that multimatrix mesalazine would result in roughly 5 more hours of sustained release of the drug compared with any of the other examined commercially available 5-ASA formulations.

INTRODUCTION: OPTIMUM study was set up in France in 2011. Its objective was to describe the progression and methods of therapeutic management of mild to moderate ulcerative colitis (UC), to assess remission rate, duration of remissions and prognostic factors for relapse in patients with a flare-up.
AIMS & METHODS: From June 2011 to June 2012, 812 patients over 18 years of age with a mild to moderate flare-up of UC (51% women, average age of 45 ± 15 years) were included in the observational study by 130 gastroenterologists (64% office based). A three-years monitoring is planned. The time period selected for a visit to one year is 365 ± 100 days after the inclusion visit.
RESULTS: In July 2013, the one-year visit data (time period of 369 ± 42 days) was available for 504 patients (62%); 419 (83%) were in remission during the first year. According to the UCCS score (Ulcerative Colitis Clinical Score), at one-year visit, 397 (79%) patients were in remission, 67 (13%) had mild activity and 33 (7%) had moderate activity. Remission was achieved after a median period of 59 days (95% CI [53–77 days]) after the inclusion consultation. At the end of the visit, treatment with 5-ASA alone was prescribed in 479 patients (59%), treatment combining 5-ASA and another UC treatment in 175 patients (22%) and another UC-treatment not including 5-ASA in 99 patients (12%). The UC treatment at the period of remission was the one prescribed at the end of the inclusion visit in 366 patients (87%). After adjusting for the UCCS score and the level of injury at visit, the patients treated solely with 5-ASA at the end of the inclusion visit were in remission faster than the patients treated without 5-ASA ($p = 0.013$); but the difference with patients treated with 5-ASA in combination with another treatment was not statistically significant ($p = 0.062$). At one year, the remission rate was 82.5% (95% IC [78.0%–86.6%]) in the group treated with 5-ASA alone prescribed at the end of the inclusion visit vs 71.4% (95% IC [64.0%–78.4%]) in the group treated with 5-ASA in combination with another treatment. At the one-year visit, a UC treatment was in on going in 426 patients (84%). Compliance was good in 92 of 394 patients (23%). In total, at least one adverse event was reported in 15 patients (3%). Colorectal cancer or dysplasia was diagnosed in three patients (0.6%).
CONCLUSION: During treatment, the period of remission of mild to moderate UC flare-up is about two months. After one year of monitoring, about 80% of patients are in remission. The continuation of the OPTIMUM observational study will help refine these results and, in particular, analyse possible relapses over three years of monitoring.

INTRODUCTION: POLARIS, a cross-sectional study employing paper-based questionnaires, assessed treatment patterns from the patients with Crohn's disease (CD) and their health care providers (HCPs). We assessed the concordance in patients and their HCPs' responses regarding the use of steroids, immunosuppressants, and biologics.
AIMS & METHODS: Surveys were administered at inflammatory bowel disease (IBD) centres and community practices in Canada and Germany. Patients ≥18 years old with a confirmed diagnosis of CD, disease duration ≥1 year and ≥2 visits with a participating HCP (consulting gastroenterologist, nurse practitioner, or physician's nurse) were eligible. Patients and their HCPs provided information on steroid use (oral steroids excluding budesonide), steroid monotherapy use, long-term (≥3 months) use of steroids, long-term use of steroid monotherapy, immunosuppressant use, and biologics use. Data were summarised overall, and by IBD centres and community practices using descriptive statistics. Agreement between patients' and HCPs' responses to survey questions was tested using kappa statistics.
RESULTS: Surveys from 809 patients and 798 HCPs were available for this analysis. Overall, a greater percentage of patients vs. HCPs reported use of any steroid (25.9% vs. 20.8%, kappa = 0.735), steroid monotherapy (4.4% vs. 3.7%, kappa = 0.514), long-term steroids (67.7% vs. 63.8%, kappa = 0.598), and long-term steroid monotherapy (11.6% vs. 7.2%, kappa = 0.433). It should be noted that the agreements between patients and HCPs were much lower in community practices than in IBD centres in all measures: use of any steroid (kappa = 0.609 vs. 0.781), steroid monotherapy (0.425 vs. 0.575), long-term steroid use (0.263 vs. 0.663), and long-term steroid monotherapy (0.250 vs. 0.520). Overall, responses from patients and their HCPs were similar regarding use of immunosuppressants (52.4% vs. 51.1%, kappa = 0.784) and biologics (49.5% vs. 47.0%, kappa = 0.909) with lower agreements observed in community practices than in IBD centres (use of immunosuppressants: kappa = 0.715 vs 0.807; use of biologics: kappa = 0.861 vs. 0.928).
Medication Use for CD in Past 12 Months.

	IBD Centres				Community Practices			
	HCPs		PTs		HCPs		PTs	
	N	%	N	%	N	%	N	%
Any steroid used	550	22.4	546	27.3	249	17.3	229	22.7
Steroid monotherapy	547	2.7	539	3.5	247	5.7	207	6.8
Long-term (≥3 months) steroid use	116	61.2	141	64.5	36	72.2	48	77.1
Long-term (≥3 months) steroid monotherapy	116	6.0	141	8.5	36	11.1	48	20.8
Immunosuppressant use	557	57.1	551	56.1	251	37.9	232	43.5
Biologics use	558	51.4	558	52.9	251	37.1	240	41.7

CONCLUSION: Results of this cross-sectional survey revealed a discordance between patients and their HCPs regarding the long-term use of steroids. The discordance was more severe in community practices than in IBD centres. These findings suggest a need to improve the care management, e.g., more coordinated follow-up visits by patients, or enhanced communication between patients and their HCPs.

P1470 DIFFERENT METHODOLOGIES FOR DETERMINING MAYO SCORE IN CLINICAL STUDIES CAN INFLUENCE DISEASE ACTIVITY ASSESSMENTS IN ULCERATIVE COLITIS

S. Ghosh[1,*], W. Sandborn[2], J. Panés[3], G. D'Haens[4,5], N. Reilly[6], A. Lazar[7], B. Huang[6], A.M. Robinson[6], R. Thakkar[6]

Center, Amsterdam, Netherlands,* [6]*AbbVie Inc, North Chicago, United States,* [7]*AbbVie Deutschland GmbH & Co, KG, Ludwigshafen, Germany*
Contact E-mail Address: *anne.robinson@AbbVie.com*

INTRODUCTION: There is no standard method to determine stool frequency (SFS) and rectal bleeding (RBS) subscores of the Mayo score in ulcerative colitis (UC) clinical trials. In adalimumab (ADA) clinical trials, SFS and RBS were calculated using the worst value from 3 days of patient diary entries (ie, worst-rank methodology).[1,2] Other clinical trials in UC have calculated RBS and SFS using the average of each subscore from the past 3 days of patient diary entries.[3,4] Recently, data from a placebo-controlled study of ADA in Japanese patients suggested that the Mayo subscore calculation method used can influence the effect size of remission rates by several percentage points.[5] The impact of the use of different Mayo score determination methods on Mayo scores in ULTRA 2[2] has not been described.
AIMS & METHODS: In this exploratory analysis, we evaluated the impact of worst vs average score methodology for SFS and RBS by recalculating Mayo scores in ULTRA 2 using the average scoring methodology for patients from sites with readily-available daily diary data. In ULTRA 2, adults with UC and a Mayo score of 6–12 with endoscopy score ≥2 were randomised to ADA (160 mg/80 mg at wks 0/2 followed by 40 mg every other wk to Wk 52) or placebo (PBO).[2] Daily diary data of 16 patients who completed the Wk 52 study visit on their originally randomised treatment (PBO: n = 7; ADA: n = 9) were evaluated. Means for full Mayo scores (FMS) at baseline and Wk 52 were recalculated using the average of daily SFS and RBS from the 3 prior days and compared to FMS obtained using the worst-rank methodology. For the average calculations, SFS and RBS were rounded to the nearest integer.
RESULTS: Average scoring methodology led to greater reduction in mean FMS from baseline to Wk 52 than worst-rank methodology in ADA-treated patients compared to PBO-treated patients (**Table**). The absolute difference in change in FMS from baseline to Wk 52 between ADA and PBO was 0.59 points greater using average scoring methodology than worst-rank methodology.

	ADA (n = 9)			PBO (n = 7)			Absolute difference between overall Δ of ADA and PBO
	FMS		Δ	FMS		Δ	
Methodology	**Baseline**	**Wk 52**		**Baseline**	**Wk 52**		
Worst	9.11	2.89	6.22[a]	9.57	4.29	5.28[a]	
Average	9.00	2.33	6.67[a]	9.00	3.86	5.14[a]	
Overall Δ			−0.45[b]			0.14[b]	0.59

Δ, difference between scores. [a]Difference between baseline and Wk 52. [b]Difference between Δ of worst-rank and average scores.

CONCLUSION: These preliminary results suggest that differences between Mayo scores calculated using worst-rank vs average scoring methodology for SFS and RBS may have a disproportionate effect between active treatment and PBO arms. These results should be confirmed in larger and more diverse data sets.

INTRODUCTION: Early and increasing use of Immunomodulators (IM) and biological agents in IBD can lead to an increase in the risk of opportunistic infections (OI). The RR of OI is 2.9 with one IM and increases to Odds ratio of 14.5 with ≥2 concomitant IMs. Age (>50 years) is an independent risk factor for OI. Vaccinations are recommended by the European Crohn's and Colitis Organisation (ECCO) to minimise OI in immunocompromised IBD patients after initial screening.

The current recommendation is to screen for Varicella Zoster Virus (VZV), latent or active Tuberculosis (TB) and Hepatitis-B and to administer annual inactivated Influenza vaccine, Pneumococcal (0 & 5 year) and Hepatitis-B (if seronegative) vaccinations. Swine Flu vaccination was also recommended following the outbreak in 2009.

AIMS & METHODS: Retrospective data was collected on the serology status for Hepatitis-B, Hepatitis-C, Varicella zoster and T-spot/ IGRA of our patients receiving biologics from pathology results reporting system. Chest X-rays were picked up from PACS, BCG vaccination status and history of Chicken pox was obtained from the clinic letters.

Information about vaccination status was obtained by contacting the general practioners, directly from patients visiting for their infliximab infusions and IBD MDT minutes.

RESULTS: Retrospective data from our 144 patients (70 (48%) female and 74 (52%) male) showed a total of 479 patient years of biologics exposure (infliximab-319 and adalimumab-160) in our cohort of Crohns 112 (78%) and Ulcerative colitis 32 (22%) patients. Combination therapy (Biologics and IM) was noted in 48 (33%) (45 azathioprine and 3 methotrexate) and biologic monotherapy in 98 (67%) patients.

TB screening with IGRA was done in 144 (100%) and CXR in 53 (37%). Hep B, Hep C and VZV serology/history of chicken pox was noted in 26 (18%), 19 (13%) and 12 (8%) respectively.

Yearly flu vaccination was given to 16% of the patients and pneumococcal vaccine was administered in less than 11% of patients.

CONCLUSION: Relevant serological screening and appropriate vaccination history pre-IM therapy was available in a minority of patients only. This may represent either non/poor-adherence to ECCO guidelines or poor documentation. Information leaflets on the ECCO-recommended vaccines directed at GPs and patients may improve compliance. Adoption of IBD registry will enable clinicians and IBD nurses to empower patients with relevant personalised information delivered at diagnosis and during the course of their treatment. This may increase the appropriate screening and vaccination of these patients at highest risk of developing opportunistic infections.

P1472 TIME TO SYMPTOM RESOLUTION IN PATIENTS WITH ULCERATIVE COLITIS ON MULTIMATRIX MESALAZINE TREATMENT: A POOLED ANALYSIS

S.D. Silva Sanchez[1,*], H. Wan[2]
[1]*Shire, Brussels, Belgium,* [2]*Shire, Wayne, PA, United States*
Contact E-mail Address: *sdasilva@shire.com*

INTRODUCTION: Ulcerative colitis (UC) is a chronic inflammatory bowel disease characterized by relapsing-remitting symptoms of abdominal pain, stool urgency, and rectal bleeding. While endoscopic remission is the ultimate treatment goal for patients with UC, alleviation of clinical symptoms (mainly rectal bleeding and stool frequency) is a signal that physicians can use to assess remission status. Improvements in UC symptom scores have also been shown to correlate with improvements in patients' quality of life. Mesalazine (5-aminosalicylic acid; 5-ASA) is standard first-line therapy for treatment of mild-to-moderate UC. This study examined pooled data from several clinical trials of multimatrix mesalazine, a once-daily (QD) formulation of 5-ASA, in patients with UC to assess time to symptom resolution in acute treatment, and for those achieving clinical remission, the proportion of patients remaining in remission after 12 months of maintenance treatment.

AIMS & METHODS: Data from three phase 3 (NCT00503243; NCT00548574; NCT00151944) and two phase 4 (NCT00446849; NCT01124149) trials were pooled for this analysis. During acute treatment, patients were randomized to receive either placebo or multimatrix mesalazine 2.4 g/day QD or twice-daily (BID), or 4.8 g/day QD or BID for a period of 8 weeks. All patients achieving symptom resolution (scores of 0 for both stool frequency and rectal bleeding on a modified UC Disease Activity Index on each of the last available 3 days immediately prior to a study visit) by the end of the acute phase were eligible for 12 months of continued treatment with multimatrix mesalazine 2.4 g/day in a maintenance phase. In 1 study (NCT01124149), those in partial remission (including combined scores ≤1 on stool frequency and rectal bleeding) at the end of the acute phase were also allowed to enroll in the maintenance phase; however, those patients were excluded from the pooled maintenance phase analysis.

RESULTS: In the acute phase, median (95% confidence interval) time to resolution for placebo and multimatrix mesalazine 2.4 g/day, 4.8 g/day, and 2.4 + 4.8 g/day, respectively, for stool frequency symptoms was: 52 days (45, not estimable

[NE]); 33 days (23, 46); 38 days (35, 43); and 38 days (34, 41). For rectal bleeding, median time to resolution was: 35 days (20, NE); 14 days (12, 18); 16 days (14, 17); and 15 days (14, 17). For stool frequency and rectal bleeding combined, median time to resolution was: NE (56, NE); 41 days (30, 48); 45 days (42, 50); and 45 days (41, 48). Of those who achieved symptom resolution at the end of acute phase, the following percentages of patients maintained scores of 0 after 12 months of maintenance treatment: 68.2% (462/677) for stool frequency; 68.3% (721/1055) for rectal bleeding; and 67.4% (438/650) for combined symptoms.
CONCLUSION: Overall, acute phase treatment with multimatrix mesalazine (either dose) led to symptom resolution in a shorter time compared with placebo (38 vs 52 days for stool frequency; 15 vs 35 days for rectal bleeding). In addition, more than 6 in 10 patients were able to maintain symptom resolution after 12 months of maintenance treatment with multimatrix mesalazine.

INTRODUCTION: Proteoglycan (PG) is a component of extracellular matrix materials that exist in connective tissues, such as skin, bone, cartilage and vascular wall. PG has been reported to potently suppress the inflammatory responses induced by heat-killed *Escherichia coli* in mouse macrophages.
AIMS & METHODS: We aimed to evaluate the efficacy and safety of oral PG intake in the treatment of ulcerative colitis (UC). In a placebo-controlled, double-blind study, 40 patients with UC were randomized into either a PG group or a placebo group for 8 weeks. PG was extracted from salmon nasal cartilage. All patients were treated with conventional medications prior to entry. Colonoscopy was done before and at the end of 8 weeks of treatment. Efficacy of treatment was assessed from clinical symptoms using the clinical activity index (CAI), which covers stool consistency, rectal bleeding, abdominal pain and global assessment, with a maximum score of 20. Endoscopic findings were assessed using the endoscopic index (EI), which is derived from a 12-point scale from observations at the most severe area of disease involvement within the area 5–15 cm from the anal verge.
RESULTS: EI scores significantly decreased ($P < 0.05$) in patients in the PG group, but showed no significant change in patients in the placebo group. CAI score significantly ($P < 0.05$) improved among patients with mild UC (CAI score < 6 at enrollment). No side effects were noted in any patient in either the PG or placebo group.
CONCLUSION: PG was safe and useful in these patients with UC as an additional therapy to conventional therapies, particularly in those at the mild stage.

P1474 THE IMPACT OF MUCOSAL HEALING ON SUBSEQUENT CLINICAL COURSE IN THE MANAGEMENT OF ULCERATIVE COLITIS: A PROSPECTIVE OBSERVATIONAL STUDY

T. Yamamoto[1,*], M. Shiraki[1], K. Matsumoto[1]
[1]*Inflammatory Bowel Disease Centre, YOKKAICHI HAZU MEDICAL CENTRE, Yokkaichi, Japan*

INTRODUCTION: In clinical trials of ulcerative colitis (UC), mucosal healing (MH) has been achieved with medical treatment such as 5-aminosalicylates (5-ASAs), corticosteroids, immunosuppressive drugs, and biologic agents. However, clinical implications of MH remain unclear.
AIMS & METHODS: This study was to prospectively evaluate the impact of MH on the subsequent clinical course in the management of UC. We included 112 UC patients who achieved clinical remission (normal stool frequency and no rectal bleeding) with medical treatment (5-ASAs, corticosteroids, leukocytapheresis, immunosuppressants, and/or biologics), and who underwent endoscopic examination when the clinical remission was confirmed. MH was defined as a Mayo endoscopic subscore of either 0 (no lesions) or 1 (mild activity). All patients were followed up for $>$ 1 year.
RESULTS: Of the 112 patients, 62 (55%) achieved MH and 50 (45%) did not. During the 1-year follow-up, 74 patients (66%) maintained clinical remission, while 38 patients (34%) relapsed. Overall, the clinical remission rate was significantly higher in patients who achieved MH (52/62, 84%) than in those who did not (22/50, 44%) ($p = 0.00001$). In a subgroup analysis of patients who received 5-ASA for remission maintenance therapy, the clinical remission rate was significantly higher in patients with MH (25/32, 78%) than in those without MH (13/32, 41%) ($p = 0.002$). Similarly, among patients who received immunosuppressive drugs and/or biologic agents during maintenance therapy, the clinical remission rate was significantly higher in patients with MH (27/30, 90%) than in those without MH (9/18, 50%) ($p = 0.002$).
CONCLUSION: Patients who achieve clinical remission with MH have a reduced risk of future clinical relapse as compared with those without MH in the management of UC.
Disclosure of Interest: None declared

INTRODUCTION: Adalimumab is a relatively new therapeutic option in ulcerative colitis (UC). After the ULTRA trials only a few data have been published from the real clinical practice.
AIMS & METHODS: The aim of this study was to prospectively follow the disease course in adalimumab-treated UC patients in Hungary. Primary endpoints were the remission and response rates at week 12 and 30; while secondary endpoints were the changes of C-reactive protein (CRP) levels and the clinical symptoms during the therapy.79 patients who was treated with adalimumab at 10 tertiary Hungarian IBD centres were prospectively enrolled from May 2013 [male/female: 43/36; mean age: 41.7 years (in range: 19-68 years)]. 65.8% of the patients previously received infliximab therapy. Switch to adalimumab in these patients was due to loss of response or intolerance. Clinical data, partial Mayo (pMayo) score and CRP levels were collected at the beginning of adalimumab therapy, at week 12 and at week 30. Colonoscopy was performed before drug administration. Endoscopic Mayo subscore was used to assess the mucosal activity. Clinical remission was defined as $\leq$2 points in pMayo score; response to adalimumab was specified as decreasing 3 or more points.
RESULTS: Adalimumab induction was administered at doses of 160 mg and 80 mg at week 0 and week 2. The mean value of Mayo score at the beginning of adalimumab therapy was 9.7 points. The mean values of pMayo subscores and CRP were 3.5 points, 6.6 mg/l at week 12, and 3.2 points, 7.8 mg/l at week 30, respectively. CRP levels and pMayo subscores decreased significantly at week 12 ($p < 0.001$, $p < 0.001$), and at week 30 remained significant also ($p = 0.027$, $p < 0.001$). Remission, response and non-response rates were 28.8 %, 43.9%, and 27.3% at week 12, and remission, response, loss of response rates were 50%, 40.9% and 9.1% at week 30. No significant difference was detected between patients previously treated with biologicals or naive to them. In addition, we did not find significant association between previous infliximab use and frequency of adalimumab side effects. Adalimumab therapy needed to be discontinued in 12 subjects.
CONCLUSION: Our results suggest that adalimumab is an effective drug for the induction of remission and for the maintenance therapy of UC.

P1476 SENSITIVITY ANALYSES OF DISEASE CONTROL AMONG MODERATE TO SEVERE ULCERATIVE COLITIS PATIENTS TREATED WITH CONVENTIONAL THERAPIES IN EUROPE: THE UC CARES (ULCERATIVE COLITIS CONDITION, ATTITUDE, RESOURCE AND EDUCATIONAL STUDY)

G. Van Assche[1], L. Peyrin-Biroulet[2], **T. Fan**[3,*], M. Lynam[4], S. Rojas-Farreras[4], Q. Ding[5]
[1]*University Hospitals Leuven, Leuven, Belgium,* [2]*Nancy University Hospital, Vandoeuvre-lès-Nancy, France,* [3]*Merck & Co., Inc, Whitehouse Station, United States,* [4]*IMS Health, Barcelona, Spain,* [5]*Temple University, Philadelphia, United States*

INTRODUCTION: A large proportion of moderate to severe ulcerative colitis (UC) patients rely on conventional therapies (5-ASA, steroids and/or thiopurines) to maintain remission. However, use of UC therapies among biologic naïve patients varies considerably in clinical practice, and it is unknown whether disease is well controlled.
AIMS & METHODS: This analysis is to comprehensively describe rates of disease control in moderate to severe UC patients who were biologics naïve and treated with conventional therapies.
Biologics-naïve patients with moderate to severe active UC (Mayo score $\geq$6), aged $\geq$18 years who received conventional therapies during the 12 months prior to enrollment were recruited from 11 European countries. Patients who underwent colectomy procedure or ileo-anal J-pouch reconstruction were excluded. Medical charts for the 12 months prior to enrollment were reviewed to collect clinical data. The primary endpoint was disease control, defined as maintaining remission status, measured by full or partial Mayo scores, and patients had to have no corticosteroid use the 2 months prior to enrollment.
Sensitivity analyses were conducted according to the criteria whether the patients had thiopurines for at least 4 months in 12 months prior to enrollment and the timeline (within 2 weeks vs. 2 weeks before; winthin 1 month vs. 1 month before) when endoscopy was taken for the patients.
RESULTS: A total of 250 patients were included in the final analysis. Patients' mean age was 46.6 (SD = 16.3) and 59% were male. The median duration of UC was 6.9 years (IQR 2.3-14.4). Extent of UC included 21.6% proctitis, 28.4% left-sided, and 49.6% extensive colitis. At the enrollment date, the percentages of patients receiving thiopurines, aminosalicylates, corticosteroids and other types

of immunosuppressants were 63.2%, 75.2%, 23.6% and 3.6%, respectively. According to the study definition, 87.2% of patients did not achieve disease control. Specifically, 87.3% of patients (55 out of 63) with endoscopy score within the 2 weeks prior to enrollment and 87.2% of patients (163 out of 187) with endoscopy score more than 2 weeks prior to enrollment had uncontrolled disease ($p = 0.98$). In addition, 86 out of 98 patients (87.8%) with endoscopy score within 1 month prior to enrollment and 132 out of 152 patients (86.8%) with endoscopy score more than 1 month were not in disease control ($p = 0.83$). Patients who had thiopurines for at least 4 months in 12 months prior to enrollment had numerically higher percentage of uncontrolled UC (89.1% vs. 85.9%, $p = 0.46$)

CONCLUSION: The majority of biologics naïve UC patients (87%) were not under control. Sensitivity analyses show that patients who had thiopurines for at least 4 months in 12 months prior to enrollment had numerically higher percentage of uncontrolled UC, but not significant difference. Disease control did not vary much according to the time of endoscopy measurement, noting that patients who had more than one endoscopy may be counted in each applicable group.

INTRODUCTION: The Japanese diagnostic criteria for Behcet's disease (BD) define it as a systemic inflammatory disorder characterized by 4 hallmark symptoms (recurrent oral aphthosis, skin symptoms, ocular symptoms, and vulvar ulceration), which can coexist with other accessory/variant symptoms (such as arthritis) that develop metachronously. BD is categorized as complete, incomplete, or suspected according to the extent of this symptom tetrad, while BD with ileocecal ulcer, vascular, and/or nervous system involvement is categorized under special types. That is, if ileocecal ulcer, vascular, or neurological symptoms are present in patients with BD, the disease is classified as gastrointestinal BD, vascular BD, or CNS-BD, respectively. Gastrointestinal lesions associated with Behcet's disease typically develop in the ileocecal ulcer, but atypical gastrointestinal lesions also often occur. This article presents our patients who had BD with esophageal ulcers, which is an atypical gastrointestinal lesion, and outlines the clinical and endoscopic features of their esophageal involvement.

AIMS & METHODS: At our hospital, 33 patients were diagnosed as having BD with gastrointestinal lesions and drug-induced mucosal injury was ruled out (sex ratio = 17:16; 3 patients with complete BD, 25 patients with incomplete BD, and 5 patients with suspected BD; special types = 14 with gastrointestinal BD, 3 with vascular BD, and 1 with CNS-BD (some patients duplicated)). Among these 33 patients, those who had esophageal lesions were retrospectively reviewed to assess their disease types and endoscopic features.

RESULTS: Among the 33 patients, esophageal lesions were found in 4 patients (12.1%). Their sex ratio was 1:1 and their mean age was 35.75±22.42 years. They had incomplete BD, although all 4 patients had oral aphthosis (skin symptoms in 2, ocular symptoms in 2, vulvar ulceration in 0, arthritis in 3, and vascular lesions in 1 patient). They all complained of chest pain. Ileocecal ulcers were found in 3 of the 4 patients. Their esophageal ulcers were located in the mid-esophagus at a mean of 33±4.27 cm from the incisors. These ulcers were generally round and punched-out in all 4 patients, although fused bead-like lesions were also observed. Three patients had multiple esophageal lesions, and one had a single lesion. Three of the 4 patients suffered relapse of esophageal ulcers that was clearly associated with exacerbation of BD. All 4 patients were treated with corticosteroids, and adalimumab was also administered to one patient to control other symptoms. With corticosteroid therapy, chest pain did not relapse, and upper gastrointestinal endoscopy confirmed healing of the esophageal lesions after 44 weeks of treatment.

CONCLUSION: Esophageal ulcers were mostly located at the mid-esophagus in BD. Their ulcers were generally round and punched-out, and also tended to be fused. The ulcers relapsed repeatedly as occurs with ileocecal lesions, which may be a characteristic of BD.

INTRODUCTION: Because Crohn's disease (CD) is described as corresponding to a Th1-proinflammatory, TNF-α-mediated response and ulcerative colitis (UC) is considered to be mediated by a Th2 immune response is adalimumab just as suitable in UC as in CD?

AIMS & METHODS: To evaluate mucosal healing in UC by examining the intracellular changes of colonic mucosa, before and after adalimumab treatment. We studied sixteen patients (14 women, 21-65 years) previously diagnosed with UC of moderate-severe form (Disease Activity Index-UCDAI > 6, Endoscopic Index-EI > 4). All patients were treated with adalimumab (Humira) subcutaneous, at standard doses as it follows: 160 mg at week 0.80 mg at week 2 and afterwards 40 mg at a 2 week interval. We performed a colonoscopy before and 6 months after the first administration of adalimumab. During colonoscopy we collected biopsies that were later processed specifically, stained with uranyl acetate and lead citrate and examined with a JEM-1010 transmission electron microscope.

RESULTS: Before treatment we noticed severe alterations of the epithelium-depletion of microvilli, shattering of epithelial junctions, cytoplasmic vacuolization, dilatation of the endoplasmic reticulum, pycnotic nuclei, destruction of mitochondria and Golgi complexes which conducted to drastic reduction of cell metabolism. Rarefaction of the goblet cells, together with abnormal mucus formation and secretion was observed. The corresponding chorion showed degeneration of collagen fibres and smooth muscle cells, obstructed capillaries, neutrophilic and mononuclear infiltration. After adalimumab therapy, we noticed improvement in morphology and function of epithelial organelles, rich mucus secretion and recovery of the chorionic components. The clinical response observed in all our patients was supported by a descent in UCDAI. Endoscopic severity diminished as well- with 14 out of 16 cases entering remission (EI≤4).

CONCLUSION: Our study clearly demonstrated signs of epithelial barrier recovery at the end of treatment which is one of the main goals of UC treatment. Also the ultrastructural features that we described, might help to a deeper understanding of UC pathogenicity and mechanism of action of the anti-TNF-alpha therapies.

INTRODUCTION: In severe corticosteroid refractory ulcerative colitis (UC) cyclosporine A (CsA) or infliximab (IFX) are advantageous to avoid colectomy, and their effectiveness is comparable (*Laherie et al. Lancet 2012*).

AIMS & METHODS: The aim of this prospective study (IBD-HOT) was to evaluate the use, efficacy, and safety of CsA in treatment of acute flare of UC. All consecutive patients with moderate to severe CU refractory, intolerant to or dependent on corticosteroids and treated with CsA between Jan-2007 and Dec-2009 were enrolled. Inclusion criteria were active ulcerative colitis with a total Mayo score of 6 to 12 and moderate-to-severe active disease at colonoscopy. Patients' outcome and adverse effects were followed-up for three years or until colectomy as the major endpoint. Clinical and laboratory data were collected at the beginning of CsA therapy and at routine scheduled visits. Patients' survival w/o colectomy was analysed by Kaplan-Meier survival analysis.

RESULTS: 61 patients (28 female) fulfilled the inclusion criteria. Mean age was 35 years (MED 33, Range 18-64). CsA induction therapy was given intravenously to 40 patients for seven days (MED 7, Range 4-8), and mean dose was 2.15 mg/kg (MED 2.0, Range 1.8-3.6). Oral induction was given to 21 patients with mean dose of 3.8 mg/kg (MED 3.8, Range 2.4-5.5). Eight patients had used thiopurins before CsA longer than two weeks, but only three of them longer than 2 months. Other patients started thiopurins during CsA induction (46 pts) or soon thereafter (7 pts). The mean MAYO scores declined significantly during the beginning of the follow-up period and stayed low thereafter. The clinical response to CsA during the one-week induction period was scored as good in 18 (29.5%), moderate in 26 (42.6%), only partial in 15 (24.6%) and poor in 2 (3.3%) patients.

Colectomy-free survival at 3 years was 72.1 % (95% CI 60.9 – 83.4). Number of colectomies during the 3-year follow-up period was 17 (27.9 %) due to continuously active colitis (14 pts) or colonic mucosal dysplasia (3 pts). All colectomised patients had disease duration under 5 years, and short disease duration was the only independent risk factor for colectomy in multivariate regression analysis including gender, hemoglobin, albumin, C-reactive protein and disease duration. Disease duration had marginally significant predictive value for colectomy ($p = 0.049$; Odds Ratio 0.74, 95% CI 0.54 - 1.00).

In addition to colectomies, two patients were re-treated with CsA during the follow-up, and twelve with infliximab due to active disease. Seven (58.3 %) of IFX treated patients needed colectomy subsequently. Thus outcome after CsA rescue therapy without colectomy or need for CsA re-treatment or infliximab was 62.3 % (95% CI 50.1 – 74.5).

Adverse events were registered in seven patients: *Cytomegalo* viral infection (3), *Pneumocystis jirovecii* infection (1), *Clostridium difficile* colitis (1), transaminase elevation (1), venous thrombosis (1).

CONCLUSION: CsA treatment was successful in 72% of patient who avoided colectomy, and we see CsA as good option in moderate-to-severe acute corticosteroid refractory or corticosteroid resistant thiopurin naïve UC. Short disease duration was independent risk factor for colectomy. Risk of infection under high immunosuppression must be remembered.

P1480 ACCEPTANCE OF INFLAMMATORY BOWEL DISEASE TREATMENT RECOMMENDATIONS BASED ON APPROPRIATENESS RATINGS: DO PRACTICING GASTROENTEROLOGISTS AGREE WITH EXPERTS?

V. Pittet[1,*], M.H. Maillard[2], S. Lauvergeon[1], M. Timmer[1], P. Michetti[2,3], F. Froehlich[2,4], B. Burnand[1], J.-P. Vader[1], C. Mottet[5]

Contact E-mail Address: *Valerie. Pittet@chuv.ch*

INTRODUCTION: Appropriateness criteria for the treatment of Crohn's disease (CD) and ulcerative colitis (UC) have been developed by experts' panels. Little is known about the acceptance of such recommendations by care providers. We aimed to explore how treatment decisions of practicing gastroenterologists differ from experts using a vignette case study and a focus group.
AIMS & METHODS: Seventeen clinical vignettes were drawn from clinical indications evaluated by the expert panel. A vignette case questionnaire asking for treatment options in 9-10 clinical situations was submitted to 26 practicing gastroenterologists. For each vignette case, practitioners' answers were compared to panel decisions by calculating the proportions of treatments judged by the panels as being appropriate, uncertain and inappropriate. Qualitative analysis was made based on focus group discussion to explore acceptance and divergence reasons.
RESULTS: 239 clinical vignettes were completed, 98 for CD and 141 for UC. Proposed treatments were more frequently considered inappropriate as compared to results from panels for CD (45%) than for UC (27%). Among UC clinical vignettes, the main divergences with the panel were linked to 5-ASA failure assessment and to situations where stopping treatment was the main decision. For CD, the care provider propositions diverged with the panel in mild-to-moderate active disease, where practitioners were more aggressive than the panel's recommendations and in stenotic complications management.
CONCLUSION: In about one third of vignettes cases, IBD treatment propositions by practicing gastroenterologists were considered inappropriate as compared to expert recommendations. Practicing gastroenterologists may not always know current evidence and guidelines, but are often aware of the difficulties of applying recommendations in real IBD patients.

P1481 TEN YEARS PROSPECTIVE STUDY OF INFLIXIMAB TREATMENT IN ULCERATIVE COLITIS PERFORMING AN ALGORITHM OF DISCONTINUATION

V. Hansen[1,1,*], K.-M. Johnsen[1], G. Rasmus[1], J. Florholmen[1]
[1]*gastroenterology, University Hospital Tromsø, Tromsø, Norway*
Contact E-mail Address: *jon.florholmen@unn.no*

INTRODUCTION: Anti-tumor necrosis factor (TNF) has the last decade become an important part of the treatment of severe ulcerative colitis (UC), but there is no international consensus of discontinuation of the therapy.
AIMS & METHODS: To study the long term time of remission performing a prospective study using an algorithm of discontinuation of the anti-TNF drug infliximab (IFX) in UC
UC patients with moderate to severe disease activity admitted at the University Hospital of North Norway in the period 2002-2011 were enrolled. Patients in the need of IFX were enrolled in a prospective study performing the following algorithm: intensive induction therapy (week 0, 2, 6, later each 4 week) until remission according the UCD activity index score (UCDAI) (score 0-2), discontinuation of treatment with subsequent re-induction of IFX treatment if relapse.
RESULTS: Of the 132 patients enrolled in the study 116 patients were evaluated according to the protocol. The mean total observation time was 43 (6-117) months and the patients were in remission 70% of the total observation time. Of the 3 first inductions therapies 96/116 (83 %), 37/61 (61 %) and 10/19 (53 %) were treated to remission, respectively. The mean time of remission was 20, 19 and 12 moths in the 3 first induction therapies, respectively, and predictors of long term remission was sex (woman) and non-smoking. The number of patients in remission that never relapsed was 58/96 (60 %), and sex (woman) was a predictor for never relapse. Eighteen patients (18 %) were withdrawn due to need of colectomi, 10 (8 %) patients were withdrawn due to severe allergic reactions.
CONCLUSION: An intensified IFX induction regime of treatment to remission in patients with UC followed by a discontinuation of treatment showed high efficacy even in the re-treatments, and a high overall time being in remission. There was no tendency of increased allergic reaction to IFX during repeated induction therapies.

Contact E-mail Address: *richard.pollok@nhs.net*

INTRODUCTION: The thiopurine (TP) analogues, azathioprine and mercaptopurine are widely used in the management of Crohn's disease (CD). Recent studies suggest they reduce the risk of intestinal resection, but their impact on perianal surgery is unknown.
AIMS & METHODS: Our aim was to determine if TPs reduced the risk of perianal surgery in CD.
We conducted a population based study using electronic primary care records in the UK using a validated research database, the Clinical Practice Research Datalink (CPRD) which represents an 8% sample of the UK population. We identified incident cases of CD between 1995 and 2009 by selecting patients registered with a practice for at least 12 months prior to diagnosis. We excluded patients who had perianal surgery before or at the time of diagnosis. We grouped patients according to treatment duration and compared rates of first perianal surgery using Kaplan-Meier survival analysis. We used a multivariable Cox proportional hazards model to adjust for confounders and compare outcomes according to duration of treatment. We used separate models for each duration of use: $\geq$12 months vs $<$12 months, $\geq$18 months vs $<$18months and $\geq$24 months vs $<$24 months. We also evaluated early TP use, within 12 months of diagnosis.
RESULTS: Overall, 5235 patients met our inclusion criteria, of whom 124 had perianal surgery during 15 years of follow up. 56.3% were female and the median age at diagnosis was 38.5 years (IQR: 24.8 – 57.1). TP use for $\geq$12 months duration did not impact on the 5 year cumulative probability of perianal surgery when compared with TP use for $<$12 months. However, the unadjusted 5 year cumulative probability of perianal surgery for those using TPs for $\geq$18 months was 2.9% (95% CI: 2.0 – 4.3%) compared to 5.8% (95% CI: 4.0 – 8.2%) for those using TPs for less than $<$18 months (log-rank test for trend $p = 0.02$). After adjustment, sustained TP use for $\geq$18 months had a 40% reduction in risk of perianal surgery (HR 0.60, 95% CI: 0.39 – 0.95, $p = 0.03$) which improved to 49% (HR 0.51, 95% CI: 0.32 – 0.99, $p = 0.004$) at 2 years. Early TP use did not offer any additional benefit.
CONCLUSION: Sustained TP use in patients with CD halves the risk of perianal surgery at 2 years, although a long duration of treatment is required. We suggest sustained use of TPs for greater than 18 months duration in patients with perianal CD and propose further study to evaluate rates of perianal surgery in CD which at present is unknown.

P1483 IN IBD OUTPATIENTS KNOWLEDGE OF FECAL CALPROTECTIN AND INFLIXIMAB TROUGH LEVELS SIGNIFICANTLY ALTERS CLINICAL DECISION MAKING

V. Huang[1,*], C. Prosser[1], C. Shalapay[1], N. Dhami[1], D. Fedorak[1], H. Wang[2], K. Kroeker[1], R. Fedorak[1]
[1]*Medicine,* [2]*Surgery, University of Alberta, Edmonton, Canada*

INTRODUCTION: Infliximab is an effective, but costly, therapy for inflammatory bowel disease (IBD). Loss of response to infliximab will occur in over 50% of patients within 3 ys, resulting in infliximab dose intensification. One third of patients with symptoms do not have actual disease recurrence.
AIMS & METHODS: Aim: The aim of this study was to determine if objective measures of inflammation using fecal calprotectin (FCP), and infliximab trough levels (ITL) would lead to different management decisions of patients on infliximab than those made when only clinical assessment was available.
Methods: IBD patients receiving maintenance infliximab at the University of Alberta IBD infusion center were consented to provide stool and blood samples for measurement of FCP and ITL prior to their infusion. FCP and ITL levels were determined by immunodiagnostic ELISA. At the time of the infusion clinical HBI and Mayo scores were recorded. An IBD panel made a "clinical decision" based on the clinical assessment recorded. The decision options were no action or an action (scope, increase dose or switch drug, decrease dose). The panel then incorporated FCP to the "clinical decision" to determine "clinical + FCP decision"; and ITL to the "clinical + FCP decision" to determine the "clinical + FCP + ITL decision". The "clinical decision" was compared to the "clinical + FCP decision" or "clinical + FCP + ITL decision", and actions analyzed for concordance.

Table to abstract P1483
Table 1 Contingency Table Showing Impact of Adding FCP and ITL to Expert Panel Clinical Decisions

			Expert Panel Decision (Clinical plus FCP)			
N = 36			No change N = 19	Investigate (Scope) N = 16	Dose escalation N = 1	Dose de-escalation N = 0
Expert Panel Clinical Decision	**No change**	N = 29	19/36 (52.8%)	**10/36 (27.8%)**	0	0
	Investigate (scope)	N = 6	0	6/36 (16.7%)	0	0
	Dose escalation	N = 1	0	0	1/36 (2.8%)	0
	Dose de-escalation	N = 0	0	0	0	0

RESULTS: A total of 36 patients were included (25 CD and 11 UC). As shown in Table 1, the addition of FCP to expert panel clinical decisions led to a change in decisions 10/36 (27.8%) of the cases – all of which were from no change to investigate (scope). The addition of ITL to the expert panel clinical plus FCP decision led to a change in decisions 10/36 (27.8%) of the cases – 6/36 (16.7%) were from no change to infliximab dose de-escalation.
CONCLUSION: The addition of an infliximab trough level or a fecal calprotectin level, incorporated via a fixed algorithm or an expert IBD panel, frequently led to different management decisions compared to clinical assessment alone. The incorporation of fecal calprotectin and infliximab trough levels into daily care requires careful assessment of their effect on outcomes.

P1484 CHARACTERIZATION OF MUCOSAL HEALING WITH ADALIMUMAB TREATMENT IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE CROHN'S DISEASE FROM EXTEND

W. Reinisch[1,*], J.-F. Colombel[2], G. D'Haens[3], W.J. Sandborn[4], P. Rutgeerts[5], J. Petersson[6], S. Eichner[6], Q. Zhou[6], A. Iezzi[7], R.B. Thakkar[6]
[1]*McMaster University, Hamilton, Canada,* [2]*Icahn School of Medicine, New York, United States,* [3]*Academic Medical Center, Amsterdam, Netherlands,* [4]*UCSD, La Jolla, United States,* [5]*U of Leuven, Leuven, Belgium,* [6]*AbbVie Inc, North Chicago, United States,* [7]*AbbVie Inc, Rungis, France*

INTRODUCTION: Patients (Pts) continuously treated with adalimumab (ADA) in the EXTEND trial were more likely to achieve and maintain mucosal healing (MH) than pts receiving induction ADA only/placebo (PBO) treatment.[1] MH of the individual ileocolonic segments with ADA maintenance therapy is evaluated in pts from EXTEND.
AIMS & METHODS: In EXTEND, pts with Crohn's disease (CD), CDAI 220-450, and documented mucosal ulceration at study screening, received open-label (OL) ADA (160/80 mg) at wks 0/2. Pts were randomized at wk 4 to double-blind maintenance ADA (40 mg every other wk) or PBO to wk 52. Pts with flare/non-response could move to OL ADA at or after wk 8. Change from baseline (BL) in the CDEIS variables surface involved and ulcerated surface were assessed in each of the five ileocolonic segments at wks 12 and 52 only in pts who had measurements at all three time points. The presence of deep and superficial ulcers was assessed at wks 12 and 52 in pts who had deep and superficial ulcers at BL. All scores were based on central reading data. Pts were analyzed according to randomized treatment group. For pts who moved to OL ADA after wk 12, the CDEIS variable score at time of moving to OL ADA was used as the wk 52 data point. Pts who moved to OL ADA before wk 12 are not included in this analysis.
RESULTS: Improvement in surface involved was observed in all segments at wk 12 in induction ADA/PBO pts and at wks 12 and 52 in ADA randomized pts (Table). Statistically significant greater mean change from BL in surface involved was observed in the rectum, sigmoid/left colon, and transverse colon at wk 52 in ADA randomized pts compared to induction ADA/PBO pts (Table). Similar results were observed for CDEIS ulcerated surface. Of the pts with deep or superficial ulcers at BL, more ADA randomized pts were without deep (13/20, 65.0%) and superficial ulcers (11/24, 45.8%) relative to induction ADA/PBO pts at wk 52 (no deep 5/20, 25.0%; no superficial ulcers 2/20, 10.0%).
Table. Mean BL values of CDEIS surface involved by segment and randomized treatment group and mean change from BL at wks 12 and 52.

	Induction ADA/PBO			ADA maintenance		
	BL mean, cm	Δweek 12, cm	Δweek 52, cm	BL mean, cm	Δweek 12, cm	Δweek 52, cm
Rectum	5.0 (N = 14)	-2.3	-0.5	3.9 (N = 12)	-3.8*	-3.6**
Sigmoid/left colon	5.5 (N = 14)	-3.0	1.4	3.6 (N = 15)	-3.4	-3.2***
Transverse colon	4.0 (N = 10)	-0.5	0.5	4.9 (N = 12)	-4.6**	-3.7**
Right colon	4.8 (N = 9)	-2.7	-2.7	3.7 (N = 7)	-3.1	-2.6
Ileum	5.2 (N = 8)	-1.1	-0.1	4.0 (N = 13)	-2.4	-2.2

CONCLUSION: ADA maintenance therapy was beneficial in healing deep and superficial ulcers in pts with moderately to severely active CD. Although continuous ADA treatment improved the mucosal surface of all ileocolonic segments, the greatest improvement was in the rectum, left colon, and transverse colon.

P1485 DURABILITY OF CLINICAL REMISSION WITH VEDOLIZUMAB IN CROHN'S DISEASE

W. Sandborn[1], **S. Danese**[2,*], B. Abhyankar[3], W. Reinisch[4], J. Xu[5], K. Lasch[6], C. Milch[5]
[1]*Division of Gastroenterology, University of California San Diego, La Jolla, United States,* [2]*IBD Center, Istituto Clinico Humanitas, Milan, Italy,* [3]*Takeda Global Research & Development Centre (Europe) Ltd, London, United Kingdom,* [4]*Department Internal Medicine III, Medical University of Vienna, Vienna, Austria,* [5]*Takeda Pharmaceuticals International Co., Cambridge,* [6]*Takeda Pharmaceuticals International, Inc., Deerfield, United States*

INTRODUCTION: Efficacy and safety of vedolizumab (VDZ) in patients with Crohn's disease (CD) were demonstrated in the GEMINI 2 study.[1] However, the proportion of patients with durable clinical remission (secondary end point; Crohn's Disease Activity Index [CDAI] score ≤150 points at 11 of 13 [80%] visits from wks 6-52) was not significantly different between the VDZ and placebo (PBO) groups. To account for factors that may have led to this result (eg, previous VDZ induction therapy in maintenance PBO patients coupled with the long half-life of VDZ), we defined alternative post hoc end points to further evaluate the effects of VDZ on durable clinical remission.
AIMS & METHODS: In GEMINI 2, patients with CD were randomly assigned to receive blinded VDZ 300 mg or PBO or open-label VDZ 300 mg at wks 0 and 2 of the induction phase (wks 0-6). Wk 6 VDZ responders were rerandomized to receive VDZ 300 mg every 8 wks (Q8W; n = 154) or every 4 wks (Q4W; n = 154) or PBO (n = 153) during the maintenance phase (wks 6-52). In post hoc analyses, durable clinical remission end points were defined as a CDAI score of ≤150 points at 60% (8/13) of maintenance phase visits, at wks 6 and 52, and at 10 of 12 visits from wks 10 to 52.
RESULTS: Mean baseline (wk 0) CD duration was 8.4 y in the VDZ Q8W group, 7.7 y in the VDZ Q4W group, and 9.6 y in the PBO group. Mean baseline CDAI score (Q8W, 325.5; Q4W, 317.0; PBO, 325.2) and previous failure of tumor necrosis factor (TNF) antagonists (Q8W, 55%; Q4W, 50%; PBO, 51%), immunosuppressants but not TNF antagonists (Q8W, 32%; Q4W, 35%; PBO, 32%), and corticosteroids only (Q8W, 13%; Q4W, 14%; PBO, 16%) were similar among the groups. Percentages of patients with durable clinical remission based on 60% (8/13) of visits and at both wks 6 and 52 were significantly higher with Q8W and Q4W than with PBO (Table). Percentages of patients with durable remission based on >80% (10/12) of visits from wks 10 to 52 were significantly higher for Q4W and numerically higher for Q8W than for PBO (Table).

Table to abstract P1485

	VDZ		
	Q8W n = 154	Q4W n = 154	PBO n = 153
Durable remission based on 60% (8/13) of visits[a]	49 (31.8)	42 (27.3)	30 (19.6)
P value	0.003	0.022	-
Remission at wks 6 and 52[b]	30 (57.7)	26 (60.5)	22 (39.3)
P value	0.040	0.020	-
Durable remission based on 10 of 12 visits from wks 10-52	37 (24.0)	33 (21.4)	24 (15.7)
P value	0.060	0.044	-

CONCLUSION: The definition of *durable clinical remission* has not been standardized. These post hoc analyses of patients with CD, including those with previous TNF antagonist failure, showed that VDZ (vs PBO) led to durable clinical remission through wk 52 as defined by multiple clinically relevant alternative end points.

P1486 RELATIONSHIP BETWEEN CLINICAL OUTCOMES AND DISEASE DURATION, EXTENT, AND SEVERITY IN PATIENTS WITH ULCERATIVE COLITIS WHO RECEIVED 6 WEEKS OF TREATMENT WITH GOLIMUMAB

W. Sandborn[1], **B. Feagan**[2,*], J.-F. Colombel[3], W. Reinisch[4], P. Gibson[5], P. Rutgeerts[6], H. Weng[7], R. Yao[7], C. Marano[8], H. Zhang[8], R. Strauss[8]

INTRODUCTION: To determine the relationship between baseline disease characteristics and efficacy of golimumab (GLM) treatment in patients with moderately to severely active ulcerative colitis (UC).

AIMS & METHODS: The PURSUIT induction study included patients with Mayo scores of 6–12 inclusive, including endoscopic subscore ≥2. Patients were randomized to receive at wk 0/2 either placebo (PBO)/PBO; GLM 200mg/100mg; or GLM 400mg/200mg. At wk 6, clinical response (≥30% and ≥3 points decrease from baseline Mayo score, with a decrease in the rectal bleeding subscore of ≥1 or a rectal bleeding subscore of 0 or 1) was analyzed by disease duration (≤5 y, >5 to ≤15 y, or >15 y), extent (limited v extensive), and severity (Mayo <9 v ≥9) at baseline. Missing data were considered nonresponse. *P* values were not adjusted for multiplicity.

RESULTS: 761 patients were randomized and included in efficacy analyses (13 patients were excluded owing to site misconduct). 98% of patients completed to wk 6. Overall, a greater percentage of patients had clinical response in both GLM dose groups than the PBO group (200/100mg: 51%, 400/200mg: 55%, PBO: 30%). This pattern was similar for patients in each category of disease duration, disease extent, and Mayo score (table). Excluding the longest disease duration group that had the smallest number of patients, odds ratios for differences between the GLM and PBO groups varied from 2.0–3.5; all differences from PBO were statistically significant.

CONCLUSION: Clinical response to 2 doses of GLM treatment (200/100mg or 400/200mg at wks 0/2) was consistently achieved in approximately 50% of patients at wk 6 regardless of UC disease duration, extent, or severity at baseline. Overall, safety was comparable among treatment groups through wk 6.

P1487 ADHERENCE TO ULCERATIVE COLITIS TREATMENT: DETAILS MATTER

W. Kruis[1,*], H. Lührs[2], B. Keck[3], H. Schmidt[4], S. Ceplis-Kastner[5], B. Reimers[5] on behalf of MUKOSA Study Group

INTRODUCTION: The adherence of patients to their therapy is essential for the success of treatment. Many determinants of adherence, especially in the long-term treatment of ulcerative colitis (UC), are, however, still inadequately understood. There is some evidence that frequency of administration and dosage form affect acceptance and compliance with mesalazine therapy.
AIMS & METHODS: The aim of this prospective, non-interventional study was to identify factors that influence adherence to mesalazine therapy in patients with UC.
In 113 specialized private gastroenterology practices, patients with UC who received mesalazine for acute treatment or maintenance of remission, rated their own compliance at time 0 (A), after 4-8 months (B) and after 12 months (C) on a visual analogue scale, where 0 signified "I have taken all medication correctly" and 10 "I have taken no medication". At the outset, patients were asked about their preference regarding the oral dosage form (tablets/granules/no preference). It was recorded whether the doctor's prescription matched the patient's wishes. The results were shown as median values.
RESULTS: 520 patients (47% female) were enrolled and observed prospectively for up to 12 months. 76% of the patients preferred granules, 14% tablets, and 10% had no preference. Almost all patients received their preferred dosage form. Among patients who preferred and received granules, compliance improved during the observation period (0.50 (A), 0.30 (B) and 0.25 (C)). Patients who preferred and received tablets rated their compliance at all times worse than those taking granules. However, their compliance also improved during the study (1.80; 0.70; 1.0). The group with no preference initially rated compliance as high, but this worsened with time (0.45; 0.70; 0.78). No evidence of other influencing factors such as age, sex, duration of disease or UC severity was found.
CONCLUSION: Documentation by the patient and consideration of the preferred dosage form of mesalazine increase adherence. Indifference of the patient is associated with poorer compliance. The dosage form of mesalazine should be discussed with the patient at the start of treatment.

P1488 SAFETY AND EFFECTIVENESS OF SEQUENTIAL INTRAVENOUS ADMINISTRATIONS IN A SINGLE SESSION OF IRON CARBOXYMALTOSE AND INFLIXIMAB IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE AND IRON DEFICIENCY

X. Cortés[1,*], J. Rodríguez[1], M. Moreno[1], J. Borrás[2], A. Garayoa[1], J.R. Molés[1], J. Clofent[1], J. Primo[1]
[1]*Intern Medicine Department, Gastroenterology Section,* [2]*Pharmacy Department, Hospital of Sagunto, Valencia, Spain*
Contact E-mail Address: *xacori@gmail.com*

INTRODUCTION: The objective of this study was to evaluate the safety and effectiveness of combined intravenous (IV) administration in a single session of ferric carboxymaltose [Ferinject®] and infliximab [Remicade®] in patients with inflammatory bowel disease (IBD) treated with infliximab for the combined management of underlying disease and iron deficiency anemia (IDA) or iron deficiency (ID), in contrast to the usual pattern of two or more hospital visits to administer both treatments.
AIMS & METHODS: Prospective observational study which included 22 consecutive patients with IBD of $\geq$ 6 months evolution (mean age 40.5 $\pm$ 10.7 years; 50% women). 16 patients had Crohn's Disease and 6 Ulcerative Colitis, all treated with infliximab and diagnosed with ID or IDA according to WHO criteria. After completion of IV administration of 5 mg/kg infliximab, 50 ml of saline were injected using the same venous access, followed by the Ferinject® infusion (accordance with Ganzoni formula). 63.4% of patients received Ferinject® infusions of 500 mg and 36.6 % received 1000 mg iron. Laboratory analyses of the ferric profile and inflammatory activity index (modified Truelove I. or Harvey-Brasdshaw I.) pre-infusion and at 2 months were performed. Presence of adverse events was evaluated at 7 and 60 days after the sequential infusions. Ferinject® effectiveness was measured after a mean of 69.0 $\pm$ 41.3 days after infusions.
RESULTS: At the end of the evaluation period no adverse events associated with sequential IV infusion of ferric carboxymaltose or infliximab were recorded. After this period, the mean hemoglobin levels increased from 11.5 $\pm$ 2.5 to 12.5 $\pm$ 1.9 g/dL ($p = 0.143$). Increases in mean levels of serum iron (41.1 $\pm$ 19.5 to 69.6 $\pm$ 33.8 µg/dL, $p = 0.002$), ferritin (73.4 $\pm$ 122.8 to 304.9 $\pm$ 390.7 ng/mL, $p = 0.001$) and mean transferrin saturation (12.3 $\pm$ 4.3 to 21.5 $\pm$ 11.4%, $p = 0.004$) were statistically significant.
CONCLUSION: Sequential IV administration of infliximab following IV ferric carboxymaltose [Ferinject®] in a single session was well tolerated and effective. Contrary to the usual practice of infusing infliximab and IV iron on separate days, this sequential regimen can offer a good cost- benefit ratio and could improve treatment adherence and patients' quality of life.
Disclosure of Interest: None declared

P1489 INTEREST OF COMBINATION THERAPY WITH IMMUNOSUPPRESSIVE TREATMENT IN IBD PATIENTS IN LOSS OF RESPONSE TO INFLIXIMAB AND EXHIBITING VERY HIGH ANTI-INFLIXIMAB ANTIBODY (ATI) LEVELS

X. Roblin[1,*], E. Deltedesco[1], L. Peyrin Biroulet[2], S. Paul[3]
[1]*CHU Saint Etienne, saint etienne,* [2]*CHU Nancy, Nancy,* [3]*CHU Saint Etiennne, Saint Etiennne, France*

INTRODUCTION: For IBD patients treated with IFX as monotherapy and exhibiting undetectable IFX levels combined with high anti-IFX levels (ATI), the recommended course is to switch to another anti TNF. A single case study has however reported a potential benefit of the addition of immunosuppressants (IS). In this study we studied the clinical and pharmacological impact of adding an IS in patients treated with IFX and exhibiting undetectable trough levels of IFX concurrent with high ATI levels.
AIMS & METHODS: Within a prospective cohort of patients with IBD, all patients receiving IFX as monotherapy at the dose of 5mg/kg were identified. Inclusion was restricted to patients exhibiting undetectable IFX levels and high levels of ATI (> 200 ng/ml) measured using ELISA LISA-TRACKER (Theradiag) technique and detected at least twice. In cases of declining clinical response an IS was added to the prescription of IFX at the same dose, for a minimum period of 6 months.
RESULTS: 15 patients (13 with Crohn's disease (CD)), sex ratio = 1, mean age = 36 years) were included. All patients had IFX levels < 0.1µg/ml and ATI > 200ng/ml. Loss of clinical response was moderate in 10 and minimal in 5, all with faecal calprotectin > 450 µg/g of stools or with an endoscopic Mayo score = 2. The addition of IS (thiopurines in 13 cases) was proposed. Pharmacological data revealed a median IFX level which increased from 0.015 µg/ml [0.01-0.02] to 0.9 µg/ml [0.01-2.2] after 6 months of combination therapy. Median ATI levels decreased from 320 ng/ml [200-600] to 60 ng/ml [20-500]. At 6 months, 8 patients out of 15 exhibited IFX levels greater than 1.5 µg/ml. assoiciated with ATI below 20ng/mL Clinically, 7 of the 13 patients with CD and in relapse on inclusion were in clinical remission at 6 months with normal faecal calprotectin values and in all cases a favourable pharmacological outcome (IFX > 1.5µg/ml with ATI < 20 ng/ml). The pharmacological profile of the 7 other patients remained unchanged.
CONCLUSION: The addition of IS in patients relapsing during IFX treatment and having high ATI levels lead to remission, in 54% of cases as evidenced by clinical, pharmacological and biomarker data. This clinical response is slow: 6 months for a pharmacological effect, 4 months for an effect on the biomarkers and 5 months for a favourable clinical outcome to be observed.

P1490 INDIRECT COMPARISON OF ADALIMUMAB AND VEDOLIZUMAB IN INFLAMMATORY BOWEL DISEASE IN THE UNITED KINGDOM: COST PER RESPONDER/REMITTER ANALYSIS

Y. Liu[1], W. Reichmann[2], **S. Wang**[3,*], D. Macaulay[2], M. Skup[3], J. Chao[3], Y. Bao[3]
[1]*University of Missouri–Kansas City, Kansas City,* [2]*Analysis Group, Inc., Boston,* [3]*AbbVie Inc., North Chicago, United States*

INTRODUCTION: Adalimumab (ADA) and vedolizumab (VDZ) have been shown to induce and maintain clinical remission in patients with moderate to severe inflammatory bowel disease (IBD). The objective was to calculate cost per responder and remitter associated with ADA and VDZ from the perspective of the National Health Service in the United Kingdom (UK).
AIMS & METHODS: RCTs comparing ADA (CHARM and ULTRA 2) or VDZ (GEMINI 1 and 2) to placebo in ulcerative colitis (UC) or Crohn's disease (CD) at 1 year were included. Relative response and remission of each biologic therapy was estimated using a network meta-analysis (NMA) in UC and CD separately. The number needed to treat (NNT) was estimated for each biologic based on the results of the NMA. In CD, the annual cost of ADA (£10,564) assumed all patients were on therapy for 1 year. In UC, the annual cost of ADA (£6,722) assumed patients not in response at week 8 discontinued therapy, as per the European Medicines Agency product information. Because VDZ is not yet approved in the UK, annual cost was assumed to be equal to the indication-specific cost of treating with ADA or the 2013 average annual cost of anti-TNF therapies in the UK (£17,915). The cost of VDZ was assumed to be the same for both VDZ 300mg every 8 weeks (Q8) and every 4 weeks (Q4) dosing regimens. The 1-year costs per responder and remitter were estimated in UC and CD by multiplying the NNT by the annual cost. Blended costs per responder and

remitter in IBD were estimated by weighting the UC and CD results by their respective market size.
RESULTS: When VDZ's annual cost was assumed to equal ADA's, the 1-year treatment costs per responder in patients with IBD were numerically lower for ADA (£60,370) than VDZ Q8 (£146,255) and VDZ Q4 (£128,462). 1-year treatment costs per remitter were also numerically lower for ADA (£60,996) than VDZ Q8 (£118,814) and VDZ Q4 (£137,521). When VDZ's annual cost was assumed to be £17,915 in IBD, the cost per responder of ADA compared to both VDZ dosing regimens was significantly different (Table).

Treatment	Cost per responder Mean (95% Credible Interval)	Cost per remitter Mean (95% Credible Interval)	Cost assumption for VDZ
ADA	£60,370 (£41,174, £98,167)	£60,996 (£38,865, £106,716)	
VDZ Q8	£146,255 (£58,751, £491,114)	£118,814 (£58,724, £271,587)	VDZ treatment costs equal ADA's
VDZ Q4	£128,462 (£58,980, £346,582)	£137,521 (£60,944, £369,964)	
VDZ Q8	£252,800 (£104,360, £836,914)	£208,382 (£102,409, £465,272)	VDZ treatment costs equal the average of all anti-TNF therapies
VDZ Q4	£223,428 (£104,808, £593,699)	£239,344 (£108,709, £635,055)	

CONCLUSION: Costs per responder and remitter in IBD in the UK were numerically lower for ADA-treated patients compared to VDZ-treated patients, indicating that ADA may have better economic value than VDZ in patients with IBD.

P1491 WHAT IS OUR SUCCESS ON COMPLEX PERIANAL FISTULA HEALING IN THE CLINIC?: FROM ANTIBIOTIC TO COMBINED ANTI-TNF BASED TREATMENT, ENDING WITH OR WITHOUT ILEOSTOMY

Y. Erzin[1,*], A. Ercaliskan[1], I. Hatemi[1], D. Eyice[1], B. Baca[1], N. Demir[1], A.F. Celik[1]
[1]*Gastroenterology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey*

INTRODUCTION: Our aim was to determine overall treatment (Tx) success and factors influencing the medical Tx (MedTx) response in complex perianal fistulas (Cpfis).
AIMS & METHODS: Patients' charts between 1999-13 retrospectively were reviewed. There were 51/705 (7%) CD patients with Cpfis. All patients were treated with different combinations of antibiotics, azathioprine (AZA) and anti-TNFs but our aim was to put them on triple MedTx if there was no drug intolerance. In case of an abscess, drainage and seton was applied remaining between 3 to 6 mo. in case of no recurrence. Tx success was stratified as complete discharge cessation or additional closure of external orifice, and ultimately radiological disappearance by MRI. In case of MedTx failure a diverting stoma was applied. Age, sex, disease duration, location, behaviour, rectal involvement, age at fistula onset, fistula duration, number of fistula, smoking, number of setons, duration of each MedTx, time with seton, total durations of drugs, and type of surgery was noted. Each patient's fistula status at the last visit was determined and re-opening and re-closing events and closure time after seton removal were noted.
RESULTS: There were 51 Cpfis pts., 20 (39%) being female with a mean age of 35.66±11.66 yrs. The mean fistula follow-up time was 41.68±31.31 mo., 19/51 (37%) patients had one fistula the remaining multiple. 34 patients (66%) were complicated by abscesses and loose seton was applied to 30/34 (88%), four of them with permanent setons for repeating abscesses. During whole follow up 50 abscesses (12 of them while having a seton) were observed. Fistula closure after seton removal was achieved between 1-21 (median 8) mo. Ileostomy was performed in 14 (28%) patients and fistula closure was achieved in only 4/14 (30%) between 2-9 mo. At the last visit 27/51 (53%) were in remission, and only 7/51 (14%) achieved radiological. The follow up Tx time was significantly longer in response-positive group (50.33 vs. 31.95 mo., $p=0.031$), and total anti-TNF Tx time significantly correlated with Tx success ($r=-0.339$, $p=0.021$). An age-sex adjusted Cox regression analysis disclosed total anti-TNF Tx time as the only independent predictor of Tx response ($p=0.001$).
CONCLUSION: Anti-TNFs necessary for even small success of complex fistula closure. Clinical response rate within the mean 41 mo. of follow up was 53% with it's own re-opening risk. Only 14% had radiological tract closure reaching our ultimate aim. Long term antibiotic use either solo or combined did not show any effect on perianal fistula closure.

P1492 RISK OF MICROSCOPIC COLITIS DURING USE OF PPIS, NSAIDS, BETA-BLOCKERS AND OTHER DRUGS

G.M. Masclee[1,2,*], P.M. Coloma[2], E.J. Kuipers[1], M.C. Sturkenboom[2]
[1]*Gastroenterology and Hepatology,* [2]*Medical Informatics, Erasmus University Medical Center, Rotterdam, Netherlands*
Contact E-mail Address: *g.masclee@erasmusmc.nl*

INTRODUCTION: Microscopic colitis (MC) is a disease characterized by chronic watery diarrhea, normal radiological and endoscopic appearance but microscopic inflammation. MC includes two distinct entities: lymphocytic (LC) and collagenous colitis (CC). In recent years, several drugs were reported to increase the risk of MC. However, these studies lacked a clear exposure definition or did not address dose- and duration-relationships. Aim of this study was to estimate the risk of MC during use of several drugs, such as NSAIDs, PPIs, beta-blockers and SSRIs.
AIMS & METHODS: Case-control study nested within a population based cohort using a primary care database from the Netherlands (1999- 2013). MC cases were identified using free text search with manual validation to ensure histological confirmation. Cases were persons aged≥18 years with incident MC diagnosis. Controls (community-based and patients with negative colonoscopy results), being MC and colorectal cancer-free, were matched to cases on age, sex and primary care practice. Drug use was determined within 1 and 2 years prior to date of earliest symptoms leading to MC diagnosis (matching date). Odds ratios (OR) with 95% CI were calculated by conditional logistic regression, while adjusting for confounders (ORa), including auto-immune diseases, type 2 diabetes mellitus, polyarthritis, colonoscopy and concomitant drug exposure.
RESULTS: From the source population of 1,458,410 subjects we identified 218 incident MC cases (92 CC, 70 LC, 56 unspecified) that were matched to 15,045 community controls. Current use (≤ 3 months) of proton pump inhibitors (PPIs), NSAIDs, selective serotonin re-uptake inhibitors (SSRIs), low-dose aspirin (LDA), ACE-inhibitors (ACEI) and beta-blockers (BBL) significantly increased the risk of MC compared to never use, with adjusted ORs ranging from 2.6 (95%CI:1.5-4.4) for BBL to 7.2 (95%CI:4.4-11.9) for PPIs when evaluating 1 year prior to date of earliest symptoms. At 2 years prior to the matching date, accounting for diagnostic delay, only current use of NSAIDs, PPIs, LDA and ACEI showed increased risk of MC. Statins did not increase the risk of MC. Increasing doses did not show higher risks for MC. When estimating the risk of MC compared to colonoscopy-test negative controls, only current use of PPIs and beta-blockers significantly increased the risk of MC (ORa 4.3 and 6.8, respectively).
CONCLUSION: The risk of microscopic colitis increases from 3 up to 7-fold with current use of drugs, including NSAIDS, PPIs, low-dose aspirin, ACE-inhibitors and beta-blockers when compared to community-based controls. When compared to colonoscopy negative controls, however, only PPIs and beta-blockers increased the risk of MC, suggesting that use of NSAIDs, low-dose aspirin, ACE-inhibitors increases the likelihood of receiving a colonoscopy or worsen underlying colonic diseases or diarrhea rather than increases the risk of MC.

INTRODUCTION: The aim of this study is to define the effect of IRT-5, new probiotics combination on the mice colitis and colitis associated cancers using mice colitis and colitis associated cancer (CAG) models.
AIMS & METHODS: IRT-5 was composed of five probiotics *(L.acidophilus, L. casei, L.reuteri, B.bifidum and S. thermophilus*). We used two mice colitis models (DSS and IL-10-/-piroxicam). After 2.5% DSS induction for 5 days, normal chow or IRT-5 (5x108 cfu/day) was administrated for 7 days and B6 mice were sacrificed at day 12. 8- to 10-week-old IL-$10^{-/-}$ mice were fed pellet-chow containing piroxicam for 2 weeks. Then normal chow or IRT-5 mixed chow was administered for 2 weeks after piroxicam induction. Four-weeks old Apc min/+ mice were given 2% DSS for 7 days and normal chow or IRT-5 was administrated for 6 weeks after the initiation of DSS. IL-$10^{-/-}$ mice were fed normal chow or IRT-5 mixed chow was administered for 6 weeks after piroxicam induction. Macroscopic tumors were measured and histologic analyses were done. Real-time PCRfor inflammatory cytokines and immunohistochemistry (IHC) for CD 163 and F4/80 were performed.
RESULTS: IRT-5 reduced the colonic inflammations in both DSS-colitis and colitis in IL-10 -/- mice. Mean tumor incidence (9.55±2.51 vs 4.72±3.09, $p<0.05$), tumor size (3.87±1.69 vs 2.63±1.01 $p< 0.05$) and the tumor portion in >3mm were significantly decreased in IRT-5 treated Apc min/+ mice compared with control mice. Histologic grade was more severe in control IL-10 -/- mice compared with IRT-5 treated IL-10 -/- mice (invasive caricinoma, 70% vs 40%). The activities of CD 163, and F4/80 were decreased in the tumor of IRT-5 treated Apc min/+ in IHC analyses.
CONCLUSION: IRT-5, combination of probiotics ameliorated mice colitis and inhibits CAC in Apc min/+-DSS model and IL-10 -/- mice by the modulation of macrophage activation.

Contact E-mail Address: *med20365nomura@yahoo.co.jp*

INTRODUCTION: Acute graft-versus-host disease (GVHD), which typically occurs within 100 days of transplantation, is an important factor influencing prognosis in transplant resipients. In this study, we retrospectively investigated the diagnostic accuracy of acute GVHD that developed in the lower gastrointestinal tract.
AIMS & METHODS: Of the 660 patients who underwent allogeneic hematopoietic stem cell transplantation at our hospital between January 2008 and June 2013, 335 developed acute GVHD-like symptoms such as watery diarrhea. Subsequently, 107 of these patients underwent lower gastrointestinal endoscopy within 100 days of transplantation, as well as biopsy for histological diagnosis. The frequency of each endoscopic findings and their probability of indicating GVHD were assessed in these 107 patients.
RESULTS: Endoscopic observation up to the terminal ileum was possible in 86 (80.4%) patients, and 98 patients were diagnosed as having GVHD based on histological findings, accounting for 29.3% of the 335 patients initially suspected of having GVHD and 91.6% of the 107 patients who underwent endoscopic examination. Of 12 patients infected with cytomegalovirus, 10 also showed the coexistence of GVHD. After excluding these 10 patients, GVHD was observed in the terminal ileum of 59 patients, with endoscopic findings of redness in 27, villous atrophy in 25, edema in 20, erosion in 19, ulcer in 4, and mucosal exfoliation in 5. GVHD was also observed in the colon of 88 patients, with endoscopic findings of reduction or loss of vascular visibility or ''orange peel'' appearance of the mucosa in 76 patients, edema in 68, redness in 42, erosion in 34, ulcer in 10, and mucosal exfoliation in 6. The diagnostic accuracy of each finding as an indicator of GVHD was 100% for villous atrophy, ulcer, and mucosal exfoliation, 97.7% for redness, and 96.3% for erosion in the terminal ilium. In the colon, the accuracy was 100% for ''orange peel'' appearance of the mucosa and mucosal exfoliation, 97.1% for erosion, and 96.2% for reduction or loss of vascular visibility. Six patients had GVHD only in the terminal ilium, and 5 had GVHD only in the right colon. The remaining 86 (87.8%) patients were diagnosed with GVHD in the left colon based on the biopsy results.
CONCLUSION: The characteristic endoscopic findings of GVHD were villous atrophy, turtleback-like appearance of the mucosa, and mucosal exfoliation. Approximately 90% of patients who underwent biopsy of the left colon were accurately diagnosed with GVHD, indicating that biopsy should be performed of the left colon regardless of poor bowel preparation.

P1495 EFFECTS OF POLY (I:C), A LIGAND FOR TOLL-LIKE RECEPTOR 3, IN COLON BARRIER FUNCTION

V. Moyano-Porcile[1], J.A. Bravo[1], **M. Julio-Pieper**[1,*]
[1]*Grupo de NeuroGastroBioquímica, Laboratorio de Química Biológica. Instituto de Química, Facultad de Ciencias, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile*
Contact E-mail Address: *marcela.julio@ucv.cl*

INTRODUCTION: The gastrointestinal (GI) tract and especially the gut wall act as a barrier to prevent translocation of harmful biological and chemical entities from the lumen. Accordingly, intestinal and colonic barrier functions depend on an adequate response to pathogens by immune but also epithelial cells. Toll-like receptor 3 (TLR-3) recognizes pathogen-associated molecular patterns, particularly double-stranded RNA. TLR-3 activation is noxious to nasal epithelial cells and perturbs blood brain barrier. Although it has been shown that systemic activation of TLR-3 induces intestinal damage, there is little information regarding the mechanisms for TLR-3 actions on epithelial cells in the GI tract. In addition, the effects of direct TLR-3 activation on gut barrier function are unknown.
AIMS & METHODS: We aimed to evaluate the effects of TLR-3 activation on rat colon permeability *ex vivo* as well as *in vivo*. For the *ex vivo* approach, we used the everted gut sac technique. The synthetic ligand for TLR-3, Poly (I:C), was applied at the mucosal side of the colon at doses of 0, 0.5, 5, 50 and 200 ug/mL, and the transit of fluorescent probes (TRITC-dextran 4.4 kD, TD4.4 and FITC-dextran 40 kD, FD40) from the mucosal to the serosal side was measured for up to 3 hours. At the end of this protocol RNA was extracted from the mucosa in order to quantify the mRNA expression of tight junction proteins ZO-1 and Occludin. The effects of Poly (I:C) on colon mucosal morphology and ZO-1 immunostaining were evaluated in another set of tissues. For the *in vivo* experiments, either saline or 100 ug of Poly (I:C) were applied along 7 cm into the colorectal cavity of adult male rats. Six hours later the colon was removed and subjected to the everted gut sac permeability test as described before.
RESULTS: Tissues exposed to 200 ug/mL Poly (I:C) *ex vivo* displayed a decreased thinning of mucosal layer after 2 hours and a decrease in the transit of FD40 (but not of TD4.4) from the mucosal to the serosal side after 3 hours, in comparison to controls. No changes were found in mRNA levels of ZO-1 and Occludin or in the immunostaining for ZO-1 in the mucosa. Colons removed from rats that received Poly (I:C) intrarrectally also showed decreased permeability to FD40 in the everted gut sac assay at 3 hours post-extraction.
CONCLUSION: Our results suggest that an acute exposure to the TLR-3 ligand Poly (I:C) reduces colon permeability to a 40 kD molecule, both *ex vivo* and *in vivo*. This effect is accompanied by a reduction in mucosal thinning *ex vivo* but not by a modification in the expression of ZO-1 or Occludin. Although the mechanism and significance of this potentially protective effect need further investigation, to our knowledge this is the first report showing a direct effect of a TLR-3 ligand in colon barrier function. FUNDED BY: Conicyt 79112017, Fondecyt 1130213.

INTRODUCTION: Among the potential environmental triggers that are implicated in the development of the diabetes-related myenteric neuropathy, the intestinal microbiome is considered as primary candidate.
AIMS & METHODS: Therefore, the aim of this study was to map the alterations of the composition of microbiota along the gut in diabetic rats. Luminal samples of streptozotocin-induced diabetic and insulin-treated diabetic rats were compared with healthy controls. Segments of duodenum, ileum and colon were dissected and microbiomes of the luminal contents were analyzed by next generation DNA sequencing from phylum to genus level.
RESULTS: No significant differences in the bacterial composition were observed in luminal contents derived from the duodenum of different experimental groups. However, distinct patterns of microbiomes were recognized in the ileum and colon, depending on the history of the luminal samples. Ileal samples from diabetics exhibited particularly striking alterations while the richness and diversity obscured some of these in the colon. Proteobacteria displayed most pronounced shifts, while the dominating phyla (Firmicutes and Bacteroidetes) apparently were modified to smaller degree. Characteristic rearrangements and diversity in the microbiome were detected after insulin replacement, although the normal gut flora was not restored.
CONCLUSION: Diabetes and also insulin treatment affect the composition of the intestinal microbiota on a different but strictly gut region-specific way. The luminal samples from the ileum appear more suitable for diagnostic purposes than the colon/faeces. Proteobacteria should be in the center of diagnosis and potential therapy.

Contact E-mail Address: *sandra.lemesch@medunigraz.at*

INTRODUCTION: Bacterial infections and sepsis are common complications leading to high morbidity and mortality in patients with chronic kidney disease (CKD). A defective gastrointestinal barrier may contribute to increased translocation of bacterial products.
The aim of this study was to investigate gut permeability, oxidative stress and phagocytic capacity of neutrophils in CKD patients.
AIMS & METHODS: Diamine oxidase (DAO),a marker of gut permeability, was measured by ELISA (DAO, Immundiagnostic, Germany). The LPS surrogate markers lipopolysaccheride binding protein (LBP) and soluble (s)CD14 were measured by ELISA (Human LBP, Human sCD14, Hycult biotech, Netherlands). Advanced Oxidation Protein Products (AOPP) were determined by HPLC. Neutrophil function was determined by co-incubating whole blood with FITC labelled E. coli (Phagotest, Glycotope, Germany) and analysed by flow cytometry.
RESULTS: Predialysis (PDL, n = 73), hemodialysis/hemodiafiltration (HD, n = 32), peritoneal dialysis (PD, n = 28) patients as well as peritoneal dialysis patients with peritonitis (PDP, n = 14) were studied and compared to healthy controls (Ctrl, n = 33). DAO levels were significantly higher patient groups (except PDP patients) compared to Ctrl (see Tab.1). LBP and sCD14 were significantly higher in patient groups compared to Ctrl (see Tab.1). Among the patient groups LBP and sCD14 were highest in the PDP group. AOPP were significantly increased in patient groups (see Tab.1). Neutrophil phagocytosis was significantly reduced in the HD group (see Tab.1).
Tab. 1 Results are shown as median (interquartile range). Significance is shown as [a] $p<0.001$, [b] $p<0.01$, [c] $p<0.05$ compared to ctrl. [A] $p<0.001$, [B] $p<0.01$, [C] $p<0.05$ compared to patient groups (DAO: compared to PDL; LBP: compared to PDP; sCD14: compared to PDP; AOPP: compared to HD; phagocytosis: compared to HD).

parameters		ctrl	PDL	HD	PD	PDP
DAO	[ng/ml]	21.0 (13.1)	33.8 (16.9)[a]	31.9 (23.0)[a]	25.6 (.10.3)[c, B]	27.5 (20.9)
LBP	[µg/ml]	16.7 (9.9)	34.1 (21.1)[a, A]	28.3 (26.3)[a, A]	28.35 (17.7)[a, A]	59.9 (48.2)[a]
sCD14	[µg/ml]	1.5 (0.8)	2.7 (2.1)[a, A]	3.3 (1.6) [a, A]	2.8 (0.7)[a]	6.3 (5.1)[a]
AOPP	[µmol/l]	31.1 (12.9)	53.2 (40.9)[a, A]	90.5 (50.3)[a]	67.9 (30.3)[a, C]	70.2 (38.4)[a]
phagocytosis	[%]	96.0 (57.4)	110.8 (60.5)[A]	75.7 (40.2)[a]	98.8 (74.5)[C]	96.8 (79.8)

CONCLUSION: These results reveal an increased gut permeability in CKD patients. It can therefore be hypothesized that translocation of bacterial products may be increased, leading to an increase in the LPS surrogate markers LBP and sCD14. Additionally, protein oxidation as measured by AOPP is increased in patient serum. Our findings are akin with previous studies showing that CKD patients are exposed to circulating endotoxemia and systemic inflammation on the basis of a leaky gut, altered intestinal microbiota and ultrafiltration- induced splanchnic ischemia. A pathophysiological role of the type of renal replacement therapy is underlined by the fact that neutrophil phagocytosis is impaired in patients undergoing hemodialysis/hemodiafiltration but not in PDL and PD-patients.

P1498 INCREASED LEVELS OF PROINFLAMMATORY SERUM CYTOKINES AND LOWER MUCOSAL EXPRESSION OF TLR4 IN IBS PATIENTS

S.M. P. Bennet[1,*], H. Törnblom[1], F. Rusu[2], S. Isaksson[1], B.L. Neve[3], M. Simrén[1], L. Öhman[1]
[1]*Dept. of Internal Medicine and Clinical Nutrition, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden,* [2]*2nd Medical Department, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania,* [3]*Dept. of Life Science, Danone Research, Palaiseau, France*

INTRODUCTION: Alterations in immune function by means of increased activity and potential low-grade inflammation have been suggested as being important in irritable bowel syndrome (IBS). We therefore studied the serum cytokine profile as well as expression of mucosal host mRNA targets of relevance to inflammation and bacterial recognition in IBS patients.
AIMS & METHODS: MesoScale Discovery (MSD) multiplex immunoassay analysis was used for the measurement of serum cytokines, IL-12p70, IL-13, IL-2, IL-4, IL-6, IL-17A, IL-5, IFN-g, IL-1β,IL-8, IL-10 and TNF in 154 IBS patients (female = 105, median age 29 years (24-40)), (Rome III; IBS-C = 16, IBS-D = 38, IBS-M = 98) and 45 healthy controls (female = 30, median age 27 years (23-41)). Mucosal expression of FOXP3, TLR4, TLR6, TLR9, NOX1, IL-8, IL-10 and TNF was determined by qRT-PCR in sigmoid colon biopsies from 114 IBS patients (female = 72, median age 32 years (27-39)), (Rome III; IBS-C = 14, IBS-D = 26, IBS-M = 73) and healthy controls (female = 25, median age 27 years (23-35)). The qRT-PCR results were normalized to the mean expression level of housekeeping (HK) genes 18s, POLR2A and RPLP0, or HPRT, and expressed as $2^{\text{-target-HK}}$. Data is shown as median, range 25-75 percentile.
RESULTS: IBS patients had higher serum levels of TNF compared to healthy controls (Table 1) with higher levels in IBS-D compared to IBS-M (2.7 pg/mL (2.2-3) vs. 2.1 pg/mL (1.7-2.5); $p = 0.02$) and healthy controls (2.7 pg/mL (2.2-3) vs. 2.2 pg/mL (1.5-2.5); $p = <0.001$), respectively. Also levels of IL-6 and IL-8 tended to be higher in serum of IBS patients (Table 1), without differences between IBS subgroups. In contrast, serum levels of IFN-g were lower in IBS patients compared to healthy controls (Table 1). Remaining serum cytokines were similarly expressed in IBS and healthy controls. In colon biopsies, the expression of NOX1 and FOXP3 tended to be lower in IBS than in healthy controls (0.02 (0.02-0.03) vs. (0.03 (0.02-0.03) arbitrary units; $p = 0.06$) and (2.5e-4 (1.8e-4-3.5e-4) vs. 3.1e-4 (2.9e-4-3.7e-4); $p = 0.1$) respectively. The expression of TLR4 was lower in IBS patients than healthy controls (2.1e-3 (1.6e-3-2.5e-3) vs. 2.4e-3 (2.0e-3-2.8e-3); $p = 0.02$), with IBS-M having lower expression of TLR4 compared to healthy controls ($1.9e^{-3}$($1.6e^{-3}$-$2.4e^{-3}$) vs. $2.4e^{-3}$($2.0e^{-3}$-$2.8e^{-2}$); $p = 0.003$). The mucosal expression of TNF, IL-8, IL-10, TLR6 and TLR9 was similar in IBS patients and healthy controls.
Table 1. Levels of serum cytokines in IBS patients and healthy controls.

Target (pg/mL)	IBS (n = 151)	Healthy (n = 48)	
TNF	2.3 (1.8-2.8)	2.2 (1.6-2.5)	$p = 0.03$
IFNg	8.0 (5.1-11.7)	11.2 (6.2-16.2)	$p = 0.01$
IL-6	0.4 (0.3-0.7)	0.4 (0.2-0.6)	$p = 0.1$
IL-8	11.4 (7.6-14.5)	9.5 (6.5-13.2)	$p = 0.1$

CONCLUSION: This study supports the notion that a subset of IBS patients has a low-grade inflammation with higher serum levels of pro-inflammatory cytokines. Also, lower mucosal expression of TLR4 and NOX1 RNA suggest impaired recognition and subsequent clearance of bacteria in intestinal tissue.

INTRODUCTION: Clostridium difficile infection (CDI) is one of the most important healthcare associated infections (HAI). Increasing incidence of CDI were reported.
AIMS & METHODS: Our aim was to analyze incidence and possible risk factors in inpatients treated with CDI between 1 January 2010 and 1 May 2013 at 1st Department of Medicine, Semmelweis University, Budapest, Hungary. A total of 11751 inpatients were treated in our clinic in the follow-up period. 247 inpatients were diagnosed with a CDI infection. For the risk analysis a 1:3 matching was used. Data of 732 matched for age, gender, inpatient care period and unit were compared to the CDI population. Inpatient records were collected and comprehensively reviewed.
RESULTS: The incidence of CDI infection was 21.0/1000 admissions (2.1% of all cause-hospitalizations and 4.45% of total inpatient days). The incidence of severe CDI was 126/1000 admission (12.55% 31/247 cases), Distribution of CDI cases was different according to the unit type, with highest incidence rates in hematology, gastroenterology and nephrology units (32.9, 25 and 24.6/1000 admissions) and lowest rates in 1.4% (33/2312) in endocrinology and general internal medicine (14.2 and 16.9/1000 admissions) units. Recurrence of CDI infection was 11.34%/12 week after discharge. Duration of hospital stay was longer (17.66 (SD:10.78) vs. 12.4 (SD: 7.71) days) in patients with CDI infection. CDI accounted for 6.3% of all-inpatient deaths, 30 day mortality rate was 21.86% (54/247 cases). Risk factors for CDI infection were: antibiotic therapy (including 3rd generational cephalosporins or fluoroquinolons, OR:4.559, $p<0.001$), use of proton pump inhibitors (OR:2.082, $p<0.001$), previous hospitalization within 12 months (OR:3.167, $p<0.001$), previous CDI infection (OR:15.32, $p<0.001$), while presence of diabetes mellitus was identified as a protective factor against CDI (OR:0.484, $p<0.001$). Treatment but not outcome of relapsing cases was significantly different with more frequent use of vancomycine alone or in combination ($p<0.001$) and longer ($p<0.02$) antibiotic therapy.
CONCLUSION: Incidence of CDI was high and CDI accounted for a significant burden with longer hospital stay and adverse outcomes. Antibiotic therapy, proton pump inhibitor therapy and previous hospitalization/CDI infection were identified as risk factors for CDI

INTRODUCTION: Both Ileocolonic tuberculosis and Crohns disease are common in developing world. In spite of all present day gadgetries at times it is difficult to differentiate Ileocolonic tuberculosis from Crohns disease.
AIMS & METHODS: Aim - The aim of our study was to assess the utility of an Interferon Gamma Release Assay, Quantiferon TB Gold in tube test (TBG), in diagnosing Ileocolonic tuberculosis.

Methods: We prospectively included 18 patients with Ileocolonic tuberculosis (ITB) and 30 patients with IBS (as per ROME III Criteria) who had a normal chest X-ray and Ileocolonoscopy and biopsy as controls. Demographic, clinical, laboratory, chest x-ray, endoscopic and histological features were noted in all the patients. All patients were evaluated with a TBG test. Diagnosis of ITB was made combining established clinical, endoscopic and histologic criteria. Patients were followed up and a repeat colonoscopy was performed at 3 months to look for response and at the end of 6 months of therapy to ensure mucosal healing. The diagnosis was revised if no healing was noted at 3 months.
RESULTS: Results: Eight of the 18 patients (44%) were male, and the mean age was 42.9 years (Range 16-81 years). All 30 control subjects had a negative TBG test. Seventeen out of the 18 ITB patients (94.4%) had a positive TBG test. The sensitivity was 94.4%, Specificity was 100%. Positive predictive value was 100% and a negative predictive value of 96.7%.

	IBS (n = 30)	TB (n = 18)	
Male/Female	18/12	8/10	
Mean Age in years (Range)	41.9 (16-80)	44 (18-81)	
TBG Positive	0	17 (94.4%)	
Abdominal pain	30	17 (94.4%)	
Diarrhoea	8 (26.7%)	9 (50%)	
Hb	12.4 ± 1.55	10.97 ± 1.83	0.016
Platelet	2.85 ± 0.75	2.67 ± 0.89	0.38
CRP	9	57	0.09
Alb	3.66 ± 0.29	2.7 ± 0.7	0.5

CONCLUSION: The TBG Test is both specific and sensitive for diagnosing ilieocolonic Tuberculosis, and can be can be added to the armamentarium for diagnosing Ileocolonic tuberculosis.

INTRODUCTION: *Clostridium difficile* (CD) is the most frequent cause of nosocomial infectious diarrhea in developed countries. Recent studies suggest asymptomatic carrier may be a major source of CD in healthcare settings. The aim of this study was to identify the prevalence and risk factors for asymptomatic CD carriage in a long-term care facility for the elderly.
AIMS & METHODS: Fecal samples were collected from 171 asymptomatic patients (68.4% woman) with a median age of 83 (range 43 to 101 years). Data on demographic or clinical information, including age, sex, body mass index, major diagnosis leading to admission, duration of facility stay, medication use of antibiotics, proton pump inhibitors (PPI), H_2 blockers, or probiotics, and concurrent diabetes mellitus were studied.
RESULTS: CD was isolated from 61 (35.7%) of 171 asymptomatic patients. 26 (42.6%) of the 61 isolates were toxin A-, B+, 18 (29.5%) were toxin A+, B+, and 17 (27.9%) were toxin A-, B-. Demographic or clinical data were analyzed between CD carriers and CD noncarriers. Multivariate analysis showed only PPI use was significant risk factor for CD carriage (odds ratio 2.193, 95% confidence interval 1.026-4.687, p = 0.043).
CONCLUSION: This study showed asymptomatic CD carriage was common in a Japanese long-term care facility for the elderly and was significant association with PPI use. The findings add to the understanding of CD carriage and have implication for prevention.

INTRODUCTION: Clostridium difficile infection (CDI) has become important cause of hospital morbidity and mortality during last decade. Recurrent CDI is difficult to treat and novel therapies (i.e. fecal transplantation) are evaluated in this group of patients. In our retrospective study we have decided to analyze group of patients with CDI from last three years in our hospital.
AIMS & METHODS: All patients with CDI from all hospital departments diagnosed during period from 1/2011 to 12/2013 were included in the study. Information about sex, age, previous antibiotic treatment, PPI therapy, various comorbidities (trauma, imobility, diabetes, dementia, COPD, IBD) and type of department (surgical/internal) were obtained. Community onset of CDI and recurrent CDI were also recorded. Hospital mortality and risk of recurrence were analyzed in univariate analysis.
RESULTS: Our group consists of 174 patients, 84 men, 90 women, average age 74 years. 27 patients had a recurrent disease (up to 4 recurrences). 51 patients died during hospital stay (hospital mortality 29%). Majority of patients stayed in internal medicine department (100/174, 57%). 39 patients (22%) had onset of disease in the community. In univariate analysis only patients with age ≥70 years (121/174) had significantly higher mortality than those with age under 70 (53/174) (OR 2.599, 95%CI 1.158-5.836, p = 0.021). Other variables were not significant. No risk factor for recurrent CDI was statistically significant.
CONCLUSION: Patients with CDI had overal hospital mortality 29%. 22% of patients had onset of their disease in the community. Age over 70 was the only significant risk factor of mortality in our group of patients. We believe that novel treatment strategies should be considered preferably in elderly patients.

P1503 NECESSITY OF COLONOSCOPY AFTER COMPUTED TOMOGRAPHY- DIAGNOSED ACUTE RIGHT-SIDED DIVERTICULITIS

R. Hashimoto[1,*], A. Chonan[1]
[1]*Gastroenterology, Sendai Kosei Hospital, Sendai, Japan*
Contact E-mail Address: *rinhahsimoto@gmail.com*

INTRODUCTION: Several recent studies have reported that screening colonoscopy is not necessary after computed tomography (CT)-diagnosed uncomplicated diverticulitis in Western countries where most diverticulitis are left-sided. In Japan, as in other Asian countries, more than half of the diverticulitis cases are right-sided. No study has reported on the need for screening colonoscopy after diagnosing diverticulitis in Asian patients.
AIMS & METHODS: The aim of this study was to determine if screening colonoscopy is required in patients with CT-diagnosed diverticulitis. A retrospective cohort study was carried out in a tertiary hospital using hospital registry codes for diverticulitis. All patients diagnosed with acute diverticulitis between April 2008 and January 2014, confirmed by CT, were included.
RESULTS: A radiological diagnosis of acute diverticulitis was made in 173 patients. Six patients (1 right-sided and 5 left-sided) underwent emergency resection at hospital admission, whereas 167 were treated conservatively. Among the conservatively treated patients, 146 (93 right-sided and 53 left-sided) underwent colonoscopy during follow up. The mean age of right-sided diverticulitis patients was significantly lower than that of left-sided diverticulitis patients (46.9 ± 14.1 years vs. 60.7 ± 15.5 years, p < 0.01). There was no colorectal cancer in both groups. There were 8 patients with advanced adenoma (6/93 [6.5%] and 2/53 [3.8%], p = 0.49) and 35 with non-malignant colonic polyp (19/93 [20.4%] and 16/53 [30.2%], p = 0.32).
CONCLUSION: This study showed that the prevalence of colorectal cancer/advanced adenoma/non-malignant colonic polyp in patients with diverticulitis, regardless of the involved side, may be similar to that of asymptomatic average-risk individuals which has been previously reported. In the absence of other indications, routine colonoscopy after CT-diagnosed diverticulitis, even if it was right-sided, may be unnecessary.

P1504 DIGESTIVE TUBERCULOSIS IN THE REGION OF CASABLANCA. EPIDEMIOLOGICAL, DIAGNOSTIC AND THERAPEUTIC ASPECTS

S. Oussama[1,*], M. Tahiri[1], R. Meharich[1], F. Haddad[1], W. Hliwa[1], A. Bellabah[1], W. Badre[1]
[1]*gastroenterology, university hospital Ibn Rochd, Casablanca, Morocco*

INTRODUCTION: Tuberculosis remains a public health problem in Morocco despite the introduction of the vaccination program. Digestive tuberculosis is a common site of extrapulmonary locations.
It can affect any segment of the gastrointestinal tract; however, peritoneal and intestinal locations remain the most frequent. Symptoms are highly variable and non specific, not necessarily referring to the diagnosis of tuberculosis. Diagnosis confirmation is based on microbiological or histological examinations. The treatment is essentially medical.
AIMS & METHODS: This is a retrospective study including 32 patients with tuberculosis over a period of 72 months in the departement of Gastroentérologie in the university hospital of Casablanca:Ibn Rochd. The data have been selected from medical records.
The diagnosis of gastrointestinal tuberculosis was selected on histological or bacteriological evidence.
RESULTS: The average age of patients was 39 years, the sex ratio: 1.8 with a male predominance. Tuberculosis contagion was found in 27% of patients. Clinically all patients had pain and abdominal distention, fever in 36% of cases, a pleural effusion syndrome in 27% and diarrhea in 34% of cases.
Abdominal ultrasonography and computed tomography have objectivied peritoneal effusion in all patients, thickening of digestive handles with lymphadenopathy in 30% of cases.
The ascites puncture revealed liquid rich in proteins in all cases with an average of 57 g/l proteins (40-94 g / l) with lymphocytic predominance.
Search of Mycobacterium tuberculosis was positive in one patient in a rectal biopsy.
At the end of this report 13 cases of peritoneal tuberculosis were isolated and the others were associated with intestinal disease in 10 patients, pleuro-peritoneal localization in 9 patients and one case of hepato-splenic tuberculosis.

Patients with tuberculosis received an antituberculous treatment for 6 months; the outcome was favorable in 82% of cases.
CONCLUSION: Digestive Tuberculosis is a common location of extra pulmonary locations (4th rank) with a predominance of peritoneal involvement, the gastrointestinal tract and solid organs.
Diagnosis is suggested by clinical, biological and radiologic arguments. The diagnosis confirmation is histological or bacteriological.

P1505 THE COST OF ANTIBIOTICS-ASSOCIATED DIARRHOEA IN HOSPITALIZED PATIENTS

S. Vermeersch[1,*], A. Tanghe[1], M. Elseviers[2], L. Annemans[3,4]
[1]*hict NV, Brugge,* [2]*Centre For Research And Innovation In Care, Faculty of Medicine and Health Sciences, University of Antwerp, Antwerp,* [3]*Faculty of Medicine and Pharmacy, Vrije Universiteit Brussel, Brussels,* [4]*Department of Public Health, Ghent University, Gent, Belgium*
Contact E-mail Address: *sebastian.vermeersch@hict.be*

INTRODUCTION: Antibiotic-associated diarrhoea (AAD) is a common adverse event of antibiotic (AB) treatment. Symptoms range from mild and self-limiting to severe diarrhoea, particularly in the case of a *Clostridium difficile* infection (CDI). The cost – be it from a societal, healthcare payer or hospital perspective – for a hospitalized patient experiencing AAD (including non-CDI) is not well established. A better insight in the cost of AAD in hospitalized patients is essential for robust health-economic evaluations of interventions aiming to prevent AAD.
AIMS & METHODS: A cost model was developed for determining the cost of AAD from a societal, healthcare payer and hospital perspective using two complementary approaches: (a) a top-down approach comparing the total (invoice) cost for hospitalization of AAD and non-AAD patients and (b) a bottom-up approach establishing the additional cost for a hospitalized patient with AAD as compared to a hospitalized patient without AAD based on additional resources used in AAD patients.
Data for the top-down and bottom-up models were obtained as part of a study investigating the prevalence of AAD in 743 patients on antibiotics therapy admitted to internal medicine wards in 4 Belgian hospitals. As part of the study protocol, hospital invoices for all included patients (both AAD and non-AAD) were collected and additional resource use specifically attributable to the occurrence of AAD was registered. Resource use registrations included medical acts, lab tests, drugs, number of days in isolation and extra nursing time for the treatment of diarrhoea. Additionally, length of stay differences were calculated from the invoice registrations comparing AAD to non-AAD patients.
For the bottom-up analysis, the cost of hospitalization was calculated by assigning unit costs to the registered additional resource use applicable for the Belgian context based on local health-economic evaluation guidelines. A literature review was performed to determine the cost per day of isolation for the hospital perspective. Length of stay and total invoice cost differences between AAD and non-AAD patients were corrected for confounders using logistic regression analysis, including age, number of AB treatments, type of ward and known risk factors for development of diarrhoea after exclusion of outlier results.
RESULTS: Using the top-down analysis approach, from a healthcare payer perspective, a hospitalization where AAD occurs is 811 EUR more expensive than a hospitalization where no AAD occurs (4,101 EUR AAD; 3,290 EUR non-AAD). Using a bottom-up analysis approach, this cost difference amounts to 1,253 EUR from a healthcare payer perspective; 2,133 EUR from a societal perspective and 274 EUR from a hospital perspective.
CONCLUSION: The results from this study using two complementary cost calculation approaches - one based on total invoice data, one based on additional resource use registrations for AAD – clearly demonstrate the significant impact of the occurrence of AAD on hospitalization cost.

INTRODUCTION: *C. difficile* infection (CDI) is a frequent hospital acquired infection in the elderly often associated with broad-spectrum antibiotics treatments. Currently, vancomycin and metronidazole are the standard therapies for CDI but increasing antibiotic resistances and high recurrence rates emphasizes the need for alternative treatments. *In vitro* intestinal fermentation and cell models are useful platforms for studying separately the interactions between complex microbiota and cell responses.
AIMS & METHODS: The objective of this study is to validate novel intestinal *in vitro* fermentation models of the elderly gut microbiota for the investigation of CDI and antibiotic treatment.
The PolyFermS models were designed to allow parallel testing under highly controlled conditions of treatments applied in test reactors simulating the conditions of the proximal or distal colon reactor. The test reactors were continuously inoculated with the same intestinal microbiota composition produced in a first stage immobilized cell reactor operated under conditions of the proximal colon. CDI was induced in test reactors by spiking *C. difficile* vegetative cells of ribotype 001 or by addition of spores of ribotypes 001 and 012. The elderly models with CDI were validated through antibiotic treatments with the application of daily 150 mg/l ceftriaxone or twice daily 330 mg/l metronidazole. The main bacterial groups (qPCR), metabolite production (HPLC), gut microbiota profiles (pyrosequencing) and cytotoxin titre (Vero cell assay) were determined.
RESULTS: The elderly PolyFermS models showed very high stability for all tested bacterial groups and metabolites over the fermentation period (two models run for 70 and 80 days). V5-V6 sequencing showed that the diversity of the fecal inoculum was maintained in the inoculum reactor while the ratios among the bacterial groups differed. Upon inoculation *C. difficile* colonized in the distal (pH 6.8) but not in the proximal intestinal reactors (pH 5.7), reaching high and stable copy numbers of up to log 8 per ml fermentation effluent and increasing toxin titre over time. Metronidazole administration during ten days strongly impaired growth of butyrate producing bacteria and decreased the *C. difficile* numbers to below the detection limit of qPCR. Two days after cessation of metronidazole treatment *C. difficile* started to re-colonize the reactors.
CONCLUSION: The new PolyFermS model of the elderly gut microbiota and CDI is especially suitable for assessing the potential and mechanisms of new antimicrobials and alternative strategies (e.g. probiotics) to prevent and/or treat CDI.

P1507 AEROMONAS SPECIES: AN OPPORTUNISTIC ENTEROPATHOGEN IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES? A SINGLE CENTER COHORT STUDY

T. Lobatón[1,*], I. Hoffman[1], S. Vermeire[1], M. Ferrante[1], J. Verhaegen[2], G. Van Assche[1]
[1]*GASTROENTEROLOGY,* [2]*MICROBIOLOGY, LEUVEN UNIVERSITY HOSPITAL, Leuven, Belgium*
Contact E-mail Address: *tlobaton@bellvitgehospital.cat*

INTRODUCTION: Exacerbation of inflammatory bowel disease (IBD) has been classically linked to pathogens such as *Clostridium difficile* (*C.diff*) and cytomegalovirus. We recently observed 4 cases with a positive *Aeromonas* stool culture at the time of a severe IBD flare or diagnosis. Its role as an enteropathogen is debated.
AIMS & METHODS: Aim: To explore the significance of positive *Aeromonas* stool cultures in IBD patients and controls.**Methods:** Observational prospective study. All patients with positive *Aeromonas* stool cultures between 1-1-2011 (start of massaspectrometry detection) to 30-10-2013 were indentified in the microbiology database at a referral hospital. Demographics, clinical, biological and endoscopic data were extracted from medical records. Ethics approval was obtained.
RESULTS: 77 patients (11 IBD) were identified. Baseline characteristics are summarized in **Table 1**. Symptoms were diarrhea in 87%, abdominal pain in 51%, fever in 35% and vomiting in 26%. Median (IQR) C-reactive protein was 28 (9-98) mg/L. In 48% of the cases, *Aeromonas* caused a very mild self-limited gastrointestinal infection (GII) and no antibiotics (ATB) were given. Among the 40 cases needing ATB, 20 had a mild-moderate GII; 4 a severe GII with complications; 4 a co-infection by *Campylobacter* and 2 *de novo* Crohn's disease (CD). Hospitalization was needed in 31 cases and in other 21 *Aeromonas* was detected during the hospitalization for other reasons. *A.caviae* and *A.veronii* were isolated in 32 and 27 cases respectively. *A.veronii* was more frequent in IBD patients (50 vs. 32%) and was isolated in 7/18 and 3/4 of the moderate and severe GII whereas *A.caviae* was found in 12/20 of mild self-limited GII. Among the IBD patients, *Aeromonas* triggered a moderate-severe flare in 2 cases of silent ulcerative colitis (UC) on 5-ASA, and appeared in the context of *de novo* CD in 2 more cases. In contrast, *Aeromonas* appeared in 3 CD patients (1 on infliximab (IFX) and azathioprine (AZA) and the other 2 with an ileostoma without treatment) with already active disease;in 3 IBD patients in remission (1 UC on 5-ASA, 1 CD with ileostoma on IFX and 1 CD on AZA) it presented as a mild GII and in 1 asymptomatic CD patient it appeared in a control culture after *C.diff* infection. IBD cases were treated more often with ATB (82 vs. 37%, $P = 0.005$) and had more complications (45 vs. 12%, $P = 0.025$).
Table 1. Baseline characteristics.
Table to abstract P1507

	N = 77
Median (IQR) age (years)	65 (27-78)
Female (%)	35 (46)
IBD: CD/UC/IBDU (%)	7/3/1 (64/27/9)
Previous chronic diarrhea/ Reflux esophafgitis/GI surgery (%)	14/8/8 (18/10/10)
Active oncologic disease (%)	22 (29)
Solid organ Transplant (%)	7 (9)
Previous hospitalization within previous 3m (%)	35 (46)
Previous ATB within previous 3m (%)	19 (25)

CONCLUSION: *Aeromonas* infection presented as a milder infection in non-IBD patients. A.*veronii* was more prevalent in IBD and was associated with worse clinical outcomes. Prospective case controlled data in larger cohorts are needed to establish the true significance of *Aeromonas* as an opportunistic enteropathogen in IBD.

P1508 COLORECTAL CANCER IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN UPPSALA COUNTY, SWEDEN 1970-2010

P.M. Hellström[1,*], K. Björner[1], P. Sangfelt[1]
[1]*Medical Sciences, Uppsala University, UPPSALA, Sweden*
Contact E-mail Address: *per.hellstrom@medsci.uu.se*

INTRODUCTION: Inflammatory bowel disease (IBD), ulcerative colitis as well as Crohn's disease, is associated with an increased risk of colorectal cancer (CRC). The level of lifetime risk of malignant development does however differ between studies and conditions in different countries over time.
AIMS & METHODS: The aim of our study was to review historic cases of IBD-related CRC in the Uppsala region, Sweden, and analyse the clinical characteristics of the cases in question.
From the patient diagnosis registry of Uppsala University Hospital, all patients with a diagnosis of IBD were scrutinized over a period spanning 40 years from 1970 to 2010. The outcome of CRC cases were retrieved and reviewed for clinical information in association with development of malignant disease.
RESULTS: Over the period of 40 years, 49 cases of CRC were found. Out of these, 37 were males and 12 females. The median age for diagnosis of CRC was 46 years, as compared to 72 years for CRC in non IBD-patients ($p<0.001$). The standardized incidence ration (SIR) calculated from 38 patients in the Uppsala region was for the whole CRC group 0.97 (95% confidence interval (CI) 0.92-1.03). For males, SIR was 1.23 (CI 1.18-1.27) and for females SIR was 0.65 (CI 0.59-0.71). There was no preponderance for CRC in smokers or patients with high BMI. The overall 5-year survival was 43.3% with no significant difference between men and women ($p=0.54$). Of note, the younger cases with CRC diagnosis before 30 years of age had a 14.3% 5-year survival, whereas those diagnosed between 30-60 years had a 49.2% 5-year survival, $p<0.013$). The 5-year survival of those diagnosed after 60 years was 44.9% ($p=0.20$).
Mortality from CRC was numerically higher for those diagnosed between 1970-1990 with a 31.7% 5-year survival rate, whereas cases between 1991-2010 had a 47.9% 5-year survival rate ($p=0.25$).
CONCLUSION: Patients with IBD are prone to develop CRC at a much younger age than the population in general. Albeit, the overall lifetime risk for CRC in IBD is similar to that of the general population. However, men seem to be at a higher risk, almost twice that of women for developing CRC in IBD. There was a considerably higher 5-year mortality among those diagnosed at an early age before 30 years of age.

INTRODUCTION: We aimed to investigate the major predictors for developing metachronous colorectal advanced neoplasms during colonoscopic surveillance after initial resections of sporadic adenoma and carcinoma.
AIMS & METHODS: The study included 403 patients (mean age 66.2±9.9yr, M:F = 1.55:1) with initial endoscopic resections of colorectal adenomas and/or intramucosal carcinomas with repeated follow up colonoscopies (an average time of surveillance: 73.9 months). During surveillance colorectal lesions less than 5mm in diameter were not resected. The patients were divided into two groups according to the following risk factors at initial resections; age of patients (less or more than 65 yr), gender (male or female), number of colorectal lesions (single or multiple), size (less or more than 10mm), location (left or right/both), histology (adenoma with low grade dysplasia or high grade dysplasia / cancer). The statistical comparisons were made by Logrank test between 2 groups as for the cumurative incidences of patients with metachronous lesions, and those with metachronous advanced lesions (larger than 10mm, adenoma with high grade dysplasia or cancer). The hazard ratio (HR) values of risk factors for metachronous lesions and those for metachronous advanced lesions according to Cox proportional hazard models were also investigated.
RESULTS: The cumurative incidences of patients with metachronous lesions were significantly higher in male patients ($p<0.001$), those with multiple lesions ($p<0.0001$), those with large lesions more than 10mm ($p<0.001$), those with right/both sided-lesions ($p<0.05$), and those with lesions of high grade dysplasia or cancer ($p<0.005$). The cumurative incidences of patients with metachronous advanced lesions were significantly higher in male patients ($p<0.01$), those with multiple lesions ($p<0.01$), those with large lesions more than 10mm ($p<0.0001$), and those with lesions of high grade dysplasia or cancer ($p<0.0001$). Multivariate analysis showed that male gender (HR 1.78, 95%CI 1.25-2.55), multiple lesions (HR 2.01, 95%CI 1.46-2.77), large lesion (HR 1.88, 95%CI 1.31-2.69), right/both sided-lesion (HR 1.38, 95%CI 1.01-1.90), and lesions of high grade dysplasia or cancer (HR 1.49, 95%CI 1.04-2.14) were statistically significant factors for metachronous lesions, and male gender (HR 2.11, 95%CI 1.18-3.75), multiple lesions (HR 1.70, 95%CI 1.02-2.82), large lesion (HR 2.26, 95%CI 1.28-3.98), and lesions of high grade dysplasia or cancer (HR 1.75, 95%CI 0.99-3.08) were statistically significant factors for metachronous advanced lesions.
CONCLUSION: Male gender and patients with multiple lesions, large lesions more than 10 mm, lesions with advanced pathology at initial resections were confirmed as the major predictors of metachronous advanced lesions during colonoscopic surveillance.
Disclosure of Interest: None declared

P1510 METABOLIC FACTORS WHICH ASSOCIATE WITH PATIENTS HAVING METACHRONOUS COLORECTAL NEOPLASMS DURING SURVEILLANCE AFTER INITIAL COLONOSCOPIC RESECTIONS

S. Kimura[1,*], M. Tanaka[2]
[1]*gastroenterology, Aomori Rousai Hospital, Hachinohe,* [2]*Pathology and Laboratory Medicine, Hirosaki Municipal Hospital, Hirosaki, Japan*
Contact E-mail Address: *georgiabroad@aomorih.rofuku.go.jp*

INTRODUCTION: Recently visceral obesity, insulin resistance, and metabolic syndrome are considered to be important risk factors for developing colorectal neoplasms. After initial resections of colorectal adenoma and carcinoma many metachronous neoplasms requiring endoscopic or surgical resections were detected during surveillance. In this study we aimed to determine the risk factors for occurrence of metachronous colorectal tumors using health examination data of patients undergoing colonoscopic surveillance.
AIMS & METHODS: The study included 348 patients with initial endoscopic resections of colorectal adenomas and/or intramucosal cancers with follow-up repeated colonoscopies after at least one year interval (a median follow-up period 63.2 months). They were classified into 156 patients with subsequent resections of metachronous colorectal lesions (group A), and 192 patients with no metachronous lesions during surveillance (group B). 306 subjects with normal colorectum were also studied as a control group (group C). Health examination data in group A, B, and C were statistically compared to determine the risk factors for developing metachronous neoplasms during surveillance.
RESULTS: Mean age and gender ratio were 66.1 yr, 113:43 (group A), 67.5 yr, 100:92 (group B), 66.4 yr, 181:125 (group C), respectively. No difference of age between 3 groups, but male to female ratio was higher in group A than group B and C ($p<0.01$). Body mass index (kg/m^2) were 24.5 (group A), 23.7 (group B), and 23.5 (group C), demonstrating higher BMI in group A than group B and C ($p<0.05$). The percentages of drinking and smoking were 31.4%, 23.7% (group A), 18.8%, 15.6% (group B), and 22.2%, 14.7% (group C), disclosing higher percentages of drinking in group A than group B and C ($p<0.05$). Mean blood pressures (mmHg) were 139.4/80.4 (group A), 136.9/79.2 (group B), and 135.1/79.1 (group C), respectively. Systolic pressure in group A was significantly higher than that in group C ($p<0.05$) but no difference from group B. Serum total cholesterol and triglyceride (mg/dl) were 203.7, 128.1 (group A), 201.0, 122.0 (group B), 200.8, 103.3 (group C), respectively. Serum triglycerides showed higher serum levels of group A and B than group C ($p<0.005$), although no significant difference of serum cholesterol. Liver function test disclosed higher serum level of γGTP in group A (59.7IU/L) than that in group B (41.6IU/L) and C (34.4IU/L) ($p< 0.005$), although no significant difference of AST and ALT levels. The prevalence of fatty liver evaluated by ultrasound were 38.3% (group A), 26.2% (group B), and 24.1% (group C), respectively. Fatty liver was significantly frequent in group A than group B and C ($p<0.05$). Fasting blood sugars (mg/dl) were 109.2 (group A), 105.6 (group B), 103.0 (group C), disclosing higher level in group A than group C ($p<0.01$) but no difference from group B.
CONCLUSION: Health examination data disclosed that male gender, obesity, high percentage of drinking, high serum level of γGTP, and high prevalence of fatty liver were considered to be the risk factors for developing metachronous colorectal tumors during surveillance after initial colonoscopic resections.

P1511 CONTRASTING COLON/RECTAL CANCER RATIOS IN TWO CHINESE CITIES WITH DIFFERENT BACKGROUND COLORECTAL CANCER INCIDENCES

W.-K. Leung[1,*], L. Gu[2], D. Long[2], W.-Q. Chen[2]
[1]*Department of Medicine, University of Hong Kong, Hong Kong, Hong Kong,* [2]*Department of Gastroenterology, Second Affiliated Hospital, Chongqing Medical University, Chongqing, China*
Contact E-mail Address: *waikleung@hku.hk*

INTRODUCTION: The incidences of colorectal cancer (CRC) are rising rapidly in Chinese, particularly in Hong Kong (HK) where it has emerged as the most common cancer. In contrast, some cities in West China like Chongqing (CQ) are still having a relatively low CRC incidence.
AIMS & METHODS: We studied the epidemiology of colon and rectal cancers in these two Chinese cities (HK and CQ) with different background CRC incidences to gain further insight into the changing CRC epidemiology in Chinese. Data on CRC incidences were retrieved from the HK Cancer Registry and from two large regional hospitals in CQ (West China). We included all patients newly diagnosed to have CRC in a 10-year period (2003-2012). The baseline demographic of CRC patients and the Colon/Rectal cancer ratios (CR ratio) of the two cities were compared.

RESULTS: There was no significant change in CRC incidence over the study period in both cities. The mean age at diagnosis of CRC was significantly younger in the lower prevalent area (CQ) than in the higher prevalent area (HK) (61 vs 71 years; P <0.001). Although the proportion of young (<40 years) CRC patients was significantly higher in CQ than in HK (6.7% vs 2.1%, P <0.001), there was a significantly higher proportion of older (≥70 years) CRC patients in HK (53.1% vs 36.3%; P <0.001). CRC was more common in men in both cities (M:F ratio, 1:3). There was also a remarkable difference in the distribution of colon and rectal cancer between the two cities. Colon cancer was more prevalent in the higher prevalent area (HK) with an overall CR ratio of 1.34, whereas rectal cancer is the predominant cancer in CQ (CR ratio 0.63; P <0.0001). In all age groups, colon cancer is more prevalent than rectal cancer in the high prevalent area (HK) with the CR ratios ≥1. In HK, the CR ratio was significantly higher in female than in male (1.79 vs 1.34; P <0.0001) and progressively increased with ages with the highest CR ratio in the ≥80 years' group (women: 2.18; men: 1.74). In contrast, rectal cancer is more prevalent than colon cancer in lower prevalent area (CQ) in all age groups (CR ratio <1). Similar patterns of rising CR ratios with age and sex were not obvious in the lower prevalent region.
CONCLUSION: When comparing two Chinese regions with different background CRC incidences, there are significantly higher proportions of rectal cancer and young patients with CRC in the lower prevalent region. The increase in CRC in higher prevalent region is attributed to the older population and the marked increase in colon rather than rectal cancer. These findings have important ramifications on the pathogenesis, screening and treatment of CRC in Chinese. The CR ratio may serve as a surrogate marker for monitoring the rapidly changing epidemiology of CRC in developing regions.

P1512 LOWER RISK OF ADVANCED ADENOMA (AA) AND COLORECTAL CANCER (CRC) AMONG PATIENTS WITH A PREVIOUS NEGATIVE RESULT FROM A FECAL IMMUNOCHEMICAL TEST (FIT) FOR CRC. PRELIMINARY DATA ON SECOND ROUND SCREENING

X. Bessa[1,*], L. Carot[2], C. Hernandez[3], C. Alvarez[1], J.M. Auge[4], J. Grau[4], A. Buron[3], F. Macia[3], A. Castells[5], M. Andreu[1]
[1]*Gastroenterology Department,* [2]*Hospital del Mar. Barcelona, Barcelona, Spain,* [3]*Epidemiology and Evaluation Unit, Hospital del Mar. Barcelona,* [4]*Preventive Medicine and Epidemiology Unit,* [5]*Gastroenterology Department, Hospital Clinic, Barcelona, Spain*

INTRODUCTION: Screening for colorectal cancer by FIT is based on consecutive rounds to detect precursor lesions or CRC in early stages. Data on consecutive rounds of FIT screening are limited and based mostly on small population studies.
AIMS & METHODS: We assessed the preliminary data regarding positivity predictive values (PPVs) for advanced adenoma (AA) and CRC among patients with a previous negative result from a FIT.
Methods: Data were collected from 2 rounds of FIT screening in population-based CRC screening program (50 to 70 years old). The PPV for AA and CRC were compared among the first-round participants and second-round participants with a previous negative FIT result.
RESULTS: The rate of positive results from FIT was significantly superior in the first vs. second round screening (6.2% vs. 4.1%, p< 0.0001). Data comparing all participants in the first and preliminary results on second round participants who tested FIT positive and were eligible for colonoscopy were compared (4.195 vs. 1.890 colonoscopy studies performed, respectively). A significant decrease in the PPV was observed for AA and CRC between the first and second round (33.3% to 23.5%; p<0.0001 and 6.29% to 3.1%; p<0.0001), respectively. There were no significant differences in stages (I+II vs. III+IV) of CRC detected in the first and second round (p<0.408). Although not achieving statistical significance, proximal AA were more frequent in the first round (9.0% vs. 7.6%, p<0.083). A significantly increase in proximal location of detected CRC were observed on second round (20.1% vs. 34.5%, p< 0.031)
CONCLUSION: In our population-based CRC screening program the rate of positive results from FIT decrease after a first round, and PPVs of FIT for AA and CRC are significantly lower among second-round participants who tested negative in the first round. Although no differences are observed in CRC stage, more proximal CRC are detected on second round screening for CRC. These results could have a significant impact on the provision cost for population-based CRC screening programs.

P1513 THE DIAGNOSTIC RELEVANCE OF FAECAL LACTOFERRIN TEST IN COLORECTAL CANCER SCREENING

Y. Kazuyoshi[1,*], K. Sato[1], Y. Yabe[1], C. Hongo[1], K. Ito[1], M. Shindo[1], M. Kojima[1], Y. Asanuma[1]
[1]*Health Administration, Japanese Sendai Red Cross Hospital, Sendai, Japan*

INTRODUCTION: Faecal haemoglobin (Hb) and transferrin (Tf) tests are often used in colorectal cancer screening. However, these tests are inadequate when the amount of blood in the test sample is very low. Lactoferrin (LF) is a glycoprotein secreted by most mucosal cells and predominantly by neutrophils as a component of inflammatory response.
AIMS & METHODS: Between June 2011 and June 2012, faecal Lf along with the conventional faecal Hb and Tf tests were undertaken in 2,012 consecutive subjects who underwent screening for colorectal cancer at our hospital. Nescauto® Hemo Plus, Nescauto® Transferrin Plus, and Nescauto® Lactoferrin Plus test reagents were used to assay faecal Hb, Tf and Lf, respectively by using the NS-PlusC15 instrument (all from Alfresa Pharma). Any subject with at least one positive test result underwent colonoscopy as an additional screening test.
RESULTS: There were 477 subjects (23.7%) with two or three positive test results. The positive rates were 6.6% for faecal Hb, 5.7% for Tf, and 17.2% for Lf, reflecting markedly better sensitivity for faecal Lf assay. Further, among the 183 subjects who underwent colonoscopy, 107 had colorectal cancer, ulcerative colitis, or other colonic lesions like diverticula or haemorrhoids. Of the 107 subjects with lesions, 79 were positive in the faecal Lf test; in 64 of these, only Lf test was positive. In contrast, in the conventional faecal Hb and Tf tests, only 43 of the 107 subjects were positive. Additionally, 3 subjects had colorectal cancer, and only one of these was positive for faecal Hb or Tf test, while all 3 were positive in the faecal Lf test.
CONCLUSION: In this comparative study, the positive rate for faecal Lf was about 3 times higher than for either faecal Hb or Tf. This led to more precise cut-off value for faecal Tf test. Therefore, in the screening for colorectal cancer and other colonic lesions that cannot be detected by using the occult blood test, faecal Lf should yield better screening outcome, and serve as a clinically relevant biomarker in this clinical setting.

P1514 LOW PREVALENCE OF SERRATED POLYPOSIS SYNDROME IN SCREENING POPULATIONS – A SYSTEMATIC REVIEW

Y.J. Van Herwaarden[1,*], M.H. P. Verstegen[1], W. Kievit[2], P. Dura[1], F.M. Nagengast[1], I.D. Nagtegaal[3], T.M. Bisseling[1]
[1]*Department of Gastroenterology and Hepatology,* [2]*Department for Health Evidence,* [3]*Department of Pathology, Radboud university medical centre, Nijmegen, Netherlands*
Contact E-mail Address: *Yasmijn.vanHerwaarden@Radboudumc.nl*

INTRODUCTION: Population screening programs offer unique opportunities to study prevalence of less common polyposis syndromes in relatively unbiased populations. For serrated polyposis syndrome (SPS) the most cited prevalence is 1 patient in every 3000 persons (Lockett et al. 2001), but this number has been subject of debate. The change of WHO criteria for diagnosis of SPS in 2010 might also affect the prevalence. An up-to-date estimate of the prevalence of SPS is necessary to predict the number of cases in screening programs.
AIMS & METHODS: A systematic literature search was conducted in the electronic databases Cochrane Library, PubMed, EMBASE and Web of Science up to February 2014 using a search strategy including the terms *serrated, hyperplastic, metaplastic, polyp, polyposis* and *syndrome*. Studies reporting the prevalence of SPS defined by the WHO criteria in screening populations were selected. Two reviewers independently calculated prevalence numbers and appraised risk of bias[1].
RESULTS: Prevalence of SPS in screening populations was reported in six studies (Table 1) and varied between 0 – 0.66%. The highest prevalence (0.34% and 0.66%) was seen in studies (2-3) based on screening programmes preselecting patients with a positive stool test. Colonoscopy based screening programmes (4-6) have the lowest risk of bias reporting prevalences ranging from 0 to 0.09%. The most cited study (1) reporting a prevalence of 0.03%, has a high risk of bias because it is based on data from a sigmoidoscopy based screening trial. Only patients with high risk adenomas or ≥ 20 distal hyperplastic polyps were referred for colonoscopy. Therefore it is likely that patients presenting with proximal serrated polyps were missed.

	Screening method	WHO criteria	SPS patients/ participants	Prevalence, *(95% CI)*	Risk of bias
1 Lockett et al, 2001	Sigmoidoscopy	2000	12/40674	0.03% (0.01-0.05)	High
2 Biswas et al, 2013	gFOBT	2010	5/755	0.66% (0.08-1.24)	High
3 Moreira et al, 2013	FIT	2010	8/2355	0.34% (0.10-0.57)	High
4 Orlowska et al, 2009	Colonoscopy	2000	28/50148	0.06% (0.04-0.08)	Intermediate
5 Kahi et al, 2012	Colonoscopy	2010	3/3170	0.09% (0 – 0.20)	Intermediate
6 Hazewinkel et al, 2014	Colonoscopy	2010	0/1426	0% (NA)	Low

Table 1. Overview of included studies. CI = Confidence Interval, gFOBT = guaiac Fecal Occult Blood Testing, FIT = Faecal Immunochemical Testing, NA = Not Applicable.
CONCLUSION: Due to the low number of high quality studies, true prevalence of SPS is unclear but is likely to be below 0.09%. Prevalence in preselected screening populations after positive stool testing are higher with reported range between 0.34 and 0.66%.

INTRODUCTION: An association between obesity and unfavorable outcomes for various types of malignancy has been established. However, the relationship between fat distribution and lymph node metastasis has not been well studied.
AIMS & METHODS: The aim of our study is to determine the impact of visceral obesity on lymph node metastasis and overall survival in colon cancer. This study reviewed medical records for consecutive patients who underwent radical resection for colon cancer between 2003 and 2008. Metastatic lymph node ratio (MLR) was defined as the number of involved nodes by tumor divided to the total number of resected lymph nodes. Visceral obesity was determined by measuring abdominal fat volume distribution via CT scan and then calculating the percentage of visceral fat (VF%) to total fat area.
RESULTS: 278 patients were divided into two groups: VFs (VF% $\leq$ 29, n = 81) and VFv (VF% $>$ 29, n = 197). The baseline characteristics showed some differences between two groups with respect to body mass index, total cholesterol and the proportion of MLR. In the multivariate analysis, MLR significantly decreased with the higher VF% (OR = 0.406, 95% CI = 0.206–0.801, $P = 0.009$). In addition, MLR was significantly associated with HbA1c, differentiation, lymphovascular invasion and perineural invasion. There was significant difference in overall survival between patients with VF% $\leq$ 29 and those with VF% $>$ 29 ($P = 0.009$).
CONCLUSION: Visceral obesity was associated with a lower ratio of metastatic lymph nodes and higher overall survival.

INTRODUCTION: ERK5 and its direct activator, MEK5, are overexpressed in prostate and breast cancer, correlating with overall poorer disease prognosis, and leading to increased proliferation, metastasis and chemoresistance. In addition, we have previously demonstrated that ERK5 silencing increases colon cancer (CC) cell apoptosis and 5-FU-sensitivity, highlighting the relevance of ERK5 signalling in CC.
AIMS & METHODS: In the present study, we evaluated the expression of MEK5, ERK5, NF-kB and IkB in 284 human CC samples, including normal colonic mucosa, tubulovillous adenomas, and adenocarcinomas with proficient or deficient DNA mismatch repair system (pMMR and dMMR, respectively). In addition, to further evaluate ERK5 signalling in CC, we produced a stable cell line model with differential ERK5 activation via lentiviral transduction and cell sorting of SW620 colon carcinoma cells, to overexpress constitutively active MEK5 (MEK5-CA), dominant-negative (MEK5-DN), or empty vector control. Next, we evaluated the impact of MEK5/ERK5 signalling in cell cycle progression, by flow cytometry following PI staining, and cell migration, by wound healing and Boyden assay. NF-kB activation was estimated by the ratio of NF-kB and IkB expression levels, NF-kB nuclear translocation, and also by luciferase reporter assay. Finally, we performed cecum orthotopic xenografts in NOD. SCID mice and evaluated tumor cell metastization.
RESULTS: Our results show that ERK5 and MEK5 are overexpressed in human adenomas ($p < 0.01$) and pMMR and dMMR adenocarcinomas ($p < 0.05$). Similarly, NF-kB is overexpressed in adenomas, pMMR and dMMR adenocarcinomas, and significantly overactivated in pMMR and dMMR adenocarcinomas ($p < 0.05$). According to TNM staging, more aggressive tumors displayed higher ERK5 overexpression and NF-kB activation ($p < 0.05$), suggesting that ERK5 might be relevant in CC progression and to the acquisition of more invasive and metastatic potential. Interestingly, we observed a significant correlation between ERK5 expression and NF-kB activation, in human adenocarcinoma samples ($p < 0.05$). We also showed that *in vitro,* ERK5 overactivation (MEK5-CA) significantly accelerates cell cycle progression ($p < 0.01$) and increases cell migration ($p < 0.001$), as compared to inactive ERK5 (MEK5-DN) and empty control cell lines. In parallel, MEK5-CA cells displayed increased NF-kB nuclear translocation and transcriptional activity ($p < 0.05$), together with increased expression of mesenchymal marker Vimentin ($p < 0.05$). Finally, we observed that 6-weeks post tumor cell injection into the cecum wall of NOD. SCID mice, MEK5-CA-injected mice presented increased incidence of lymph node metastasis (2/4), compared to MEK-DN mice (0/5).
CONCLUSION: Our results suggest that ERK5/NF-kB signalling pathway is important for tumor onset, progression and metastization, possibly representing a novel therapeutic target in CC treatment.

INTRODUCTION: Colorectal adenoma-dysplasia-cancer (AD-CRC) development is characterised by sequential, random and sporadic ($<45\%$ frequency) mutations of certain genes. Recent epigenetic investigations showed that methylation of selected genes occurs in high frequency ($>95\%$) in early stages of cancer already. New generation sequencing and array technologies now allow the systematic investigation and comparison of genetic or epigenetic alterations in AD-CRC.
AIMS & METHODS: We aimed to evalate the role of epigenetic and genetic alterations in the AD-CRC development using new generation sequencing and DNA methylation arrays. DNA was isolated from fresh frozen biopsy specimens (20 normals; 33 adenomas; 17 CRCs). First, a multiplex PCR panel was designed to amplify mutation hot spots of 12 selected genes (APC, BRAF, CTNNB1, EGFR, FBXW7, KRAS, MSH6, NRAS, PIK3CA, SMAD2, SMAD4, TP53). Amplicons of eight samples were sequenced together at once by a GS Junior instrument (Roche) using ligated, barcoded adaptors for library preparation. Further methylation analysis of 94 genes was performed on Human Colon Cancer EpiTect Methyl II Signature PCR Array (Qiagen) from the same DNA specimen. After RNA isolation whole genome expression analysis was performed with HGU133plus2 microarrays (Affymetrix) from 49 normal, 49 adenoma and 49 CRC specimens and on HT-29 cells with and without 5-aza-deoxycytidin treatment. Immunohistochemistry confirmation of expression changes on protein level was performed using tissue microarrays.
RESULTS: Mutations were found in 76% of adenomas and 78% of the cancer cases. The average number of mutations found in mutated samples was 1; 1,8; 1,9 and 2,3 in low grade adenomas, high grade adenomas, carcinomas and serrated adenomas, respectively. The only mutation found in normal samples was a germ line APC mutation. The APC suppressor gene was mutated in adenomas more frequently than in carcinomas (36% vs. 24%). The most frequently mutated genes were APC, TP53 and KRAS with 36%, 18% and 26% frequencies in adenomas and 24%, 47% and 45% frequencies in carcinomas. Interestingly, no sample was found bearing APC and TP53 mutations together. DNA methylation was found in 100 % of the investigated colorectal adenoma and cancer specimens. Eight genes were found to be methylated in all of the cases. This gen set included SFRP1, MAL, SLIT2, SST, VIM; another set of genes (DKK1, SLI3, TMEFF2) was found to be hypermethylated in adenomas and cancers in $>75\%$ of the cases. In adenomas 56 genes, in dysplasias 40 in cancer 37 genes were methylated ($>50\%$ of the cases). The effect of methylation could be confirmed by decreased mRNA and protein expression. Demethylation treatment successfully restored the expression profile of the top methylated genes.
CONCLUSION: Methylation occurred in early premalignant stages in parallel followed by somatic random mutations in increasing number through the AD-CRC development. Demethylation treatment could reverse the systematic, robust methylation alterations. Epigenetic alterations precede the somatic mutations of the AD-CRC and show higher significance in CRC development than genetic.

P1518 AN ABNORMAL BODY MASS INDEX IS ASSOCIATED WITH AN INCREASED RISK OF RECTOSIGMOID CANCER RISK: INTEREST A SHORT RECTO-SIGMOIDOSCOPY FOR EARLY DETECTION

C. Eveno[1,*], Y. Parc [2], A. Laurent [3], C. Tresallet[4], J.C. Vaillant [4], M. Ducreux[5], J.F. Emile [6] on behalf of COINCIDE group
[1]*lariboisiere hospital,* [2]*saint antoine,* [3]*mondor,* [4]*Pitié,* [5]*IGR,* [6]*ambroise paré, paris, France*

INTRODUCTION: Obesity is a well-known risk factor for colorectal cancer (CRC) and is associated with underweight with a poor prognosis. The French CRC screening is based on cancer register which allow diagnosing one cancer for 2000 performed colonoscopy. We studied the influence of body mass index (BMI), which is evolving during past decades, on the location of CRC and its relevance to adapt the screening.
AIMS & METHODS: From January 2008 to December 2010, all patients consecutively operated for CRC in 20 Parisian centres were collected in a prospective database (COINCIDE project). Data analysis was done through its proprietary algorithm clustering supervised non-parametric (Q-Finder®).
RESULTS: Of the 1908 patients, CRC primary localization was sigmoid or rectal in 1095 patients. Six subgroups of patients with an excess risk of developing rectosigmoid cancer were linked to abnormal BMI. For example, 142 patients from 42 to 69 years, with a BMI from 24 to 33 (overweight and obese) had a surrisk of 1.8. Another subgroup of 123 patients from 53 to 63 years, with a BMI from 14 to 22.4 (underweight) had a 1.9 times higher risk.
CONCLUSION: COINCIDE database is representative, on a very recent period, of the Parisian population of CCR. Abnormal BMI (overweight and underweight) is associated with an excess risk of rectosigmoid CRC. We discuss an intensification of CRC screening for this population by achieving a sigmoidoscopy at the age of 45 years. The validation of the cost and effectiveness of such a practice should be performed prospectively.

P1519 MEK5-ERK5 SIGNALLING INHIBITION DECREASES PROLIFERATION AND INCREASES 5-FLUOROURACIL-INDUCED APOPTOSIS IN COLON CANCER CELLS

D.M. Pereira[1,*], A.E. S. Simões[1], S.E. Gomes[1], R.E. Castro[1,2], P.M. Borralho[1,2], C.M. P. Rodrigues[1,2]

INTRODUCTION: Aberrant MEK5-ERK5 signalling has been reported in several types of human cancer, being established as a critical player in cancer development, and as a key survival signal for chemoresistance in response to several antitumor agents. In colon cancer (CC), MEK5 overactivation was correlated with disease stage progression. Moreover, recent data from our group demonstrated that MEK5 and ERK5 expression is increased in human colon adenomas and adenocarcinomas. Importantly, we have also demonstrated that ERK5 silencing enhances CC cell sensitivity to 5-fluorouracil (5-FU), the most widely used chemotherapeutic for CC treatment.
AIMS & METHODS: In the present study, we aimed to investigate the role of MEK5-ERK5 signalling in CC cell proliferation and sensitivity to 5-FU exposure. For this purpose, HCT116 and SW620 cell lines expressing a constitutively active (CA) or a dominant negative (DN) form of MEK5 were produced by lentiviral transduction, followed by sorting of stably transduced cells.
RESULTS: Our results demonstrate that CA-MEK5 increased cell proliferation ($p < 0.05$) and KRAS expression ($p < 0.01$), in both HCT116 and SW620 cells. In turn, in the HCT116 model, DN-MEK5 increased the expression of p53 ($p < 0.05$) and its transcriptional targets p21 and Puma ($p < 0.01$), as well as cell death following 5-FU exposure ($p < 0.05$). This was further associated with increased caspase-3/7 activation and apoptosis ($p < 0.05$). Conversely, CA-MEK5 reduced 5-FU-induced cytotoxicity and apoptosis ($p < 0.05$). Furthermore, 5-FU exposure markedly decreased the levels of endogenous MEK5 and ERK5 expression and activation ($p < 0.05$). Finally, our results show that MEK5-ERK5 activation may modulate cell proliferation and sensitivity to 5-FU through downregulation of the expression of the tumour suppressor miRNAS, miRNA-143, -145, and -34a ($p < 0.05$).
CONCLUSION: Overall, our results indicate that MEK5/ERK5 pathway overactivation may contribute to CC aggressiveness and chemoresistance, suggesting ERK5-targeted inhibition, via siRNA, miRNA or small-molecule inhibitors, may provide a promising therapeutic approach for CC treatment.

P1520 PTP1B EXPRESSION AND PHOSPHATASE ACTIVITY ARE INCREASED IN PRIMARY COLORECTAL CANCER WHICH LEADS TO A MORE INVASIVE PHENOTYPE

E. Hoekstra[1,*], M. Bruno[1], J.van Der Woude[1], M. Peppelenbosch[1], G. Fuhler[1]

INTRODUCTION: Cell signaling is dependent on the balance between phosphorylation of proteins by kinases and dephosphorylation by phosphatases. This balance if often disrupted in colorectal cancer (CRC), leading to increased cell proliferation and invasion. For many years research has focused on the role of kinases as potential oncogenes in cancer, while phosphatases were commonly assumed to be tumor suppressive. However, this dogma is currently changing as phosphatases have also been shown to positively affect cancer growth. One of these phosphatases is protein tyrosine phosphatase 1B (PTP1B).
AIMS & METHODS: The aim of this study was to investigate the expression and phosphatase activity of PTP1B in CRC, and elucidate its effects on cellular functions and signaling. PTP1B expression was analysed by immunohistochemistry on microsections from biopsies of dysplasia (n = 6), adenocarcinoma (n = 9) and control (inactive ulcerative colitis, n = 5), as well as by western blotting of paired freshly frozen CRC and normal adjacent tissue (n = 10). Phosphatase activity was also assessed in these latter samples by immunoprecipitating PTP1B under saturating conditions, followed by a phosphatase activity assay using PNPP as substrate. To investigate the effects of PTP1B on proliferation, adhesion, migration, and elucidate its downstream targets, we manipulated the PTP1B expression *in vitro* by lentiviral transduction of HCT116 and Caco-2 cells with 2 different shRNAs against PTP1B.
RESULTS: PTP1B expression in intestinal epithelial cells (IECs) is low in normal colon (14% positive; mean intensity 0.2±0.1) and increases from dysplasia to carcinoma (100% positive IECs; with mean intensity rising from 1.4±0.3 to 1.8±0.3 respectively). These results were confirmed by western blot analysis. The intrinsic enzymatic activity of the PTP1B protein is significantly increased in cancer compared to adjacent normal tissue (mean OD 1.0 in CRC compared to 0.2 in normal tissue) (p = 0.001). Knocking down PTP1B in CRC cells reduced the phosphorylation of the mitogenic kinase ERK by approximately 50%, and decreased mRNA levels of downstream targets involved in proliferation; i.e. c-MYC and CyclinD1. Furthermore, adhesion, migration, and proliferation were significantly reduced in PTP1B knockdown cells.
CONCLUSION: Not only is the expression of PTP1B is increased in colorectal cancer as compared to normal tissue, but strikingly, the intrinsic enzymatic activity of the protein is also enhanced, suggesting a role for PTP1B phosphatase activity in CRC progression. Knocking down PTP1B in CRC cell lines results in a less invasive phenotype with lower adhesion, migration and proliferation capabilities, by interfering in the RAS-RAF-ERK pathway. Together these results suggest that inhibition of PTP1B activity is a promising new target in the treatment of colorectal cancer and the prevention of metastasis.

INTRODUCTION: Loss of stroma-mediated inhibitory mechanisms can contribute to uncontrolled proliferation and growth of tumor cells. Expression changes of stromal secreted frizzled-related protein 1 (*SFRP1*) Wnt pathway inhibitor were not evaluated in colorectal carcinoma (CRC) development yet.
AIMS & METHODS: Our aims were to evaluate *SFRP1* expression changes in CRC development by mRNA analysis and immunohistochemistry (IHC). We also aimed to analyse SFRP1 promoter DNA methylation levels in order to identify epigenetic alterations from laser microdissected epithelial and stromal components as well as from isolated myofibroblasts. We aimed to examine the effect of recombinant SFRP1 protein administration and demethylation treatment to CRC cell lines harboring different mutations. For *SFRP1* gene expression examination biopsy samples from CRC (moderately differentiated tumors from sigmoid colon and rectum; n = 49) areas and paired histologically normal colonic mucosa (n = 49) were analyzed by HGU133Plus2.0 microarrays (Affymetrix) and were validated with real-time PCR. SFRP1 IHC was detected on normal biopsy samples (n = 20), surgically removed CRC (n = 35) and colonic tissues containing normal adjacent tumor (NAT), adenoma and CRC areas on the same slide (n = 14). We microdissected at least 10^4 cells from epithelial and stromal components, furthermore, approx. 10^3 α-smooth muscle actin immunopositive myofibroblasts from similar stromal areas of consecutive slides. SFRP1 promoter DNA methylation was evaluated by bisulfite sequencing. Effect of recombinant SFRP1 protein treatment to cell proliferation and apoptosis were examined on SW480 (APC mutant) and HCT116 (APC wild type, β-catenin mutant) cell lines. SFRP1 gene expression analysis was performed on HT-29 (p53 mutant) cells with or without 5-aza-2-deoxycitidine demethylation treatment.
RESULTS: SFRP1 showed decreased expression in mRNA and no expression on protein level in parallel in adenoma and CRC epithelium. We identified α-smooth muscle actin positive myofibroblasts as the main source of stromal SFRP1 protein in NAT areas and adenomas, but this protein expression disappeared along the transition into the malignant stage. DNA hypermethylation of the *SFRP1* promoter was detected in microdissected epithelium in adenoma and CRC and in CRC only in myofibroblasts. Recombinant SFRP1 treatment induced apoptosis and inhibition of proliferation in SW480 and less in HCT116 cells. Demethylation treatment could increase SFRP1 expression significantly in HT-29 CRC cell line.
CONCLUSION: Decreased expression of SFRP1 in CRC development is related to DNA hypermethylation. Epithelial methylation of SFRP1 could be observed in NAT, adenoma and cancer, but myofibroblast SFRP1 methylation could be detected in cancer stage only. The restored expression of SFRP1 in colorectal cancer cell lines leads to decrease in proliferation and apoptosis induction. 5-aza-deoxycytidin is a potential demethylation agent for SFRP1 with consecutive increase in gene expression.

INTRODUCTION: The connection between intestinal inflammation and tumorigenesis is well-established. We previously showed that upregulation of the enteroglial-derived S100B protein amplifies intestinal inflammation via its interaction with the Receptor for Advanced Glycation Endproducts (RAGE). Recently, S100B-p53 protein-protein interaction has been described to be involved in the melanoma. Our aim is to investigate the role of S100B and its interactions with the tumor suppressor p53 in human sporadic colon cancer.
AIMS & METHODS: The expression of S100B, RAGE, p53 was evaluated in cancer and control colonic tissues (n = 8 and 6 subjects, respectively); secretion of VEGF and Filamin was also assessed to estimate cancer cell invasion and angiogenesis, respectively. In order to investigate the direct involvement of the enteroglial protein in tumorigenesis, control colonic tissues were challenged with increasing concentration of S100B (0.05, 0.5 and 5μM, for 48 h) and expression of RAGE, p53, VEGF and Filamin were analysed. Similarly, the effect of Pentamidine (0.05, 0.5 and 5μM, for 48 h), that was previously demonstrated to disrupts the S100B-p53 protein-protein interaction, on p53 expression was assessed on control colon tissues.
RESULTS: In colon cancer the expression of p53 was significantly reduced (18±2 vs. 0.8± 0.1 mm^2, $p < 0.001$), while S100B, RAGE, VEGF and Filamin A were all significantly higher than in control tissues (28±2 vs. 6±0.8 mm^2, 18±3 vs. 2±1 mm^2, 7±1 vs. 1.8±0.9 ng/ml and 7±2 vs. 2.5±1ng/ml, all $p < 0.001$).

In vitro challenge with 5μM of S100B induced a tenfold decrease of p53 (15±0.4 vs. 2.2±0.6 mm^2, $p<0.01$) and a significant increase of RAGE VEGF and Filamin (12±3 vs. 1.3±0.2 mm^2, 1.9±0.3 vs. 5±1 and 1.3±0.2 vs. 8±2 ng/ml, respectively, all $p<0.01$ vs. control); data with S100B 0.05 and 0.5 μM are not shown. Most interestingly, pentamidine treatment yields to a concentration-dependent (0.05-5μM) and significant increase of p53 (8±0.3, 10±3 and 18±3 vs. 3±0.3 mm^2, $p<0.05$, <0.01 and <0.001, respectively).

CONCLUSION: We showed that the S100B protein is significantly increased in human sporadic colon cancer. We also showed that exogenous S100B is able to significantly reduce the expression of p53 protein, together with a consistent increase of RAGE, VEGF and Filamin A and that these effects were completely abolished by pentamidine, that is known to disrupts the S100B-p53 protein-protein interaction. Our data for the first time indicate that the enteric glia is likely involved in the tumorigenesis of colon cancer; at the same time we indicate in the disruption of S100B-p53 protein-protein interaction a new potential target of intervention for colon cancer.

INTRODUCTION: Similar to the cellular hierarchy that drives normal/healthy intestinal crypts, only a limited number of colon cancer cells possess the ability to self-renew and to give rise to all the different cancer cell types of the tumor[1, 2]. These cells, called cancer stem cells (CSCs), are thought to be responsible for colorectal cancer (CRC) initiation, propagation and recurrence. Current views in the field suggest that similar to normal intestinal stem cells, CSCs are regulated by their niche composed of resident or recruited cells that have been hijacked/altered by the tumor in order to exploit them as nurturing cells delivering paracrine signals crucial to CSC maintenance and tumor growth. Among CSC neighboring cells are enteric glial cells (EGCs) that are potent regulators of intestinal epithelial barrier functions[3], but whose impact on CSCs has not yet been studied. We hypothesized that EGCs modulate CSC functions and associated tumorigenesis.

AIMS & METHODS: *In vitro*. CSCs have been FACS-isolated from HT29 CRC cell line based on CD44 and CD133 expression ($CD133^{High}/CD44^{High}$), and cultured in 3D Matrigel in presence of EGCs seeded on Transwell filters. Two types of EGCs were used: a non-transformed EGC line purified from rat embryo (EGC-JUG) and primary cultures of human EGCs (EGC-HOG). Impact of EGCs was assessed on numbers and size of tumorspheres grown from CSCs, and compared to non-transformed human fibroblast CCD-18Co cells as well as known glial-derived soluble factors. *In vivo*. CSCs were injected alone *vs*. concomitantly with EGCs subcutaneously in immunodeficient mice.

RESULTS: Our data demonstrate that *in vitro* EGC-JUG massively increased numbers and size of tumorspheres grown from CSCs. These results were recapitulated by EGC-HOG. In contrast, CCD-18Co fibroblasts induced an increase in tumorspheres size but not in numbers. *In vivo*, concomitant injection of CSCs and EGCs increased tumor load as compared with CSCs injected alone. Furthermore, our *in vitro* preliminary data indicate that EGC-conditioned medium (CM) did not impact CSCs, suggesting that at basal state, EGCs do not release pro-tumorigenic factors. However, CM of EGCs that have been pre-incubated with CRC cells exhibited similar impact on CSCs than direct co-culture with EGCs, indicating that tumor cells activate EGCs to acquire pro-tumorigenic abilities. Among all known EGC-derived soluble factors tested, only prostaglandin E2 (PGE2) reproduced EGC effects on CSC-derived tumorsphere growth *in vitro*. Furthermore, RT-qPCR data show that CRC cells induced increased expression of mPGES-1, the terminal synthase responsible for generating PGE2, in EGCs. Finally, CM of EGCs that have been first pre-incubated with CRC cell-CM and then treated with a specific inhibitor of mPGES-1 (CAY10526), did not impact CSCs, indicating that CAY10526 abolished pro-tumorigenic properties induced by CRC cells in EGCs.

CONCLUSION: Altogether these results strongly suggest that CRC cells activate EGCs to acquire pro-tumorigenic abilities, and that tumor-activated EGCs stimulate CSC clonogenicity and tumorigenicity *via* PGE2-dependent pathways.

INTRODUCTION: Despite recent advances in diagnostics and therapy of colorectal cancer (CRC) the prognosis is still limited, especially in patients with advanced stages of the disease. New diagnostic and therapeutic approaches are therefore highly desirable. Aim of this study was to establish an orthotopic tumor model for CRC by endoscopy-guided implantation of tumor cells in the colon of immunodeficient mice.

AIMS & METHODS: The implantation of CRC tumor cells (Caco-2 and HT29) was primarily performed either subcutaneously or orthotopic by submucosal injection during murine colonoscopy (coloview miniendoscopic system) in CD1 nude mice (n = 6) as well as in NOD/SCID mice (n = 10). For monitoring of tumor development, matrixmetalloproteinases (MMP) expression of tumors was assessed 24h after i.v.-injection of a Cy5.5-labeled MMP-selective tracer (Cy5.5-AF443) by *Fluorescence Reflectance Imaging (FRI)* and *Fluorescence Endoscopy*. Finally, tumors were histologically evaluated.

RESULTS: Subcutaneaously implanted HT-29 cells resulted in a marked tumor growth 14 days after implantation. In contrast, orthotopic implantation in the colon of CD1 mice lead to decelerated tumor development after 17 weeks. In the NOD/SCID mice, distinct tumor growth could already be detected beginning at day 14 after submucosal cell injection. Subsequently, rapid tumors growth with occupation of the entire colonic circumference could be observed. Notably, post mortem analysis revealed suspect liver lesions, which were confirmed to be metastasis by histological evaluation. Pathology revealed CRC limited to the submucosa, explaining the low signal detected by fluorescence endoscopy.

As opposed to HT-29 cells, successful implantation of Caco-2-cells could not be achieved, neither by s.c. nor by orthotopic implantation.

FRI revealed only a discreet tracer uptake in s.c. implanted tumors with a target-to-background ratio of 1.55 ± 0.49. Confirmatively, western blot analysis and IHC proved no significant MMP-2/-9 expression in s.c. implanted tumors. In contrast, MMP-tracer uptake was markedly enhanced in orthotopic implanted tumors.

CONCLUSION: Orthotopic, endoscopy-guided implantation of HT-29 colorectal carcinoma cells was successful in immunodeficient NOD/SCID mice. Therefore, this model appears to be promising for examination of tumor biology and preclinical evaluation of novel diagnostic and therapeutic approaches in the future.

INTRODUCTION: Genomic defects in DNA mismatch repair (MMR) genes (MSH2, MLH1, PSM2 or MSH6) characterize the hereditary non polyposis colon cancer (HNPCC). Moreover, most colorectal cancers (CRC) have MMR defect caused by DNA methylation. Several studies demonstrated that patients with MMR-deficient colon cancers have a more favourable stage-adjusted prognosis. Since the immune environment has been demonstrated to influence CRC prognosis, we aimed to investigate whether MMR genes modulate the immune response in CRC.

AIMS & METHODS: A group of 108 consecutive patients operated on for CRC was retrospectively analysed. The presence of Bethesda criteria for HNPCC diagnosis was assessed. Inflammatory infiltration was quantified by standard histology. Immunohistochemistry for costimulatory molecule CD80, innate immunity (TLR4 and MyD88), tumor infiltrating lymphocytes (CD4, CD8) and MMR genes was performed. Patients were stratified in three groups: no MMR genes defect, MMR genes defects alone and MMR genes defects and at least one positive Bethesda criteria. HT29 (CRC cell line) cells were cultured and transfected with specific siRNAs (siMSH2, siMLH1, siMSH6 and siPSM2) and the rate of CD80+ positive cells was quantified by flow cytometry in presence and in absence of oxidative stress condition. Non parametric statistics and survival analysis were used.

RESULTS: Patients with at least one MMR gene defect had more frequently a high CD8+ lymphocytes infiltration ($p = 0.01$) and more frequently a high CD8/CD4 ratio ($p = 0.01$). Patients with MMR defects alone had a better survival than patients with no defects (HR = 0.40 (95% CI 0.06-1.03), $p = 0.051$). LPMC infiltration, frequency of highCD8+ lymphocytes infiltration and frequency of highCD8/CD4 ratio were significantly higher in patients who had a MMR genes defect alone compared to those who had no MMR genes defect and to those with MMR genes defect and positive Bethesda criteria ($p = 0.014$, $p = 0.01$ and $p = 0.05$). A significantly greater frequency of patients with high CD80 expression was observed in patients who had a MMR genes defect alone compared to patients who had no MMR gene defect and to those with MMR genes defect and positive Bethesda criteria ($p = 0.048$). In standard condition, RNA silencing of MSH2, MLH1 and MSH6 significantly increased CD80+ cells rate ($p = 0.007$, $p = 0.023$ and $p = 0.015$). In oxidative condition, RNA silencing of MSH2 and MSH6 further increased CD80+ cells rate ($p = 0.031$ and $p = 0.015$).

CONCLUSION: Patients with MMR defects and no Bethesda criteria have a better survival. In this group, the antigen presenting cells and CD8+ tumor infiltrating lylmphocyte cross talk was enhanced as shown by higher LPMC infiltration and higher frequency of hiCD80+ and hiCD8+ patients. In vitro silencing of MMR genes expression significantly increase CD80 expression in CRC cells. All together these data support the view that a more effective immune activation in CRC may be responsible of a better prognosis in patients with MMR defects.

INTRODUCTION: Several studies have indicated that continuous exposure to high concentrations of Nitric Oxide (NO), produced by inducibile-NO synthase (iNOS), promote neoplastic transformation in many human cancers and especially in colon cancer (CC). Recently, it has also been suggested that high NO synthesis is a distinctive feature of "cancer stem cells" (CSC), a tumor subpopulation with self-renewal capacity, that may be identified by the expression of the CD133 surface marker.
AIMS & METHODS: Aims of this study were to explore the contribution of NO in the definition of colon CSC features and evaluate potential strategies to treat CC by modulating NO production. By immunohistochemistry analysis we evaluated iNOS and CD133 expression in 30 samples of human CC. Using the DAF-2DA detection system, we assayed the production of intracellular NO in 5 colon CSC lines obtained from human CC tissues. By FACS sorter, we purified the NO^{high} and NO^{low} fractions from all colon CSC lines. We compared the tumorigenic potential of both cell fractions by *in vitro* and *in vivo* assays. To tested the potential antitumor effects of iNOS modulation, we treated colon CSCs with the selective iNOS inhibitor 1400W or we stably transfected these cells with two distinct iNOS-directed short-harpin RNA (shRNAs).
RESULTS: NO^{high} CSCs display an overespression of stem cell markers and higher expression levels of iNOS than NO^{low} cells. Interestingly, immunohistochemistry analysis confirmed that, regardless of tumor differentiation grade and TNM stage, there was a significant association between iNOS overexpression and higher expression level of the stem cell marker CD133, in human CC.
Moreover, we demonstrated, by *in vitro* and *in vivo* assays, that NO^{high} cells displayed higher tumorigenic abilities than NO^{low} fractions. The blockade of endogenous NO availability using a specific iNOS inhibitor and genetic knockdown of iNOS resulted in a significant reduction of colon CSC growth and tumorigenic capacity: a lower capacity to give rise to colonies in soft agar, a dramatic decrease of invasivness and *in vivo* tumor growth (xenotransplantations in nude mice). These data confirmed an integral role for endogenous NO and iNOS activity in the biology of colon CSCs. Interestingly, analysis of the genes altered by iNOS-directed shRNA showed that the knockdown of iNOS expression was associated with a significant down regulation of a wide range of signaling pathways in colon CSCs, especially genes involved in stemness and tumor progression (such as CD133, BMI, b-Catenin and NF-kB pathway).
CONCLUSION: These findings have demonstrated for the first time that endogenous NO plays an important role in defining the stemness properties of colon CSCs through cross-regulation of several cellular signaling pathways. This discovery could shed light on the mechanisms by which NO induces the growth and invasiveness of CC gathering new insights on the link between inflammation and colon tumorigenesis.

INTRODUCTION: In patients with ulcerative colitis, the inconsistency between cumulative risk of colon cancer and cumulative rate of dysplasia suggested the presence of an immune surveillance mechanism. In non inflammatory colorectal cancer, T cell populations were demonstrated to play a significant role in the patients prognosis although it is not clear the trigger of this immune response and its efficiency. Costimulatory interactions are decisive in sensitization of T cells by antigen presenting cells and important for the elicitation of the immune responses. In previous studies, we observed a significant overexpression of CD80 costimulatory molecule in the colonic mucosa of patients with UC with dysplasia and its down-regulation at more advanced stages of carcinogenesis [1,2].
AIMS & METHODS: The aim of this study was to explore the effect of CD80 signaling modulation in a murine model of sporadic carcinogenesis of the colon. Male C57/Bl6 mice (12 weeks old) were injected i.p. with AOM (10 mg/Kg) once a week for 6 weeks. Neutralizing antibodies against CD80 or its inhibitory receptor CTLA4 were administered in order to inhibit or enhance CD80 signaling, respectively. Mice were randomized into three groups and treated i.p. with specific abs or isotype control twice, 3 and 4 months after the first AOM injection. Mice were euthanized 6 months after the first AOM injection. Colons were removed, flushed with PBS, fixed as "Swiss rolls" in formalin and paraffin embedded for histology. Hematoxylin and eosin colonic sections were examined for high grade dysplasia (HGD), low grade dysplasia (LGD), adenoma and inflammation. Non parametric statistics was used.
RESULTS: Invasive carcinoma was absent in all the three groups while adenoma was more frequent in mice injected with anti-CD80 compared to control and anti-CTLA4 treated mice ($p = 0.10$). HGD frequency was significantly augmented in mice treated with anti-CD80 antibody compared to the other two groups ($p = 0.02$). Moreover, HGD extension resulted increased in mice administered with anti-CD80 antibody and minimal in anti-CTLA4 treated mice ($p = 0.034$). LGD foci number and extension were significantly reduced in mice injected with anti-CTLA4 ($p = 0.005$). The inflammatory score resulted lower in mice treated with anti-CD80 but it was similar in control mice and those who received anti-CTLA4.
CONCLUSION: CD80 signaling inhibition caused a significant increase in HGD frequency and extension while its enhancement triggered a complete elimination of HGD and a dramatic reduction of LGD extension. These data suggest that CD80 signaling may control the immune surveillance mechanism in sporadic colon carcinogenesis.

P1528 SUPPRESSION OF INTESTINAL TUMOR-INITIATING CELLS BY INHIBITION OF DNA METHYLATION

Y. Saito[1,*], K. Sakai[1], K. Toshimitsu[1], T. Muramatsu[1], M. Kimura[1], T. Sato[2], H. Suzuki[2], T. Kanai[2], **H. Saito**[1]

INTRODUCTION: Cancer stem cells with self-renewal and multipotent capacity play critical roles in refractory cancers with high metastatic and invasive potential. Although DNA methylation inhibitors such as 5-aza-2'-deoxycytidine (5-Aza-CdR) are emerged as promising drugs in the treatment of malignant disorders, little is known about the effect of DNA methylation inhibition on cancer stem cells. Recently, the new 3-D culture system for stem cells called organoid culture has been developed (Sato T. *et al*. Nature; 459: 262-5, 2009).
AIMS & METHODS: To investigate the effect of DNA methylation inhibition on colon cancer stem cells, treatment with 5-Aza-CdR and knockdown of *Dnmt1* were performed in organoids derived from intestinal tumors of $Apc^{Min/+}$ (*Min*) mice, which is an animal model of colon cancer. *Min* mice were treated with 5-Aza-CdR (1 μg/body weight, $n = 12$) or PBS ($n = 11$) by subcutaneous injection weekly from 6 weeks of age. At 21 weeks of age, mice were dissected and number of intestinal polyps was counted. Stem cells were isolated from intestinal tumors of *Min* mice and maintained by organoid culture. Treatment with 5-Aza-CdR and lentivirus-mediated knockdown of *Dnmt1* were performed in organoids derived from intestinal tumors. Expression profiles of genes including microRNAs after treatment with 5-Aza-CdR and *Dnmt1*-knockdown were analyzed.
RESULTS: Treatment of *Min* mice with 5-Aza-CdR significantly reduced the average number of intestinal adenomas from 66 to 44 (male) and from 65 to 47 (female). The average number of large adenomas ($\geq$ 3 mm) in *Min* mice treated with 5-Aza-CdR was significantly decreased from 24 to11, whereas there was no significant difference in the average number of small adenomas ($<$ 3 mm). We successfully established organoids containing stem cells from intestinal adenomas of *Min* mice by 3-D culture with serum-free medium including epidermal growth factor (EGF) and Noggin. Treatment with 5-Aza-CdR and *Dnmt1*-knockdown significantly reduced the cell proliferation activity of tumor organoids. Microarray analyses of tumor organoids after treatment with 5-Aza-CdR and knockdown of *Dnmt1* revealed that interferon-related genes including *interferon regulatory factor 7 (IRF7)* were activated by inhibition of DNA methylation.
CONCLUSION: These findings indicate that inhibition of DNA methylation prominently suppresses the growth of intestinal tumor-initiating cells through activation of interferon-related genes. Treatment of colon cancers with DNA methylation inhibitors such as 5-Aza-CdR may be a novel therapeutic strategy targeting cancer stem cells.

INTRODUCTION: miRNA expression alterations can be observed in colorectal cancer (CRC), however dysregulation of miRNA might be present in various stages of precancerous lesions, such as adenoma. High-throughput screening platforms became available recently: whole genome miRNA expression microarrays and RT-qPCR panels with hundreds of miRNA specific oligos.
AIMS & METHODS: Our primary aim was to identify the microRNA expression alterations between normal colonic tissue (N), tubular adenoma (AD$<$SUB$>$T$<$/SUB$>$), tubulovillous adenoma (AD$<$SUB$>$TV$<$/SUB$>$) and colorectal cancer (CRC) samples. Another purpose was to determine the

level of miRNA by different methods and in several types of samples such as fresh frozen, FFPET.
Sixty fresh frozen biopsy samples (n = 20 N, n = 11 AD_T, n = 9 AD_{TV}, n = 20 CRC) were collected; and, total RNA were isolated. A miRNA microarray experiment was performed. Then, a series of pools of RNA from the same groups of samples was made to validate the data of microarray by RT-qPCR. Then, RT-qPCR data of FFPET tissues (N n = 3, AD_{TV} n = 3, CRC n = 3) were compared to the microarray and PCR results from fresh-frozen samples. miRNA-mRNA interactions were predicted based on four algorithm and validated by biopsy mRNA microarray data. miRNA-126 was selected to be visualized by in situ hybridization.
RESULTS: Out of the 1733, the detectable number of miRNAs, which could be detected in each group was only a small percentage (N n = 442, AD n = 460, CRC n = 441). 12 miRNA were upregulated (miR-31 logFC = 3, p < 0.001) and 11 miRNA were downregulated only (e.g. miR-10b, logFC = -1.7 p < 0,001) in neoplastic lesions (AD+CRC) compared to N samples. 11 miRNA showed altered expression between AD_T and AD_{TV} (e.g. miR-183 LogFC = 1.5 p < 0.007). Expression levels of 9 miRNA were found to be changed between AD_{T,TV} and CRC groups based on microarray data (e.g. miR-196a logFC = -1.8 p < 0.001). MiRNA expression data could be confirmed by RT-PCR in both FFPE and fresh frozen samples. miRNA-126 array expression results could be confirmed by in situ hybridization. MAP3K1 were identified as the targets of miR-196a in the MAPK signaling pathway.
CONCLUSION: A small number (n = 23) miRNA showed characteristic alteration during neoplastic development, but their impact is remarkable and systematic as a key control element of the upstream mRNA pathways. The identified miRNA expression changes are reproducible through adenoma-dysplasia-carcinoma sequence and in the FFPE tissues as well.

INTRODUCTION: To determine whether texture features of rectal cancer on T2-weighted MR images can predict tumoral response in patients treated with neoadjuvant chemoradiotherapy (CRT)
AIMS & METHODS: We prospectively enrolled 15 consecutive patients (6 females, 63.2±13.4 years) with rectal cancer, who underwent pre- and post-treatment 3T MRI. Treatment protocol consisted of neoadjuvant chemoradiotherapy (CRT) with oxaliplatin and 5-Fluorouracile. Texture analysis using a filtration-histogram technique was performed using a commercial research software algorithm (TexRAD Ltd, Somerset, England, UK) on unenhanced axial T2-weigthed images by manually delineating a region-of-interest (ROI) around the tumor outline for the largest cross-sectional area. The technique selectively filters and extracts textures at different anatomic scales followed by quantification of the histogram using kurtosis, entropy, skewness and mean value of positive pixels (MPP). After chemoradiotherapy, all patients underwent complete surgical resection and the surgical specimen served as the gold standard.
RESULTS: Six patients showed pathological complete response (pCR) and 4 patients, partial response (PR). Five patients were classified as non-responders (NR). Baseline medium texture-scale quantified as kurtosis was significantly lower in the pCR sub-group in comparison with PR+NR (p = .01). Post-treatment kurtosis without filtration was significantly higher in pCR in comparison with PR+NR (p = .045). The change in kurtosis between post-treatment and pre-treatment images was significantly lower in the PR+NR sub-group compared to pCR (p = .038). At baseline, the area under the ROC curves (AUC), to discriminate between pCR and PR+NR, was significantly higher for kurtosis (0.907, p < 0.001) compared to all others parameters. The optimal cut-off value for baseline kurtosis was ≤0.19. Using this value, the sensitivity and specificity for pCR prediction were 100% and 77.8%.
CONCLUSION: Texture parameters derived from T2w images of rectal cancer have the potential to act as imaging biomarkers of tumoral response to neoadjuvant chemoradiotherapy.

INTRODUCTION: The M2 pyruvate kinase (M2-PK) is known a specific enzyme produced in undifferentiated and proliferating tissues. This study aims to evaluate the usefulness of the immunochromatographic M2 pyruvate kinase (iM2-PK) for screening of colorectal cancer (CRC) and premalignant lesions.
AIMS & METHODS: Healthy volunteers and patients with colorectal neoplasms were enrolled in six academic hospitals in capital province of Korea. The value of iM2-PK was compared with immunochromatographic fecal occult blood test (iFOBT) and fecal tumor M2-PK enzme-linked immunosorbent assay (ELISA).
RESULTS: A total of 323 subjects were enrolled. The sensitivity of iM2-PK for CRC was 92.8%, and was superior to that of iFOBT, 47.5% (p < 0.0001). For adenomatous lesions, the sensitivity of iM2-PK was 69.4% and was also superior to 12.1% of iFOBT (p < 0.001). In comparison with M2-PK ELISA, iM2-PK proved significantly better sensitivity for CRC, 97.5% and 80.0% (p = 0.0289). The sensitivity of iM2-PK was higher in advanced stage of CRC compared to cancers confined to mucosa and submucosa (p < 0.05), however, lymph node metastasis had no influence on the sensitivity of iM2-PK.
CONCLUSION: The iM2-PK proved higher sensitivity for CRC and adenomatous lesions than iFOBT. With rapidity and convenience, CRC screening using iM2-PK is promising.

INTRODUCTION: There are discrepancies regarding the effect of antiplatelet and/or anticoagulant therapies in the diagnostic accuracy of fecal immunochemical test (FIT) for colorectal cancer (CRC) detection.
AIMS & METHODS: The aim of this analysis is to assess the influence of anticoagulant and/or antiplatelet treatments in FIT diagnostic accuracy for CRC detection in symptomatic patients. COLONPREDICT study is a prospective blind study of diagnostic tests that has evaluated FIT diagnostic accuracy for CRC detection in symptomatic individuals undergoing a colonoscopy. In the 1567 patients included chronic treatment with acetylsalicylic acid (ASA), clopidogrel and/or acenocumarol was collected. The overall diagnostic accuracy was compared with ROC curves, area under the curve (AUC) and homogeneity test areas and the sensitivity and specificity (at a 100 ng/ml cutoff) was compared using the chi-square test.
RESULTS: 426 (27%) patients were receiving antiplatelet and/or anticoagulant treatments. 215 CCR were detected no difference in prevalence between the two groups (treatment = 12%, control = 14.3%; p = 0.2). FIT diagnostic accuracy for CRC was statistically lower in the treatment group (treatment AUC = 0.81, control AUC = 0.88; p = 0.04). With a 100ng/ml cutoff, 175 (41.1%) patients in the treatment group and 434 (38%) in the control group had a positive result (p = 0.2). At this cutoff, treatment with antiplatelet and/or anticoagulant treatments produced a non significant reduction of FIT sensitivity (90.2%, 91.5%, p = 0.7) and specificity (65.6%, 71%; p = 0.05) for CRC detection. Comparisons of the diagnostic accuracy according to the treatment received are shown in the accompanying table.

Table to abstract P1532

Treatment		AUC	p	Sensitivity	P	Specificity	p
ASA	Yes (16.2%)	0.78	0.04	84.6%	0.2	64%	0.05
	No (83.8%)	0.87		92.1%		70.6%	
Clopidogrel	Yes (3.8%)	0.79	0.2	90%	0.9	70%	0.9
	No (96.2%)	0.86		91.2%		69.4%	
Acenocumarol	Yes (7.9%)	0.80	0.3	94.1%	0.6	62.6%	0.1
	No (92.1%)	0.86		91%		70%	

CONCLUSION: Treatment with acetylsalicylic acid reduces FIT diagnostic accuracy for CRC detection in symptomatic patients.

INTRODUCTION: Advanced colorectal cancers were conventionally considered to develop from sessile-type "polyps". And it has been maintained as the mainstream of development of cancers in colorectum.
But recently advances in endoscopic diagnosis and colonoscopy technology have revealed the existence of many depressed-type cancers, which have a growth pathway different from "*adenoma-carcinoma sequence*".
AIMS & METHODS: The aim is to clarify the pathological features of depressed-type colorectal carcinomas compared with flat- and sessile-type. A total of 20160 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to September 2013. Of these, 847 lesions were T1 carcinomas. According to the morphological/development classification, 194 lesions (22.9%) were depressed-type, 281 lesions (33.2%) were flat-type and 372 lesions (43.9%) were sessile-type. We analyzed the pathological features of these lesions.
RESULTS: The rate of submucosal invasion in all the lesions was 45.9% in depressed-type, 2.7% in flat-type and 2.8% in sessile-type. Within under 5mm in diameter, that was 8.8%, 0.02% and 0.02% respectively. In T1 carcinomas, the rate of vessel permeation was 65.0% in depressed-type, 32.4% in flat-type and 37.6% in sessile-type, that of tumor budding was 37.6%, 15.7% and 17.7%, and that of poorly differentiated adenocarcinoma was 9.8%, 3.9% and 4.6% respectively. The rates of these pathological factors were significantly higher in the depressed-type lesions. On the other hand, the rate of adenomatous component was 6.2%, 51.2% and 55.4%, respectively. This was significantly lower in depressed-type lesions, suggesting that they emerge directly from the normal epithelium without going through the adenoma stage.
CONCLUSION: Depressed-type early colorectal carcinomas tend to invade submucosal layer and grow downward even when they are small in size and show the worth pathological characteristics than the other types. Therefore, more careful endoscopic diagnosis - whether the lesion is depressed type or not - would be needed.

P1534 GENE EXPRESSION PROFILING OF LATERAL SPREADING COLORECTAL TUMORS

S. Minemura[1,*], T. Tanaka[1], M. Arai[1], K. Okimoto[1], D. Maruoka[1], T. Matsumura[1], T. Katsuno[1], O. Yokosuka[1]

INTRODUCTION: Laterally spreading tumors (LSTs) are generally defined as lesions >10 mm in diameter, characterized by lateral expansion along the luminal wall with a low vertical axis. In contrast to other forms of tumor, LSTs are generally considered to have a superficial growth pattern and the potential for malignancy.
AIMS & METHODS: We focused on this morphological character of LSTs, and analyzed the gene expression profile of LSTs. The expression of 168 genes in 41 colorectal tumor samples (17 LST-adenoma, 12 LST-carcinoma, 12 Ip (pedunculated type of the Paris classification)-adenoma, all of which were 10 mm or more in diameter) was analyzed by PCR array. Based on the results, we investigated the expression levels of genes up-regulated in LST-adenoma, compared to Ip-adenoma, by hierarchical and K-means clustering. Next, using an additional 61 samples (39 LST-adenoma, 22 Ip-adenoma), we confirmed the results of the array analysis and determined the localization of the gene product by immunohistochemical staining.
RESULTS: The expression of 129 genes differed in colorectal tumors from normal mucosa by PCR array analysis. As a result of K-means clustering, the expression levels of 5 genes, AKT1, BCL2L1, ERBB2, MTA2 and TNFRSF25, were found to be significantly up-regulated ($p<0.01$) in LST-adenoma, compared to Ip-adenoma. Analysis by immunohistochemical analysis showed that the BCL2L1 protein was significantly up-regulated in LST-adenoma compared to Ip-adenoma ($p=0.0089$).
CONCLUSION: Our findings suggest that LSTs have an unusual profile of gene expression compared to other tumors. BCL2L1 might be an important gene for the organization of LST.

P1535 EVALUATION OF FECAL TUMOR M2-PYRUVATE KINASE (M2-PK) AS A SCREENING TOOL FOR ORGANIC BOWEL DISEASES – PRELIMINARY RESULTS

S. Siminkovitch[1,*] on behalf of Tankova L., Gerova V., Vladimirov B., Penchev P., Nakov V., Valerieva Y.
[1]*Gastroenterology, University Hospital Tzarica Ioanna, Sofia, Bulgaria*
Contact E-mail Address: *sylvie.mitova@abv.bg*

INTRODUCTION: Evaluation of the potential role of fecal M2 pyruvate kinase (M2-PK) test as a screening tool for colorectal cancer (CRC), inflammatory bowel disease (IBD) and colonic polyps and to compare the rapid chromatographic qualitative and ELISA quantitative test for M2-PK determination.
AIMS & METHODS: Fecal samples of 40 patients (19 male, 21 female) at mean age 56±17 were collected in our centre for the period March – November 2013. Ten patients had CRC, 11 patients – IBD (3 had Crohn's disease, 7 ulcerative colitis), 8 had colon adenomas (4pts >1 cm), 11 had normal colonoscopy findings. We also subdivided patients according to disease burden – subgroup A comprised of CRC, IBD and adenomas > 1cm and subgroup B - of small polyps and controls. Rapid M2-PK immunochromatographic test, M2-PK ELISA test and immunological fecal occult blood test (FOBT) were performed in all samples.
RESULTS: In the CRC group Rapid M2-PK test results were positive in 100%, in IBD group – 72.7%, in adenomas group – 50% positive (all >1cm), controls - 18.2%. The M2-PK ELISA test results were positive in 100%, 63.6%, 37.5% and 18.2% respectively. The FOBT resulted positive in 90% of CRC, 72.7% of IBD, 12.5% in polyps group and 0% of controls. In the subgroup analysis the Rapid test was positive in 88% of patients in subgroup A, and negative in 86.7% of subgroup B ($p<0.001$), while the FOBT was positive in 72% of subgroup A and negative in 100% of subgroup B. When comparing the immunochromatographic qualitative test with M2-PK ELISA test we found statistically significant correlation – 91.7% of patients with positive Rapid test had positive ELISA test ($p<0.001$). The estimated sensitivity and specificity of Rapid M2-PK for patients in subgroup A is 91% with a positive predictive value of 92%. The sensitivity and specificity of M2-PK ELISA in the same subgroup is 90% and 81% respectively with a positive predictive value of 90%.
CONCLUSION: Fecal rapid M2-PK test is an easily performed and reliable tool for screening of bowel pathology. The Rapid test correlates with the quantitative ELISA for the determination of M2-PK

INTRODUCTION: Accumulating data indicate that some microRNAs (miRNAs or miRs) function as tumor suppressors or oncogenes in cancer development. The certain miRNAs (miR-143, -145, -34a, -7) were differently expressed in the samples between the tumor and the paired non-tumorous samples in the same patient in colorectal tumors, which was reported by us and others. On the other hand, recent studies indicated that exophytic tumors and flat elevated tumors were different for the expression profile of genome. In the current study, we demonstrated the difference in the miRNA expression profile between exophytic tumors and flat elevated tumors in colorectal tumors.
AIMS & METHODS: We examined the expression of these miRNAs in 131 sporadic exophytic adenomas or early cancers, and 52 sporadic flat elevated adenomas or early cancers to clarify the relationship between the expression of the miRNAs and the endoscopic morphological appearance in the colorectal tumors.
RESULTS: The expression levels of miRs-143, -145, and 34a were significantly reduced in exophytic tumors compared with those in flat elevated tumors. The expression levels of miR-7 and were significantly up-regulated in flat elevated adenomas compared with those in exophytic adenomas.
CONCLUSION: These findings indicated that the expression of onco-related miRNA associated with the morphological appearance of colorectal tumors.

P1537 IMMUNOHISTOCHEMICAL ANALYSIS USING D2-40 AND EVG ENHANCE THE DETECTABILITY OF LYMPHOVASCULAR INVASION IN RECTAL NETS LESS THAN 10MM IN DIAMETER

Y. Kitagawa[1,*], T. Suzuki[2], T. Hara[2], D. Ikebe[3], M. Itami[3], T. Yamaguchi[1]
[1]*Gastroenterology,* [2]*Endoscopy Division,* [3]*Pathology Division, Chiba Cancer Center, Chiba, Japan*

INTRODUCTION: Rectal neuroendocrine tumors less than 10mm in diameter (RNETs≦10mm), confined to submucosal layer (SM), are usually treated by endoscopic resection (ER), and ER is reported to successfully achieve clear resection margin [1]. Previous studies have demonstrated that RNETs≦10mm had relatively low incidence of lymphovascular invasion [2]. Nonetheless, we often detect lymphovascular invasion by immunohistochemical analysis using D2-40 and EVG in addition to HE stain.
AIMS & METHODS: This study aimed to demonstrate enhancement of detection rate of lymphovascular invasion in RNETs≦10mm using D2-40 and EVG stain. We retrospectively reviewed consecutive RNETs≦10mm patients treated by EMR or ESD between November 2005 and March 2014 at Chiba Cancer Center Hospital. Specific data extracted from the medical records included patient sex, age, tumor site, tumor size, depression in the lesion, margin status, depth of SM invasion, mitotic rate, and lymphovascular invasion. According to World Health Organization 2010 classification, tumors were divided into the two groups: G1 (<2/10 high-power fields [HPF]) or G2 (2≧10HPF). In addition to conventional HE stain, lymphatic invasion was identified by D2-40 and venous invasion by EVG stain.
RESULTS: Thirty three patients were recruited in the study (18 male, 15 female; median age 59 years). Characters of the tumor were as below: 3 located in upper rectum, 30 in lower; median size 5 mm (range 1-10); no surface depression in all. On histopathological examination, resection margin was free in 23 patients, indeterminate in 7 and positive in 3. The median depth of SM invasion was 1500μm (range 800-7000) and all tumors were classified as G1. Regarding lymphatic and venous invasion, they were 0% (0/33) and 3.0% (1/33) by HE stain, respectively. While by D2-40 and EVG stain, lymphatic and venous invasion were detected in 6.1% (2/33) and 36.4% (12/33), respectively. Finally, the rate of lymphovascular invasion detected by D2-40 and EVG stain was increased to 36.4% (12/33) as compared to 3.0% (1/33) by HE stain. Assessing the rate of lymphovascular invasion according to tumor size, lymphatic and venous invasion were 7.1% (1/14) and 42.9% (6/14) in the size of >5mm, and 5.3% (1/19) and 31.6% (6/19) in the size of ≦5mm, respectively, showing no significant difference. Similarly assessing the rate according to SM invasion, lymphatic and venous invasion were 11.1% (2/18) and 33.3% (6/18) in the depth of SM invasion >1500μm, and 0% (0/15) and 40% (6/15) in ≦1500μm, respectively, showing no difference.
CONCLUSION: Compared to HE stain, D2-40 and EVG stain is proved to significantly increase detection rate of lymphovascular invasion in RNETs≦10mm. Therefore, application of D2-40 and EVG stain is considered to be indispensable to RNETs≦10mm after ER.

INTRODUCTION: The leucovorin (FOL) and fluorouracil (5-FU) plus oxaliplatin (*l*-OHP; FOLFOX) or FOL and 5-FU plus irinotecan (SN-38; FOLFIRI) regimens with or without molecularly-targeted drugs are widely used as first-line chemotherapy in the treatment of advanced colorectal cancer (CRC). Whether FOLFOX or FOLFIRI is administered first is not significant, however, it is essential that full administration of the targeted dosages of all 3 drugs, 5-FU, *l*-OHP, and SN-38 is achieved. However, this is not always possible and second-line chemotherapy must be abandoned in certain cases due to disease progression, adverse effects or high medical cost in clinical setting. Where possible, the most effective regimen should be selected as the first line of treatment.
AIMS & METHODS: The aim of this study was to determine whether first-line chemotherapy mat be individualized using the collagen gel droplet-embedded drug sensitivity test (CD-DST).
Specimens of primary tumors were obtained between March 2008 and November 2013 from 87 CRC patients who had received no preoperative chemotherapy. Informed consent to measure drug sensitivity was obtained from all patients. The CD-DST allows evaluation of drug sensitivity using isolated, 3-dimensionally cultured tumor cells in a small collagen gel droplet. The CD-DST was performed and the growth inhibition rate (IR) obtained under incubation conditions (5-FU with *l*-OHP at 6.0 and 3.0 μg/ml, or 5-FU with SN-38 at 6.0 and 0.2 μg/ml, respectively, for 24 h). The cumulative distributions of the IR under each condition were evaluated based on evidence that the clinical response rates to FOLFOX and FOLFIRI were almost the same; approximately 50%, respectively. The histogram of individual discrepancy of antitumor effects between FOLFOX and FOLFIRI was also evaluated. Histogram was analyzed with D'Agostino-Pearson omunibus normality test.
RESULTS: Individualization of first line treatment was possible in all patients. FOLFOX and FOLFIRI were recommended as first line chemotherapy in 37 and 44 patients, respectively, and equal efficacy in 6 cases. The histogram of the individual discrepancy showed normal distribution ($p = 0.00679$). The standard deviation (SD) was 15.82.
CONCLUSION: This method has the potential to facilitate the establishment of individualized first line chemotherapy for CRC patients. Improvement in the further prognosis is expected by selection of more effective regimen for advanced CRC patients whose discrepancy of anti-tumor effects between two regimens is greater than one SD in clinical setting.

INTRODUCTION: The introduction of molecular biomarkers as predictive factors for palliative chemotherapy improved the clinical outcome and led to efficient treatment personalization in metastatic colorectal cancer (CRC). However, such a predictive value has not yet been established in patients with locally advanced CRC receiving adjuvant chemotherapy. Since EGFR- and VEGFR-signalling cascades are fundamental for the development of cancer, we assessed correlations of VEGF-C, VEGF-D, VEGFR-3, Hif-1 alpha, PTEN, amphiregulin (AREG) and epiregulin (EREG) expression levels with the clinical outcome in a randomized phase III study of patients with stage II/III CRC receiving adjuvant treatment.
AIMS & METHODS: The patients' data examined in this study were from the collective of the 5-FU/FA versus 5-FU/FA/irinotecan phase III FOGT-4 trial. Tumor tissues from 269 patients were stained via immunohistochemistry for VEGF-C, VEGF-D, VEGFR-3, Hif-1 alpha, PTEN, AREG and EREG expression. The results were evaluated by two independent, blinded investigators. Survival analyses were calculated for all patients receiving 5-FU/FA vs. 5-FU/FA/irinotecan in relation to expression of all makers above.
RESULTS: Patients with negative AREG and EREG expression had a significant longer disease free survival (DFS) in comparison to AREG/EREG positive ones ($p < 0.05$). The benefit on DFS in AREG-/EREG- patients compared to AREG+/EREG+ patients was even stronger under 5-FU/FA/irinotecan ($p = 0.002$). Patients expressing PTEN on their tumor tissues lived longer receiving adjuvant treatment including irinotecan than PTEN- ones ($p < 0.05$). No correlation between clinical outcome and markers related with the VEGFR-pathway was found. Patients with negative VEGF-D expression had a trend for a loobger DFS when treated with 5-FU/FA ($p = 0.106$). Patients with lack of Hif-1 alpha expression remained longer disease free than Hif-1 alpha+ ($p = 0.007$) and profited more treated with the triple adjuvant regime ($p = 0.026$). Finally, patients who were AREG-/EREG-/PTEN+ showed a trend for better overall survival (OS) under 5-FU/FA/irinotecan than without irinotecan ($p = 0.071$).
CONCLUSION: Patients with AREG/EREG negative, PTEN positive and Hif-1 alpha negative CRC tumors might profit in terms of DFS from a treatment containing fluoropyrimidines and irinotecan. Our results suggest a predictive value of these biomarkers concerning adjuvant chemotherapy with 5-FU/FA +/- irinotecan in stage II/III colorectal cancer.

P1540 A PRO-ACTIVE MODEL TO IDENTIFY PATIENTS AT HIGH RISK FOR FAMILIAL CANCER SYNDROMES – RESULTS OF A HIGH YIELD OUTREACH PROGRAM

T. Adar[1,*], L. Tribich[1], S. Lieberman[2], E. Levy-Lahad[2], E. Goldin[1]
[1]*Digestive Diseases Institute,* [2]*Genetic Institute, Shaare Zedek Medical Center, Jerusalem, Israel*
Contact E-mail Address: *adartom@szmc.org.il*

INTRODUCTION: Identifying patients with familial colorectal cancer syndromes is of great importance, for both patients and their family members. Some centers have utilized a reflex testing system, in which every colorectal cancer (CRC) patient is screened for Lynch syndrome (LS). However, the associated cost of such programs hampers their widespread implementation. One possible alternative is to refer only high risk patient for genetic evaluation. We present the results of a proactive outreach program, set to identify patients at risk for familiar colorectal cancer.
AIMS & METHODS: Aim: To evaluate the yield of a proactive outreach program designed to identify patients at high risk for familial colorectal cancer, using discharge letters following surgery for colorectal cancer.
Methods: Charts of patients hospitalized in our tertiary center during 2011-2013 with the diagnosis of CRC were identified. For each case, the discharge letter

from the hospitalization during which they underwent surgery was identified. Un-operated patients were excluded. Then, patients were alphabetically contacted by phone to complete follow up and personal details to ascertain their Bethesda criteria status. We then compared the data from the discharge letters to the follow-up, mainly – the recommendation to complete genetic counseling for either LS or polyposis syndromes.
RESULTS: The program included 96 patients (M:F ratio of 1:1), with a mean age of 67.79. The mean age at diagnosis was 66.29y (31-93y). Mean time to follow up was 545 days after surgery, during which 13 patients had died, one patient was admitted to hospice and 4 were lost to follow up.
After revising the clinical and pathological data of the 96 patients, 26 (27%) have had an indication to complete genetic counseling. Two patients had an indication to complete evaluation for polyposis syndromes, while the other 24 qualified for testing for LS according to the modified Bethesda criteria (16 were under the age of 50y at diagnosis, 4 patients had synchronous or metachronous tumors of the colon, 1 patient had a metachronous Lynch associated tumor, 1 patient was known to have LS, 1 had a suggestive family history and in 1 patient's evaluation was recommended according to tumor's biopsy). From the entire study groups, 2 patient were already after genetic counseling (1 with known LS), and only two patients with indication were referred to genetic counseling (ages 31 and 43y at diagnosis). This means that out of the patients with indication to complete genetic evaluation who have not received previous counseling, approximately 90% of cases did not receive the recommendation.
CONCLUSION: The rate of identification of high risk patients for familial CRC in surgical departments is sub-optimal, even when the indication is obvious at the time of discharge after surgery for CRC. We present a high yield out-reach program which can be easily implemented in any center, and offers a potential for identifying missed cases of LS.
Furthermore, identification of high risk patients and adequate referral for genetic counseling following surgery for CRC should be considered a quality control measurement for surgical departments.

P1541 COLONIC STENTING AS BRIDGE TO SURGERY VERSUS EMERGENCY SURGERY IN OBSTRUCTIVE COLORECTAL CANCER

T. Stigaard[1,*] on behalf of Dr Kristina Safir-Hansen, **dr Trine Stigaard**, dr Jakob Lykke, dr Per Jess.
[1]*Endoscopy unit, The gastrounit, Herlev Hospital, Denmark, Herlev, Denmark*
Contact E-mail Address: *Trine@stigaardlarsen.dk*

INTRODUCTION: About 7-29 % of the colorectal cancers presents with acute obstruction. Acute obstruction is an emergency situation with risk for necrosis, perforation due to colonic distention, bacterial translocation and intracorporal electrolytic fluid imbalance. The situation calls for decompression, traditionally emergency surgery (ES) is performed. ES is associated with a high mortality in 15-34 % of patients and morbidity in 32-64 %, compared to $<5\%$ for elective surgery.
AIMS & METHODS: Comparing patients with malignant obstruction treated with self-expanding metal stent (SEMS) versus primary surgery. Endpoints: 30 days mortality, technical and clinical success. Tumor placement and cancer related death.
Method: Retrospective register study done in the period of 1.1.2008-1.9.2013. 364 patients from the surgical department Køge-Roskilde. 99 treated with SEMS and 256 had surgery.
RESULTS: 130 patients, median age 72 years, 66 women and 64 men. ASA 1: 19.5 %, ASA 2: 79.7% and ASA 3: 0.8 %. Median follow-up 22 months (5-56). There is a significant difference between patient groups and tumor placement. Most patients with palliative stent and patients with bridge to surgery without later surgery, had tumor placed in the sigmoid colon 41.5 %, and the recto sigmoid colon 17 %. Technical and clinical success is respectively 94.6 % and 93.8 %. 6.9 % had complications after SEMS, no significant difference between patient groups. No significant difference in 30 days complications between SEMS versus primary surgery. Overall survival SEMS versus primary surgery shows no significant difference. 15.4 % died before 30 days. No significant difference between patient groups. The number of dead is larger among patients with primary operation, patients with SEMS 9.6 % versus 31.4 % patients with primary operation. Cancer related mortality sjows no significant difference, $p=0.6$. Regarding adjuvant chemotherapy and cancer related mortality no significant difference found between the patient groups.
CONCLUSION: Colonic stenting followed by elective surgery shows no significant difference compared to primary surgery regarding 30 days mortality and complications, but a trend towards higher mortality in the group who went through primary surgery.

P1542 CRC SCREENING USING FEACAL IMMUNOCHEMICAL TEST (FIT) IN IBARAKI PREFECTURE, JAPAN -AN ADVANTAGE OF A TWO-DAY SAMPLING METHOD-

Y. Saito[1,2,*], H. Suzuki[3], I. Hyodo[2,3], I. Yamaguchi[4]
[1]*Department of Gastroenterology, Ibarakiken Medical Center,* [2]*Sub-committee for Colorectal Cancer, Ibaraki Prefectural Council for Controlling and Preventing Life Style-related Disease, Mito,* [3]*Department of Gastroenterology, University of Tsukuba, Tsukuba,* [4]*Ibaraki Health Service Association, Mito, Japan*

INTRODUCTION: A two-day method was shown to have higher sensitivity than a one-day method in 1988, therefore a two-day sampling method through immunological fecal occult blood test (FIT) has been widely accepted by colorectal cancer screening program according to Japanese Colorectal Cancer (CRC) screening guidelines.
AIMS & METHODS: The purpose of this study is to evaluate the positive predictive values and Dukes classification of identified colorectal cancer between the first day positive and the first day negative group. For Regional Screening Program from 2007 to 2012, FIT participants, who were over 40 years old, were screened with 2 samples of stool measured by the OC-SENSOR (Eiken, Japan) with a cut-off value of 100ng/mL (20μg Hb/g stool). The number of participants was 750,839. The participant gender was 41.3% male and 58.7% female. The FIT positive participants were classified into the first day positive group (++) (+-) (+) and negative group (-+).
RESULTS: The positive FIT participants was 53,847 in number, and the total FIT positive rate was 7.17%. The number of the first day positive and negative participants were 33.172 (61.6%) and 20.675 (38.4%) respectively. Work-up examination rates were 72.8% and 74.3% respectively. The number of two-day positive participants was 10.163 (18.8%). CRCs were identified in 1,330 cases. One thousand and forty-one (1,041) cases were from the first day positive group and 289 cases were from the first day negative group. The positive predictive values between the first day positive and negative group were 3.138% and 1.398% respectively. The positive predictive value of FIT-positivity in both days was 6.839%. Identified CRCs were classified according to Dukes classification. Those were 632 (Dukes A intra-mucosal carcinoma), 387 (Dukes A invasive carcinoma), 128 (Dukes B), 153 (Dukes C), 23 (Dukes D) and 7 (unknown). Seventy-eight % of total identified CRCs were from the first day positive group; 459/632 (Dukes A intra-mucosal carcinoma), 72.6%; 310 /387 (Dukes A invasive carcinoma), 80.1%; 116/128 (Dukes B), 90.6%; 130/153 (Dukes C), 85.0%; and 20/ 23 (Dukes D), 87.0%.
CONCLUSION: If one-day sampling of FIT were adopted in the screening program, 27.4% (173/632) of Dukes A intra-mucosal carcinoma and 19.9% (77/387) of Dukes A invasive one would be missed. The highest positive predictive value was shown in the FIT both days-positive group.

INTRODUCTION: Rectal neuroendocrine tumor (NET) incidence is low. So previous studies of Endoscopic treatment in rectal NET have been small sample size studies.

AIMS & METHODS: The aim of this study was to investigate effectiveness of endoscopic treatment in rectal NET below 2cm. From Jan. 2003 to Dec. 2012. 1366 patients diagnosed Rectal NET in 24center was enrolled. Inclusion criteria were endoscopic treatment, under 2cm size, over 18 age. Exclusion criteria included no treatment, treatment, operation, chemotherapy, octreotide therapy, imcomplete data. After exclusion, 411 patients was enrolled. We analyzed the clinicopathologic data and factors affecting incomplete resection. We used Ki-squre, t-test statistically.
RESULTS: In total 411 patients, Age was 49.64±11.33, Male were 238 (57.9%), All symptom were 59 (14.4%), Carcinoid symptom were 13 (3.2%), Family history of NET were 4 (1%), Multiple lesion were 15 (3.6%), Elevated /Flat/ Depressed lesions were 407 (99)/2 (0.5%)/2 (0.5%), Lesion size was 0.58 ± 0.32cm, In histology, Well differentiated neuroendocrine tumor/Well differentiated neuroendocrine carcinoma wred 403 (98.1%)/8 (1.9%), Mucosa/ Submucosa/Proper muscle invasion were 117 (28.5%)/288 (70.1%)/6 (1.5%), Lymphovascular invasion were 4 (1%), EMR/ESD were 300 (73%)/111 (27%), Complete/Incomplete resection were 344 (83.7%)/67 (16.3%), Additional treatment after incomplete resection were 5 (1.5%), Recurrence were 8 (1.9%). The lymphovascular invasion, ESD, Recurrence were significant factor in Incomplete resection.
CONCLUSION: We suggest endoscopic treatment was effective in rectal neuroendocrine tumor below 2cm size. But further study including complication result will be needed.

INTRODUCTION: Increased intestinal permeability plays a role in the pathophysiology and symptom generation in celiac disease (CD), non-celiac gluten sensitivity (NCGS) and irritable bowel syndrome (IBS). The pre-haptoglobin 2, also known as zonulin, is an endogenous modulator of epithelial tight junctions (TJs) and intestinal permeability. Zonulin is the human homolog of the zonula occludens toxin secreted by Vibrio cholerae. Intestinal bacterial infections and gluten evoke zonulin release in the intestinal milieu and in the bloodstream. Zonulin serum levels, their correlation with symptoms and diagnostic value as a disease biomarker in NCGS and IBS remain undetermined.
AIMS & METHODS: In the present study, we aim at characterizing zonulin serum levels in patients with NCGS (n = 11) and IBS-D (n = 9) compared with CD (n = 7; positive control) and healthy controls (n = 7; HC, negative control). NCGS patients were diagnosed based on the presence of gastrointestinal symptoms referable to the ingestion of gluten and in the absence of serological and histological criteria for celiac disease. IBS patients were diagnosed according to Rome III criteria. Celiac disease patients were identified on the basis of symptoms, antibodies and confirmation with duodenal biopsy. ELISA assay was used to evaluate zonulin serum levels; total protein amount was evaluated spectrophotometrically using Nanodrop (Thermo Scientific) and used to normalize data. Clinical data were recorded for each patient including: anti-transglutaminase (TTG) antibodies, anti-deamidated gliadin peptide (DPG) antibodies, IgE, abdominal symptoms and bowel habit.
RESULTS: Zonulin serum levels were significantly different among the four groups ($p < 0.001$). CD patients showed significantly higher serum zonulin levels compared to HC (0.044 ± 0.003 vs 0.01 ± 0.002, $p < 0.001$) and to IBS-D patients (0.018 ± 0.003, $p < 0.05$). NCGS zonulin serum levels were significantly higher than HC (0.01 ± 0.002 vs 0.036 ± 0.007, $p < 0.05$). Compared to all other subgroups, zonulin values in NCGS patients showed a broader range of distribution. Compared to IBS-D, NCGS zonulin values were higher although did not reach statistical significance ($p = 0.06$). Zonulin levels were positively correlated with the titer of anti-DPG antibodies (r:0.6; $p < 0.05$,) and anti-TTG antibodies (r:0.6; $p < 0.05$). In NCGS patients zonulin levels were positively correlated to total serum IgE levels (r:0.6; $p < 0.05$).
CONCLUSION: Our results suggest that zonulin could play a role in the pathophysiology of NCGS and IBS-D. Further studies are needed to assess its role as a biomarker with diagnostic potential in conditions characterized by increased intestinal permeability.

INTRODUCTION: The development of effective treatments for Irritable bowel syndrome (IBS), a functional gastrointestinal (GI) disorder, have been hampered by the lack of animal models. We have established a model of anomalous GI contractility secondary to persistent infection *of Herpes simplex* virus type 1 (HSV-1) in enteric nervous system (ENS) (Gastroenterology 2010;138:1790).
AIMS & METHODS: Since previous studies have suggested that *S. boulardii* may improve quality of life in IBS patients we assessed its effects on HSV-1-induced GI neuromuscular dysfunctions. Male C57/Bl6 mice were inoculated intranasally with HSV-1 and 4 weeks (W) later intragastrically (IG). Mice were allocated to receive IG either *S. boulardii* or vehicle. In an experimental group, the treatment started 1W before IG viral inoculum and lasted until the sacrifice (1W after viral inoculum). The second experimental group were treated from 6W to 10W after IG viral inoculum. At the time of sacrifice (1 or 10W after viral IG inoculum) we determined a) GI motility, fecal pellet expulsion and water content, and distal colonic transit; b) ENS integrity by immunohistochemistry and WB; c) changes in isometric muscle tension following electric field stimulation of ileal segments; d) inflammation by IL-1$\beta\alpha$, TNFα and MCP-1 ELISA in LMMP.
RESULTS: After 1 W, HSV -1 infection of ENS caused delayed GI transit time, impaired cholinergic neuromuscular transmission, altered expression and distribution of the neurofilaments peripherin and βIII-tubulin, and increased expression of MCP-1. Even if supplementation with *S. boulardii* reduced the production of inflammatory cytokines and the deregulated expression of neurofilaments, the treatment failed to influence HSV-1-induced GI neuromuscular dysfunction. However, 10 W after HSV-1 IG administration, *S. boulardii* supplementation almost completely corrected the severity of GI neuromuscular anomalies, restoring GI transit time, cholinergic neuromuscular contractility, faecal water content and colonic expulsion time to levels comparable to those obtained from control mice. Furthermore, *S. boulardii* completely abolished ENS structural alterations and the mild inflammation in ileal LMMP.
CONCLUSION: Dietary *S. boulardii* ameliorates GI neuromuscular dysfunction and ENS anomalies secondary to chronic but not acute HSV-1 infection, underlying its beneficial effects for the treatment of enteric dysmotility disorders associated to mild inflammatory conditions.

P1546 IMMUNE ACTIVATION IS ASSOCIATED WITH SYMPTOM FLARE IN DIARRHOEA PREDOMINANT IRRITABLE BOWEL SYNDROME

M. Moretta[1], J.M. Andrews[1,2], P.A. Bampton[3], **P.A. Hughes**[1,2,*]

INTRODUCTION: IBS has historically been described as a functional neurological motility disorder resulting from alterations in the brain-gut axis, but the underlying mechanisms remain unclear. There is increasing evidence that the immune system is also altered in IBS patients, consistent with a chronic low grade immune activation (Hughes et al. Am. J. Gastro. 2013). However the nature of the immune response remains controversial with conflicting findings as to whether it comprises a predominantly typical or atypical allergic or autoimmune type response. Much of this controversy stems from grouping of all IBS patient subtypes and the use of cross-sectional data.
AIMS & METHODS: We aimed to investigate immune activation in IBS patients longitudinally, comparing immune responses in patient flare vs. when symptom free. 5 IBS-D patients were enrolled in the study and blood samples were taken quarterly (baseline) over a 1 year period and again whenever the patient self-reported symptom flare (flare). Questionnaires related to symptom severity (IBSS) were completed at each blood sample. PBMC were isolated from whole blood via density centrifugation and $1*10^6$/ml cells were cultured in culture media only (unstimulated) overnight, in the presence of PMA/ionomycin for 4 hours or LPS overnight. Cell culture supernatants were collected and analysed for cytokine concentrations using multiplex bead based assay (eBioscience). Baseline cytokine concentrations and IBSS scores were averaged and compared against cytokine concentrations and IBSS scores from patients in flare using paired student t-test.
RESULTS: IBSS scores were significantly increased during self-reported symptom flare compared to baseline. PMA/ionomycin stimulation increased concentrations of IFN-gamma, IL-2, IL-13, IL-21, GMCSF and TNF-alpha and decreased concentrations of IL-4, IL-5, IL-9, IL-10, IL-22, IL-23 and IL-27 relative to concentrations in unstimulated supernatants. LPS stimulation increased concentrations of GMCSF, IFN-gamma, IL-10, IL-13, IL-17, IL-18, IL-21, IL-22, IL-23, IL-27 and TNF-alpha, and decreased concentrations of IL-4 relative to unstimulated supernatants. Cytokine concentrations varied considerably between patients but remained stable at baseline within patient samples. The concentration of unstimulated cytokines did not differ between baseline and flare. The concentration of PMA/ionomycin stimulated IFN-gamma, IL-2, IL-4, IL-5, IL-18 and IL-23 were significantly increased during flare relative to baseline. The concentration of LPS stimulated GMCSF and IL-10 were significantly increased during patient flare vs baseline.
CONCLUSION: Our preliminary findings indicate both innate and adaptive arms of the immune response are altered in IBS-D patients in symptom flare vs baseline. Future investigations with more patients, including IBS-C and IBS-A subtypes, will indicate whether these alterations are IBS-D specific. These studies will potentially identify biomarkers for IBS patients in symptom flare and also novel treatments targeting specific aspects of the immune response.

P1547 LOW SERUM LEVELS OF SHORT-CHAIN FATTY ACIDS AFTER LACTULOSE INGESTION MAY INDICATE IMPAIRED MICROBIAL FERMENTATION IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

R. Undseth[1,*], G. Jakobsdottir[2], M. Nyman[2], A. Berstad[3], J. Valeur[3]

INTRODUCTION: Poorly absorbable, but fermentable carbohydrates may provoke symptoms in patients with irritable bowel syndrome (IBS). This indicates that fermentation plays a role in symptom generation.
AIMS & METHODS: We aimed to measure microbial fermentation products before and after ingestion of an unabsorbable carbohydrate (lactulose) in IBS patients compared to healthy subjects.
Patients with IBS according to Rome III criteria (n = 22) and healthy controls (n = 20) ingested a 10 gram lactulose solution. Short chain fatty acids (SCFA) were measured in serum in fasted state and 90 minutes after lactulose intake, using hollow fiber supported liquid membrane extraction coupled with gas chromatography (1). Symptoms following lactulose ingestion were also assessed.
RESULTS: Lactulose induced more symptoms in patients with IBS than in healthy controls ($p = 0.0004$). Fasting serum levels of SCFA were not different in patients and controls ($p = 0.1$). Levels of SCFA in serum obtained after 90 minutes were significantly lower in patients with IBS compared to healthy controls, both for total SCFA ($p = 0.0002$), acetic acid ($p = 0.0049$), propionic acid ($p = 0.0204$) and butyric acid ($p = 0.0111$).
CONCLUSION: Patients with IBS had lower serum levels of SCFA in response to lactulose ingestion than healthy controls. The results suggest a failure of colonic salvage of carbohydrates in IBS that may be involved in abdominal symptom development.

INTRODUCTION: Corporal discourse is the pronounced utilization of somatic modalities as a mean of communication and emotional expression. The maturity level of defense mechanisms allows the quantification and understanding of developmental level of psychological defenses used by an individual. In irritable bowel syndrome (IBS), both, the developmental level of defense mechanisms and the tendency of corporal discourse have not been extensively assessed.
AIMS & METHODS: To evaluate the developmental level of defense mechanisms and the tendency of corporal discourse among IBS patients compared to healthy volunteers and medical staff members.
We performed a survey assessing for the maturity level of defense mechanisms and the tendency of corporal discourse in 40 adult patients with IBS, 40 adult healthy volunteers and 39 local medical staff members. All participants completed the Defense Style Questionnaire (DSQ-40) and the Corporal Discourse questionnaire. Responses were statistically analyzed by group using one way ANOVA and the Pearson correlation coefficient.
RESULTS: IBS patients tended to use a lower order of defense mechanisms compared to medical staff, but not to healthy volunteers ($F(2.116) = 3.27$, $p = 0.04$). Compared to the other groups, IBS patients tended to use more extensively a corporal discourse ($F(2.116) = 28.36$, $p < 0.01$). In IBS patients, correlations were found between maturity level of defense mechanisms and tendency of corporal discourse (mature factor $r = -0.41$, $p < 0.01$; neurotic factor $r = -0.35$, $p = 0.03$) and between tendency to use somatization as a defense mechanism and tendency to use corporal discourse ($r = -0.38$, $p = 0.01$). Finally, a correlation between situational anxiety/depression and the tendency of corporal discourse was found in both IBS patients and medical staff, (IBS: $r = 0.65$, $p < 0.01$; $r = 0.59$, $p < 0.01$ respectively. Medical staff: $r = 0.42$, $p < 0.01$; $r = 0.41$, $p < 0.01$ respectively).
CONCLUSION: A lower developmental level of defense mechanisms and a higher tendency of corporal discourse are more pronounced in IBS patients. Furthermore, medical staff members and IBS patients share a relation between situational anxiety/depression and the tendency of corporal discourse.

P1549 INFLUENCE OF A LOW-FODMAP DIET ON SYMPTOMS AND GUT MICROBIOTA IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

J. Valeur[1,*], T. Knudsen[2], T. Mellin-Olsen[2], A. Røseth[1]
[1]*Unger-Vetlesen Institute,* [2]*Department of Clinical Nutrition, Lovisenberg Diakonale Hospital, Oslo, Norway*

INTRODUCTION: Reducing intake of fermentable oligo-, di- and monosaccharides and polyols (FODMAP) may improve functional bowel symptoms. We aimed to investigate the effect of such a dietary change on intestinal and extra-intestinal symptoms and gut microbiota in patients with irritable bowel syndrome (IBS).
AIMS & METHODS: IBS patients admitted to Lovisenberg Diakonale Hospital were investigated consecutively from April 2013 to January 2014. Symptoms were assessed by using validated questionnaires to measure both intestinal (IBS-SSS) and extra-intestinal symptoms (HADS, FIS) before and after 4 weeks on a low-FODMAP diet. Fecal gut bacteria DNA analysis was performed by using the GA-map™ Dysbiosis Test (Genetic Analysis AS, Oslo, Norway). This 16S rRNA DNA test utilizes DNA probes to recognize gut bacteria (1) found to best correlate with dysbiosis in patients with IBD and IBS. Dysbiosis index is an index calculated by an algorithm based on bacterial abundance and profile in a fecal sample, measured on a scale from 1 to 10, where values above 2 are considered abnormal. Change in dysbiosis index between week 0 and 4 were investigated.
RESULTS: Forty-eight patients (4 M, 44 F) completed the study. At baseline, 23 and 25 patients had a dysbiosis index classified as "normal" and "abnormal", respectively. These two groups were significantly different regarding intestinal symptom severity (mean IBS-SSS scores 263 versus 304, respectively; $p = 0.04$), but similar regarding extra-intestinal symptom severity. A correlation between dysbiosis index and IBS-SSS was demonstrated ($r = 0.29$, $p = 0.04$), including the subscale measuring pain ($r = 0.30$; $p = 0.04$). Following dietary intervention, symptomatic improvement was demonstrated as a reduction in IBS-SSS (from 285 to 157; $P < 0.0001$), HADS (from 14 to 9; $P < 0.0001$) and FIS (from 72 to 38; $P < 0.0001$). The dysbiosis index changed in 31 (65%) patients while it remained unchanged in 17 (35%) patients. There was no correlation between change in dysbiosis index and change in symptoms following diet.
CONCLUSION: A low-FODMAP diet seems to improve not only intestinal, but also extra-intestinal symptoms in patients with IBS. The GA-map™ Dysbiosis Test showed that patients with higher dysbiosis indices had more severe intestinal symptoms at baseline. The test thus provides information on alterations in bacterial abundance and profiles that may prove valuable for individual patients. However, we did not demonstrate any associations between change in dysbiosis indices and symptoms following dietary intervention.

P1550 TREATMENT SATISFACTION AFTER RETREATMENT AND LONG-TERM THERAPY WITH LINACLOTIDE

C. Díaz[1,*], M. Falques[1], M. Moya[1], D. Vilardell[1], J. Fortea[1], S.J. Shiff[2], J.M. Johnston[3]
[1]*Almirall SA, Barcelona, Spain,* [2]*Forest Laboratories, Jersey City, NJ,* [3]*Ironwood Pharmaceuticals, Cambridge, MA, United States*

INTRODUCTION: The chronic nature of irritable bowel syndrome (IBS) requires pharmacological treatments to achieve long-term sustained symptom control. As IBS symptoms fluctuate over time, it is important that symptom control with pharmacological treatment can be re-established if treatment is re-introduced after a period of discontinuation. Linaclotide (LIN) is a first-in-class, minimally absorbed, guanylate cyclase-C agonist for the treatment of adults with IBS with constipation (IBS-C). One of the pivotal Phase 3 LIN trials (Trial 31) included a 4-week post-treatment randomised withdrawal period (RWP); upon completion of the trial, including the RWP, patients were allowed to continue treatment in an open-label, long-term study (LTS).
AIMS & METHODS: This post-hoc analysis examined the impact on treatment satisfaction of reintroducing LIN after 4 weeks off treatment in patients who were randomised to LIN 290μg once daily in the initial 12-week treatment period in Trial 31. Of these, 158 were subsequently re-randomised to LIN (LIN-LIN) and 154 were re-randomised to PBO (LIN-PBO) in the 4-week RWP. Eligible patients could then receive LIN for a further 78 weeks in the LTS. Patient-reported treatment satisfaction was used as an efficacy measure in the LTS, measured at study visits during Weeks 2, 4, 8, 12, 14 and 16 during Trial 31 and at Weeks 2, 6, 14, 26, 39, 52, 65 and 78 during the LTS. Patients were asked to rate how satisfied they were with the ability of the study medication to relieve their IBS symptoms on a 1-5 point scale (1 = not at all satisfied, 2 = a little satisfied, 3 = moderately satisfied, 4 = quite satisfied, 5 = very satisfied). Data were analysed using a last observation carried forward approach.
RESULTS: At the end of the 12-week treatment period in Trial 31, treatment satisfaction was similar for LIN patients who were re-randomised to PBO and patients who remained on LIN (mean [standard deviation, SD] treatment satisfaction at Week 12: 3.42 [1.34] vs 3.37 [1.34]). During the 4-week RWP, patients re-randomised from LIN to PBO (LIN-PBO) showed a statistically significant ($P < 0.05$) mean reduction in treatment satisfaction compared to patients who remained on LIN (LIN-LIN) and at the end of the RWP the mean (SD) treatment satisfaction for patients in the LIN-PBO group was 3.18 [1.34] vs 3.47 [1.37] for patients in the LIN-LIN group. Following reintroduction of LIN during the

LTS, mean (SD) treatment satisfaction increased to previous levels in the LIN-PBO treatment group within 2 weeks of starting LIN (LIN-PBO, 3.69 [1.17] vs LIN-LIN, 3.70 [1.05]) and this effect was sustained to the end of the 78-week follow-up period (LIN-PBO, 3.93 [1.32] vs LIN-LIN, 3.81 [1.21]). LIN treatment satisfaction increased throughout the long-term study. Similar to the Phase 3 trials, the most common AE observed during the LTS among LIN-treated patients was diarrhoea.

CONCLUSION: Patients with IBS-C who discontinued LIN therapy for a 4-week period experienced a significant reduction in treatment satisfaction; however, subsequent reintroduction of these patients to LIN therapy resulted in a similar, relatively high level of treatment satisfaction to patients who remained on LIN during long-term therapy.

P1551 BASELINE CHARACTERISTICS AS A PREDICTOR OF RESPONSE TO LINACLOTIDE IN PATIENTS WITH IRRITABLE BOWEL SYNDROME WITH CONSTIPATION: A POOLED ANALYSIS OF 2 PHASE 3 TRIALS

C. Díaz[1,*], M. Falques[1], M. Moya[1], D. Vilardell[1], J. Fortea[1], J.M. Johnston[2]
[1]*Almirall SA, Barcelona, Spain,* [2]*Ironwood Pharmaceuticals, Cambridge, MA, United States*

INTRODUCTION: In 2 Phase 3 trials in irritable bowel syndrome with constipation (IBS-C), linaclotide (LIN) treatment was superior to placebo (PBO) based on European Medicines Agency co-primary endpoints (rate of abdominal pain/discomfort responders [Trial 31: 54.8% vs 41.8%; Trial 302: 54.1% vs 38.5%; $P<0.001$] and IBS degree-of-relief responders [Trial 31: 37.0% vs 18.5%; Trial 302: 39.4% vs. 16.6%; $P<0.0001$]). Improvements after 1 month of LIN therapy were highly likely to be maintained at 3 months.[1] A potential association between baseline patient characteristics and likelihood of therapeutic response to LIN is unclear.

AIMS & METHODS: This pooled analysis evaluated potential predictive value of baseline characteristics in 2 pivotal Phase 3 IBS-C trials by comparing demographics (age, sex, body mass index [BMI]) and baseline symptoms (Complete Spontaneous Bowel Movements [CSBM] rate, Bristol Stool Form Scale [BSFS], straining, abdominal pain, discomfort, and bloating) for LIN non-responders vs responders, defined as (1) 12-week abdominal pain/discomfort responders (≥30% reduction in abdominal pain and/or discomfort score [11-point scales], with neither worsening from baseline, for ≥6/12 weeks) and (2) 12-week IBS degree-of-relief responders (symptoms 'considerably' or 'completely' relieved for ≥6/12 weeks).

RESULTS: The pooled analysis included 1602 patients (LIN, n = 805; PBO, n = 797). Baseline characteristics were similar for responders and non-responders in the LIN group and the PBO group (Table). Abdominal discomfort scores and BMI were also similar for responders and non-responders (not shown).

CONCLUSION: Baseline demographics and disease characteristics did not predict treatment response to LIN or PBO in patients with IBS-C in the Phase 3 pivotal trials.

P1552 PINAVERIUM BROMIDE PLUS SIMETHICONE IMPROVES BLOATING IN IBS PATIENTS INDEPENDENTLY OF BMI WHILE DAY/NIGHT VARIABILITY IN DISTENSION IS RELATED TO WEIGHT

G. Mateos[1,*] on behalf of Mexican IBS Working group, J.C. Soto-Perez[2], J. Chiu-Ugalde[3], A. Vargas[4], J.C. Lopez-Alvarenga[5], M. Schmulson[6]

Contact E-mail Address: *jazmin.chiu@takeda.com*

INTRODUCTION: In IBS, bloating seems related to visceral hypersensitivity, while visible abdominal distension to related to hyposensitivity due to delayed intestinal transit.[1] We have previously shown that pinaverium bromide 100 mg + simethicone 300 mg (PB+S), bid, improves bloating but not distension in IBS.[2] However, the relationship of BMI over these responses is unknown. Therefore, in this *post hoc* analysis, we explored the effect PB+S on bloating/distension according to BMI.

AIMS & METHODS: In this *post hoc* analysis, we explored the effect PB+S on bloating/distension according to BMI.

IBS-Rome III patients were randomly allocated to PB+S (n = 127) or placebo (n = 128) during 12-weeks in a double-blind placebo-controlled trial. A 10-cm VAS was used to evaluate the severity of bloating. Abdominal girth was measured twice a day (morning and night) during 7 consecutive days in weeks 1, 6 and 12. Abdominal volume (V) was calculated as: V = (girth cm)3/[6 p2] and day/night differences were determined. Partial etha^2 was calculated by ANCOVA for abdominal volume differences due to treatment and body weight adjusted by the initial volume differences and sex.

RESULTS: Patients were (mean±SD) 35.9±8.9 years old, women: 83.2% and BMI: 26.5±5.3 (Normal: 43%, Overweight: 36%, Obesity: 21%). IBS-subtypes were classified as IBS-C: 44%, IBS-D: 23%, IBS-M: 31% and IBS-U: 2%. At 12 weeks, bloating severity decreased by 18% in the overweight patients and 22% in the obese with respect to normal-weight subjects ($p = 0.32$); PB+S had a 37% effect size vs. placebo ($p < 0.006$). Also, a higher variability in the day/night change of abdominal volume was found in the overweight (39%) and obese (42%) patients compared to the normal ones ($p < 0.03$); the effect size of PB+S was 13% vs. placebo ($p < 0.39$).

CONCLUSION: While PB+S improved bloating in IBS patients independently of BMI, variability in abdominal volume was higher in overweight and obese patients compared to those with normal-weight with a low treatment effect.

P1553 BLOATING IN IRRITABLE BOWEL SYNDROME WITH CONSTIPATION: BASELINE SEVERITY AND RESPONSE TO TREATMENT IN 2 PHASE 3 TRIALS OF LINACLOTIDE

B. Lacy[1], B. Lavins[2], S.J. Shiff[3], J. MacDougall[2], R. Blakesley[3], X.D. Jia[3], M. Currie[2], C. Kurtz[2], **J.M. Johnston**[2,*]
[1]*Dartmouth-Hitchcock Medical Center, Lebanon, NH,* [2]*Ironwood Pharmaceuticals, Cambridge, MA,* [3]*Forest Research Institute, Jersey City, NJ, United States*

INTRODUCTION: Irritable bowel syndrome with constipation (IBS-C) is defined by the presence of abdominal pain or discomfort in association with symptoms of constipation; another common symptom of IBS-C is bloating, but its severity and association with bowel movements (BMs) are not well defined. Linaclotide (LIN) is a guanylate cyclase C agonist approved in the United States and European Union for the treatment of IBS-C.

AIMS & METHODS: The aim of this post-hoc analysis was to: (1) characterise the severity of bloating in IBS-C patients; (2) describe the effect of LIN on bloating; and (3) assess the relationship between bloating and complete spontaneous BMs (CSBMs). Data from 2 LIN phase 3 IBS-C trials (Trials 302 and 31) were pooled for this analysis. Both trials randomised patients to oral once-daily LIN 290 μg or placebo (PBO) after a 2-week pretreatment period. Trial 302 had a 26-week treatment period; Trial 31 had a 12-week treatment period. Patients rated their bloating on a 0-10 point scale (0 = none; 10 = very severe) daily during the pretreatment and treatment periods. Patients also reported spontaneous BM (SBM) and CSBM frequency, stool consistency, straining, and other abdominal symptoms (pain, discomfort, fullness, cramping). Effect of CSBMs on bloating

Table to abstract P1553
Table Pooled responder rates in Phase 3 trials stratified by baseline characteristics

Characteristic	Abdominal pain/discomfort		IBS degree of relief		Abdominal pain/discomfort		IBS degree of relief	
	LIN R	LIN NR	LIN R	LIN NR	PBO R	PBO NR	PBO R	PBO NR
Age, years*	44.50 (12.05)	43.36 (13.91)	45.03 (12.08)	43.33 (13.41)	43.61 (13.75)	43.96 (12.71)	42.34 (13.45)	44.13 (13.05)
Female, n (%)	408 (92.9)	327 (89.3)	287 (93.2)	448 (90.1)	288 (90.0)	420 (88.1)	125 (89.9)	583 (88.6)
CSBM* (no. per week)	0.19 (0.44)	0.19 (0.42)	0.20 (0.44)	0.19 (0.43)	0.25 (0.49)	0.21 (0.47)	0.31 (0.51)	0.21 (0.47)
BSFS* (1-7)	2.34 (1.01)	2.31 (1.08)	2.41 (0.99)	2.27 (1.07)	2.32 (1.00)	2.38 (1.00)	2.25 (0.89)	2.38 (1.02)
Straining* (0-5)	3.60 (0.79)	3.53 (0.80)	3.53 (0.76)	3.59 (0.82)	3.49 (0.79)	3.48 (0.80)	3.42 (0.81)	3.50 (0.79)
Abdominal pain* (0-10)	5.63 (1.67)	5.65 (1.72)	5.66 (1.70)	5.63 (1.69)	5.27 (1.68)	5.79 (1.71)	5.42 (1.70)	5.61 (1.72)
Abdominal bloating* (0-10)	6.73 (1.83)	6.62 (1.81)	6.63 (1.82)	6.71 (1.82)	6.22 (1.79)	6.67 (1.87)	6.26 (1.80)	6.54 (1.86)

was assessed by stratifying the patient's change in daily bloating score by number of days since the patient had a CSBM.
RESULTS: The pooled intent-to-treat (ITT) population consisted of 1602 patients; 98% had baseline bloating scores ≥3. During pretreatment, ≥50% of patients had an average bloating score ≥6.5; only 6% of patients reported ≥1 day with no bloating (score of 0). LIN significantly reduced bloating within the first week of treatment compared with PBO and provided sustained benefit across 26 weeks of treatment. Mean percentage reduction in bloating from baseline for LIN vs PBO was 16% vs 7% at Week 1, 39% vs 24% at Week 12 and 44% vs 24% at Week 26. During the treatment period, the number of days since a patient had a CSBM was strongly associated with a patient's bloating score (i.e. a greater reduction in bloating was associated with more recently having had a CSBM), in both LIN and PBO patients. When controlling for days since last CSBM, the percent decrease in bloating for the LIN group was consistently greater than the PBO group (with non-overlapping 95% confidence intervals). For patients with 0 days since last CSBM, mean percentage improvement in bloating from baseline was 42% vs 33% in the LIN vs PBO treatment groups; this decreased to 35% vs 28% for patients with 2 days since last CSBM and to 21% vs 13% for patients with 4+ days since last CSBM.
CONCLUSION: Bloating is a significant issue in IBS-C patients, as evidenced by high baseline scores. LIN provides sustained reduction in bloating over PBO starting at Week 1 of treatment. Having a CSBM was associated with reduced bloating for LIN and PBO patients, with greater decreases in bloating on LIN vs PBO regardless of time since last CSBM.

P1554 EFFECT OF NICKEL FREE DIET IN IBS PATIENTS WITH NICKEL SENSITIZATION

L. Laterza[1,*], A. Rizzi[1], E. Gaetani[2], E. Nucera[1], V. Valenza[1], D. Schiavino[2], A. Gasbarrini[1]
[1]*CATHOLIC UNIVERSITY OF ROME, Rome, Italy,* [2]*Internal Medicine and Gastroenterology, CATHOLIC UNIVERSITY OF ROME, Rome, Italy*

INTRODUCTION: Irritable bowel syndrome (IBS) is characterized by chronic abdominal pain or discomfort accompanied by abnormal bowel movements, such as diarrhoea or constipation.
In sensitized subjects, the ingested nickel may induce gastrointestinal symptoms similar to IBS, in addition to typical systemic cutaneous lesions.
This clinical picture is known as Systemic Nickel Allergy Syndrome (SNAS).
Although there is no general agreement, a low nickel diet could improve the systemic manifestations. The prevalence of nickel allergy and the effect of nickel-free diet on IBS symptoms are not known.
AIMS & METHODS: To evaluate the prevalence of nickel allergy among IBS patients and to evaluate the effect of nickel-free diet on gastrointestinal symptoms in patients with IBS and nickel-sensitized patients. We selected *35 consecutive patients* affected by IBS defined by Rome III criteria and tested them with nickel patch tests. Patients positive for nickel allergy and meeting criteria for suspected SNAS (history for abdominal symptoms and nickel patch-test) underwent intestinal permeability test. Gastrointestinal symptoms (bloating, abdominal pain, flatulence, cramps, constipation, diarrhoea, epigastric pain, nausea, vomiting) were evaluated using visual analogue scale (VAS–IBS: 0–10) before and after diet. Gut permeability was evaluated by measuring 24-hour urine excretion of orally administered ^{51}Cr-EDTA and expressed as percentage of urinary excretion of the orally administered dose of ^{51}Cr-EDTA (%, cut off < 3%/24h). Then, all patients started a three months low nickel diet. Subjects with increased intestinal permeability at baseline repeated nuclear exam after the diet.
RESULTS: Thirteen patients (M/F: 3/10; age: 39±9) met inclusion criteria. The most frequent profile was diarrhoea predominant IBS (IBS-D, 10/13) compared to mixed (IBS-M, 2/13) and constipation (IBS-C, 1/13). Lactose intolerance was found in 9 patients. 6 subjects showed also sensitization to other haptens (palladium, cobalt, kathon). Mean urinary output of ^{51}Cr-EDTA was 5.88%/24h (±1.44). There was a variable and inconstant behaviour of the change of intestinal permeability after treatment. Conversely, low nickel diet induced a significant and constant improvement of gastrointestinal symptoms (i.e. a reduction of VAS–IBS) in all patients.
CONCLUSION: There is a high prevalence of suspected SNAS and intestinal permeability impairment in patients with IBS. Low nickel diet has significant beneficial effects on gastrointestinal symptoms in subjects with IBS and positive nickel patch test. The effect of such diet on gastrointestinal permeability requires further investigation.

P1555 HOW DO IBS PATIENTS TREAT THEIR SYMPTOMS UNDER REAL LIFE CONDITIONS? RESULTS FROM A SURVEY AMONG THE MEMBERS OF A GERMAN IBS PATIENT ORGANIZATION (DEUTSCHE REIZDARMSELBSTHILFE E. V.)

M. Plomer[1,*], T. Weiser[1], H. Weigmann[1], T. Mück[1], M. Eberlin[1], U. Köhler[2]
[1]*Medical Affairs Germany,* [2]*Corporate Medical Affairs, Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany*
Contact E-mail Address: *manuel.plomer@boehringer-ingelheim.com*

INTRODUCTION: Irritable bowel syndrome (IBS) is a chronic, relapsing and often life-long gastrointestinal disorder[1]. Although not being life-threating, patients suffering from IBS report a significant impact on quality of life by their various symptoms which consist of abdominal discomfort (stomach cramps and bloating) and disordered defaecation (constipation, diarrhea, or both)[1,2]. Besides dietary and lifestyle advices, guidelines recommend pharmacological treatment, adjusted to individual symptoms and patient preferrences[2]. Little data is yet available about patient preferences and treatment habits.
AIMS & METHODS: To investigate the prevalence and severity of the main IBS complaints, as well as the preferred treatment options among the members of a German IBS patient organization (Deutsche Reizdarmselbsthilfe e. V.).
In 2013, non-personalized questionnaires were sent to all the members of the Deutsche Reizdarmselbsthilfe e. V., and returned questionnaires were analyzed by the patient organization.
RESULTS: 717 questionnaires were returned. 62% of respondents were female; on average, IBS patients were 54 years old and over 73% suffered from IBS symptoms for at least 10 years. 87% reported abdominal cramping and pain at least several times per month (categories: up to once every three months/once per month/several times per month/once per week/every day or several times per week), followed by 84% reporting flatulence with the same frequency. There were fewer patients reporting diarrhea, gastric cramps and constipation (several times per month or more often: 69%, 62% and 61%, respectively).
When asked "Do abdominal pain and spasms affect your quality of life permanently and massively? (categories: very strong/strong/moderate/weak/not at all)", 93% of patients answered with "moderate", "strong", or" very strong".
Open questions were asked concerning the preferred therapeutics. Abdominal cramping and pain, as well as gastric cramps were most often treated with the antispasmodic hyoscine butylbromide (N = 318 and 172, respectively), flatulence with simethicone (N = 320). The preferred treatment for diarrhea was loperamide (N = 205), and constipation was treated most often with bisacodyl (N = 138). 68% of hyoscine butylbromide users report ''good'' or ''very good'' efficacy against their abdominal cramps, 86% at least moderate efficacy (categories: very good/ good/ moderate/ not sufficient/ very bad).
CONCLUSION: Abdominal cramping and pain was reported most often and had a high and sustainable influence on quality of life among IBS patients. The preferred treatment options for all symptoms consisted of classical OTC drugs. Hyoscine butylbromide was the most often named and best rated treatment option for the most frequent symptom abdominal cramping and pain.

P1556 SAMPLE SIZE CALCULATION IN CONFIRMATORY TRIALS IN IRRITABLE BOWEL SYNDROME WITH CONSTIPATION: EXPERIENCE WITH LINACLOTIDE

M. Falques[1,*], C. Díaz[1], M. Moya[1], D. Vilardell[1], J. Fortea[1], J.M. Johnston[2]
[1]*Almirall SA, Barcelona, Spain,* [2]*Ironwood Pharmaceuticals, Cambridge, MA, United States*

INTRODUCTION: Calculation of sample size (SS) with sufficient power to detect expected meaningful significant differences vs placebo is necessary for the success of confirmatory pivotal trials in irritable bowel syndrome with constipation (IBS-C). Phase 2b trial data on linaclotide in IBS-C were used as a benchmark to simulate different approaches for SS calculation in Phase 3 linaclotide trials to identify the best option for obtaining sufficiently powered results, and to assess the corresponding power to reject the null hypothesis that no difference in effect exists between active treatment and placebo.
AIMS & METHODS: Protocol design, patient population and endpoint assessments of a pilot Phase 2b (Trial 202) and two Phase 3 pivotal trials (Trial 302; Trial 31) of linaclotide in IBS-C were compared. Two statistical assumptions for the Phase 3 SS calculation for European Medicines Agency (EMA) co-primary endpoints were compared: 1) replication of Phase 2b 290 μg/day results and 2) minimally important clinical differences (MICD).
RESULTS: No relevant differences in protocol design or patient population were identified in the Phase 2b/3 trials. For endpoint assessments, only the range of the pain/discomfort scale differed (Phase 2b: range 1-5; Phase 3: range 0-10). For both clinical endpoints, Phase 2b data showed a non-statistically significant higher placebo effect and a non-statistically significant higher improvement over placebo compared with Phase 3 data (Table). The SS for the Phase 3

Table to abstract P1556
Table Responder rates in Phase 2b/3 studies of linaclotide

Endpoint	Study	Linaclotide 290 μg/day (%)	Placebo (%)	Delta
12-week abdominal pain or discomfort responder rate Patient with ≥30% improvement from baseline in either abdominal pain or abdominal discomfort (with neither getting worse) for ≥50% of the treatment period	Phase 2b (Trial 202) N=169	68	45	23 ($P<0.001$)
	Phase 3 (Trial 302) N=804	54.11	38.46	15.65 ($P<0.0001$)
	Phase 3 (Trial 31) N=800	54.81	41.77	13.04 ($P=0.0002$)
12-week IBS degree-of-relief responder rate Patients who are 'considerably relieved' or 'completely relieved' (score ≤2/5) for ≥50% of the treatment period	Phase 2b (Trial 202) N=169	47	21	26 ($P<0.0001$)
	Phase 3 (Trial 302) N=804	39.40	16.63	22.77 ($P<0.0001$)
	Phase 3 (Trial 31) N=800	37.04	18.48	18.56 ($P<0.0001$)

trials was estimated to have ≥95% power to detect a MICD of 15% in both co-primary endpoints. Based on replication of Phase 2b results for SS calculation assumptions, an SS of 134 patients per treatment arm in Phase 3 trials would have been sufficient to achieve ≥95% power to detect the expected efficacy (i.e. comparable efficacy to Phase 2b). However, this SS would have only 46% and 67% overall power to detect the actual observed results of Trial 31 and Trial 302, respectively, and even less overall power (13% and 47%, respectively) when the MICD is reduced to 10%.
CONCLUSION: In the linaclotide IBS-C clinical programme, Phase 2b results were not a good predictor of Phase 3 outcome, even without major differences in study design. Caution should be exercised when calculating SS for Phase 3 pivotal trials in IBS-C to ensure sufficient power to detect clinically relevant differences vs placebo.

P1557 STATISTICAL APPROACHES TO MISSING DATA IN TRIALS OF IRRITABLE BOWEL SYNDROME WITH CONSTIPATION: EXPERIENCE WITH LINACLOTIDE

M. Falques[1,*], C. Díaz[1], M. Moya[1], D. Vilardell[1], J. Fortea[1], J.M. Johnston[2]
[1]*Almirall SA, Barcelona, Spain,* [2]*Ironwood Pharmaceuticals, Cambridge, MA, United States*

INTRODUCTION: Missing data may affect validity and interpretation of clinical trials and different statistical approaches for handling missing data may lead to different conclusions. As patterns of missing data are often unknown until unblinding, pre-planning the most appropriate method can be difficult but may be guided by experience from similar trials in the same therapeutic area. Information on handling missing data in trials in irritable bowel syndrome with constipation (IBS-C) is limited.
AIMS & METHODS: This post-hoc analysis compared imputation methods for missing data in 2 pivotal Phase 3 clinical trials of linaclotide in IBS-C. Both were randomised, double-blind, placebo-controlled, multicentre trials of linaclotide 290μg once-daily for 12 (Trial 31) or 26 weeks (Trial 302). Pre-specified European Medicines Agency (EMA)-recommended co-primary endpoints were (1) 12-week abdominal pain/discomfort responder rate (patients with ≥30% reduction in abdominal pain and/or discomfort [11-point scales], with neither worsening from baseline, for ≥6/12 weeks) and (2) 12-week IBS degree-of-relief responder rate (patients with symptoms 'considerably'/'completely' relieved for ≥6/12 weeks). These endpoints were analysed using observed cases (OC), last observation carried forward (LOCF), baseline observation carried forward (BOCF), drop-out as non-responder and multiple imputation analysis.
RESULTS: In Trial 302, the different imputation methods for missing data yielded results consistent with the initial OC approach for both co-primary endpoints (Table). Results were similar for Trial 31, with statistically significant treatment differences for all imputation methods for both endpoints ($P<0.0001$ for all except for 12-week abdominal pain/discomfort responder: OC, $P=0.0002$ and drop-out as non-responder, $P=0.0056$).
CONCLUSION: All five imputation methods for handling missing data yielded non-biased results in both linaclotide Phase 3 IBS-C trials, supporting the robustness of linaclotide treatment effects on EMA endpoints. The approach that could be considered to be the most conservative, if any, was 'drop-out as non-responder' because using this method, the treatment effect estimates for both co-primary endpoints were numerically lower than those obtained by other methods.

P1558 REGION-SPECIFIC EFFECTS OF THE HERBAL MEDICINE STW 5 (IBEROGAST®) AND ITS INDIVIDUAL EXTRACTS ON HUMAN INTESTINAL MOTILITY

S. Allam[1,*], D. Krueger[1], O. Kelber[2], I.E. Demir[3], G. Ceyhan[3], F. Zeller[4], M. Schemann[1]
[1]*Human Biology, TUM, Freising,* [2]*steigerwald, Darmstadt,* [3]*Surgery, TUM, Munich,* [4]*Surgery, Freising, Germany*
Contact E-mail Address: *shadyallam@yahoo.com*

INTRODUCTION: The multiherbal drug STW5 (Iberogast® a hydroethanolic extract ofangelica, peppermint, liquorice, greater celandine, caraway, lemon balm, chamomile, bittercandy tuft and milk thistle) is approved in Germany to treat functional dyspepsia and IBS. Recently, we reported region-specific effects in guinea pig and human stomach. Additionallywe demonstrated prosecretory effects on human intestinal epithelium and proposed thatthese effects may be involved in its clinical efficacy.
AIMS & METHODS: Now we investigated the effects ofSTW5 and its individual extracts on smooth muscle from different regions of human gut, alsoto address its mode of action. Methods: We recorded changes in muscle strip activity due to STW5 in 575 circular (CM) orlongitudinal muscle (LM) strips of small or large human intestine from 114 patientsundergoing abdominal surgery. Measured parameters were muscle tone (MT) and phasiccontractions (Motility index, MI).
RESULTS: STW5 induced significantly and dose dependently MT inhibition (64-5120μg/ml). Relaxation was significantly higher in large vs. small intestine and in CM vs. LM. STW5. At aconcentration of 5120μg/ml (which is still subtherapeutic) duodenum and jejunum (D+J) CMshowed comparable spasmolytic effect compared to ileum CM (-5.5±2.2 vs. -6.8±1.1mNrespectively $n=6$, $p=0.6$). However, they showed region-specific responses to MI reduction (ΔMI; -147.5±68.4mN/min, $n=6$, $p=0.004$ vs. -20.6±54.2mN/min, $n=6$, $p=0.6$). MT relaxationof large intestinal CM was significantly higher than in small intestine by 224.2% ($n=12$, $p=0.01$). In large intestinal CM STW5 changed the pattern of contractions into clusters with ahuge transient increase in MI (ΔMI; 292.4±150.4 mN/min; $n=11$, $p<0.05$) followed byinhibition of phasic contractility. Apart from milk thistle and bitter candy tuft, all extractscontributed to inhibitory actions of STW5 on MT and MI of small intestine. G.

Table to abstract P1557
Table Imputation methods for Trial 302

Analysis	12-week abdominal pain/discomfort responder, n (%)			12-week IBS degree-of-relief responder, n (%)		
	Placebo (N=403)	Linaclotide (N=401)	Δ; OR (95% CI)	Placebo (N=403)	Linaclotide (N=401)	Δ; OR (95% CI)
OC	155 (38.5)	217 (54.1)	15.6; 1.89 (1.43;2.51)*	67 (16.6)	158 (39.4)	22.8; 3.26 (2.34;4.53)*
LOCF	172 (42.7)	246 (61.3)	18.7; 2.15 (1.62;2.85)*	74 (18.4)	174 (43.4)	25.0; 3.39 (2.46;4.67)*
BOCF	132 (32.8)	191 (47.6)	14.8; 1.88 (1.41;2.51)*	68 (16.9)	158 (39.4)	22.5; 3.20 (2.30;4.44)*
Drop-out as non-responder	134 (33.3)	186 (46.4)	13.1; 1.75 (1.31;2.33)*	65 (16.1)	139 (34.7)	18.6; 2.75 (1.97;3.84)*
Multiple imputation approach	177 (43.8)	246 (61.3)	17.5; 2.05 (1.53;2.74)*	70 (17.4)	167 (41.7)	24.3; 3.40 (2.42;4.76)*

celandineincreased MI in D+J vs. reduction of ileum contractility (ΔMI; 74.7±29.0mN/min, n = 9, p = 0.001vs. -76.6±20.7mN/min, n = 7, p = 0.001 respectively). In large intestine, additionally caraway had no influence on MT. Peppermint, liquorice and angelica mimicked STW5 effect on MI. G. celandine increased MT without affecting MI. STW5 effects on MT and MI were reduced by blockade of TRPA1 channels (HC030031, by 50.4 and 74.0%, respectively), SOCs blocker (SK&F96365, by 35.2% and 69.5%), and TRPC3 antagonist (Pyr3, by 39.3% and 100.0%)(all 10μM).

CONCLUSION: *Our experiments identified region and layer specific effects of STW5 in human intestinal smooth muscle. The inhibitory effects were mediated by a closure of SOCs belonging to the TRPC3/TRPA1 family, resulting in decreased intracellular calcium levels. With the exception of milk thistle and iberis amara all extracts contributed to the effects of STW5. Peppermint, angelica and liquorice mimicked its inhibitory action on muscle activity. Due to the region and target specific effects of STW5 and its components we propose a potential to treat motility disorders of small and large intestine.*

P1559 REDUCED QUALITY OF LIFE (QOL) IN SUBJECTS WITH IRRITABLE BOWEL SYNDROME (IBS) – HOW COULD IT BE IMPROVED?

V.L. Michalsen[1,2,*], P.O. Vandvik[2,3], P.G. Farup[1,2]
[1]*Faculty of Medicine, Norwegian University of Science and Technology, Trondheim,* [2]*Dept. of Medicine, Innlandet Hospital Trust, Gjøvik,* [3]*Faculty of Medicine, University of Oslo, Oslo, Norway*
Contact E-mail Address: *pfarup@gmail.com*

INTRODUCTION: Reduced Quality of Life (QoL) is common and often the main problem for subjects with Irritable Bowel Syndrome (IBS), and treatment should focus more on this problem to improve and individualize the treatment of these patients.

AIMS & METHODS: This study aimed at finding predictors of reduced physical and mental QoL in patients with IBS. Consecutive subjects with IBS (Rome II criteria) in general practice were included in this cross-sectional study. Information about gender, age (years), smoking habits (daily: yes/no), alcohol (more or less than twice a week), education (more or less than 10 years), duration of IBS (years), and severity of IBS-symptoms (a product of severity and frequency, score 0-12) were noted. Short Form 12 (SF12) was used for the measurement of physical QoL (SF-12 PCS, reference value 50) and mental QoL (SF-12 MCS, reference value 50). Somatic comorbidity was measured as the number of organic diseases and unspecified organic symptoms with Subjective Health Complaints 17 (SHC-17, reference value 6.2). Mental health complaints (anxiety, depression and somatization) was measured with Hopkin Symptom Checklist 10 (SCL-10, score 1-4, reference value < 1.85), hypochondria with Whiteley index (WI, score 14-70, ref. value < 40), and personality with Eysenck Personality Questionnaire (EPQ) short form 10 with focus on neuroticism (score 0-10). The study conforms to the principles of the Declaration of Helsinki and was approved by the Norwegian Regional Committees for Medical and Health Research Ethics. Results are given as mean (SD) or median (range), and multivariable analyses as partial correlation (pc) and p-values (p).

RESULTS: Out of 208 consecutive subjects with IBS, 149 were included in the study. Demographics; age: 52 years (SD 15.3); women: 105 (70%); daily smokers: 49 (36%); alcohol ≥ twice a week: 23 (17%); duration of IBS: 10 years (1-55); and IBS symptom score: 2 (0-12). Somatic comorbidity: number of organic diseases: 2 (0-9); and SHC-17: 12 (0-42). Psychiatric comorbidity: SCL-10: 1.7 (1.0-3.8); WI: 25 (14-60); and EPQ: 4 (0-10). QoL: SF-12 PCS: 38.4 (11.9); and SF-12 MCS: 45.0 (11.3). Independent predictors (multivariable analyses) of high SF-12 PCS were number of organic diseases (pc = - 0.168; p = 0.046) and SHC-17 (subjective health complaints, pc = - 0.304; p < 0.001). Independent predictors of high SF-12 MCS were SCL-10 (anxiety, depression and somatization, pc = - 0. 421, p < 0.001) and EPQ (neuroticism, pc = - 0.174, p = 0.050). Neither duration nor severity of IBS symptoms was independent predictors of QoL.

CONCLUSION: Somatic comorbidity and subjective health complaints were significant predictors of physical QoL, and anxiety/depression, somatization and neuroticism were significant predictors of mental QoL. Neither duration nor severity of IBS symptoms was associated with QoL. The study indicates that treatment of patients with IBS and reduced QoL should focus more on comorbidity than on IBS symptoms.

P1560 FECAL CALPROTECTIN IN PREDICTING RECURRENCE AFTER ATTACK OF COLONIC DIVERTICULITIS

A. Tursi[1], W. Elisei[2], M. Picchio[3], L. Di Cesare[4], P.G. Lecca[4], **G. Brandimarte**[4,*]
[1]*Gastroenterology Service, ASL BAT, Andria,* [2]*ASL Roma H, Division of Gastroenterology, Albano Laziale (Roma),* [3]*Division of Surgery,* "*P. Colombo*" *Hospital, ASL Roma H, Velletri (Roma),* [4]*Division of Internal Medicine and Gastroenterology,* "*Cristo Re*" *Hospital, Rome, Italy*
Contact E-mail Address: *antotursi@tiscali.it*

INTRODUCTION: Colonic diverticulitis shows a high recurrence rate, but the role of fecal markers in predicting recurrence is unknown.

AIMS & METHODS: The aim of this study was to investigate the role of fecal calprotectin (FC) in predicting recurrence of diverticulitis.

A prospective cohort study was performed on 54 patients suffering from Acute Uncomplicated Diverticulitis (AUD) and treated with antibiotics to obtain remission. After remission, patients underwent to clinical follow-up every 2 months. During the follow-up, C-reactive protein (CRP) and FC was analysed at each medical control visit starting 2 weeks after the end of the antibiotic therapy. Recurrence of diverticulitis was defined as return to our observation due to left lower quadrant pain with or without other symptoms (e.g. fever), associated with leucocytosis and/or increased CRP, and confirmed by means of Computerized Tomography (CT).

RESULTS: The mean follow-up was 20 months (range 12-24 months). Forty-eight patients were available for the final evaluation, and 6 patients were lost to follow-up.

During the follow-up, increased FC was detected in 17 (35.4%) patients. Diverticulitis recurred in 8 (16.7%) patients: 7 (87.5%) patients showed increased FC during the follow-up, and only 1 (12.5%) patient with recurrent diverticulitis didn't show increased FC.

FC sensitivity, specificity, positive predictive value and negative predictive value were 87.5%, 75.0%, 41.2%, and 96.8%, respectively.

Only higher FC values (>60 μg/g) correlated with CRP levels (rho = 0.351, 95% CI 0.163 to 0.5267; p = 0.001). Finally, extension of diverticulosis showed correlation with FC expression (rho = 0.632, 95% CI 0.515 to 0.791; p = 0.000).

CONCLUSION: Increased FC was found to be predictive of diverticulitis recurrence.

INTRODUCTION: A validated endoscopic score on Diverticular disease (DD) of the colon is lacking at present.

AIMS & METHODS: We developed a simple endoscopic score of DD, the Diverticular Inflammation and Complication Assessment (DICA) score. The DICA score for DD resulted in the sum of the scores for extension of diverticulosis (left and right colon), number of diverticula per district (up to 15 and >15 diverticula), presence and type of inflammation (edema, hyperemia, erosions), and presence and type of complications (rigidity, pus, stenosis, bleeding): DICA 1 (up to 3 points); DICA 2 (score from 4 to 7 points); DICA 3 (over 7 points).

Videos of 70 consecutive patient at first diagnosis of DD were visualized during plenary session and classified by endoscopists that did not know the DICA classification.

Validation was carried out by estimating the correlation between DICA score and symptoms, Erythro-Sedimentation Rate (ESR) and C-Reactive Protein (CRP) expression. Finally, 50 videos of DD patients not involved in the development of DICA were reassessed in order to investigate the predictive role of DICA on the outcome of the disease.

RESULTS: A total of 960 ratings were performed. Overall agreement in using DICA was 0.847 (95% CI 0.812 to 0.893). It was 0.878 (95% CI 0.832 to 0.895) for DICA 1, 0.765 (95% CI 0.735 to 0.786) for DICA 2, and 0.891 (95% CI 0.845 to 0.7923) for DICA 3. Intra-observer agreement kappa was 0.91 (95% CI 0.886 to 0.947).

A significant correlation was found between DICA score and both ESR (p = 0.0001) and CRP values (p = 0.0001), as well as between median pain score and DICA score (p = 0.0001).

With respect to the 50 patients reassessed, recurrence or occurrence of disease complications were recorded in 10 pts (34.5%) classified as DICA 1 and 19 pts (65.5%) as DICA 2 (p = 0.036).

CONCLUSION: Diverticular Inflammation and Complication Assessment (DICA) score is a simple, reproducible, validated, and easy-to-use endoscopic scoring system for diverticular disease of the colon.

INTRODUCTION: The association of diverticula on bowel habits are unclear. We therefore analyzed the association between diverticula and bowel habits in over 1000 Japanese individuals.
AIMS & METHODS: Japanese subjects who underwent total colonoscopies at seven centers in Japan from June to September 2013 were analyzed. Bowel habits were evaluated using the Gastrointestinal Symptom Rating Scale, and stool form was assessed using the Bristol Scale. Diverticula were diagnosed by colonoscopy with a transparent soft-short hood.
RESULTS: The study evaluated 1066 subjects, 648 males and 418 females (ratio, 1.55:1), of mean age 63.9 ± 13.0 years. After adjusting for age and gender, the presence of constipation was associated with a significantly reduced likelihood of diverticula (odds ratio [OR] = 0.70, 95% confidence interval [CI] 0.52–0.93, p = 0.0152). When assessed according to the location of diverticula, the presence of constipation was associated with a significantly decreased likelihood of left-sided (OR = 0.39, 95% CI 0.16–0.93, p = 0.0338), but not right-sided (OR = 1.10, 95% CI 0.48-2.53, p = 0.8230), diverticula. Furthermore, stool form was unrelated with the presence or absence of diverticula.
CONCLUSION: The wide-spread hypothesis that hard, small caliber stools could lead to colonic diverticula was not supported. Rather, we found that the absence of diverticula was associated with constipation, suggesting the need to reassess the etiology of colonic diverticula.

P1563 ARE CT SCAN BASED SCORING SYSTEMS OF ANY USE IN THE PRACTICAL MANAGEMENT OF ACUTE DIVERTICULAR DISEASE?

K. Macconaill[1,*], J. Downing[1], D. Pai[2], G. Kaur[1]
[1]*Surgery,* [2]*Radiology, SCUNTHORPE GENERAL HOSPITAL, Scunthorpe, United Kingdom*
Contact E-mail Address: *gkaur@email.com*

INTRODUCTION: A large number of emergency patients are admitted with complaints of pain in the left lower quadrant, fever, and soiling and labeled 'acute diverticulitis'. Contrast enhanced CT scans are the most important imaging modality for acute diverticular disease in today's clinical practice. A CT scan can demonstrate an associated abscess and assist with direct percutaneous drainage. In the case of diverticular bleeding, CT angio may demonstrate a contrast blush. Hinchey described a traditional classification for 'acute diverticulitis' in 1978; since then, several CT based modifications have been presented to display a more contemporary overview of the disease; these translate into management strategies for the patient. However, not all patients admitted with left iliac fossa pain undergo a CT scan; far fewer have CT scoring.
AIMS & METHODS: We aimed to look at patients diagnosed with 'acute diverticulitis' in our Hospital, with specific reference to CT scans, classification, management and outcomes.
Methods: Data was retrospectively collected for all patients admitted with a diagnosis of 'acute diverticulitis', during the period November 2013 to February 2014. Data collected included CT scans, surgery/ radiological drainage, outcomes etc. All CT scans were then reviewed by a single GI radiologist and scored using a modified Hinchey scoring system.
RESULTS: 271 patients were identified with a diagnosis of acute'diverticulitis; of these, only 144 had had a CT scan. Of these, only 29 had a CT diagnosis of diverticulitis, with no scoring used. On review by the GI radiologist, this number further dwindled to 21. Of these, 18 had a modified Hinchey score assigned- 8 patients were IA, 5 were IB, 2 were II and 3 were III. 5 of these underwent Hartmans procedure/ sigmoid colectomy. One patient was successfully managed with CT guided drainage, while 1 underwent attempted drainage. There was no mortality. Of the 24 patients with an original CT diagnosis of diverticulitis who did not undergo surgery/ drainage, 15 were followed up with a colonoscopy later.
CONCLUSION: Since the introduction of the CT in the 1980s, this imaging modality has established itself as the primary diagnostic tool in the assessment of diverticular disease, leading on to the use of new treatment strategies, such as CT-guided percutaneous drainage of abscesses. A good CT scan based classification system of acute diverticular disease helps guide clinical decision making and management; unfortunately, we found this lacked a translation into daily clinical practice. Many patients with diverticulosis were therefore unnecessarily treated as acute diverticulitis; fortunately, pelvic abscesses, purulent and fecal peritonitis were accurately diagnosed clinically and managed appropriately. We emphasise the importance of performing a CT scan at acute presentation of diverticular disease to diagnose/ rule out/ manage complicated disease; this baseline scan is also crucial if the patient deteriorates during conservative treatment.

P1564 ARE ANTIPLATELET AGENTS OR HEMODIALYSIS RISK FACTORS FOR COLONIC DIVERTICULAR RE-BLEEDING?

K. Sato[1,*], N. Toda[1], T. Yamada[1], M. Yamagami[1], K. Kojima[1], T. Ohki[1], T. Arizumi[1], M. Seki[1], K. Tagawa[1]

INTRODUCTION: Colonic diverticular bleeding is frequently encountered, but there have been few reports of its recurrence. In general, antiplatelet and hemodialysis are reported to be risk factors of gastrointestinal bleeding of various situations.
AIMS & METHODS: The aim of this study was to identify risk factors for diverticular rebreeding, especially whether antiplatelet and hemodialysis contributed or not.131 hospitalized patients, who were diagnosed with diverticular bleeding on the basis of colonoscopy findings between April 2002 and May 2013, were analyzed. The cumulative bleeding recurrence rate and potential risk factors for rebleeding, such as patient attributes (Age, sex, underlying conditions, and medication), treatment methods, were retrospectively investigated.
RESULTS: The 131 patients diagnosed with colonic diverticular bleeding included 96 men (73 %) and 35 women (27 %). The mean age was 62.5 ± 3.5 years, and the location of the diverticulum was the right colon in 31 cases, left colon in 21 cases, and both sides in 79 cases. 57 patients used antiplatelets and 9 underwent hemodialysis for end-stage renal failure. The method of hemostasis for first bleeding was clipping in 31 patients (23 %), local injection in 23 (17 %), surgery in 2, and conservative treatment in 91 (69 %). Rebleeding was noted in 51 patients (38 %), with the mean period before recurrence being 54 ± 30 months (mean follow up periods: 43.5±38.5 months). By multivariate analysis, conservative treatment (hazard ratio, 2.57; $p = 0.02$) is the only significant risk factor of rebleeding. But antiplatelet (hazard ratio, 1.51; $p = 0.27$) or hemodialysis (hazard ratio, 1.05; $p = 0.94$) were not significant.
CONCLUSION: In this study, antiplatelet or hemodyalysis were proven to be not significant risk factors for colonic diverticular rebleeding. Conservative treatment was identified as only independent risk factor.

INTRODUCTION: The association between diverticulosis and colorectal cancer (CRC) is controversial, since some of the data indicated a positive association, whereas some studies could not confirm this. Addressing this issue is very important since finding an association between diverticulosis and CRC may have implications for CRC prevention.
AIMS & METHODS: Therefore, we aimed to examine the association between the presence of diverticulosis and polyp detection rate (PDR).
Methods: We included 13,554 subjects aged 50 years and above (mean 65.4±10.3y) who underwent their first colonoscopy with acceptable preparation at our endoscopy unit between the years 2003-2010. Multivariable logistic regression analysis including the patients' age and gender, the examination hour, the quality of preparation and the presence of diverticulosis, were carried out to assess the association between diverticulosis and the presence of the polyps that were detected.
RESULTS: Polyp was detected in 4,667 (34.4%) subjects and increased from 26.2% at age 50-54y to 38.3% at age ≥84y. Diverticulosis was reported in 2,229 (16.4%), and increased from 6.9% at age 50-54 to 32.8% at age ≥84y. Both diverticulosis and PDR were increased significantly with age ($p < 0.001$ for both). Among 11,325 subjects without diverticulosis, 4,048 (35.7%) had polyps, as compared to 2,029 subjects with diverticulosis, out of them only 619 (27.8%) had polyps ($p < 0.001$). Using multivariable logistic regression analysis the presence of diverticulosis was negatively associated with PDR, (OR: 0.60 95% confidence interval 0.53-0.66, $p < 0.001$). An older age, male gender and the preparation quality were all significantly associated with PDR.
CONCLUSION: Although both diverticulosis and PDR were increased with age, the presence of diverticulosis was negatively associated with PDR. Whether this finding reflects a true phenomenon or could the presence of diverticulosis interferes with detecting polyps, should be further investigated.

INTRODUCTION: No previous reports have shown an association between location of diverticular disease (DD) and irritable bowel syndrome (IBS).
AIMS & METHODS: We included 1009 consecutive patients undergoing total colonoscopy in 7 centers in Japan from June 2013 to September 2013. IBS was diagnosed using Rome III criteria and diverticulosis was diagnosed by colonoscopy with transparent soft-short-hood. Left-sided colon was defined as sigmoid colon, descending colon, and rectum. Right-sided colon was defined as cecum, ascending colon, and transverse colon. We divided the patients into IBS and non-IBS groups and compared characteristics.
RESULTS: Patient characteristics included: mean age, 64.2 ± 12.9 years and male: female ratio, 1.62:1. Right-sided DD was identified in 21.6% of subjects. Left-sided and bilateral DD was identified in 6.6% and 12.0% of subjects, respectively. IBS was observed in 7.5% of subjects. Multiple logistic regression analysis showed left-sided DD (odds ratio, 3.1; 95% confidence interval (CI), 1.4–7.1; $P = 0.0060$) and bilateral DD (odds ratio, 2.6; 95% CI, 1.3–5.2; $P = 0.0070$) were independent risk factors for IBS. Right-sided DD was not a risk factor for IBS.
CONCLUSION: Our data showed that the presence of left-sided and bilateral DD, but not right-sided disease, were associated with a higher risk of IBS, indicating that differences in pathological factors caused by the location of the DD is important in the development of IBS. Clarifying the specific changes associated with left-sided DD could lead to elucidation of the pathogenesis of IBS.

INTRODUCTION: Colonic diverticulum is one of the common diseases especially in elderly patients. However diverticular bleeding occasionally causes massive bleeding that requires urgent colonoscopy (CS) and treatment.
AIMS & METHODS: The aim of this study is to clarify the significant risk factors for the diverticular hemorrhage in the colorectum.
Between January 2009 and December 2012, 26602 patients had a CS in our institution. One hundred twenty three patients had an urgent CS with the symptom of acute lower gastrointestinal hemorrhage. Seventy-two (72) patients of them received diagnosis with colonic diverticular hemorrhage. Age and sex matched 149 controls were selected from non-bleeding diverticulum patients who underwent CS by other reasons during the same period. The information checked were included the presence of cerebrovascular disease, ischemic heart disease, hypertension, hyperlipidemia, diabetes mellitus, chronic renal disease, osteoporosis, hyperuricemia. The information also contained medication including NSAIDs, antithrombotic agents. The relationship between these factors and diverticular bleeding were compared between cases and controls.
RESULTS: Among the 123 patients, 72 patients were diagnosed as colonic hemorrhage caused by colon diverticular. Age range of patients was from 33 years to 93 years old (average70±12.8). Sex ratio of men versus women of patients was 51:21. In the result of the univariate analysis, the factors of cerebrovascular disease, hypertension, hyperuricemia, chronic renal disease and usage of antithrombotic agents, and NSAIDs were significant to increase of ORs. Using these factors, we performed multivariate conditional logistic regression with stepwise variable selection. Finally, present usage of NSAIDs (OR = 14.70, 95% CI: 3.890-55.800, P < 0.0001), cerebrovascular disease (OR = 8.66, 95% CI: 2.330-32.100, p = 0.00126), and hyperuricemia (OR = 15.5, 95% CI: 1.740-138.000, p = 0.014) remained statistically significant.
CONCLUSION: This study indicated the present usage of NSAIDs, cerebrovascular disease, and hyperuricemia were significant risk factors for colonic diverticular hemorrhage. The knowledge obtained by this study may give some insight in the diagnostic process for the patients with acute lower gastrointestinal bleeding.

P1568 ENDOFLIP: A NEW DIAGNOSTIC MODALITY FOR MEASURING ANAL CANAL FUNCTION

L. Kumar[1,1,*], F. Zaman[1], A. Emmanuel[1]
[1]*GI Physiology Unit, UCLH, London, United Kingdom*

INTRODUCTION: Anorectal manometry is a commonly used technique to assess patients with fecal incontinence, but is known to have low reproducibility and poor validation in assessment of anal sphincter function. We report a pilot study on a novel technique using Functional Lumen Imaging Probe (FLIP) to improve assessment. Although FLIP has been used in upper GI studies its use in anorectal region is limited to three published studies, all of which used a 12 cm probe (as in upper GI studies). We used a purpose built shorter catheter to demonstrate bio-mechanical properties of the anus.
AIMS & METHODS: Aims: Primary objective was to demonstrate reproducibility of measurement taken by EndoFLIP. Secondary objective was to demonstarte its utility in assessment of anal canal. Methods: 19 healthy volunteers were recruited (9 females), mean age 34 (20-75). Catheters were purpose built, incorporating a rectal and anal canal balloon (three different sizes 2, 3 and 4cm long). Appropriate sized catheter corresponding to the length of subject's anal canal (based on manometry) was used. Participants underwent standard water-perfused anal manometry followed by FLIP on the same day. To test repeatability the FLIP was repeated after 30 minutes on the same day. The parameters checked for repeatability included CSA during rest, squeeze, endurance squeeze and cough in addition to the intra balloon pressure during these phases. Anal canal was divided into three parts- distal, mid and proximal based on anatomy and preliminary data analysis. There were different inflation volumes used, according to the balloon size, determined by analysing the pre-study test results.
RESULTS: 3 cross sectional area (CSA) readings were obtained with 2cm balloon, 5 with 3cm and 10 with 4cm balloon. Study established the test-retest and intra-observer repeatability for CSA using Bland-Altman plot and Intra-class correlation coefficient (ICC). Pearson correlation coefficient (PCC) was used to establish a correlation between CSA and pressure.
Bland Altmans plots showed measurement points for all parameters to be within 2 SD of line of equality. ICC calculated individually for each part of anal canal showed high levels of repeatability for CSA measurements (Table 1). Pressure readings were also repeatable (Table 1). Pearson correlation coefficient esablished a negative correlation between CSA and pressure during resting phase, at all the balloon volumes apart from the highest.

Measured phase	ICC for proximal anal canal	ICC for proximal anal canal	ICC for proximal anal canal	ICC for pressure readings
Resting	.960	.960	.928	.806
Squeeze	.978	.960	.919	.776
Cough	.970	.970	.943	.867
Endurance squeeze	.965	.960	.937	.868

Table 1

CONCLUSION: By allowing determination of serial CSAs during distension EndoFLIP allows detailed and segmental description of geometric and mechanical properties of the anal canal. The CSA and intra balloon pressure were repeatable and lower CSA was associated with higher pressure across all balloon volumes apart from the highest. Most likely cause for this was excessive distension of anal canal at higher balloon volumes. Validity and repeatability of EndoFLIP have been demonstrated by this study and future work will assess its utility in patients with faecal incontinence.

P1569 PERCUTANEOUS TIBIAL NERVE STIMULATION IS INEFFECTIVE FOR PATIENTS WITH CONSTIPATION

L. Kumar[1,*], A. Alam[1], V. Aikins[1], A. Raeburn[1], A. Emmanuel[1]
[1]*GI Physiology Unit, UCLH, London, United Kingdom*
Contact E-mail Address: *l.kumar@ucl.ac.uk*

INTRODUCTION: The efficacy of percutaneous tibial nerve stimulation (PTNS) in faecal incontinence has been well proven. However its value in managing constipation has not been studied. Current literature search (Pubmed & Embase) brings up only one study assessing its effect in managing constipation. Chronic constipation can be aetiopathogenically classified into slow transit (STC), rectal evacuation difficulty (RED) or a combination (BOTH). We studied the effects of PTNS in these patient subgroups.
AIMS & METHODS: Aims: We aimed to evaluate the effectiveness of PTNS in patients with range of constipation aetiologies by measuring change in wexner score, atransit study and anorectal physiology. Methods: 34 patients (30 women, median age 50 years, range 20-79) with constipation previously failing maximal laxative and biofeedback therapy participated in the study. All patients underwent baseline transit study and anorectal physiology to identify constipation subtype. All patients had 12 sessions of 30 minutes of PTNS. Responder rate (judged by Wexner constipation score fall to ≤15 or by ≥5points) was the primary outcome. Transit study and anorectal physiology were evaluated post-treatment.
RESULTS: There were 11 STC, 14 RED and 9 BOTH patients. Response was seen in 5 patients (2/11 STC, 2/14 RED and 1/9 BOTH). Comparing pre- vs post-PTNS, change in mean wexner scores was not significant (p = 0.10). There was no change in colonic transit time in the whole population (p = 0.56) or those with STC (p = 0.47). Balloon expulsion did not significantly improve in the whole group (p = 0.73) or those with RED (p = 0.69).
CONCLUSION: The data available from single study done so far, evaluating PTNS response in constipation, demonstrated a response rate of 33% based on reduction of improvement in constipation score of ≥ 5 points. However, this was not replicated in our study which had a response rate of only 15% based on the same criteria. Common finding in both the studies was a lack of improvement in transit time. Percutaneous tibial nerve stimulation is not of benefit in patients with constipation, whatever aetiopathogenic mechanism is responsible for their symptoms.

P1570 RECTAL HYPOSENSITIVITY TO BALLOON DISTENSION IS INFLUENCED BY RATE OF INFLATION

L. Kumar[1,*], J. Gosling[1], A. Raeburn[1], A. Emmanuel[1]
[1]*GI Physiology Unit, UCLH, London, United Kingdom*

INTRODUCTION: Impaired rectal sensation to mechanical distension, rectal hyposensitivity (RH), has been suggested to be causally linked to constipation in a quarter of patients. Although the exact mechanism of rectal distension sensitivity remains uncertain it is postulated to relate to populations of slow- and fast- adapting mechanoreceptor populations in the rectal wall. In clinical practice the measurement is elicited by manual inflation of a balloon, rather than the more predictable (but cumbersome) use of barostat-driven inflation. Interventions such as behavioural retraining, neuromodulation and rectal surgery have suggested that 'normalising' distension volume thresholds, is a desirable biomarker of treatment outcome. In an attempt to standardise protocols, we conducted a study to investigate the influence of rate of ramp rectal distension on volume thresholds.
AIMS & METHODS: Aims - To investigate the influence of rate of ramp rectal distension on rectal volume thresholds. Methods: We studied 49 patients (42 female, mean age 40 [21-74]) and 23 asymptomatic controls (18 female, mean age 36 [22-60]). Patients underwent transit studies and MR proctography, and accordingly stratified in to slow transit, ST (n = 18, 15 female, mean age 38 [21-60]) and puborectalis dyssynergia, PD (n = 21, 16 female, mean age 41 [23-74]): 10 patients had combined abnormalities and were excluded from further analysis. The participants underwent anorectal physiology test in the following sequence: rectal distension – manometry – RAIR – expulsion – rectal distension. Rectal distension was done by hand at rate of 1ml/sec and 5ml/sec in random order. Patients were asked to report first sensory awareness, urge to defaecate and maximal tolerable thresholds.
RESULTS: Results are shown in the table. There was no order effect, and no difference in thresholds between constipation subtypes. At 1ml/sec distension 5/18 and 6/21 ST and PD patients, respectively, were determined to have rectal hyposensitivity; this fell to 1/18 and 1/21 at 5ml/sec. Amongst controls 4 had elevated volumes at 1ml/sec and none at 5ml/sec.

	1ml/sec	5ml/sec	p value
FS in healthy controls (n = 23)	115 ± 61	49 ±23	0.01
FS in slow transit (n = 18)	142 ±64	71 ±33	0.04
FS in puborectalis dyssynergia (n = 21)	131 ±74	78 ±34	0.07
DDV in healthy controls (n = 23)	165 ±79	91 ±37	0.08
DDV in slow transit (n = 18)	202 ±87	129 ±49	0.03
DDV in puborectalis dyssynergia (n = 21)	189 ±90	128 ±51	0.05
MTV in healthy controls (n = 23)	304 ±111	202 ±93	0.03
MTV in slow transit (n = 18)	349 ±150	221 ±101	0.03
MTV in puborectalis dyssynergia (n = 21)	333 ±145	223 ±105	0.05

CONCLUSION: We have shown a significant difference in thresholds between slow and rapid distension rates. Slower rate of distension was associated with higher thresholds across all the three sensory volumes. Rectal hyposensitivity is identified less often at more rapid distension rate. Distension rates play a crucial part in diagnosing RH and standardised of protocol is required in future studies.

Contact E-mail Address: *mzwcislo@su.krakow.pl*

INTRODUCTION: The chronic inflammation in gastrointestinal tract in celiac disease (CD) patients may cause alterations of the upper-gut motility. The aim of study was to investigate the influence of CD on the upper-gut motility and release of enterohormones.
AIMS & METHODS: We studied 25 CD patients (8 males, 17 females, aged 42.4±15.8 years). CD was diagnosed by serological (serum level of anti-endomysial antibodies) and histological evaluation of duodenal mucosa. The gastric myoelectric activities (EGG), performed by 4-channels electrogastrography, were measured in fasted and fed subjects. The ghrelin and pancreatic polypeptide (PP) plasma level were measured. The results obtained were compared with a healthy, asymptomatic control group (9 males and 21 females, aged 42.1 ± 9.2 years).
RESULTS: Fasting CD patients showed decreased parameters of % of normogastria (54.8±24.5 vs. 86±12.3, p = 0.02) and SWC (61.1±17 vs. 67±18, p = 0.01) with increased dominant power (log DP) (13.3±1 vs. 11.1±1.1, p = 0.0001) compared to control group. In fed CD patients: % of normogastria, log DP, dominant frequency (DF), slow wave coupling (SWC) did not improve on the contrary for the control group in which log DP, DF, SWC and percent of normogastria increased ($p < 0.05$). Fasting ghrelin plasma level was lower in CD in comparison to control group 156.8±86.7 pg/ml vs 260.2±87.6 pg/ml ($p < 0.05$) but PP level was higher 265.2±123.1 pg/ml vs 211.4±114.6 pg/ml ($p < 0.05$) consequently.
CONCLUSION: CD causes subsequent disturbances of gastric myoelectric activity and fasting enterohormones levels. CD patients demonstrated diminished response to food. Observed diminished responsiveness suggests dysfunction of autonomic nervous system as common pathophysiological mechanisms.

INTRODUCTION: Management of patients with persistent dysphagia and / or recurrent reflux after anti-reflux surgery is challenging [1,2]. This prospective, case-control study tested the hypothesis that, compared to standard high resolution manometry (HRM) with single water swallows (SWS), adding multiple water swallows (MWS) and solid swallows increase diagnostic yield and clinical impact of physiological investigation after fundoplication surgery.
AIMS & METHODS: 57 symptomatic and 12 asymptomatic control patients underwent HRM with SWS, MWS and a solid test meal. Diagnostic yield of standard and full HRM studies with 24hr pH-impedance monitoring was compared. Clinical outcome of pneumatic dilatation for outlet obstruction on HRM studies was assessed on an analogue scale from inadequate <40%, satisfactory 40-60%, good 60-80% to excellent >80% improvement. A "satisfactory" response was defined by a clear improvement in symptoms from baseline to a level where no further treatment was necessary.
RESULTS: Baseline EGJ pressure was similar in all groups. Abnormal EGJ morphology ("double high pressure band") was more common in symptomatic than control patients (13/57 vs. 0/12; p = 0.004). Overall diagnostic yield of HRM was 11 (19%), 11 (19%) and 33/57 (58%) with SWS, MWS and solids respectively ($p < 0.001$), being greatest for solids in patients with dysphagia (19/27 (70%)), see table. Outlet obstruction was present in 4 (7%), 11 (19%) and 15/57 (26%) patients with SWS, MWS and solids respectively ($p < 0.009$). Note that 4 patients that presented with reflux had outlet obstruction on HRM and negative pH-impedance studies. No asymptomatic control had clinically relevant dysfunction on solid swallows. Dilatation was performed in 12/15 patients with symptomatic outlet obstruction during the test meal. Symptom response was satisfactory, good or excellent in 7/12 (58%) with no serious complications.
Table: Diagnosis based on SWS and solid test meal (*$p < 0.05$, ** $p < 0.01$)

Main Symptom		Overall HRM	Outlet Obstruction	Peristaltic Dysfunction	Reflux	Functional (no cause)
Dysphagia n = 27	SWS	8 (30%)	4 (15%)	4 (15%)	2 (7%)	17 (63%)
	Meal	19 (70%)**	11 (41%)*	8 (29%)		6 (22%)**
Reflux n = 30	SWS	3 (10%)				
	Meal					
		14 (46%)**	0 (0%)	3 (10%)	10 (33%)	17 (57%)
		4 (13%)	10 (33%)*			9 (30%)*
Asymptomatic n = 12	SWS	1 (8%)	0 (0%)	1 (8%)	0 (0%)	n/a
	Meal	0 (0%)	0 (0%)	0 (0%)		

CONCLUSION: The addition of MWS and a solid test meal increases the diagnostic yield of HRM studies in patients with symptoms post-fundoplication and identifies additional patients with clinically relevant, symptomatic esophageal dysfunction. This includes patients with outlet obstruction post-fundoplication that benefit from endoscopic dilatation.

P1573 THE ASSOCIATION OF SOMATIZATION WITH IRRITABLE BOWEL SYNDROME (IBS) AND UNINVESTIGATED DYSPEPSIA IN THE U. S. GENERAL POPULATION

O. Palsson[1,*], M.van Tilburg[1], W.E. Whitehead[1]
[1]*Department of Medicine, Division of Gastroenterology and Hepatology, University of North Carolina, Chapel Hill, United States*
Contact E-mail Address: *opalsson@med.unc.edu*

INTRODUCTION: Multiple studies have reported elevated somatization, i.e., excess frequency of general non-gastrointestinal physical symptoms, in clinical samples of IBS and functional dyspepsia (FD) patients. Much less is known about whether somatization is associated with these disorders in the general community.
AIMS & METHODS: Data from a nationwide U. S. internet survey of 1,665 adults were used to assess somatization in FD and IBS in the general population. The survey included the validated Recent Physical Symptoms Inventory (RPSQ)

developed by our team to measure somatization in IBS (MacLean et al. J Psychosom Res. 2012;73 (5):351-5), the SF-12 quality of life scale, the Rome III Diagnostic Questionnaire with new validated response formats (Gastroenterology 2013;144 (5) Suppl.1:S-916) planned for Rome IV, and demographic and health history questions. Responders providing inconsistent survey answers on 3 repeated quality-check questions were excluded from analysis, leaving 1277 response sets. Somatization scores were calculated as the number of different non-GI symptoms (out of the 26 on the RPSQ) experienced more than once in the past month.

RESULTS: The analysis sample was 648 females and 629 males; 701 white, 218 black, 240 hispanic and 118 other or undeclared race/ethnicity. Mean age was 46.4 years (range 18-94). A total of 91 individuals (7.1%) met Rome III IBS criteria (after subjects with organic bowel diagnoses were excluded), 146 (11.4%) met FD criteria, and 57 (4.5%) met both criteria. Mean somatization score was twice as high ($p < 0.0001$) in subjects with IBS (Mean +/- SD: 14.1 +/- 6.4) and FD (13.1 +/- 6.7) compared to those qualifying for neither diagnosis (6.5 +/- 5.7). These subgroup differences were significant even when all individuals reporting physician diagnosis of any upper or lower GI disorders were removed from the analysis, and were found within every race/ethnicity, gender and age group. Whole sample analysis showed that somatization scores were significantly correlated with frequency of each of the key gastrointestinal symptoms defining FD and IBS, including pain anywhere in the abdomen ($r = 0.50$), uncomfortable fullness after meals ($r = 0.49$), pain/burning in the middle of the abdomen ($r = 0.41$), and frequency of hard ($r = 0.38$) and loose ($r = 0.38$) stools; all correlations $p < 0.01$. All 26 non-GI symptoms of the RPSQ were significantly more prevalent in IBS and FD than in other subjects, even after controlling for multiple comparisons. The most common non-GI symptoms were the same in IBS and FD: Sleep difficulties (IBS = 86%,FD = 74%), muscle aches (82%,78%), back pain (81%,75%), headaches (79%,76%), and muscle stiffness (66%,60%). Excess somatization (score above 95th percentile in the comparison subjects meeting neither disorder criteria) was seen in 42.9% of IBS and 30.8% of FD cases. For both IBS and FD, somatization was negatively correlated ($p < 0.01$) with the physical ($r = -0.51, -0.42$) and mental ($r = -0.35, -0.32$) composite SF-12 quality-of-life scales.

CONCLUSION: Increased somatization (excess number of general non-GI symptoms) is robustly associated with both FD and IBS not only in clinic samples but also in the general population, and is seen across all gender, race and age groups. Somatization tendency is associated with higher frequency of functional GI symptoms and impairment in quality of life. [Supported by funding from the Rome Foundation]

P1574 DOES PERCEIVED STIGMA AFFECT HEALTHCARE CONSULTING AND QUALITY OF LIFE IN FECAL INCONTINENCE?

O. Palsson[1,*], S. Heymen[1], W.E. Whitehead[1]
[1]*Department of Medicine, Division of Gastroenterology and Hepatology, University of North Carolina, Chapel Hill, United States*
Contact E-mail Address: *opalsson@med.unc.edu*

INTRODUCTION: Fecal incontinence (FI) is a sensitive social topic, but it is unknown to what degree the perceived stigma of the condition impairs the quality of life (QoL) of FI sufferers or contributes to the common avoidance of healthcare-seeking for the problem.

AIMS & METHODS: We aimed to quantify the associations of perceived FI stigma with QoL impairment and the tendency to consult doctors about FI. A validated Perceived Stigma Scale (PSS) developed to measure gastrointestinal illness stigma and previously used (Taft et al Qual Life Res 2011;20:1391–1399) in irritable bowel syndrome and inflammatory bowel disease was adapted for FI (FI-PSS). Subjects indicate for each of 10 questions how often on a 5-point frequency scale from 0 = "Never" to 4 = "Always" they perceive potential or actual FI-associated stigma (like concerns that they would be treated differently or their opportunities limited if people knew about their FI) from six categories of people in their life; family members, friends, significant others, healthcare workers, coworkers and boss/supervisor. A nationwide U. S. internet survey that included the FI-PSS, Fecal Incontinence Quality of Life (FI-QOL), Fecal Incontinence Severity Index (FISI) and demographic questionnaires was completed by 234 adults with FI (defined as accidental loss of liquid or solid stool at least once a month in the past 6 months). Subjects who responded inconsistently ($n = 48$) on either of two repeated quality-check questions were excluded from analysis, leaving 186 response sets for analysis.

RESULTS: The 186 FI subjects were 52.2% female. Race/ethnicity was 82.8% white, 9.1% hispanic, and 8.1% black. Subject ages ranged from 20-91; 39.2% under age 40, 38.2% ages 40-65, and 22.6% age 65+. Nearly all subjects (93.5%) reported some perceived FI-related social stigma on the FI-PSS; least stigma was perceived from healthcare providers (mean score 15.6) and most from co-workers and employers (mean score 21.5 for both). Respondents who had consulted doctors about their FI (55.4% of the sample) had substantially greater FI severity (FISI mean +/- SD: 39.5 +/- 15.7 vs. 18.0 +/- 10.2) and higher perceived FI-PSS stigma scores (118.3 +/- 51.9 vs. 91.1 +/- 51.5) than non-consulters, and were also younger, more educated and more affluent ($p < 0.0001$ for all comparisons). However, when these variables were combined in a binary logistic regression equation, FI severity was the only significant predictor of consulting doctors for FI, explaining 53% of the variance (Nagelkerke $R^2 = 0.53$). FI-QOL scores (higher score = better QoL) were negatively correlated with FI severity (Pearson $r = -0.73$), stigma scores ($r = -0.51$), younger age ($r = -0.37$), education ($r = -0.28$) and household income ($r = -0.36$). When these were all combined in a linear regression equation, FI severity was the only significant contributor to the 56% total variance in QoL scores explained (adjusted $R^2 = 0.56$).

CONCLUSION: Perceived stigma is pervasive among FI sufferers. It is robustly associated with symptom severity, but it does not seem to be associated with avoidance of healthcare consultation for FI nor to have an independent effect on quality of life. P1575 NEUROTRANSMITTER CONCENTRATION IN PREGENUAL ACC IN STOOL CONSISTENCY PATIENT SUBGROUPS WITH IBS

O. Bednarska[1,*], S. Tapper[2,3], P. Lundberg[2,3], A. Tisell[2,3], M. Lowén[1], M. Engström[2,3], S. Walter[1,3]

INTRODUCTION: The Anterior Cingulate Cortex (ACC) is a key region of the central autonomic brain network. Irritable Bowel Syndrome (IBS) is characterized abdominal pain and bowel habit disturbances. Autonomic dysregulation has been reported in IBS as well as altered ACC activation in pregenual ACC during visceral stimulation [1] [2]. Glutamate is the major excitatory and Gamma-aminobutyric acid (GABA) the major inhibitory neurotransmitter in the brain.

AIMS & METHODS: We aimed to measure neurotransmitter concentration in the pregenual ACC, in stool consistency subgroups with IBS by using quantitative neurotransmitter Magnetic Resonance Spectroscopy (qMRS)

Seven patients with IBS-mixed (6 women) and five patients with IBS -diarrhea (4 women) according to Rome 3 were included. Mean age was 34.2 years (SD 5.3) with no significant difference between subgroups. Patients completed symptom severity score (IBS-SSS). Quantitative MRS was measured in a 3T MRI scanner. A water-suppressed MEGA-PRESS sequence (TR 2.0 s, TE 68 ms) was used with the editing pulses placed at 1.90 ppm ('ON-dynamics') and at 7.46 ppm ('OFF-dynamics') with a voxel (3x3x3 cm3) placed in the pACC. Each MEGA-PRESS measurement resulted in a sequence of 40 OFF- and ON-dynamics, where each was computed by 8 phase cycles. Directly after each water-suppressed MEGA-PRESS measurement, a shorter 2-dynamic unsuppressed water MEGA-PRESS measurement was performed within the same voxel, which was used to obtain the concentrations in physically well-defined units of [mM]. The GABA concentrations were computed by averaging the difference spectra obtained by subtracting each OFF-dynamic from subsequent ON-dynamic and using LCModel (Version 6.3) for the final quantification. The Glutamate concentrations were obtained by only averaging the OFF-dynamics, which were not affected by the editing pulses. Additionally, all dynamics were phase and frequency corrected prior to the averaging. For group comparison unpaired T-tests were used.

RESULTS: Patients had moderate to severe symptoms with IBS-SSS of 367 (SD 79.7). There was no significant difference between IBS subgroups in terms of IBS-SSS. Mean pACC GABA concentration was 1.66 (SD 0.17) mM in IBS-M and 1.65 (SD 0.27) mM in IBS-D. There was no significant difference between groups ($p = 0.9$). Mean pACC Glutamate concentration was 4.54 (0.35) mM in IBS-M and 5.13 (SD 0.64) mM in IBS-D. There was no significant difference between groups, although a trend with $p = 0.06$ was observed.

CONCLUSION: Further qMRS data have to be collected in IBS patients as well as healthy controls to evaluate if IBS subgroups demonstrate alterations in pACC glutamate and GABA concentrations.

P1576 GLP-1 INHIBITS PRE- AND POSTPRANDIAL ANTRO-DUODENO-JEJUNAL MOTILITY IN HEALTHY SUBJECTS AND PATIENTS WITH IRRITABLE BOWEL SYNDROME

P.M. Hellström[1,*], M. Degerblad[2], M.A. Halim[1], D.-L. Webb[1] on behalf of IBS, Motility
[1]*Medical Sciences, Uppsala University, UPPSALA,* [2]*Endocrinology, diabetologi and metabolism, Karolinska Institutet, Stockholm, Sweden*

INTRODUCTION: Glucagon-like peptide-1 (GLP-1) is secreted from gut endocrine L-cells in response to nutrient ingestion. GLP-1 acts as an incretin to lower blood glucose via stimulation of pancreatic islet beta cells. GLP-1 also exerts actions independent of insulin, including inhibition of gastrointestinal (GI) motility, inhibition of gastric emptying and acid secretion. IBS is characterized by abdominal pain or discomfort, associated with altered bowel habits and motor function in the GI tract. The positive actions of the GLP-1 in preclinical motility research and clinical IBS studies, highlights potential use of GLP-1 for treatment of IBS. Since recent studies indicate IBS symptoms to be prominent postprandially, we found it reasonable to investigate if GLP-1 would have an effect on upper GI motility in the pre- and postprandial period.

AIMS & METHODS: To investigate if GLP-1 can reduce GI motility after a meal.

The motility pattern of the proximal small intestine was monitored using a multichannel polyvinylchloride recording tube with its distal recording site at the angle of Treitz. Pressure transducers were connected via a PC Polygraph HR

(Synectics) to a PC. The software program Polygram Lower GI 6.40 (Synectics) was used with sampling frequency 4 Hz.
The over-all frequency of contractions, their amplitude and duration were computed during the respective 4-h infusion periods with saline and GLP-1 and transferred to a motility index.
Studies in vitro were done with muscle strips mounted between two platinum ring electrodes in 5 mL organ bath chambers containing Krebs solution, continuously bubbled with 5% CO_2 and 95% O_2 and and pH 7.4. Data acquisition was performed using Powerlab hardware and LabChart 7 software (ADInstruments). Tissues were equilibrated to a 2 g tension. After equilibration, muscle strips were studied with GLP-1 alone and in combination with the nitric oxide synthase inhibitor, LNMMA.
RESULTS: After food-intake, GI motility index increased in healthy volunteers and IBS patients. In volunteers, GLP-1 0.7 pmol/kg min^{-1} suppressed motility index in antrum, duodenum and jejunum from 6.2 ±0.4 to 4.8 ±0.7, from 5.6 ±0.6 to 4.9 ±0.6 and from 5.8 ±0.1 to 5.6 ±0.4 $Ln(\Sigma$ (mmHgsmin^{-1})), respectively. In IBS patients, GLP-1 2.5 pmol/kg min^{-1} decreased motility index in antrum from 6.2 ±0.1 to 6.0 ±0.2 $Ln(\Sigma$ (mmHgsmin^{-1})) whereas, in duodenum and jejunum inconsistent motility responses were found. Studies on gastrointestinal smooth muscle strips confirmed our results in by inducing an inhibitory action of GLP-1 on spontaneous motility.
CONCLUSION: Inhibitory motility responses to GLP-1 in healthy volunteers are similar to that in earlier animal studies. In IBS, an inhibitory effect of GLP-1 seems to require higher dosage of the peptide. Studies in vitro confirm our studies by relaxing intestinal smooth muscle strips. The relaxatory effect of GLP-1 on motility together with its inhibitory action on gastric emptying and small intestinal motor activity opens the possibility of using GLP-1 as a plausible treatment of IBS.

P1577 COMBAT-TRAINING STRESS MEDIATES METABOTYPIC CHANGES ASSOCIATED WITH GASTROINTESTINAL SYMPTOMS AND ALTERED INTESTINAL PERMEABILITY

L.C. Phua[1], **R.K. Wong**[2,*], Y.M. Tan[1], T. Gopalakrishnan[1], M.E. Kan[3], J. Lu[3], A. Keshavarzian[4], E.C. Chan[1], C.H. Wilder-Smith[5]

Contact E-mail Address: *leecheng.phua@gmail.com*

INTRODUCTION: Physical and psychological stress have been shown to precipitate gastrointestinal (GI) symptoms and impair intestinal barrier function. The neuroendocrine and –immune axes, as well as probably modulation of the microbiome, are involved mechanisms, but the molecular basis of stress-induced GI manifestations remains elusive. Global urinary metabolic profiling represents a novel approach for interrogating the multiparametric metabolic fluxes that occur in response to pathophysiologic stimuli such as stress.
AIMS & METHODS: Here, we characterized the stress-induced metabolic phenotype (metabotype) in soldiers during high-intensity combat-training and correlated the metabotype with changes in GI physiology, particularly the development of GI symptoms and alteration in intestinal permeability. In a prospective, longitudinal study, urinary metabotyping was conducted on 38 male soldiers (ages 19-23) during combat training and the subsequent rest period using gas chromatography-mass spectrometry. Stress was measured using the perceived stress scale-10 item (PSS-10) questionnaire, while incidence and severity of GI symptoms were assessed using the irritable bowel syndrome symptom severity score (IBS-SSS). Whole gut intestinal permeability was evaluated by quantifying the 24h urinary excretion of sucralose as a percentage of the orally administered 1g dose.
RESULTS: PSS-10 stress and IBS-SSS scores were higher during the combat-training period than at rest. The urinary metabotype was clearly distinct from the rest period [partial least squares discriminant analysis (PLSDA) $R^2X = 0.386$, $R^2Y = 0.712$, Q^2 (cumulative) = 0.563], confirming the presence of a unique stress-induced metabotype. Based on PLSDA, differential metabolites related to combat stress were uncovered (e.g. elevated pyroglutamate and fructose; reduced gut microbial metabolites such as hippurate and m-hydroxyphenylacetate) [$p < 0.05$]. The extent of pyroglutamate upregulation exhibited a positive correlation with the increase in IBS-SSS in soldiers during combat-training [$r = 0.504$, $p < 0.05$]. Additionally, the rise in fructose levels during combat-training was positively correlated with an increase in intestinal permeability [$r = 0.630$, $p < 0.005$].
CONCLUSION: Protracted and mixed psychological and physical combat-training stress yielded unique metabolic changes that corresponded with the incidence and severity of GI symptoms and alteration in intestinal permeability. Taken together, our data provided new insights into the molecular changes underlying stress-induced GI perturbations which could be exploited for future biomarker research or therapeutic strategies.

INTRODUCTION: Parkinson's disease (PD) is a neuro-degenerative disorder with frequent involvement of the gut. Symptoms arise throughout the gastrointestinal tract through dysmotility secondary to autonomic and enteric nervous system involvement, as well from skeletal muscle involvement in the oropharynx and anorectum. It has been speculated that gut involvement may precede motor symptoms. The Wireless Motility Capsule (WMC) yields data on transit and motility throughout the gut.
AIMS & METHODS: We report the first use of WMC to systematically assess motility in PD patients with and without gut symptoms, compared to controls. 15 patients with established PD completed the study: eight (2 f, mean age 70 [47-85]) had GI symptoms and seven (2 f, mean age 61 [49-77]) did not based on history and baseline scores on the Gastroparesis Cardinal Symptom Index (GCSI) and Wexner constipation score. Data comparison with seven controls (3f, mean age 52 [39-63]). Medications affecting GI motility /pH were discontinued for the study and the WMC was ingested following a standardized nutrient bar meal. Data on gastric emptying time (GET), small bowel transit time (SBTT), colonic transit time (CTT) and whole gut transit time (WGTT) were calculated.
RESULTS: PD patients with gut symptoms showed significantly slower transit in the stomach (GET 5.2 vs 2.7h, $p = 0.0003$), colon (CTT 57.8 vs 27.4h, $p = 0.02$) and overall gut (WGTT 67.2 vs 34.7h, $p = 0.02$) compared to asymptomatic patients. Small Bowel transit (mean SBTT 4.17h) did not significantly differ. GET, SBTT, CTT and WGTT did not differ between asymptomatic PD and controls. There was a significant correlation between the Wexner constipation score and CTT in all patients ($p < 0.01$), but no correlation between GCSI and gastric emptying ($p > 0.05$).
CONCLUSION: This study demonstrates that symptomatic PD patients have markedly delayed transit times throughout the whole gut compared to asymptomatic PD patients and controls. The correlation between scores and transit times suggest that WMC is a less useful indicator of gastric emptying than small bowel and colonic transit.

Contact E-mail Address: *wms89@hanmail.net*

INTRODUCTION: Delayed gastric emptying (GE) is one of the important pathogenic mechanisms of functional dyspepsia. Traditionally, oral gavage of phenol red/methylcellulose mixture has been used to measure the change of GE in small animals like rat or mice. However this method has a disadvantage to sacrifice animals at each measurement. 3D micro-CT has been used in the study for bone and soft tissues with the small animal, however it has not been applicated to the functional gastrointestinal study until now.
AIMS & METHODS: We aimed to establish a novel method for measurement of gastric volume and GE without sacrifice of rat using 3D micro-CT (Polaris-G90, NanoFocusRay, Jeonbuk, Korea). Sprague-Dawley rat (210~310g) were used. Rats were divided into Control (vehicle, n = 5), Delayed GE (atropine, n = 6), and Enhanced GE (bethanechol, n = 5) groups. After overnight fasting, distilled water, atropine (7.5mg/kg), and bethanechol (1mg/kg) was given by I. P. route in each group, respectively. After 20 minutes of IP, 3ml of radiopaque semisolid food was fed into stomach by gastric gavage under isoflurane anesthesia. Immediately after gastric gavage, baseline CT (fed volume) was performed, and after 1h freely moving time, 2nd CT (residual volume) was performed. Conventional CT image was converted to 3D image and the volume of radiopaque intragastric food was measured from baseline and 2nd CT. GE was calculated as [(fed volume-residual volume)/residual volumex100].
RESULTS: Fed food volume was 3.0 ± 0,02 ml, 2.99 ± 0.05 ml, and 2.4 ± 0.7 ml and residual volume was 1.33 ± 0.22 ml, 2.59 ± 0.35 ml, and 0.74±0.24 ml in Control, Delayed GE, and Enhanced GE groups, respectively. Fed volume at baseline CT of bethanechol treated rat was lower than 3ml because gastric contraction was very active and food was emptied immediately after gavage. The 1h GE rate, which was calculated using fed volume and residual volume on CT, was 55.9 ± 7.09 %, 13.5 ± 11.9 %, and 68.7 ± 6.64 % in Control, Delayed GE, and Enhanced GE group, respectively. ($P < 0.05$ compared to vehicle).
CONCLUSION: Gastric food volume was measured by 3D micro-CT in live small animal and GE rate was calculated using CT volume. This novel method can measure GE serially in a same animal. It seems that this method will be useful in the functional study for FD with decreasing the sacrifice of animal.

P1580 THE MOTILITY RESPONSE OF ESOPHAGUS TO PER-ORAL ENDOSCOPIC MYOTOMY IN PATIENTS WITH ACHALASIA: HIGH-RESOLUTION MANOMETRY APPROACH WITH CHICAGO CLASSIFICATION

Y. Ren[1,*], F. Cheng[1], Z. Deng[1], X. Tang[1], J. Wu[1], F. Zhi[1], W. Gong[1], B. Jiang[1]
[1]*Gastroenterology, Nanfang Hospital, Southern Medical University, Guangzhou, China*
Contact E-mail Address: *renytpumc@hotmail.com*

INTRODUCTION: Although per-oral endoscopic myotomy (POEM) is widely studied for achalasia, the motility response has been mainly focused on lower esophageal sphincter (LES). This study investigated the esophageal motility response including upper esophageal sphincter (UES), esophageal body (EB) and LES in subtypes of achalasia.
AIMS & METHODS: Achalasia patients who received POEM were included for analysis. Eckardt score was used to assess symptom improvement. High-resolution manometry was applied for studying motility change. HRM parameters analyzed were (i) LES: resting pressure (restP), 4-second integrated relaxation pressure (4s-IRP), intrabolus pressure (IBP); (ii) EB: contraction amplitude (CA); contraction duration (CD), distal contraction integral (DCI); distal delay (DL); esophageal length; (iii) UES: resting pressure (restP), relaxation pressure (relaxP); relaxation duration (RD).
RESULTS: There were 11 type I achalasia and 21 type II achalasia patients included. (i) LES tone was reduced significantly in both subtypes. (ii) Motility parameters of EB (length, CA, CD and DCI) were all lowered in type II achalasia, but were not in type I achalasia. (iii) UES relaxP was reduced in type II achalasia (13.90±6.76 vs. 5.22±6.80 cm, $p<0.001$); change of UES parameters in type I achalasia was insignificant. (iv) Eckardt score decreased more in type II achalasia without statistical significance [6.00 (3-10) vs. 5.00 (3-9), $p=0.056$]. (v) Proximal segment of esophagus without myotomy changed with distal segment with myotomy in both subtypes.
CONCLUSION: Type I and type II achalasia had different motility response patterns to POEM, which could lead to different clinical outcome. Distal myotomy of POEM would have a feedback l inhibition on proximal esophageal motility such as body contraction and relaxation of upper esophageal sphincter.

INTRODUCTION: The portion of patients with a combination of bronchial asthma (BA) and gastroesophageal reflux disease (GERD) grows steadily. We must understand particular features of this combined pathology to treat lung symptoms of these diseases. Our hypothesis: immune response abnormalities in the lungs during bronchial asthma (BA), GERD and in their combination is determined by faulty reprogramming of alveolar macrophages.
AIMS & METHODS: To verify the hypothesis and compare changes in immune response in the lungs with changes in phenotype of alveolar macrophages in patients with BA, GERD and their combination.
Methods: We measured the concentration of pro-inflammatory M1 cytokines: IL-1β, IL-8, IL-12, IFN-γ, TNF-α and TNF-β; anti-inflammatory M2 cytokines: IL-4, IL-5 и IL-10 and bivalent cytokines: IL-2 и IL-6 in bronchoalveolar lavage fluid (BALF) and in the alveolar macrophages culture medium. Changes in immune response in the lungs and changes in phenotype (reprogramming) of macrophages were evaluated using M1 cytokines to M2 cytokines ratio (M1/M2 index) in BALF and culture medium, respectively.
RESULTS: Patients with GERD had M1/M2 index of 4.2 in BALF; patients with combined pathology – 0.6; patients with BA – 0.9. So in GERD immune response in the lungs shifts to proinflammatory, in BA and combined pathology – to anti-inflammatory. Pro-inflammatory shift in GERD is due to increased concentration of M1 cytokines and decreased concentration of M2 cytokines in BALF, anti-inflammatory shift in BA is due to decreased concentration of M1 cytokines IL and decreased concentration of M2 cytokines, anti-inflammatory shift in combined pathology is due to decreased M1 cytokines and increased M2 cytokines. Along with specificity of cytokine pattern all three diseases have similar features: increased concentration of TNF-α, IL-6 and IL-2 in BALF. Phenotype of cultivated macrophages isolated from BALF in GERD and BA shifts to M1, in combined pathology shifts to M2. CD markers of phenotype confirmed these shifts. Pro-inflammatory shift of macrophage phenotype in GERD is due to the increased production of M1 cytokines and decreased production of M2 cytokine; pro-inflammatory shift in BA is due to decreased production of M1 cytokines and decreased production of M2 cytokine; anti-inflammatory shift in combined pathology is due to decreased production of M1 cytokines and and increased production of M2 cytokines. Along with specific changes in production of cytokines by macrophages in GERD, BA and their combined pathology, similar features were observed: increased production of M1 cytokines IL-8 and TNF-β, M2 cytokine IL-10 and cytokine IL-6.
CONCLUSION: analysis of cytokine spectrum from BALF and those produced by macrophages proved our hypothesis, that immune response abnormalities in the lungs during BA, GERD and in their combination is determined by faulty reprogramming of alveolar macrophages. This allows us to initiate new clinical direction – abnormalities in reprogramming of immune cells in the pathogenesis of lung diseases. Our results also indicate that the therapy of inflammatory component in the lungs should be conducted with consideration about specificity of the cytokine response abnormality.

P1582 ACTIVATION OF CB2 RECEPTORS HAS GASTROPROTECTIVE EFFECT ON EXPERIMENTALLY INDUCED GASTRIC ULCERS IN MICE

INTRODUCTION: Cannabinoid (CB) receptors type 2, which belong to the endogenous CB system, are distributed in the central nervous system and in the periphery. Recent studies indicated that CB2 receptors are expressed profusely in the non-neuronal systems, including immunocytes and the gastrointestinal (GI) tract. It has therefore been suggested that cannabinoids may be involved in alleviating GI inflammation and the CB2 receptor agonists may represent potential therapeutics in GI inflammatory states, where immune system is activated. The aim of the study was to investigate the effect of the activation of CB2 receptors by a novel and highly selective CB2 agonist, MJ2010, on the development of gastric lesions in two murine models of gastric ulcer.
AIMS & METHODS: We used two well-established mouse models of gastric ulcer, induced by oral administration of acidified ethanol (60% EtOH in 0.3 M HCl) and a non-steroid anti-inflammatory drug (NSAID) diclofenac (30 mg/kg). Clinical parameters for gastroprotection were assessed based on the inhibition of gastric lesion area. To establish the mechanism of gastroprotective action, myeloperoxidase (MPO) and superoxide dismutase (SOD) activity, as well as glutathione (GSH), thiobarbituric acid reactive substances (TBARS), and H_2O_2 levels were assessed in gastric tissues.
RESULTS: CB2 agonist MJ2010 produced a dose-dependent gastroprotective effect in NSAID-induced gastric lesions, as evidenced by significantly lower macroscopic damage score. Moreover, we observed that the administration of MJ2010 (5 mg/kg p.o.), stimulated the oxidative stress protection mechanisms in the tissue, as demonstrated by an increased GSH level. We also found that our compound reduced the superoxide dismutase (SOD) activity, which was followed by lower levels of H_2O_2 in the tissue.
CONCLUSION: Activation of CB2 receptors by MJ2010 reduced gastric lesion through enhancing cell response to oxidative stress. Our data suggest that CB2 receptors are a new potential target in the treatment of gastric ulcers.

INTRODUCTION: The prevalence of autoimmune thyroiditis in the general population is high (5-15%) and it is often associated in the same subject with other autoimmune disorders. One of them is the autoimmune atrophic gastritis, which occurs in 20-30% of asymptomatic patients carrying an autoimmune thyroiditis and likely affects 2-8% of the general population. This is a precancerous lesion of the stomach greatly affecting the absorption of vitamins, oligonutrients and some oral given drugs. Diagnosis is currently made by the serum detection of antibodies against parietal cells (APCA) and histology. Gastropanel, a combination of PG-I (pepsinogen-I), PG-II (pepsinogen-II), sG-17 (gastrin-17) and *Helicobacter pylori* antibodies, has been proposed as a simple non-invasive serological test to select patients with a high risk of harboring atrophic gastritis, who deserve endoscopic examination. This study assessed, non-invasively, the presence of chronic atrophic gastritis in patients carrying autoimmune thyroiditis, as managed in the primary care setting.

AIMS & METHODS: Patients (n = 160) with autoimmune thyroiditis were extracted from the database of n = 16 Italian primary care physicians. After exclusion of thyroid cancer, drug-induced hypothyroidism, inability to suspend PPI and contraindications to perform endoscopy, n = 145 of them (females = 130, median age 52 yrs) were further studied for gastric alterations. After overnight fasting, venous blood was taken for APCA and Gastropanel. PG I/II <3 was considered suggestive of moderate to severe body gastric atrophy and an indication to perform an upper gastrointestinal endoscopy.
RESULTS: APCA was positive in n = 22 (15.2%) and PG I/II <3 in n = 20 (13.8%) patients with autoimmune thyroiditis. Fifteen patients (75%) with PG I/II < 3 were also APCA positive. Gastric atrophy was present in 24/145 (16.6%) patients: 11/22 (50%) APCA positive, 13/20 (65%) PG I/II < 3 and in 10/15 (67%) with both APCA positivity and PG I/II <3. Patients (n = 24) with atrophy at histology were 11/24 (46%) APCA positive, 13 (54%) PG I/II <3, 10 (42%) positive and 10 (42%) negative for both markers. By multiple = "multiple" logistic regression, APCA alone showed a positive predictive value for atrophic gastritis of 50%, PG I/II <3 alone had a positive predictive value of 67%, whereas the PG I/II >3 had a negative predictive value of 86%. The presence of both APCA positivity and PG I/II <3 increased to 69% the positive predictive value for chronic atrophic gastritis.
CONCLUSION: Although based on a low number of patients, our results indicate that PG I/II <3 has a higher predictive value than APCA for gastric atrophy. The simultaneous presence of both APCA and PG I/II <3 increases the predictive value for gastric atrophy in patients with autoimmune thyroiditis. Gastropanel together with APCA positivity may represent a promising non-invasive tool to select patients needing endoscopy and histology.

P1584 EXPLORATION OF THE POTENTIAL OF TUMOUR-ASSOCIATED AUTOANTIBODIES AS BIOMARKERS FOR GASTRIC CANCER DETECTION

Z. Kalnina[1,*], I. Meistere[1], P. Zayakin[1], K. Silina[1], A. Pismennaja[1], M. Leja[2], A. Line[1]

INTRODUCTION: Gastric cancer (GC) represents the third leading cause of cancer-related deaths worldwide in both sexes, which is mainly due to the belated diagnosis. Currently there are no reliable non-invasive biomarkers in clinics that could be used for prompt and early GC diagnosis. Research by many research groups including ours has demonstrated that circulating IgG class autoantibodies that are generated against tumour-associated antigens, due to their specificity, stability in serum and production even in early stages of cancer development may serve as promising non-invasive biomarkers for early detection of certain malignancies.
AIMS & METHODS: In a previous study[1], we applied T7 phage display-based SEREX (PhD-SEREX) approach and phage-displayed antigen microarray (PDAM) technology to identify GC-associated antigens and analyse Ag-specific autoantibody responses in patients with GC, which resulted in the identification of 45 autoantibody biomarker panel having promising diagnostic value (AUC = 79). The aim of the current study was to assess the GC-associated antigen repertoire in the proportion of patients that tested negative with the assay, and to evaluate its potential to increase the diagnostic performance of the serological test. We applied PhD-SEREX to identify GC antigen repertoire in 28 patients, and exploited PDAM for serum autoantibody reactivity profiling against the identified antigens in 67 GC patients (from these, 56 tested negative previously) and 54 healthy controls (HC). After microarray data processing and normalisation, each antigen was ranked basing on the detected serum signal intensity and frequency of reactivity in the two groups. For each of the tested serum, a score was calculated by summing up the intensities of sero-positive antigens.
RESULTS: By using serum samples from 28 GC patients, 183 different serum-reactive clones were identified. Clone sequence analyses revealed different antigen repertoire in comparison to that identified in our previous study[1]. According to the serum autoantibody profiling results, positive rank was assigned to 50 antigens, autoantibody responses against which were detected predominantly in GC patients. Autoantibody reactivity to individual antigens ranged from 1-7% of the GC patients. Mean serum score in GC group was 3.19 and 0.6 in HC group. From the top ranked antigens, autoantibody responses against 29 were found only within the group of GC patients that tested negative previously, and thus might represent valuable biomarker candidates. From these, majority represented novel serologically active tumour-associated antigens.
CONCLUSION: The results of this study demonstrate that there might exist different sets of induced autoantibody responses possibly reflecting immunologically distinct processes induced during tumour development in stomach or, alternatively, immune responses to molecularly different types of GC. The addition of the newly identified biomarker candidates to the previously established serological GC test set may substantially increase its diagnostic performance and thus awaits for further testing and validation within larger serum sample sets.

INTRODUCTION: Non-variceal upper gastrointestinal bleeding (NVUGIB) constitutes one of the most frequent emergency presentations in the gastroenterology field. Esophagogastroduodenoscopy (EGD) plays a predominant role in its approach and management.
AIMS & METHODS: Our objective was to identify variables at hospital admission with predictive value for the presence of high risk hemorrhagic lesions in EGD.
We included consecutive patients undergoing emergency EGD for upper gastrointestinal bleeding presenting with hematemesis or melena during a one-year period. Patients with either esophageal or gastric varices as well as portal hypertensive gastropathy were excluded.
Lesions with active hemorrhage, ulcers with a visible vessel and ulcers with adhering clot were defined as high risk hemorrhagic lesions, warranting endoscopic therapy.
Statistical analysis was performed using SPSS 21.0, and a p-value <0.05 was considered statistically significant.
RESULTS: Ninety-two patients were included, 54.3% (n = 50) were male, mean age 69 years (23-93 years). Ulcers (53%) and Mallory-Weiss lesions (12%) were the most frequently observed hemorrhagic lesions; no potentially bleeding lesion was found in 14% of the procedures.
Lesions with high hemorrhagic risk criteria were observed during EGD in 32.6% (n = 30) of the patients. In multivariate analysis, hematemesis (p = 0.026), systolic hypotension (p = 0.022), leukocytosis (p = 0.004) and EGD performed in the first 12 hours after the bleeding event (p = 0.002) were significantly associated with the presence of high risk hemorrhagic lesions.
CONCLUSION: One third of the patients undergoing EGD for non-variceal gastrointestinal bleeding were shown to have a high risk hemorragic lesion. Patients undergoing EGD during the first 12 hours of the hemorrhage, presenting with hematemesis, systolic hypotension or leukocytosis were more frequently diagnosed with high risk hemorrhagic lesions.

P1586 THE IMPACT OF MANDATORY INCLUSION OF GLASGOW BLATCHFORD BLEEDING SCORE IN THE INPATIENT REFERRAL PATHWAY TO A TERTIARY ENDOSCOPY UNIT

R. I. **I. Rusu**[1,*], G. Chakrabarty[1], C. Groves[1], R. Pollok[1]
[1]*Gastroenterology Department, St George's Hospital, London, United Kingdom*

INTRODUCTION: The Glasgow Blatchford Bleeding Score (GBS) is a validated pre-endoscopy scoring system, which stratifies patients presenting with acute upper gastrointestinal (GI) haemorrhage according to the likelihood of the need for intervention. Previous research indicates that patients with a low GBS score (0 or 1) are safe to have endoscopy as outpatients. An initial review in our own institution indicated 10% of inpatient endoscopies were in this low risk group. We therefore aimed to assess the impact of the introduction of GBS as standard part of the referral pathway on inpatient endoscopic activity. We also aimed to establish whether patients with a score of 2 could also avoid inpatient endoscopy.
AIMS & METHODS: We undertook a retrospective study of all inpatient referrals over a 6 month period. The GBS scores were completed by the referrer or calculated based on information recorded in patient's notes and electronic patient record. A review of the endoscopic findings and use of proton pump inhibitors (PPI) prior to endoscopy was performed and compared with previous findings.
RESULTS: During the study period (comparative first study data included in parenthesises) there were 140 (97) referrals, 137 (97) patients mean GBS 8.92 +/- 3.79 (6.2 +/- 4.2). Mean difference between the two studies was 2.72 (CI 1.68, 3.75), p < 0.0001. GBS was completed for 48 referrals - 34% (10–10%) and calculated in 92 – 66% (87–90%). Overall GBS was 0 or 1 in 2 patients – 1.5% (18–18.5%), 2 in 5 patients- 3.5% and 2 or more in 138 patients – 98.5% (79 – 81.5%). Of those with GBS 0 or 1, only 1 patient (18) had inpatient endoscopy. Endoscopic findings in the five patients scoring 2 were: normal-2, oesophagitis-2, Barrett's-1 and oesophageal ulcer-1. None had stigmata of recent haemorrhage or required end therapy. Amongst the whole group 21 patients – 15.2% (12 – 15.2%) required endotherapy. 102 patients – 72.8% (69–71.1%) were prescribed PPI prior to endoscopy. Of these, 48 patients – 47% (43–62.3%) had oral PPI, 51 – 50% (22–31.8%) had IV PPI and 3 – 3% (3–5.9%) PPI infusion.
CONCLUSION: Completion of the GBS proformas improved substantially from 10 to 34%. There was also a concurrent significant reduction in the number of inpatient referrals for endoscopy with a low risk score of 0 or 1 from 10% to 1.5 %. It appears the introduction of the GBS score has led to a wider appreciation of the importance of risk stratification amongst referrers in triaging inpatient endoscopy. Our findings also support recent research suggesting low risk stratification may safely be extended to include patients with a score of two.

P1587 IMPORTANCE OF ANGIOTENSIN-(1-7), A VASOACTIVE METABOLITE OF ANGIOTENSIN I IN THE MECHANISM OF GASTRIC ADAPTATION TO REPEATED ASPIRIN INSULT. A KEY IN UNDERSTANDING OF GASTRIC ADAPTATION TO ASPIRIN?

R. Pajdo[1,*], Z. Sliwowski[1], M. Pawlik[1], S. Kwiecien[1], B. Bujak-Gizycka[2], S.J. Konturek[1], W.W. Pawlik[1], T. Brzozowski[1]

INTRODUCTION: The rodent and human gastric mucosa of the stomach can adapt to damaging action of aspirin (ASA) but the contribution of renin-angiotensin system (RAS) and vasoactive metabolites of angiotensin I, e.g. angiotensin-(1-7) (Ang-(1-7) in phenomenon of gastric adaptation to ASA has been little studied.
AIMS & METHODS: Using advance LC-ESI-MS method we determined whether 1) Ang-(1-7) is detectable in gastric tissue and whether 2) the treatment with Ang II, the blockade of specific Ang-(1-7)/Mas receptor, exogenous Ang-(1-7) or AVE 0991, the agonist of Mas receptor, could influence the gastric damage induced by single and repetitive ASA treatment. Gastric adaptation was induced by daily repeated exposure of acidified ASA (100 mg/kg-d) given p.o. for 5 days to rats treated daily i.g. with or without: 1) Ang II (100 μg/kg), 2) A-779 (50 μg/kg), 3) Ang-(1-7) (20 μg/kg), and 4) AVE 0991 (50 μg/kg i.p.). The area of gastric lesions was determined by planimetry, the gastric blood flow (GBF) was assessed by H_2-gas clearance technique, the mucosal malondialdehyde (MDA) content as an index of lipid peroxidation, the plasma levels of IL-10, IL-1β and TNF-α (ELISA) were assessed. The expression of mRNAs for ACE, HIF-1α, IL-10, IL-1β and TNF-α, cNOS and iNOS was analyzed by RT-PCR.
RESULTS: We found that the rat stomach mounted in organ bath ex vivo is a source of Ang-(1-7) which is abundant metabolite product of Ang I conversion in the gastric mucosa. The single treatment with ASA produced gastric lesions and decreased GBF while raising both the mucosal MDA contents and the plasma IL-1β and TNF-α levels but significantly decreased the plasma IL-10 levels. The lesion area was reduced by 75% at 5 repeated exposures to ASA followed by a significant increase in the GBF and the significant decrease in the MDA content and the plasma IL-1β and TNF-α. Treatment with Ang-(1-7) (50 μg/kg i.g.) significantly reduced ASA-induced gastric lesions and the mucosal MDA content and raised GBF and these effects were reversed by concurrent treatment with A-779 ($p < 0.02$) or Ang II (10 μg/kg i.g.). In ASA-adapted rats the reduction in the lesion area and an increase in GBF were further improved by concomitant treatment with Ang-(1-7) or AVE 0991. Expression of mRNA for ACE was normal in intact mucosa but mRNAs for IL-1β, TNF-α, HIF-1α and iNOS which were negligible in intact gastric mucosa, were strongly upregulated in single ASA-treated mucosa and these effects were significantly attenuated in rats treated 5 times with ASA with or without treatment with AVE 0991.
CONCLUSION: We conclude that 1) Ang-(1-7) produced in excessive amounts by the gastric mucosa of the stomach is involved in the mechanism of gastric mucosal defense and mucosal resistance to subsequent repetitive ASA treatment, 2) blockade of specific Ang-(1-7) Mas receptor impairs the ASA adaptation suggesting that Ang-(1-7) plays an important role in the mechanism of gastric adaptation to repetitive ASA insult, and 3) Ang-(1-7) mediates ASA-induced adaptation *via* its antiinflammatory, vasodilatatory and hyperemic properties resulting in suppression of proinflammatory cytokines, lipid peroxidation and attenuating effect on oxidative stress.

P1588 A NEW SIMPLE SCORING SYSTEM FOR UPPER GASTROINTESTINAL BLEEDING – COLOGNE-WATCH RISK PREDICTION (C-WATCH)

V. Hoffmann[1,*], M. Hellmich[2], A. Bowe[1], A. Pelc[1], M. Demir[1], S. Schulte[1], U. Toex[1], D. Nierhoff[1], H.-M. Steffen[1]

INTRODUCTION: Acute upper gastrointestinal bleeding (UGIB) is the leading indication for emergency endoscopy. Scoring systems have been developed for immediate risk stratification. However most of these scores include endoscopic findings and are based on data from patients with non-variceal bleeding. The aim of our study was to design a pre-endoscopic scoring system for acute UGIB - including variceal bleeding – in order to differentiate between high-risk patients in need of early endoscopy from low-risk patients with justifiable outpatient management.
AIMS & METHODS: The scoring system was developed using a training set consisting of 586 patients with acute UGIB. These patients were recruited from the emergency department as well as all inpatient services at the University Hospital of Cologne within a two year period (01/2007 – 12/2008). A cohort of 322 patients, who presented to our endoscopy unit with acute UGIB in 2009 served as validation set. Clinical, laboratory and endoscopic parameters as well as further data on medical history and medication were retrospectively collected from the electronic clinical documentation system. A multivariate logistic regression was fitted to the data to obtain a predictive risk score using recurrent bleeding, need for intervention (angiography, surgery) or death within 30 days as composite endpoint.
RESULTS: Only **C**RP, **w**hite blood cells, **A**LT, **t**hrombocytes, **c**reatinine, and **h**emoglobin could be identified as significant predictors for the composite endpoint. Based on the odds ratios of these variables an easy to use point scoring scheme (C-WATCH) was derived predicting the risk of complications from 3% to 86% with an AUC of 0.723 in the training set and 0.704 in the validation set. None of the low risk patients (0-1 points) needed any intervention included in our composite endpoint, while 36% of patients in the high risk group ($\geq$ 2 points) experienced a complication.
CONCLUSION: In emergency settings, our easy to use scoring system is able to separate high-risk patients who need hospitalization or immediate upper endoscopy from low-risk cases that are suitable candidates for outpatient management or in whom endoscopy can be postponed. A prospective validation of the C-WATCH risk score in different patient populations outside a university hospital setting seems warranted.

P1589 HEALTHCARE COSTS AND QUALITY OF LIFE ASSOCIATED WITH ACUTE UPPER GASTROINTESTINAL BLEEDING IN THE UK

H. Campbell[1], E. Stokes[1], D. Bargo[1], R. Logan[2], M. Murphy[3], **V. Jairath**[4,*] on behalf of TRIGGER Investigators
[1]*Nuffield Department of Population Health, Oxford,* [2]*University of Nottingham, Nottingham,* [3]*NHS Blood and Transplant,* [4]*Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom*

INTRODUCTION: Acute upper gastrointestinal bleeding (AUGIB) accounts for over 70,000 hospital admissions in the UK annually. Its incidence is likely to rise due to an ageing population and increasing burden of liver disease. Data on the healthcare costs and health related quality of life (HRQoL) associated with this condition are sparse.
AIMS & METHODS: The TRIGGER trial is a cluster randomised feasibility trial evaluating restrictive versus liberal red cell transfusion for patients with AUGIB. The study collected data on resource use, costs and outcomes during hospitalisation and up to day 28 to explore the feasibility of gathering inputs required for a cost-effectiveness analysis. Resource use data were collected during the inpatient episode on the use of laboratory tests, medications, blood components, endoscopy and endoscopic therapy, clinical events including ischaemic/thromboembolic events and length of hospital stay (LOS) by ward type. Data were also collected on primary and secondary care resource use, as well as informal care/days off work, post-discharge to day 28. Resource use for each patient was multiplied by national unit costs to generate an estimate of the costs of AUGIB to 28 days. HRQoL was measured on a scale anchored at 0 (death) and 1 (full health), using the EuroQol EQ-5D-3L questionnaire at day 28.
RESULTS: 936 patients were enrolled into TRIGGER between August 2012 and March 2013 in 6 UK hospitals. Preliminary analyses show that the mean (standard error (SE)) cost of the inpatient episode was £2436 (£87) per patient. LOS was a key cost driver; mean LOS was 5.3 days with an associated cost of £1432. Additional cost drivers included: (1) endoscopy, with mean of 0.8 endoscopies per patient at a cost of £627; (2) red cell transfusion, with a mean of 1.6 units transfused per patient at a cost of £198. Mean (SE) costs from hospital discharge to 28 days were £386 (£25) per patient. The main cost driver post discharge was readmission to hospital; 11% of patients were readmitted within 28 days for a mean of 4.8 days. The mean cost associated with readmission across all patients was £145. HRQoL was on average (SE) 0.68 (0.01) at 28 days.
CONCLUSION: The mean (SE) cost up to 28 days for patients presenting with AUGIB is £2822 (£90). At 28 days, the mean HRQoL in patients who have experienced an AUGIB is well below the average population level of 0.86. This is the first study to provide detailed estimates of the costs and HRQoL associated with AUGIB in the UK. These data can be used by healthcare providers and researchers to inform the design of subsequent cost-effectiveness analyses of interventions for AUGIB.

INTRODUCTION: Balloon-occluded retrograde transvenous obliteration (B-RTO) has been widely adopted for the management of gastric fundal varices (GV). We previously reported the efficacy and safety of simultaneous combined B-RTO and partial splenic embolization (PSE) based on the hypothesis that concomitant PSE can diminish the increase in portal venous pressure following B-RTO for GV (JVIR 2012). With more cases and long-term observation, we re-evaluated the efficacy of simultaneous combined B-RTO and PSE.
AIMS & METHODS: We performed B-RTO in 36 consecutive patients with GV between 2005 and 2013 at a single institute. Of these, 8 and 4 patients with ruptured GV were treated emergently and electively, respectively. The remaining 24 patients with unruptured GV were treated prophylactically. Twenty-three patients received simultaneous combined B-RTO and PSE (Group 1) and 13 received B-RTO monotherapy (Group 2). Outcomes were retrospectively assessed.
RESULTS: No significant differences were observed in the baseline characteristics between the two groups except for significantly larger spleen volumes in Group 1. B-RTO was performed successfully in 33 of 36 patients (91.7%). Gastrorenal shunts were well-embolized, and GV resolved in all patients successfully treated by B-RTO. The procedure time was not significantly different between Groups 1 and 2 ($p = 0.2623$). In Group 1, the volume of sclerosing agent required for B-RTO was significantly smaller ($p = 0.0118$) and exacerbation of esophageal varices was significantly less frequent ($p = 0.0013$) than in Group 2.
CONCLUSION: This study indicated that concomitant PSE may improve the success of B-RTO.

P1591 NO CORRELATION OF ALARM SYMPTOMS AND CLINICALLY SIGNIFICANT FINDINGS IN UPPER ENDOSCOPY IN AMBULATORY SETTING: CONTINUATION OF THE PROSPECTIVE STUDY

L. Jonaitis[1,*], G. Kiudelis[1], S. Sriuoginys[1], L. Mockute[1], L. Kupcinskas[2]
[1]*Gastroenterology,* [2]*Institute of Digestive diseases, Lithuanian University of Health Sciences, Kaunas, Lithuania*
Contact E-mail Address: *laimasj@takas.lt*

INTRODUCTION: In our former report (1) we represented the interim results on the correlation of alarm symptoms and clinically significant findings found on EGDS in 502 ambulatory patients. The results raised the doubts if the presence of alarm symptoms yields in much more clinically significant findings. Therefore we continued the study and the amount of patients was doubled.
AIMS & METHODS: Aim. To evaluate the correlation of alarm symptoms and clinically significant findings found on Esophagogastroduodenoscopy (EGDS) in the routine clinical practice in ambulatory setting.
Methods. A prospective study performed in 5 hospitals in Lithuania: Hospital of Lithuanian University of Health Sciences (tertiary level), and 4 secondary level hospitals. The data of ambulatory patients referred to upper endoscopy were collected and analyzed. Alarm symptoms that were evaluated as an indication to perform EGDS were: dysphagia, odynophagia, anemia, signs of upper GI bleeding (suspicion of melena), weight loss, recurrent vomiting, fever. The following endoscopic findings were considered as a clinically significant: erosive esophagitis, gastric ulcer, duodenal ulcer, gastric or duodenal polyps, malignant tumors.
RESULTS: Data from 1010 patients (mean age- 56.4±16.3) were analyzed: 379 (37.5%) males and 631 (62.5%) females. Mean age of males – 53.8±15.9, of females – 58.0 ±16.3 years, $p<0.01$. Alarm symptoms were found in 137 (13.6%) patients: in 75 (11.9%) females and in 62 (16.4%) males, $p<0.05$. Mean age of patients with alarm symptoms- 57.6±18.6, without alarm symptoms- 56.2±15.9, $p>0.05$. Clinically significant findings found in 381 (37.7%) patients. Malignant tumor found only in 7 (0.7%) patients. Mean age of patients with clinically significant findings was 56.3±15.4, without clinically significant findings- 56.5±16.8, $p>0.05$. Among patients with alarm symptoms, clinically significant findings were found in 48 (35.0%) patients, among patients without alarm symptoms– in 333 (38.1%), $p>0.05$. Duodenal or gastric ulcer was found in 4 (26.7%) out of the 15 patients with melena, and in 66 (6.6%) out of 995 patients without melena, $p<0.05$. We did not find any differences in clinically significant findings if the patients were referred to upper endoscopy by gastroeneterologist or not gastroenterologist.
CONCLUSION: The presence of alarm symptoms in our cohort was not associated with the clinically significant findings. Only the presence of signs of upper gastrointestinal bleeding was associated with more frequent detection of peptic ulcer. There is no correlation between the age and alarm symptoms and clinically significant findings in our cohort. The prevalence of esophageal, gastric and duodenal malignancies is extremely low (0.7%) in our studied setting. Therefore it is not feasible to determine the role of alarm symptoms in predicting the malignant diseases.

P1592 UPPER GASTROINTESTINAL MUCOSAL INJURY AND SYMPTOMS IN ELDERLY PATIENTS TAKING LOW-DOSE ASPIRIN

Y. Shimada[1,*], A. Nagahara[1], I. Tanaka[1], Y. Nakagawa[1], K. Izumi[1], K. Matsumoto[1], H. Ueyama[1], H. Sasaki[1], K. Matsumoto[1], D. Asaoka[1], M. Hojo[1], S. Watanabe[1]

INTRODUCTION: It is well known low-dose aspirin (LDA) not only increases the risk of gastrointestinal (GI) mucosal injury but also worsens the quality of life (QOL) because of the symptoms like dyspepsia. Today, many elderly patients are taking LDA to prevent atherosclerosis diseases. Moreover, the number of LDA users is expected to increase in the future.
AIMS & METHODS: To reveal the clinical features of LDA related upper gastrointestinal mucosal injury (u-GI) especially in elderly patients, we investigated the prevalence, severity and symptom of esophageal mucosal injury (EI), gastric mucosal injury (GI) and duodenal mucosal injury (DI) individually between elderly patients (sixty-five years of age or over) LDA users (Users) and non-users (Non-users). Data was extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2008 and December 2013. Among 3162 elderly patients answering Frequency of Scale for Severity of GERD (FSSG) and SF8-QOL (SF8) were analyzed after excluding proton pump inhibitor or histamine type 2 receptor antagonist users. Prevalence was compared between Users and Non-users. Among patients who were diagnosed to have mucosal injuries, symptoms and QOL were compared between Users and Non-users. FSSG items were classified into total score (TS), reflux score (RS) and dyspepsia score (DS). SF8 has physical component summary (PCS) and mental component summary (MCS).
RESULTS: The study included 281 Users (199 men, 82 women; mean age, 72.7 years), and 2881 Non-users (1617 men, 1264 women; mean age, 71.7 years), respectively. Prevalence of EI in Users: Non-users was 10.0% ($n=28$): 9.6% ($n=276$) ($p=0.83$), GI was 35.9% ($n=101$): 27.5% ($n=792$) ($p=0.003$) and DI was 3.2% ($n=9$): 3.4% ($n=99$) ($p=0.84$). Regarding symptoms and QOL, TS, RS and DS of EI were Users: Non-users = 5.8 ± 6.6: 6.4 ± 6.3 ($p=0.61$), 3.3 ± 4.3: 3.7 ± 3.9 ($p=0.57$) and 2.5 ± 3.1: 2.7 ± 2.9 ($p=0.72$), GI were 5.0 ± 5.8: 6.0 ± 6.3 ($p=0.13$), 2.6 ± 3.2: 3.1 ± 3.7 ($p=0.15$) and 2.4 ± 3.1: 2.9 ± 3.1 ($p=0.17$), DI were = 2.6 ± 2.1: 4.8 ± 4.5 ($p=0.13$), 0.7 ± 1.1: 2.6 ± 2.8 ($p=0.04$) and 1.9 ± 1.8: 2.6 ± 2.8 ($p=0.69$). PCS and MCS of EI were Users: Non-users were 44.5 ± 9.1: 48.9 ± 5.8 ($p=0.0004$) and 50.6 ± 5.9: 50.0 ± 6.3 ($p=0.65$), GI were 47.4 ± 7.1: 47.8 ± 6.4 ($p=0.60$) and 50.5 ± 5.4: 49.5 ± 6.6 ($p=0.14$), DI were 48.8 ± 6.7: 49.0 ± 6.6 ($p=0.93$) and 45.3 ± 6.6: 50.3 ± 6.3 ($p=0.02$).
CONCLUSION: Prevalence of gastric mucosal injury in elderly LDA users was significantly higher than Non-users, although the prevalence of esophageal and duodenal mucosal injury was about the same. LDA users diagnosed with duodenal mucosal injury had significantly less symptom score on RS. LDA users diagnosed with esophageal mucosal injury had significantly less PCS score and LDA users diagnosed with duodenal mucosal injury had significantly less MCS score. These results give us the important clinical information that symptom based management was not appropriate in elderly LDA users in terms of upper gastrointestinal mucosal injuries.

P1593 ESOPHAGEAL MUSCULAR RING: CLINICAL REVIEW OF 10 CASES

H.S. Hwang[1,*], J.S. Oh[1], H.H. Kim[1], H.N. Choi[1], J.S. Park[1], S.H. Kim[1], S.M. Kang[1], J.G. Kwon[1], E.Y. Kim[1], J.T. Jung[1]
[1]*Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of*

INTRODUCTION: The lower esophageal muscular ring remains a poorly defined entity. Distinguishing the muscular ring from achalasia and other causes of focal esophageal stenosis is important because of the differences in treatment and outcome.
AIMS & METHODS: The aim of this study is to analyze clinical characteristics of lower esophageal muscular ring. Medical records of 10 cases of lower esophageal muscular ring diagnosed at Daegu Catholic University Hospital from 2002 to 2013 were reviewed and analyzed retrospectively.
RESULTS: 10 patients comprised of 5 men and 5 women, with mean age of 57.4 years (range 43-72 years). The nine patients (90%) had symptoms consisting of chronic, intermittent dysphagia for both liquids and solids. Upper gastrointestinal endoscopic examinations revealed a focal smooth concentric narrowing of esophagus located a few centimeters above the squamocolumnar junctions. Endoscopic ultrasound examination showed a focal thickening of inner circular muscle at the luminal narrowing and mean thickness of muscle ring was 5.2 ± 1.4 mm. Nine patients underwent esophageal manometry and mean lower esophageal sphincter (LES) pressure was 35.2 ± 18.4 mmHg. Five cases showed complete LES relaxation and 8 cases showed well propagated esophageal body peristalsis. Mean amplitude of distal esophageal body contraction was 105.9 ± 43.9 mmHg. Barium esophagogram showed concentric narrowing of distal esophagus or patent esophageal lumen. Mean maximal diameter of luminal narrowing was 6.1 mm (range 2.6 -12 mm). Six cases were treated with calcium channel blocker and 4 cases had significant symptomatic improvement.
CONCLUSION: We have presented a series of 10 cases of patients with lower esophageal muscular rings. Considering a possibility of a muscular ring in the distal esophagus, well propagated esophageal body peristalsis, complete LES relaxation and variable luminal opening at barium esophagogram may help differential diagnosis of focal esophageal stenosis.

INTRODUCTION: Reactivators of acetylcholinesterase (AChE) are essential in the treatment of organophosphate intoxication. Wider clinical use of several AChE modulators is limited because of the significant side effects, including serious gastrointestinal toxicity. Our research team has synthesised our own priority compound K027, 1-(4-carbamoylpyridinium)-3-(4-hydroxyiminomethylpyridinium)-propane dibromide. This novel oxime AChE reactivator was already tested in-vitro and on small laboratory animals with excellent results. K027 might thus be a candidate for human therapeutic use in the event of industrial poisoning or catastrophic situations. The small adult pig can be used in experiments as an omnivorous representative due to its relatively very similar gastrointestinal functions in comparison to man.
AIMS & METHODS: The aim of this study was to evaluate the effect of K027 on porcine electrogastrography (EGG). Six mature female pigs (3 months old, mean weight 23.2±2.1 kg) were included in the study. All EGG recordings were performed under general anaesthesia in the morning after 24 hours of fasting (by means of the MMS EGG System, Enschede, the Netherlands). After 10-minute baseline EGG, K027 (1500 mg i.m.) was administered. The EGG trial recording lasted 150 min. Running spectral analysis was used for initial evaluation of the EGG. The gastric myoelectric activity was estimated by EGG power analysis (areas of amplitudes) and by power ratio assessment (ratio of the areas of amplitudes after and before K027 administration).

RESULTS: After i.m. administration, K027 did not cause any significant changes in EGG dominant frequency. EGG power results displayed non-normal distribution. The power increased from the baseline mean values 648±326 (μV^2) to 4881±7756 (at 5 min.) and 12730±24404 (at 10 min.), p = 0.032, p = 0.151. Afterwards, the power values decreased gradually to those comparable with baseline ones (536±301 μV^2 at 150 min.). The EGG power ratio reached the highest values at 5 min. (11.3±20.3) and 10 min. (31.2±62.7), decreased significantly at 20 min. (3.0±2.9; p < 0.001) and stayed at low values until 150 min. (1.0±0.9).
CONCLUSION: K027, a novel AChE reactivator, caused only a transient increase in the EGG power with quick subsequent equalisation comparable with initial basal myoelectric values.

P1595 EFFECTS OF NESFATIN-1 ON GASTRIC DISTENSION SENSITIVE NEURONAL DISCHARGE AND GASTRIC MOTILITY IN THE ARCUATE NUCLEUS OF RATS

L. Xu[1,*], F. Guo[1], S. Gao[1], X. Sun[1], Y. Gong[2]
[1]*Pathophysiology, Medical College of Qingdao University,* [2]*Department of Pharmacy, Qingdao University of Science and Technology, Qingdao, China*
Contact E-mail Address: *xu.luo@163.com*

INTRODUCTION: Nesfatin-1, derived from the precursor NEFA/ nucleobinding-2 (NUCB2), is a newly identified 82-amino-acid anorexigenic neuropeptide which was initially discovered in the neurons of the hypothalamus. Several studies have showed that central administration of nesfatin-1 could suppress food intake and body weight gain, underscoring the potential importance of this peptide in the controlling of feeding behavior. Although the novel satiety peptide nesfatin-1 has been revealed to regulate the motor function, the underlying mechanisms have yet to be elucidated.
AIMS & METHODS: The study aims to explore effects of nesfatin-1 in arcuate nucleus (Arc) on gastric distension sensitive neurons (GD) and gastric motility, and the potential regulation mechanisms by lateral hypothalamic area (LHA). Single unit discharges in Arc were recorded extracellularly and gastric motility in conscious rats was monitored when administration of nesfatin-1 to Arc or electrical stimulation of LHA. Retrograde tracing and fluo-immunohistochemistry staining were used to determine NUCB2/nesfatin-1 neuronal projections.
RESULTS: Nesfatin-1 could inhibit most of GD-excitatory neurons (GD-E), but excite GD-inhibitory neurons (GD-I) in Arc. The reduced firing by nesfatin-1 on GD-E neurons could be partly absorbed by SHU9119 (P < 0.05), an antagonist of melanocortin 3/4 receptor. The gastric motility was significantly reduced by administration of nesfatin-1 into Arc (P < 0.05). Electrical stimulation of LHA could excite most of GD neurons in Arc (P < 0.05) and promote gastric motility (P < 0.05). However, pretreatment of anti-NUCB2/nesfatin-1 antibody in Arc could further increase the firing rates of GD-E neurons induced by electrical stimulating LHA (P < 0.05). NUCB2/nesfatin-1/fluorogold-double labeled neurons were observed in the LHA.
CONCLUSION: The results suggested that the effects of nesfatin-1 on GD-E neurons may be related with melanocortin signal pathway. Nesfatin-1 in the LHA perhaps was involved in the regulation of Arc on gastric activity.

P1596 IMPEDANCE PLANIMETRY (ENDOFLIP®) MEASUREMENTS AT THE ESOPHAGO-GASTRIC JUNCTION DISTINGUISH NEUROMUSCULAR DISEASE FROM FIBROTIC LESIONS IN DYSPHAGIA PATIENTS

J. Lenglinger[1,*], E. Rieder[1], S.F. Schoppmann[1]
[1]*Surgery, MEDICAL UNIVERSITY OF VIENNA, Wien, Austria*
Contact E-mail Address: *johannes.lenglinger@meduniwien.ac.at*

INTRODUCTION: Impaired opening of the esophago-gastric-junction (EGJ) is a frequent cause of dysphagia and may be due to neuromuscular disease or fibrosis. Aim of this study was to test whether impedance planimetry parameters can be used to distinguish these etiologies.
AIMS & METHODS: Based on endoscopy, histopathology, HR-manometry and videofluoroscopy dysphagia was ascribed to be of neuromuscular (NM) or fibrotic (F) origin. A catheter fitted with a 25 mm balloon (EndoFLIP® EF-320) was inserted into the stomach transnasally and retracted until it was centered across the esophagogastric junction. The EndoFLIP® catheter acts as a functional imaging probe (FLIP) converting voltage measurements inside the balloon to estimations of balloon diameters at 5 mm intervals over 8 cm length. Intraballoon pressure is monitored by a solid state pressure transducer, facilitating the calculation of compliance data. EGJ distensibility measurements over 30 seconds were performed with balloon filling volumes of 20, 30, 40, and 50 ml volumes, respectively. Estimations of diameter and the distensibility index (DI, cross sectional area in mm2 divided by intraballoon pressure in mm Hg) were used as parameters. Study hypothesis was that DI is inversely correlated with balloon filling volume in patients with fibrotic lesions whereas it remains constant in subjects with neuromuscular disease affecting the esophago-gastric junction. The quotient of DI at 50 ml and at 30 ml volumes (DI 50 ml/DI 30 ml) was used to account for the change of distensibility with balloon filling volume.
RESULTS: The NM group comprised 20 subjects (4 females). Diagnoses were achalasia in 7, hypertensive lower esophageal sphincter (LES) in 4, and impaired LES relaxation upon swallowing in 9 patients. In the F group of patients (1 female) 4 had eosinophilic esophagitis, 5 a Schatzki-ring, and 6 a peptic stenosis.

	NM n = 20	F n = 15	p-value
Age (yrs)	42.1 ± 19.4	52.9 ± 17.8	n.s.
EGJ diameter 30 ml (mm)	6.2 (5.0 - 7.9)	7.2 (6.5 - 10.0)	0.007
EGJ diameter 50 ml (mm)	11.6 (8.7 - 12.7)	9.3 (8.7 - 10.7)	n.s.
DI 30 ml (mm2/mm Hg)	1.4 (0.9 - 2.4)	2.3 (1.7 - 3.0)	n.s.
DI 50 ml (mm2/mm Hg)	2.1 (1.5 - 2.7)	1.3 (0.9 - 1.6)	n.s.
Distensibility Index Quotient (DI 50 ml/DI 30 ml)	1.4 (1.0 - 2.0)	0.6 (0.5 - 0.9)	0.001

CONCLUSION: In patients with neuromuscular disorders DI remained constant or increased with filling volume, whereas a decrease was encountered in patients with fibrosis. In this study we have shown that a new parameter, the distensibility index quotient (DI 50 ml/DI 30 ml), can be used to distinguish neuromuscular disease from fibrotic lesions at the EGJ. This might have implications for the choice of treatment.

P1597 CLINICAL OUTCOME OF PATIENTS UNDERGOING ESOPHAGEAL HIGH-RESOLUTION MANOMETRY (HRM) IS ASSOCIATED WITH MANOMETRIC FINDINGS

J. Keller[1,*], V. Andresen[1], P. Layer[1]
[1]*Internal Medicine, Israelitisches Krankenhaus, Hamburg, Germany*
Contact E-mail Address: *j.keller@ik-h.de*

INTRODUCTION: Esophageal manometry is the reference method for diagnosis of achalasia and other esophageal motility disorders. It is also frequently recommended for patients with refractory reflux disease, particularly for those scheduled for fundoplication. The association between manometric findings obtained by HRM and clinical outcome parameters is unknown.
AIMS & METHODS: It was our aim to investigate clinical outcome in patients undergoing HRM with special respect to patients with impaired relaxation of the lower esophageal sphincter (IR-LES). Between September 2011 and June 2013 250 patients undergoing HRM were enrolled into a prospective study assessing demographics, manometric findings, pH-data, reflux symptoms (GerdQ) and dysphagia (HODQ, 5 items). Quality of life (QoL, SF-36) was also evaluated at the time of the investigations and 4-6 months later. The kind of treatment was assessed and patients rated overall treatment satisfaction. Data of all subjects with IR-LES and of an identical number of subjects with normal LES relaxation (NR-LES) were analysed.
RESULTS:

	LES basal tone, mmHg	pH < 4, %	GerdQ	HODQ	SF-36 pre	Invasive TX	SF-36 post
Achalasia	32±3 7	4±3.5	11±1	12±2	79±6	70%	100±6
EGJ-OO	31±2	3.4±1.6	9±1	3±1	90±3	14%	97±3
NR-LES	13±1	9.7±1.4	11±1	2±1	96±3	22%	106±3
p-value	< 0.0001	0.017	< 0.0001	< 0.0001	0.026	0.002	NS

Age and BMI were similar for subjects with IR-LES (n = 55) and NR-LES (n = 55). NR-LES patients were more frequently male (53% vs. 26% p < 0.05). 15 patients with IR-LES were diagnosed with achalasia, 40 had signs of EGJ outlet obstruction (EGJ-OO). Only 7 subjects with NR-LES had completely normal manometric findings. Patients with achalasia had similar GERD symptoms compared with NR-LES patients but more severe dysphagia and the lowest QoL (table). They received more invasive treatment (endoscopic or surgical) and had a more profound increase in QoL, although QoL improved significantly in all patient groups (p < 0.05 pre vs. post).
CONCLUSION: HRM has a high diagnostic yield and manometric findings are associated with choice of treatment modalities and posttherapeutic alterations of QoL. Patients identified as having achalasia according to HRM receive more invasive treatment and have the highest increase in QoL.

P1598 EFFECTS OF PNEUMATIC DILATION ON LES AND UES PARAMETERS AND THEIR CORRELATION WITH SYMPTOMS IMPROVEMENT IN PROSPECTIVELY EVALUATED PATIENTS WITH ESOPHAGEAL ACHALASIA

M. Pesce[1,*], R. Cuomo[1], P. Andreozzi[1], F.P. Zito[1], A. D'Alessandro[1], A. Santonicola[1], N. Gennarelli[1], G. De Carlo[1], G. Sarnelli[1]
[1]*Clinical Medicina and Surgery, UNIVERSITY OF NAPLES " FEDERICO II", Naples, Italy*
Contact E-mail Address: *mapesc@hotmail.com*

INTRODUCTION: An impairment in lower esophageal sphincter (LES) function is recognized as the hallmark feature of idiopathic achalasia; however, it has

become apparent that malfunctioning in upper esophageal sphincter (UES) may also occur in achalasia, but not in other esophageal motor disorders. In a recent study, pneumatic dilation has been retrospectively linked to an improvement in UES function.
AIMS & METHODS: Aim of this study was to prospectively evaluate the impact of pneumatic dilation on HRMI parameters. 27 (14 Males; age 41 ± 12 ys) newly diagnosed achalasia patients were enrolled. All patients underwent to pneumatic dilatation with a 30 mm diameter balloon, inflated for 120 seconds at 12 psi. In all patients a standardized questionnaire assessing the frequency and the intensity of achalasia-related symptoms (dysphagia for solids and liquid graded from 0:absent to 9: at each meal and precluding daily activities) was administered before and 6 months after pneumatic dilation. At the same time points, a HRMI study was performed in all patients. Manometric parameters studied were (i) LES basal pressure (LESbasalP) and 4-second integrated relaxation pressure (IRP4); (ii) UES resting pressure (restP) (iv) UES basal pressure (UESbasalP) and (v) incomplete esophageal clearance. All data are given as mean ± SD.
RESULTS: According to the Chicago Classification, 20 out of 27 were classified as having type-2 achalsia, 2 patients had type-3 achalasia and 5 patients were diagnosed as type 1. Six months after treatment, patients showed a sustained symptomatic improvement in terms of dysphagia for both solids and liquids (1±1.4 vs 6.7±2.2 and 0.6±1.1 vs 5.3±3.2 respectively; all $p<0.001$). After the pneumatic dilation, a significant reduction in LES basal pressure and IRP4 was observed (28±12 vs 46±12 mmHg and 17±9 vs 35±11 mmHg respectively; all $p<0.001$). Similarly, UES resting pressure resulted significantly decreased as compared to pretreatment values (8±5 vs 16±8 mmHg; $p=0.002$); whilst no differences were observed in UES basal pressure or incomplete esophageal clearance (90±32 vs 78±42 mmHg and 75±29 vs 74±29%, respectively; all p = NS). A positive correlation between the severity of dysphagia and LES pressure, IRP4 and UES resting pressure was observed ($r^2=0.305$, $r^2=0.592$ and $r^2=0.419$, respectively, all $p<0.001$), while UES basal pressure or incomplete esophageal clearance were not significantly correlated.
CONCLUSION: Here we demonstrated that pneumatic dilation of LES induced a sustained reduction of UES resting pressure, showing a positive correlation with patients' symptomatic improvement. Although LES pressure remains the main target of pneumatic dilatation; the positive effect of this technique on UES appears to contribute to the symptomatic improvement of these patients, supporting the idea that pneumatic dilatation has an undervalued effect on UES function.

INTRODUCTION: POEM is a complex and demanding endoscopic procedure with a potential of serious complications. Therefore it requires a set of endoscopic skills. Training requirements and a learning curve for POEM are to be still defined. Increasing experience with POEM leads to an urgent need of defining adequate training program for new trainees to assure the appropiate clinical safety.
AIMS & METHODS: We report results of our training program for experienced endoscopists using a preclinical porcine model. Prospective cohort study from a single center involved 39 patients (24 men, 15 women) undergoing POEM. All procedures were performed by one experienced endoscopist after training on 10 pigs. The first clinical procedure was supervised by an expert in the field. All patients had a diagnosis of esophageal achalasia. We divided patients into 3 consecutive groups (3x n = 13). We set the length of procedure (LOP) divided by length of myotomy (LOM) as an appropriate outcome (LOP/LOM) of skill's progression in time. Analysis of a learning curve was based on LOP/LOM and frequency of complications (e.g. inadvertent mucosotomies).
RESULTS: POEM was successfully completed in all ten pigs. As for complications we reported 5 bleedings, 2 esophageal perforations and 2 inadvertent mucosotomies in animal model. Autopsies revealed safe closures of porcine esophagus (6.1±1.1 clips), LOP/LOM was 5.1±1.8 minutes/cm. All POEM procedures in 39 patients (aged 45.6 ± 13.6 years; BMI 25.2 ± 4.5 kg/m^2) were performed without any serious intraoperative complications. Mean length of hospitalization was 2.5 ±.0.7 days. The mean LOP was 83.6 ± 22.6 minutes and the mean myotomy length was 12.5 ± 2.6 cm. The mean LOP/LOM (7.1 ± 2.7 minutes/cm) decreased with increasing experience (P-value < 0.001): first group (10.1 ± 1.9 minutes/cm); second (5.9 ± 1.5 minutes/cm); and third (5.3 ± 1.6 minutes/cm).
An inadvertent mucosotomy was reported in 3 patients (7.7%), all of them occurred in the first group of patients and were successfully treated endoscopically with clips. The frequency of carbon dioxide extravasation (capnoperitoneum requiring a puncture (41%) and subcutaneous emphysema (23%)) were not influenced by experience (P-value = 1).
Plateau phase of learning curve (based on LOP/LOM) began with the 12th patient and has fully stabilized since the 14th patient (24th procedure including animal training).
CONCLUSION: A significant learning curve of POEM after preclinical animal training was recorded in decreasing LOP, faster myotomy itself and decreasing number of inadvertent mucosotomies. Carbon dioxide extravasation was not influenced by learning. Our results suggest that primary POEM training of experienced endoscopist on at least ten pigs might shorten the achievement of plateau phase to approximately 14 clinical procedures.

P1600 HYDRAULIC DILATION IN IDIOPATHIC ACHALASIA USING THE ESOFLIP DILATION BALLOON: A FEASIBILITY STUDY

W. Kappelle[1,*], A. Bogte[1], P. Siersema[1]
[1]*Gastroenterology and hepatology, UMC Utrecht, Utrecht, Netherlands*
Contact E-mail Address: *w.f.w.kappelle@umcutrecht.nl*

INTRODUCTION: Pneumatic dilation is a commonly used treatment in achalasia. Fluoroscopy enables positioning of the balloon at the oesophagogastric junction (OGJ) but has the disadvantage of radiation exposure. An important element of dilation is oesophageal distensibility, defined as compliance of the wall at a certain point, which can be used to assess the effect of dilation and possibly the risk of perforation. It is currently not possible to measure distensibility during dilation. A new hydraulic dilation balloon, the EsoFLIP, is able to visualise the shape of the balloon in vivo, thereby obviating the need for fluoroscopy, and measures distensibility during dilation.
AIMS & METHODS: The aim of this study was to evaluate technical feasibility and safety of the 30mm EsoFLIP hydraulic dilation balloon in patients with achalasia. Consecutive patients with newly diagnosed achalasia were dilated on two separate days using the EsoFLIP balloon under endoscopic visualisation. Patients were contacted one week, one month and three months after dilation. Technical success (placement at the OGJ and successful dilation while measuring diameter, pressure and distensibility), clinical success and major complications were evaluated.
RESULTS: Ten patients (4 male [40%], median age 50 years, range 27-62) were included between August 2013 and February 2014. Patients were subjectively symptomatic for a median of 9 months (range 3-24) prior to dilation. Technical success was achieved in all cases. Gradual inflation showed that the balloon had a tendency to migrate during inflation but in vivo imaging enabled precise placement at the OGJ. On day one, the median minimal diameter (mm) of the OGJ before and after dilation were 9.5 (range 7.2-12.9) and 16.3 (range 13.4-21.4), respectively. On day two, these diameters were 13.9 (range 8-15.2) and 16.7 (range 14.2-18.6), respectively. Median difference in diameter before the first and after the second dilation was 7.2 (range 3.2-9.2). Median pressures (mmHg) used during the first and second dilation were 551 (range 310-1130) and 603 (range 390-815), respectively. Median oesophageal distensibility (mm^2/mmHg) on the first day before and after dilation were 1.0 (range 0.2-2.2) and 8.2 (range 0.8-20.1), respectively, while on the second day this was 1.7 (range 1-4.3) and 5.9 (range 3.3-29.3). Median difference in distensibility before the first and after the second dilation was 5.7 (range 2.1-28.3). No major complications were seen. Three patients (30%) reported recurrent dysphagia and laparoscopic Heller myotomy was performed in two (66.7%).
CONCLUSION: Dilation with the 30mm EsoFLIP balloon in achalasia is feasible and safe. In vivo imaging of the balloon shape facilitates placement of the balloon while oesophageal distensibility and diameter measurements allow for a patient-specific dilation regimen, which may improve effectiveness and safety of the procedure.

P1601 PATTERNS OF PERISTALSIS RECOVERY AFTER PERORAL ENDOSCOPIC MYOTOMY IN ACHALASIA PATIENTS

Z. Vackova[1,*], J. Krajciova[1], H. Svecova[1], L. Fremundova[2], P. Loudova[3], R. Dolezel[4], J. Spicak[1], J. Martinek[1]

INTRODUCTION: A detailed analysis of whether impaired esophageal peristalsis in achalasia patients can recover after peroral endoscopic myotomy (POEM) has not been performed. We tested the hypothesis that the normalization of esophagogastric junction outflow obstruction after POEM is associated with a partial recovery of esophageal peristalsis.
AIMS & METHODS: We performed an analysis of prospectively collected high resolution manometry (HRM) data of patients undergoing POEM at a single institution (IKEM). 27 patients (8 women, 19 men) underwent HRM before and 3 months after POEM. Twenty-six patients were diagnosed with achalasia (type I- 2 patients, type II- 22 patients, type III-2 patients) and one patient had Jackhammer esophagus. Detailed HRM analysis according to the Chicago classification was performed. The main outcome measurements were: changes in integrated relaxation pressure (IRP) and changes in esophageal peristalsis pattern related to the symptomatic response after POEM.
RESULTS: Before POEM, peristaltic fragments were present in 3 patients only (2 with type III achalasia and 1 with Jackhammer esophagus). After POEM, 15 patients (55%) were classified according to the Chicago classification as either frequent failed peristalsis (n = 6) or weak peristalsis with large breaks (n = 9). Nine patients (33%) persisted in having absent peristalsis and three patients (11%) were still meeting the criteria of achalasia (type II). In 17 patients out of 22 with type II achalasia (77%), the panesophageal pressurization completely disappeared or has been reduced to compartmentalized pressurization after POEM. The mean IRP decreased from 24.7 (± 11) mmHg before to 12.0 (±5) mmHg after POEM. All patients with IRP normalization (IRP < 15 mmHg) had an excellent symptomatic response. Among 4 patients with post-POEM IRP > 15

mmHg, three had only partial symptomatic improvement (Eckhard score 2, 3 and 5), which corresponded with persistence of panesophageal pressurization.
CONCLUSION: More than half of achalasia patients with IRP normalization after POEM have signs of partial recovery of esophageal peristalsis. Successful POEM is associated with a disappearance of panesophageal pressurization in type II achalasia. Patients with abnormal IRP after POEM have partial symptomatic improvement without signs of peristaltic recovery.
Supported by a grant form IGA NT-13634-4.

INTRODUCTION: The positive correlation between GERD symptoms and weight gain is well defined. However, we previously demonstrated that severe upper-GI symptoms may negatively affect body weight by limiting food intake. The aim of our study is to evaluate the correlation between BMI and GERD features and symptoms severity in a large cohort of GERD patients.
AIMS & METHODS: 201 (119 F, mean age: 46.2±15.6 ys, BMI: 25.9±6) outpatients referring for GERD symptoms (heartburn, regurgitation, chest pain, epigastric pain, dysphagia, odynophagia, respiratory symptoms) were enrolled. All patients underwent careful history taking, physical examination and upper-GI endoscopy. Upper-GI symptoms were scored according to standardized questionnaire, assessing the type and the severity of symptoms and their impact on quality of life (PAGY-SYM/QoL). A pH-impedance monitoring was performed in 198 patients, with 89 and 109 of them being off and on-therapy (68 F, mean age: 45.2±13.7 ys; BMI 25.3±5.3 and 67 F, mean age 47.4±14.7 ys; BMI 26.2±5.9, respectively). BMI was recorded and patients were divided, according to internationally accepted criteria, in normal- and overweight. Patients with history of diabetes mellitus were excluded.
RESULTS: Among all the investigated parameters, acid exposition and number of proximal refluxes were significantly higher in over- than in normal-weight patients (3±4.4 vs 1.8±2.6 %pH < 4 and 40.6±22.5 vs 31.9±22.2; all $p < 0.05$). This finding was confirmed in both off- and on-therapy patients' subgroups (4.5±5.5 vs 2.3±1.9 and 1.8±2.9 vs 0.6±0.9 %pH < 4, all $p < 0.05$); while the number of proximal refluxes resulted significantly higher only in off-therapy subgroup (39.7±20 vs 28.6±16.7; $p < 0.05$). The analysis of symptoms' severity yields no significant differences in terms of cumulative symptoms score between over- and normal-weight patients (12.7±9.9 vs 13.9±10). However, a significant correlation between GERD-symptoms score and BMI values was overall observed ($r^2 = 0.03$, CI:-0.3 to -0; $p < 0.01$), with a significant correlation being present in the subgroup of off-therapy ($r^2 = 0.01$, CI:-0.4 to 0; $p < 0.05$), but not in those on therapy ($r^2 = 0.01$, CI: -0.3 to 0.1; p = n.s.). The reduced symptoms' severity in overweight patients did not reflect a significantly different quality of life.
CONCLUSION: In this study we observed that despite a higher esophageal acid exposition and increased number of proximal refluxes, overweight GERD-patients had less severe symptoms and this did not significantly affect their quality of life. Although the underlying mechanisms are unknown, if confirmed by mechanistic studies, our results suggest that the reduced sensitivity in overweight GERD, by limiting patients complaining, may explain the increased risk of GERD-complications frequently observed in this subset of patients.

P1603 SYNDROMIC ACHALASIA IN ALGERIA: ABOUT A NOVEL SERIES

A. tebaibia[1,*], M.A. Boudjella [1], M. Lahcene[1], F. Benmediouni[1], N. Oumnia[1]
[1]*Internal medicine department, Kouba Hospital, Algiers, Algeria*
Contact E-mail Address: *tebaibia@hotmail.com*

INTRODUCTION: non-syndromic or isolated achalasia represents the most commonly found form in adults. It is most often observed in sporadic cases. In rare cases, achalasia can occur in genetic syndromes or be associated with isolated abnormalities.
AIMS & METHODS: To identify the conditions associated with achalasia and study the clinical profile in these syndromes.
This is a prospective study of 86 consecutive patients (M: 41, F: 45, mean age 18.23 + / - 10.4 (3 months - 42 years) enrolled over a period of 21 years (Jan1992 - Oct 2013). There were 52 children (60%) and 34 adults (40%). All patients underwent a standardized symptoms questionnaire, a complete clinical check up, an ophthalmologic check up with a Schirmer test, an adrenal hormone balance, an esophageal barium swallow, upper endoscopy and an esophageal manometry.
RESULTS: Down syndrome (mental retardation, particular facies.) was observed in 6 isolated cases from 6 families. Allgrove syndrome was noticed in 80 cases. It was familial (siblings) in 35 cases (16 families). Consanguineous parents were found in 71% of cases. All patients had alacrima at birth, they all developed achalasia later (100%). Whereas, adrenal insufficiency was found in 43 cases (54%) and autonomic dysautonomia/ neurological abnormalities (thenar and hypothenar muscle atrophy, reduced force of abduction and adduction of fingers, mental retardation, optic atrophy, ataxia, ...) in 19 cases (24%). It was a 3A syndrome (achalasia, alacrima, Addison) in 46 cases and a 4A syndrome in eight cases. The syndrome was incomplete or called syndrome 2A (alacrima, achalasia) in the other cases. In familial 3A (08 families), 17 cases of probable Allgrove syndrome who had at least alacrima were identified, they died probably after an acute adrenal insufficiency.
CONCLUSION: Allgrove and Down syndrome are the two most common conditions associated with achalasia. They are more frequent in children than in adults. Every achalasia or alacrima of children should lead to look for the others components of the syndrome.

INTRODUCTION: Gastric motor physiology can be assessed by gastric emptying scintigraphy (GES), ^{13}C breath testing (GEBT) and real time gastric ultrasound (GUS). The aim of this study was to evaluate how commonly these tests are abnormal in patients with functional dyspepsia (FD).
AIMS & METHODS: Twenty-seven patients fulfilling the Rome III criteria for FD were enrolled in the study. All patients had a normal upper GI endoscopy and underwent standard GES using ^{131}I-technetium labeled mashed potato. On a separate day, these patients underwent a combined liquid GEBT (four hour breath test protocol using 170ml chocolate Ensure liquid substrate + 50mg ^{13}C-acetate) and GUS (calculating antral area at the time of ingestion and 15 minutes after ingestion of the GEBT liquid test meal).
RESULTS: Eight of the 27 patients had one abnormal test, six had two and in five, all three tests were abnormal. In fifteen of the 27 patients with a normal GES (56%), eight had normal GEBT and GUS studies. Of the remaining seven patients, four had a normal GEBT and an abnormal GUS, two had normal GUS with an abnormal GEBT, and in one, both the GEBT and GUS were abnormal. GES was delayed in ten of the 27 patients (37%). In four of these, both GEBT and GUS were abnormal, three had delayed gastric emptying on GEBT with a normal GUS, two had delayed gastric emptying on GUS with normal GEBT, and in one patient, both GUS and GEBT were normal. GES was abnormally rapid in two patients (7%). In one patient, both GEBT and GUS indicated rapid gastric emptying and in the other, GUS revealed rapid gastric emptying with a normal GEBT. Assuming GES as the gold standard for diagnosing abnormal gastric emptying, GUS has a sensitivity and specificity for detecting a motor disorder of 66% and GEBT has a sensitivity of 66% and a specificity of 80%.
CONCLUSION: In this group of FD patients, 70% had at least one abnormal test of gastric motor function. Whilst GES is regarded as the gold standard test, in seven patients with normal GES, the GEBT, GUS, or both, were abnormal. This discrepancy might reflect the day-to-day variability of gastric motor function testing or that each investigation measures a different component of gastric motor physiology. We conclude that in FD, adding GEBT and GUS to GES substantially increases the positive diagnostic yield and the heterogeneous patterns might indicate a variety of FD subtypes.

P1605 SCREENING OF GASTRITIS IN A POPULATION OF DYSPEPTIC PATIENTS: ROLE OF STOMACH SPECIFIC PLASMA BIOMARKERS

A. Antico[1], M.P. Panozzo[1], M. Franceschi[2], F. Tomba[2], A. Ferronato[2], S. Bencivenni[2], D. Sella[2], E. Vanzetto[3], F. Di Mario[4], **G. Baldassarre**[2,*]
[1]*Laboratory Service,* [2]*Endoscopic Unit - Department of surgery,* [3]*Health Service, ULSS4 - Alto Vicentino, Santorso (VI),* [4]*Department of Clinical and Experimental Medicine, University of Parma, Parma, Italy*

INTRODUCTION: A no invasive screening procedure able to identify subjects at high or low risk for gastritis should allow to limit unnecessary endoscopy and histology. The role of specific stomach plasma biomarkers in diagnosis and screening for chronic atrophic gastritis (CAG) is emerging as useful tool in provide informations about gastric mucosa function.
AIMS & METHODS: To evaluate the utility of a serological stomach panel as screening method for identifying patients with high or low risk for gastritis with respect to those with normal gastric function or gastro esophageal reflux disease. 652 dyspeptic patients (M = 223, F = 429, mean age = 42.4±15.3 years, range = 18-87 years) without any alarm symptom (dysphagia, anemia, weight loss and vomiting) were selected from General Practitioners for fasting blood collection and stomach markers assays (Biohit Plc, Finland).
For each of them a standard questionnaire was requested including upper gastrointestinal symptoms, thyroiditis history and PPI therapy. For the study 429 patients were examinated; 223 patients were excluded because of PPI therapy.
Patients affected by CAG were submitted to EGDS and histology and to parietal cell antibodies (PCA) assay (IFA method).
RESULTS: The table reports four groups of patients subdivided according to the stomach marker results.

	Normal (N)	Gastroesophageal reflux Disease (GERD)	*H. pylori* Gastritis (HPG)	CA Gastritis (CAG)
Patients (n°)	132	163	114	20
Age (years)	40.8±22.2	39.6±11.1	42.4±12.4	58.0±15.8
Thyroiditis (%)	6.1	11.7	12.3	50
PG1 (ug/L)	79.4±26.8	84.8±37.7	130.4±11.7	15.2±11.5
PG2 (ug/L)	5.8±2.4	6.2±2.9	14.1±8.2	7.3±3.6
PG1/PG2	14.5±4.3	14.5±4.6	10.0±3.9	2.5±2.5
G17 (pmol/L)	5.4±13.2	0.6±0.3	12.6±15.2	47.4±42.9
Hp Abs (EIU)	5.8±5.9	4.9±5.1	83.9±31.8	29.8±32.8

GERD patients showed significantly lower G17 values with respect to the other groups ($p<0.0001$). HPG subjects had higher Hp Abs and PG2 values ($p<0.0001$). 3.3% were identified as CAG and presented significant lower PG1 and PG1/PG2 values and higher G17 levels ($p<0.0001$). CAG subjects were older than the other patients. 65% of CAG patients showed PCA positivity.
CONCLUSION: A no invasive serological stomach panel allows to distinguish Normal and GERD from HPG and CAG groups in a general population of dyspeptic patients; particularly, patients showing CAG serological findings are also characterized by histological alterations and PCA positivity. Considering these findings, it is necessary to identify as early as possible patients at risk of developing precancerous gastric lesions.

INTRODUCTION: Psychological factors play a role in the development of functional gastrointestinal disorders (FGIDs). The work of firefighters is characterized by its danger, urgency, unique work environment, and by its considerable high level of job stress.
AIMS & METHODS: The purpose of this study was to determine the effect of job stress and other psychosocial factors on FGIDs in this high risk population. Within a cross-sectional survey, 1140 firefighters completed validated questionnaires regarding FGIDs including gastroesophageal reflux disease (GERD), functional dyspepsia (FD), irritable bowel syndrome (IBS) and functional constipation (FC) by at least once a week of typical reflux symptoms and Rome III criteria. Self-reported questionnaires for perceived job stress (KOSS-26), anxiety (GAD-7), depression (PHQ-9), coping styles (WCC), social support and quality of life (WHOQOL-BREF) was also completed. Odds ratio with 95% confidence intervals were estimated using unconditional logistic regression in adjusted models.
RESULTS: A total of 425 (37.3%) subjects reported to be bothered by at least one FGIDs and the proportions of GERD, FD, IBS, FC was 362 (31.8%), 132 (11.6%), 101 (8.9%) and 124 (10.8%), respectively. Perceived job stress significantly associated with GERD (OR = 6.4, 95% CI: 2.2-18.3, $p<.001$) and FD (OR = 8.2, 95% CI: 1.1-38.0, $p=.007$), modestly associated with IBS (OR = 4.2, 95% CI: 0.8-20.8, $p=.070$), but not in FC (OR = 1.2, 95% CI: 0.4-4.1, $p=.697$). Subjects reporting anxiety had a 4.1, 3.7, 3.1-fold (95% CI: 2.7-3.8, 2.5-5.4, 2.0-4.8) increased risk of GERD, FD and IBS, respectively ($p<.001$), and with depression had a 5.4, 4.3, 4.3-fold (95% CI: 4.1-7.1, 2.8-6.5, 2.7-6.9) increased risk compared to subjects without depression ($p<.001$). We observed a weak inverse association between measures of emotional support and GERD (OR = 0.3, 95% CI: 0.1-0.8, $p=.020$); esteem, informative support and FD (OR = 0.2, 0.2; 95% CI: 0.4-1.0, 0.0-0.8; $p=.032$, .024). Among the subdomain of job stress, physical environment, job demand and lack of reward were related to the occurrence of FGIDs. Impaired quality of life was found in all FGIDs. The overlap syndrome was observed in 134 (11.8%) and highly associated with perceived job stress (OR = 10.6, 95% CI: 2.3-49.3, $p=.002$) compared to non-overlap FGIDs (OR = 5.3, 95% CI: 1.6-17.3, $p=.005$). We also observed a weak inverse association between informative support and overlap syndrome (OR = 0.1, 95% CI: 0.0-0.9, $p=.043$). Among the subdomain of job stress, all domains were related to the overlap syndrome.
CONCLUSION: Perceived job stress is strongly associated with FGIDs in firefighters. Anxiety and depression was related to FGIDs and weak inverse association between social support while no consistent association regarding coping styles was found. The psychosocial factors such as high level of job stress and lack of social support could affect the development of FGIDs. Recognition and management of these psychosocial factors may aid in the management of FGIDs.

P1607 SAFETY AND EFFICACY OF PNEUMATIC BALLOON DILATION AFTER HELLER'S MYOTOMY

J. Mikaeli[1], M. Amani[1], **N. Fazlollahi**[1,*], R. Sotoudehmanesh[1], M. Khatibian[1], R. Malekzadeh[1]
[1]*Tehran University of Medical Sciences, Iran, Digestive Disease Research Institute, Tehran, Iran, Islamic Republic Of*

INTRODUCTION: Although Heller's myotomy is one of the most effective treatments for achalasia, symptoms of disease relapse after that in some patients.
AIMS & METHODS: Aim: To evaluate the safety and efficacy of pneumatic balloon dilation (PBD) in cases of symptoms relapse after Heller's myotomy (HM).
Method: 36 patients with achalasia in whom symptoms had relapsed after HM referred to our center from 1993 to 2013. Nine patients who had comorbid diseases or epiphrenic diverticula were treated by botulinum toxin injection and excluded from the study. 27 patients were treated with PBD and followed up prospectively. A good initial response was defined as a decrease in symptom score to 4 or less and a reduction greater than 80% from the baseline in the height and volume of barium in timed barium esophagogram at 1.5 months after the first PBD (with 3 cm rigiflex balloon). Achalasia symptom score (ASS) was assessed every six months in all patients and when symptoms relapsed (ASS > 4), PBD was repeated.
RESULTS: The Mean age of the patients was 47.48±13.91 years (range: 21-73). Good initial response was seen in seventeen patients and five others revealed good response after second PBD with 3.5 cm rigiflex balloon. The mean ASS of patients dropped from 6.88 before treatment to 3.18 at the end of the study ($p=0.003$). The mean duration of follow up was 11.81±5.97 years. At the end of the study sustained good response was reported by twenty two patients (81%). No major complications like perforation or gross bleeding were seen after PBD sessions.
CONCLUSION: We conclude that PBD is effective and safe treatment option of achalasia patients in whom symptoms relapse after Heller's myotomy.

INTRODUCTION: Whether there are distinct pathogenesis in subgroups of functional dyspepsia (FD), the postprandial distress syndrome (PDS) and epigastric pain syndrome (EPS), remain controversial.
AIMS & METHODS: Aims: We aimed to identify the risk factors of FD and its subgroups in Chinese.
Methods: Patients with dyspepsia and health subjects who underwent gastric cancer screening were enrolled in this multicenter study from 2010 to 2012. All patients were evaluated by questionnaire, esophagoduodenoscopy, histological examination, and *Helicobacter pylori* tests. Subgroups of FD were classified according to Rome III criteria. Psychiatric stress was assessed by short form Brief Symptom Rating Scale.
RESULTS: Of the 2378 patients with dyspepsia, 818 and 512 fulfilled the diagnostic criteria of uninvestigated dyspepsia and FD, respectively. Of them, 310 (60.6%) and 368 (71.9%) subjects fulfilled the diagnosis of EPS and PDS, respectively, whereas 176 (34.4%) had overlap syndromes. As compared to 1033 healthy controls, we found that PDS and EPS shared some common risk factors, including females (Odd ratio [OR] 1.91, 95% confidence interval [CI] 1.36~2.68), younger age (OR 0.96, 95%CI 0.94~0.97), nonsteroidal anti-inflammatory drugs (OR: 6.70, 95%CI 4.17~10.77), and anxiety (OR 3.30, 95%CI 2.35~4.63). In contrast, *Helicobacter pylori* (OR 1.83, 95%CI 1.21-2.79), unmarried status (OR 4.06, 95%CI 2.45-6.72), sleep disturbance (OR 2.57, 95%CI 1.61-4.1), and depression (OR 2.12, 95%CI 1.22-3.69) were independently associated with PDS, but not with EPS. Betel nut chewing (OR 5.32, 95% CI 1.42-20) and psychological inferiority (OR 0.38, 95% CI 0.19-1.78) were independently associated with EPS, but not with PDS.
CONCLUSION: Different risk factors exist for subgroups of FD based on Rome III criteria, supporting the distinct etiopathogenesis of the subdivisions that might necessitate different therapeutic strategies.

P1609 SUPRAGASTRIC BELCHING: PREVALENCE AND ASSOCIATION WITH GASTRO-OESOPHAGEAL REFLUX DISEASE AND OESOPHAGEAL HYPOMOTILITY

N. Koukias[1,*], J. Jafari[1], E. Yazaki[1], P. Woodland[1], D. Sifrim[1]
[1]*Barts and the London School of Medicine and Dentistry, Queen Mary, University of London, London, United Kingdom*
Contact E-mail Address: *nkoukias@gmail.com*

INTRODUCTION: Supragastring belching (SGB) is a phenomenon during which air is sucked into the oesophagus and then rapidly expelled through the mouth without reaching the stomach. Patients often complain of excessive belching with a severe impact on quality of life. SGB is considered to be a behavioral disorder, and in some cases a response to an unpleasant sensation originating from the oesophagus or the abdomen. Furthermore, SGB has been shown in itself to induce gastro-oesophageal reflux.

AIMS & METHODS: We aimed to investigate the prevalence of pathological SGB and its association with gastro-oesophageal reflux and motility disorders. We established normal values for SGB by analyzing 24h pH-impedance in 20 healthy asymptomatic volunteers. We interrogated the database of the Upper GI Physiology Unit of the Royal London Hospital (total number of patients referred for assessment of GORD, dysphagia, chest pain) between 2010-2013 n = 2950). We identified all patients with diagnosis of SGB in their final report and reviewed predominant symptoms, 24h pH-impedance and high resolution oesophageal manometry (HRM).
RESULTS: Asymptomatic controls had between 0 and 15 SGB episodes per 24h. The 95th percentile was 12 episodes. 100/2950 patients showed excessive SGB (54 females), mean age 48 (range 12 – 84 years). The median number of SGB in this group was 69/24h (range 17-510). The 25th percentile was 37 and the 75th 125 SGB episodes. 15 patients had undergone prior Nissen fundoplication.
86 of the patients complained of excessive belching, with 50 feeling that belching was their predominant symptom. 95 patients complained of typical reflux symptoms (heartburn and/or regurgitation). 65 patients complained of dysphagia, 51 had excessive bloating, 16 chest pain and 15 epigastric pain. On 24h pH-impedance, 41 patients had pathological oesophageal acid exposure. In these patients, 27% of oesophageal acid exposure was due to reflux occurring immediately after a SGB. On HRM, 44/100 patients had oesophageal hypomotility (frequent failed peristalsis and weak peristalsis with defects). 31 of these patients referred dysphagia.
CONCLUSION: Increased SGB was identified in 100/2950 patients investigated at the GI physiology Unit over a 4 years period. Increased belching is rarely a symptom in isolation and almost always coexists with other oesophageal symptoms, most commonly dysphagia (65%) and heartburn/regurgitation (95%). Whether SGB is a disordered response to other oesophageal symptoms or their cause is still unclear. Behavioral therapy and baclofen have shown promising results in patients with predominant belching. The role of SGB reduction in patients with SGB-associated reflux symptoms or dysphagia is under current investigation.

INTRODUCTION: A large, multicenter trial of antidepressants in individuals with functional dyspepsia (FD) was conducted and the primary outcome of adequate relief was presented at DDW 2013. In addition to symptom data, physiologic data was collected including gastric accommodation. The effect of antidepressants on gastric accommodation in FD patients is not known.
AIMS & METHODS: Aims: To determine whether antidepressant use affects gastric accommodation in individuals with FD. **Methods:** This NIH-funded study (DK065713) is a prospective, randomized, double-blind, placebo-controlled 12-week treatment trial conducted at 8 sites in North America that recruited 292 subjects with FD to 3 arms: 50 mg amitriptyline (AMI), 10 mg escitalopram (ESC), placebo (PLA). Gastric accommodation data was collected at baseline in 162 participants at three sites (MCR, MCJ, MCS). Gastric volume was measured using single photon emission computed tomography (SPECT) gastric imaging after administration of intravenous 99 mTc pertechnetate. The ANALYZE^{TM} program was used for volume rendering, three-dimensional reconstruction, and estimation of volumes. The Kruskal-Wallis test was used to assess treatment differences.
RESULTS: Data was analyzed from 59 individuals with post-treatment gastric accommodation data, 46 (78%) female, median age 43 (IQR: 35-52). 46 (78%) were dysmotility-type FD; 13 (22%) were ulcer-like FD. At baseline, 3 (5%) had impaired gastric accommodation, defined by a change in gastric volume $<$428 mls). Post-meal gastric volume changes at baseline were similar among treatment arms (517±23 ml PLA (n = 18), 542±21 ml AMI (n = 21), 591±23 ml ESC (n = 20). At followup after 12 weeks of treatment, no differences in fasting volumes or fed volumes between treatment arms ($p = 0.71$ and $p = 0.09$). Changes in gastric volume from fasting to fed were modestly different between arms (565±22 ml PLA [n = 18], 494±27 ml AMI [n = 21], 508±16ml ESC [n = 20], $p = 0.08$).
CONCLUSION: Data from this small sample suggests that both tricyclic and SSRI antidepressants may decrease gastric accommodation in individuals with FD. Additional studies are warranted to evaluate whether this finding is real and correlates with FD symptoms.

P1611 SYMPTOMS DON'T REFLECT MUCOSAL HEALING IN PATIENT WITH REFLUX ESOPHAGITIS DURING MAINTENANCE THERAPY

A. Nagahara[1,*], D. Asaoka[1], M. Hojo[1], H. Sasaki[1], Y. Shimada[1], H. Ueyama[1], K. Matsumoto[1], S. Watanabe[1]

INTRODUCTION: During the maintenance therapy for reflux esophagitis (RE), patients take PPIs regardless presence of symptoms. Many studies are carried out about endoscopic finding or symptom relief in maintenance therapy, however there has been few studies investigating correlation among endoscopic healing, symptom and dosing schedule.
AIMS & METHODS: The aim of this study is to reveal correlation among endoscopic healing, symptom and dosing schedule during maintenance therapy. Among patients with RE who enrolled randomized prospective study for 24 weeks PPI maintenance therapy (continuous arm (Omeprazole 20mg od) or on-demand arm (Omeprazole 20mg on-demand)), we extracted patients data who undertook EGD at 24 week. Patients were divided to healing group and non-healing group by LA classification at 24week EGD. Symptom relief was defined as percentage of patients who achieved no or minimal symptom at 24week visit by Global Overall Symptom questionnaires. Difference of symptom relief and endoscopic findings was analyzed between continuous group and on-demand group.
RESULTS: Seventy patients (M/F:48/22, mean60.9 (range 29-89)yr) were extracted. Patients with LA classification Grade A:B:C:D were 35:29:5:1 before initial therapy and healing group/ non-healing group were 49/21 (Grade A:14, B:5, C:2, D:0) at 24week, respectively. Regarding patients characteristics between healing and non-healing group, age, gender, BMI, presence of hiatal hernia, drinking and smoking had no significant difference but prevalence of recurrent RE was significantly higher in non-healing group ($p < 0.01$). Although there was no significant difference in symptom relief between healing (70.8%) and non-healing group (80.0%) at 24 week, number of non-healing patient was significantly higher in on-demand group (44.4%) than in continuous group (14.7%) ($p < 0.01$).
CONCLUSION: Symptoms were well controlled regardless endoscopic mucosal healing and on-demand therapy was insufficient to maintain mucosal healing during maintenance therapy. These results suggest that PPI should be taken continuously regardless presence of symptoms in patients with reflux esophagitis to prevent recurrence especially recurrent reflux esophagitis.

INTRODUCTION: Diet is recommended as first-line treatment for gastroesophageal reflux disease (GERD), but its role is debated. Refractory disease is often due to residual reflux and proximal extent of reflux.
AIMS & METHODS: Colonic fermentation may affect gastroesophageal motility in GERD and we therefore aimed to evaluate the effect of a diet with less fermentable carbohydrates, the FODMAP-restricted diet, on gastroesophageal reflux. 12 patients with symptoms of GERD and/or reflux esophagitis (6M/6F, age 36.8±12.3y) underwent 24h multichannel intraluminal impedance and pH (MII-pH) before and after diet intervention lasting 7.3±2.2 weeks. 8 patients were on stable medication with a proton pump inhibitor (PPI) during the intervention. The patients were instructed in the diet and followed by a dietitian. Symptoms (GerdQ and ReQuest) and health related quality of life (SF36) were recorded before and after the diet intervention. Results (median [IQR] or mean±SD) were compared with Wilcoxon signed rank test or paired t-test ($p < 0.05$).
RESULTS: Intake of FODMAPs was significantly reduced from 19±7 to 2±2 g/day ($p < 0.0001$). The total number of reflux episodes decreased on FODMAP-restricted diet compared to a normal diet (115±135 vs. 152±164, $p = 0.0305$), and particularly the number of proximal refluxes (22±24 vs. 42±37, $p = 0.0076$). Fewer symptom episodes were recorded during the MII-pH on FODMAP-restricted diet compared to a normal diet (12 [16] vs. 24 [46], $p = 0.0278$). For GerdQ there was a decrease in total score on FODMAP-restricted diet compared to a normal diet (8±3 vs. 9±2, $p = 0.0679$). Less frequent heartburn and regurgitation (3±2 vs. 5±1, $p = 0.0028$), less impact of GERD (1±2 vs. 2±2, $p = 0.0311$) and more nausea and epigastric pain (5±1 vs. 3±2, $p = 0.0039$) was reported. However the patients did not experience any differences by nausea (from 0.0 [2.1] to 0.0 [0.0], $p = 0.3125$) and epigastric pain (from 1.8 [4.6] to 0.4 [4.1], $p = 0.5703$) while engaged in daily life activities as recorded on ReQuest.
CONCLUSION: FODMAP-restricted diet improved symptoms of GERD and reduced total and proximal gastroesophageal reflux. This may be effective both as a first-line treatment and in patients refractory to PPI treatment.

P1613 DURABILITY OF EFFECT AND LACK OF REBOUND SYMPTOMS FOLLOWING A 14-DAY REGIMEN OF ESOMEPRAZOLE 20 MG TREATMENT IN SUBJECTS WITH FREQUENT HEARTBURN

D.A. Peura[1], A.L. Moigne[2], **C. Pollack**[2,*], P. Nagy[2,3]
[1]*University of Virginia, School of Medicine, Charlottesville,* [2]*Pfizer Consumer Healthcare, Madison, United States,* [3]*Astra Zeneca, Mölndal, Sweden*

INTRODUCTION: Durability of effect and lack of rebound symptoms following a 14-day regimen of esomeprazole 20 mg were evaluated in 2 identical randomized, double-blind, placebo-controlled studies (study one: NCT01370525; study two: NCT01370538) in subjects with frequent heartburn (HB) who are likely to self-treat with over-the-counter (OTC) medications.
AIMS & METHODS: Adults without a confirmed diagnosis of gastro-oesophageal reflux disease who were experiencing HB ≥2 days per week in the past 4 weeks were eligible for study inclusion. Following HB medication washout and a 7-day placebo run-in period, subjects continuing to meet inclusion criteria were randomly assigned to double-blind treatment with esomeprazole 20 mg (administered as esomeprazole magnesium trihydrate 22.3 mg) once daily or placebo for 14 days. All subjects entered a 1-week single-blind placebo follow-up period after the 14-day treatment period. Episodes of HB were documented by daily patient diary via interactive voice response system during the placebo run-in period, treatment period, and placebo follow-up. The primary efficacy outcome was the percentage of HB-free 24-hour days (defined as days when the subject had no HB episodes) during 14 days of treatment. Primary and secondary outcomes from the treatment period have been reported separately elsewhere. The current report presents data collected during the placebo follow-up period.
RESULTS: In study one, 331 subjects were treated in the double-blind treatment phase and 321 entered the placebo follow-up period; study two included 326 and 303 subjects, respectively. The percentage of HB-free 24-hour days achieved during the treatment period for esomeprazole 20 mg was greater than with placebo and remained consistent in the placebo follow-up period (**Table**). The percentage of HB-free 24-hour days in the placebo follow-up for study one was 43% for those who had been treated with esomeprazole 20 mg compared to 35% for placebo. Similarly, in study two, the percentages of HB-free 24-hour days were 43% and 39% in the esomeprazole 20 mg and placebo groups, respectively.
Table: Percentage of 24-Hour Heartburn-Free Days During the 3 Study Phases.

	Study One		Study Two	
	ESO-20mg	Placebo	ESO-20mg	Placebo
7-day single-blind placebo run-in period, mean (%)	18	19	22	21
14-day double-blind treatment period, mean (%)	43	29	47	31
7-day single-blind placebo follow-up period, mean (%)	43	35	43	39

CONCLUSION: In frequent HB sufferers who are likely to self-treat with OTC medications, the rate of HB control during the 14-day double-blind treatment period with esomeprazole 20 mg was maintained for the 7-day placebo follow-up after cessation of study medication. No evidence of rebound symptoms was observed following 14-day treatment with esomeprazole 20 mg.

P1614 IMPACT OF SHORT-TERM ESOMEPRAZOLE TREATMENT ON PERFORMANCE OF DAILY ACTIVITIES AND ANTACID USE IN SUBJECTS WITH NONEROSIVE SYMPTOMATIC GASTRO-OESOPHAGEAL REFLUX DISEASE AND FREQUENT HEARTBURN

P. Katz[1], A. LeMoigne[2], K. Park[2], **C. Pollack**[2,*]
[1]*Einstein Medical Center, Philadelphia, Philadelphia,* [2]*Pfizer Consumer Healthcare, Madison, United States*

INTRODUCTION: Symptomatic gastro-eosophageal reflux disease (GORD) can impair performance of daily activities, and self-treatment of reflux symptoms (e.g., heartburn [HB] and acid regurgitation) with antacids is common. We evaluated subject-reported outcomes and antacid use in 2 studies of short-term esomeprazole (ESO) in a population likely to seek self-treatment in an over-the-counter setting.
AIMS & METHODS: Study 1 (N = 368) and study 2 (N = 349) were similarly designed randomized, double-blind, placebo-controlled trials conducted at 26 and 27 gastroenterology centres, respectively, in the US. Subjects with frequent HB for ≥6 months without endoscopic erosive oesophagitis were randomized to ESO 20 mg, ESO 40 mg, or placebo once daily. Antacid tablets (≤6/day) were permitted as rescue for breakthrough symptoms. Week 4 data were previously published (Katz et al. *Aliment Pharmacol Ther*. 2003;18[9]:875-82). The current report includes data from a subject-reported overall treatment evaluation questionnaire and use of rescue medication in the first 2 weeks.
RESULTS: At end of week 2, significantly more subjects (all $P \leq .001$) taking ESO 20 mg and 40 mg vs placebo had relief of HB (≤1 mild HB episode for 7 consecutive days) and rated themselves as "better" than baseline. The majority of those who improved rated it as at least "important" in performing daily activities (ESO 20 mg, 79%–86%; ESO 40 mg, 78%–82%; placebo, 65% > 79%). Mean antacid use in weeks 1 and 2 was lower with ESO (0.9-1.0 tablets/day) vs placebo (1.7 tablets/day).
CONCLUSION: ESO 20 mg for 2 weeks (typical over-the-counter dose/duration) was associated with improvement deemed by subjects as important for daily functioning and lower rates of rescue antacid use.

P1615 CLINICAL AND IMPEDANCE-PH FEATURES PREDICT RESPONSE TO PROTON PUMP INHIBITORS IN PATIENTS WITH NON-CARDIAC CHEST PAIN

C. De Cassan[1,*], V. Savarino[2], E. Marabotto[2], M. Furnari[2], P. Zentilin[2], N.de Bortoli[3], S. Marchi[3], M. Frazzoni[4], E. Savarino[5]

INTRODUCTION: Non cardiac chest-pain (NCCP) is defined as recurrent angina-like retrosternal chest-pain diagnosed after a negative cardiac workup. Gastroesophageal reflux disease (GERD) is by far the most common cause of NCCP. Previous studies showed that proton pump inhibitors (PPIs) are less effective in relieving NCCP than heartburn, but predictors of PPI response in NCCP patients have not been yet investigated.
AIMS & METHODS: We aimed to determine whether any symptom profile or reflux pattern at impedance-pH monitoring was associated with refractoriness to PPI therapy. Consecutive patients with NCCP lasting more than 6 months and with at least three episodes per week, were prospectively enrolled. Demographics, clinical data and symptoms of functional diseases (i.e. functional dyspepsia and irritable bowel syndrome) were collected by means of previously validated questionnaires based on Rome III criteria for functional gastrointestinal disorders. All patients underwent upper endoscopy and, within 3 days, conventional manometry and 24-hour impedance-pH testing while off-PPI therapy. During impedance-pH tracings analysis we measured distal esophageal acid exposure time (AET), characteristics of reflux episodes (acid/weakly acidic) and symptom-reflux association using both symptom association probability (SAP+ if ≥95%) and symptom index (SI+ if ≥50%). Patients were classified as PPI-non responders (PPI-NR), if they had a symptom relief > 50% from baseline or if they had fewer than 1 day of mild NCCP per week while receiving a double dose of PPI treatment for at least 8 weeks.
RESULTS: One-hundred and twenty-two NCCP patients (56F/66M; mean age 47; 4% erosive esophagitis/ 96% endoscopy negative; 100 PPI-NR/22 PPI-Responders) reporting NCCP during the impedance-pH monitoring were included. At univariate analysis, PPI-R presented more frequently erosive esophagitis and hiatal hernia ($p = 0.057$ and $p = 0.03$, respectively). Moreover, PPI-R complained of NCCP more frequently in association with either typical (heartburn and/or regurgitation) or atypical (cough and/or asthma) reflux symptoms compared to PPI-NR ($p = 0.003$) and reported less often symptoms of dyspepsia ($p = 0.02$). Finally, PPI-R had more frequently an abnormal AET (45% vs. 21%, $p = 0.02$), a greater mean AET (9.9 [2.9-48] vs. 1.15 [0.6-15], $p < 0.01$), an higher mean number of total (80 [16-177] vs. 47 [10-228], $p = 0.0037$), weakly-acidic (34.5 [7-101] vs. 24 [2-145], $p = 0.031$) and acidic (44 [6-91] vs. 24 [8-98], $p = 0.011$) reflux episodes compared to PPI-NR. No differences were found between PPI-r and PPI-NR in terms of SI and SAP positivity for acid, weakly acid or both kind of reflux (data not shown). At multivariate analysis, the factors associated with the absence of response were the lack of concomitant reflux symptoms, functional dyspepsia, normal AET and reduced number of reflux episodes ($p < 0.01$).
CONCLUSION: Our data show that symptom profile (concomitant reflux symptoms and functional dyspepsia) and reflux features detected at impedance-pH (AET and number of reflux episodes) are associated with response to PPI therapy in patients with NCCP. On the other hand, reflux symptom association analysis does not seem useful to predict PPI response.

Contact E-mail Address: *teofillina84@yahoo.it*

INTRODUCTION: Bariatric surgery is the gold-standard treatment for morbid obesity because it has low morbidity rates and generates long term sustaned weight loss.
AIMS & METHODS: The aim of this study was to compare short and midterm results between LSG and BGAL. Weight loss, comorbidity improvement or resolution, effect on reflux disease and post-operative complications were evaluated. An observational retrospective study from a database of patients undergoing LSG and BGAL between 2011 and 2012. Patients were followed at 3, 6 and 12 months.
RESULTS: A total of 52 obese patients who underwent sleeve gastrectomy (26 patients) and gastric banding (26 patients). The first group (LSG) comprised 23 female and 3 males with a median age 44 years and a median preoperative BMI of 45.65 kg/m^2. The second group comprised 24 female and 2 males with a median age 42.8 years and a median preoperative BMI of 43.36 kg/ m^2. In the first group (LSG) the incidence of comorbidity was 42% (incidence of hypertension was 38%, of diabetes 30%); in the second group (BGAL) was 38% (incidence of hypertension was 26%, of diabetes 23%). The incidence of reflux disease was 77% in patients undergoing sleeve gastrectomy and 46% in patients undergoing gastric banding. The excess weight loss at one year was 55% in LSG and 29% in BGAL. The complications rate was 7.6% for LSG (one bleeding treated with conservative therapy and one gastric fistula). Diabetic remission and hypertension at six months and sustained at one year were 100% in the first group and 50% and 80% in the second group. The reflux disease improved in 30% of patients (suspension or reduction of therapy).
CONCLUSION: LSG and BGAL are safe procedures that provide good results in weight loss and resolution of comorbidities at 12 months. Our data confirmed recent studies that LSG may be effective in improving/resolving diabetes in obese patients and confirmed some studies that improved reflux disease.

P1617 WEIGHT LOSS PRODUCES SYMPTOMATIC IMPROVEMENT IN PATIENTS WITH GERD: PROSPECTIVE, CONTROLLED AND RANDOMIZED

D. Fernandes[1,*], R. Gurski [1]
[1]*Gastroenterology, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil*
Contact E-mail Address: *daienifernandes@ig.com.br*

INTRODUCTION: Objective: Assess the dietary intervention effect for weight loss, in the improvement of symptoms of gastroesophageal reflux disease in patients with over weight and obesity. The secondary objective was to assess the quality of life through the domain general health (SF-36).
AIMS & METHODS: Prospective, controlled and randomized with individuals in out patient follow-up and who fulfilled the criteria of inclusion (age $\geq$ 18 years, BMI $\geq$ 25 m^2/kg, present typical symptoms: heartburn or regurgitation 1 x per week or more, the presence of confirmed diagnosis through digestive endoscopy and GERD treatment with Omeprazole 20 mg, voluntary acceptance to participate in the study) and exclusion (hospitalized patients, pregnant or lactating women, subjected to surgery of the esophagus and/or stomach, inability of cognitive understanding of the guidelines, with chronic diseases such as: diabetes mellitus and neoplasms, presence of GERD complicated with grade C or D esophagitis, Barrett's esophagus, desire to opt for surgical treatment). All patients underwent evaluation anthropometric (weight, height, BMI) and randomized to receive guidance from individualized, low-calorie diet with out patient follow-up monthly (n = 31) for six months, or to a control group that received general guidelines for healthy eating, but without action oriented (n = 31). Validated questionnaires were applied: QS-GERD for symptoms of GERD and the generic quality of life questionnaire SF-36, addressing the General State of health in both groups in two moments. The comparison between the groups was performed by Student paired t-test. For confounders factors control ANCOVA and was applied to evaluate the association between weight loss and improvement of symptoms by QS-GERD, the Pearson correlation coefficient. considered statistically significant when p value was < 0.05.
RESULTS: The mean age was 59.1 in intervention group and 59.7 years in the control group. Dietary intervention provided a weight loss average of 4.4 ($\pm$ 5.3, $p < 0.001$) kg, representing 5% of the initial weight, an average reduction of IMC 1.7 ($\pm$ 2.9, $p < 0.023$) kg/m and a decrease in symptoms of GERD 6.8 ($\pm$ 5.5, $p < 0.001$). Individuals in the control group had worsening of their symptoms with increase of 3.3 points ($\pm$ 4, $p < 0.001$) and won on average 2 kg ($\pm$ 4.4 $p < 0.001$). The intervention group showed improvement in the General Health State domain, 56.6 vs 64 ($p < 0.001$).
CONCLUSION: The study showed that weight loss through dietary intervention for 6 months with low-calorie diet individualised led to reduction of GERD-related symptoms, as well as improvement in the quality of life as general health status score.

P1618 EFFECTS OF METOCLOPRAMIDE ON ESOPHAGEAL MOTOR ACTIVITY AND ESOPHAGOGASTRIC JUNCTION COMPLIANCE IN HEALTHY VOLUNTEERS

H. Mikami[1,*], N. Ishimura[1], K. Fukazawa[2], M. Aimi[1], G. Uno[1], S. Ishihara[1], Y. Kinoshita[1]
[1]*Second Department of Internal Medicine, Shimane University Faculty of Medicine, Izumo,* [2]*Department of Gastroenterology and Hepatology, Kasai city hospital, Kasai, Japan*

INTRODUCTION: Presently, proton pump inhibitors are used as first-line treatment against gastroesophageal reflux disease (GERD). However, approximately 30% of GERD patients fail to respond. Esophageal motor activities and compliance of the esophagogastric junction (EGJ) are important for prevention of GER[1], thus prokinetic agents, such as mosapride and metoclopramide, are often used as second-line therapy for patients with GERD in clinical settings, though their beneficial effects remain unclear. We previously showed that high-dose mosapride not only augmented peristaltic contractions and mean resting lower esophageal sphincter (LES) pressure, but also significantly reduced EGJ compliance[2]. Although metoclopramide has been reported to increase LES pressure, its effects on EGJ compliance have not been evaluated.
AIMS & METHODS: The aim of this study was to investigate the effects of metoclopramide on esophageal motor activities and EGJ compliance. Nine healthy male volunteers without abdominal symptoms were enrolled. Peristaltic esophageal contractions and LES pressure were measured using high resolution esophageal manometry (ManoScan^{360}; Sierra Scientific Instruments), while EGJ compliance was evaluated with an endoluminal functional lumen-imaging probe (EndoFLIP; Crospon Ltd). After obtaining baseline values for esophageal motor activities and EGJ compliance, metoclopramide (10mg) was intravenously administered, then all measurements were repeated at 15 and 30 minutes after administration in each subject.
RESULTS: We successfully analyzed EndoFLIP data in 8 subjects, with 1 excluded because of mechanical trouble. All subjects subjected to ManoScan^{360}measurements completed the protocol. Consistent with previous reports, mean resting LES pressure was significantly increased after administration of metoclopramide (15minutes,26.7mmHg; 30minutes, 27.6mmHg) as compared with the baseline (13.7mmHg) ($p < 0.05$ for both). In addition, metoclopramide significantly augmented peristaltic contractions, especially in the distal esophageal segment ($p < 0.05$). On the other hand, distensibility index (DI) did not change after administration of metoclopramide (5.2 vs. 5.8mm^2/mmHg), suggesting no significant difference in EGJ compliance caused by its administration.
CONCLUSION: This is the first study to evaluate the effects of metoclopramide on esophageal motor activity and EGJcompliance in healthy volunteers using high resolution esophageal manometry and an EndoFLIP device. Although metoclopramide significantly augmented esophageal motor activities, no significant effect on EGJ compliance was seen in healthy volunteers, unlike mosapride. Our findings indicate that the effect on EGJ compliance differs between these prokinetic agents, despite their similar pharmacological characteristics. This difference may be derived from the mechanism between the dopamine D_2receptor antagonist and serotonin 5-HT_4receptor agonist, and may also explain, at least in part, the different effects of these prokinetic agents on GERD.

P1619 INFLUENCE OF URSODEOXYCHOLIC ACID ON PROGRESS OF ATROPHIC GASTRITIS IN COMBINATION WITH DUODENAL GASTRIC REFLUX

M.Y. Drzak1995[1,*]
[1]*Medicine and Pharmacology, Prydneprovskyy Scientific Center, Dnepropetrovsk, Ukraine*
Contact E-mail Address: *maxzak@ua.fm*

INTRODUCTION: Reflux of biliary acids (BA) in gastric (G) opening favors to epitheliolysis or destruction of protective epithelium and leads to inflaming, atrophic and metaplastic lesions in gastric mucosa (GM). Ursodeoxicholic acid (UDCA) has a binding effect on toxic fractions of GM which gives grounds to apply these for patients with AG in combination with DGR. This give the grounds to make an assumption that application of UDCA will allow neutralizing an aggressive impact of toxic fractions of BA and will promote repair of cell structure of gastric epithelium.
AIMS & METHODS: To determine the influence of UDCA in combination with itoprid on AG progress of DGR patients. Clinical series of 45 Hp – negative patients with AG combined with DGR carried out. Morphological diagnostics of GM lesions have been done based on Sydney – Huston recommendations and OLGA system. Verification of DGR carried out based on endoscopic data, daily intragastric pH-monitoring and biochemical testing of gastric aspirate. All patients were referred to take UDCA with dosage of 10 mg per kg of body weight during 6 months period in combination with standard drug therapy of

pro-kinetic. Assessment of therapy efficiency carried out on the basis of endoscopic, pathogistological examinations data and analysis of proliferation index (IP) (marker Ki 67). Investigation results were processed using analysis of variance.

RESULTS: Dynamics of indicants characterized progress of AG and DGR were assessed at average in 12 months from start of therapy. Disappearance of DGR resulting from therapy referred to daily pH-monitoring recorded for 39 (86.7%) of patients. And reflux load which remained for 6 (13.3%) of patients were minor. Based on endoscopic data minimal symptoms of DGR took place in 8 (18.6%) of 43 cases. Morphological characteristics of inflammation of GM were determined for 41 of patients (17 –II stage, 24 –I stage by criterions of OLGA system). Up to the end of monitoring minimal inflammation remained only for 7 (17.1%) of patients. Regress of MT G atrophy registered for 8 (17.6%), foveolar hyperplasia –20 (55.6%) of 36, full intestinal metaplasia (IM) –10 (40.0 %) of 25, and partial IM – 5 (14.7 %) out of 34 patients. Therapy applied promoted decrease of IP: from 87.34±5.54 points to 51.23±3.22 points ($p<0.01$) in hotbeds of partial IM and from 56.32±4.11 points to 49.41±3.96 points ($p<0.01$) at atrophy areas.

CONCLUSION: UDCA therapy associated with DGR leads to disappearance of reflux in 86.7% of cases, jugulation of chronic inflammation, regress of atrophy and metaplasia of gastric epithelium. Ongoing therapy has contributed to the reduction of proliferation index in the centers of full and partial intestinal metaplasia.

P1620 LOWER ESOPHAGEAL SPHINCTER (LES) ELECTRICAL STIMULATION IMPROVES SLEEP QUALITY, WORK PRODUCTIVITY, AND QUALITY OF LIFE IN PATIENTS WITH REFRACTORY GERD

N. Bouvy[1,*], N.F. Rinsma[1], A. Escalona[2], J.P. Ruurda[3], J. Conchillo[1], A. Bredenoord[4], M.van Berge Henegouwen[4], P. Chiu[5], M. Booth[6], A. Hani[7], D. Reddy[8], A. Smout[4], J. Wu[5], P. Siersema[3]

[1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Pontificia Universidad Catolica de Chile, Santiago, Chile, [3]University Medical Center, Utrecht, [4]Academic Medical Center, Amsterdam, Netherlands, [5]Chinese University of Hong Kong, Hong Kong, Hong Kong, [6]Watemata Specialist Centre, Auckland, New Zealand, [7]Pontificia Universidad Javeriana - Hospital San Ignacio, Bogota, Colombia, [8]Asian Institute of Gastroenterology, Hyderabad, India

INTRODUCTION: Sleep-Quality and Work-Productivity are commonly affected in refractory GERD patients which in-turn negatively affects patients' quality of life.

AIMS & METHODS: AIM: Evaluate Sleep-Quality, Work-Productivity and QoL in refractory GORD patients undergoing long-term electrical stimulation therapy (EST) using the LOS Stimulation System (EndoStim BV, the Hague, Netherlands).**METHODS** We evaluated GORD patients ($n=37$) partially responsive to PPI with Off-PPI GERD HRQL$\geq$20 and at least 5 point improvement on PPI, % 24 hour esophageal pH<4 for $\geq$5%, hiatal hernia$\leq$ 3cm and esophagitis$\leq$ LA Grade-C. The LOS stimulation system was implanted laparoscopically and EST was initiated at 20Hz, 220usec, 5 mAmp in 12, 30-min sessions. Patients completed the Pittsburgh Sleep Quality Index (PSQI), Work-Productivity and Activity-Impairment Questionnaire: Specific Health Problem V2.0 (WPAI:SHP) and SF-12 QoL instrument both On-PPI and Off-PPI at baseline, and at 6 and 12-mo on LOS-EST

RESULTS: Sleep scores [median (IQR)] at baseline On-PPI were 6.5 (5.2-9.5) and 8 (6.2-10.5) when Off-PPI. At 6mo, sleep scores significantly improved to 5 (3.2-6; $p=0.02$ vs. On-PPI and $p=0.02$ vs. Off-PPI scores) and was sustained at 12months [5 (3.2-7) $p=0.057$ vs On-PPI, $p=0.075$ vs. Off-PPI) on LOS-EST.

Patients' median %time missed from work due to GORD at baseline was 0 (0-6.9)% On-PPI and 3.8 (0-11.2)% Off-PPI. At 6mo, this improved to 0 (0-0)% ($n=15$; $p=0.04$ vs. off-PPI) and was sustained at 12mo 0 (0-0)% ($n=8$; $p=0.10$ vs. off-PPI). Median percent impairment while working due to GERD at baseline was 15 (0-45)% on-PPI and 60 (30-80)% off-PPI. At 6mo, this improved to 0 (0-10) ($n=16$; $p=0.07$ vs. On-PPI and $p=0.002$ vs. Off-PPI) and was 0 (0-10) at 12mo ($n=9$; $p=0.21$ vs. On-PPI, $p=0.15$ vs. Off-PPI) on LOS-EST. Median % overall impairment due to GERD at baseline was 20 (0-55.5)% On-PPI and 63 (33.3-81.8)% Off-PPI. At 6mo, this improved to 0 (0-10)% ($n=16$; $p=0.05$ vs. baseline On-PPI and $p=0.003$ vs. Off-PPI) and was sustained at 0 (0-2.5)%; $n=8$; $p=0.02$ vs. On-PPI, $p=0.06$ vs. Off-PPI] at 12mo on LOS-EST.

Subjects reported a median % activity impairment due to GERD of 25 (10-50)% On-PPI and 60 (30-80)% Off-PPI at baseline. This improved to 0 (0-20)% at 6mo, ($n=27$; $p=0.04$ vs. On-PPI, $p<0.001$ vs. Off-PPI) and remained improved at 5 (0-30)% at 12mo ($n=18$; $p=0.03$ vs. On-PPI, $p=0.02$ vs. Off-PPI) on LOS-EST.

Median SF-12 physical health score was 44 on-PPI, 37 off-PPI at baseline, 52 at 6mo ($p<0.0001$), and 50.5 at 12mo ($p<0.0001$). Median SF-12 mental health score was 49 on-PPI, 46 off-PPI at baseline, 52 at 6mo, and 55 at 12mo ($p=$NS) on LOS-EST. There was improvement in all other GORD specific outcomes.

CONCLUSION: In refractory GERD patients, LES-EST significantly improves sleep-quality, work-productivity and overall impairment in activity resulting in improvement in patient QoL. These results were significantly better than baseline PPI therapy in many of the parameters evaluated.

P1621 ELECTRICAL STIMULATION THERAPY (EST) OF THE LOWER ESOPHAGEAL SPHINCTER (LES) – AN EFFECTIVE THERAPY FOR REFRACTORY GERD – INTERIM RESULTS OF AN INTERNATIONAL MULTICENTER TRIAL

P.D. Siersema[1,*], A.J. Bredenoord[2], J.M. Conchillo[3], J.P. Ruurda[1], N. Bouvy[3], M. I.van Berge Henegouwen[1], P.W. Chiu[4], M. Booth[5], A.C. Hani[6], D.N. Reddy[7], A.J. Smout[2], J. Wu[4], A. Escalona[8]

[1]University Medical Center, Utrecht, [2]Academic Medical Center, Amsterdam, [3]Maastricht University Medical Center, Maastricht, Netherlands, [4]Chinese University of Hong Kong, Hong Kong, Hong Kong, [5]Waitemata Specialist Centre, Auckland, New Zealand, [6]Pontificia Universidad Javeriana-Hospital San Ignacio, Bogota, Colombia, [7]Asian Institute of Gastroenterology, Hyderabad, India, [8]Pontifica Universidad Catolica de Chile, Santiago, Chile

INTRODUCTION: A long-term single-center trial previously showed that LOS-EST significantly improves esophageal acid exposure and symptoms in GORD patients (Endoscopy 2013; 45:595-604).

AIMS & METHODS: We studied GORD patients partially responsive to proton pump inhibitors (PPI) with off-PPI GORD-HRQL $\geq$20 and $\geq$5 point improvement on-PPI, LOS end-expiratory pressures of >5 mmHg, % 24 hour oesophageal pH$\leq$4 for >5%, hiatal hernia $\leq$3cm and esophagitis $\leq$LA Grade C. Bipolar stitch electrodes and a pulse generator (EndoStim BV, Hague, Netherlands) were implanted laparoscopically. EST was initiated at 20Hz, 220usec, 5mAmp in 12 30-minute sessions post-implant. Patients' GERD-HRQL, daily symptom diaries, SF-12, oesophageal pH, and manometry were evaluated at regular intervals. Stimulation sessions were optimized based on residual symptoms and oesophageal pH.

RESULTS: Thirty-seven patients (50.1yr, men = 19) were implanted with the LOS stimulator. Twenty-nine subjects completed their 6mo, and 19 their 12mo visits. Median (IQR) GORD-HRQL improved from 33 (25-37) off-PPI and 16 (8-22) on-PPI at baseline to 5 (3-9) and 5 (0.2-16.8) at 6mo and 12mo ($p<0.001$), respectively. Median oesophageal acid exposure (pH<4.0) improved from 9.9 (8-12.9)% at baseline to 5.4 (2.8-10)% and 5.2 (1.8-6.1) at 6 mo and 12mo, respectively ($p<0.01$). Seventy-nine% of patients (15/19) at 12mo were completely off PPI; one patient reported intermittent PPI use (<50% days with PPI) and 3 patients reported regular ($\geq$50% days with PPI) use. There were statistically significant improvement in SF-12 physical health scores and trends towards improvement in SF-12 mental health scores on LOS-EST vs. both on and off-PPI baseline SF-12 scores. There was significant improvement in sleep quality as measured by PSQI ($p=0.02$) and work productivity as measured by WPAI ($p=0.003$) in patients treated with LOS-EST. Subgroup analysis revealed numerically better distal esophageal pH response (normalized or >50% improved) in women (75% vs. 57% in men; $p=0.4$) and comparable response in patients with and without hiatal closure performed at the time of implant (60% vs. 69%; $p=0.7$).

One procedure related serious adverse event; trocar perforation of the small bowel during laparoscopy, successfully repaired and device prophylactically explanted; was reported. Thirty-seven non-serious device or procedure-related events were typical of surgical implant procedures, e.g. post-op nausea and pocket pain. Five instances of dysphagia in 4 patients (all in patients with hiatal closure) resolved without intervention.

CONCLUSION: Our interim results show that LOS-EST is safe and effective in treating refractory GORD. LOS-EST results in significant improvement in oesophageal acid exposure, GORD symptoms, and PPI usage, with no device or therapy-related serious events reported. Subgroup analysis revealed comparable results in patient with a significant hiatal defect requiring a hiatal closure to those without a significant hiatal defect.

P1622 LONG-LASTING ESOPHAGEAL MUCOSAL PROTCTION WITH ALGINATES: A POTENTIAL FOR TOPICAL MUCOSAL THERAPY IN GASTROESOPHAGEAL REFLUX

P. Woodland[1,*], C. Lee[1], P. Dettmar[2], D. Sifrim[1]
[1]*Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London,* [2]*Technostics Ltd, Hull, United Kingdom*
Contact E-mail Address: *p.woodland@qmul.ac.uk*

INTRODUCTION: Introduction.
Patients with non-erosive reflux disease (NERD) exhibit impaired esophageal mucosal integrity in the form of dilated intercellular spaces and low transepithelial electrical resistance (TER). Such refluxate-induced changes to the mucosal integrity may underlie increased sensitivity to perception of reflux events, even on PPI, and could potentially be modified by application of topical solutions.
Sodium alginate solutions are used in treatment of GERD, with proposed mechanisms of action including acid buffering, displacement of the gastric acid pocket, and reduction of GER events. We have recently described that in vitro topical application of a sodium alginate solution is able to protect mucosal biopsies against impairment of esophageal mucosal integrity when exposed to acidic solutions shortly after application. The potential durability of this protection is unclear.
We **aimed** to assess the protective effect and physical location of a topically applied sodium alginate solution 1 hour after application.
AIMS & METHODS: Methods.
3 mucosal biopsies were taken from the distal oesophagus (3 cm above the z-line) in 15 patients attending the Royal London Hospital for gastroscopy examination. All biopsies were transferred immediately to Krebs buffer pH 7.4. Biopsies were then each placed in a specially adapted Ussing chamber and bathed in Krebs pH 7.4 (neutral) solution for 20 minutes to equilibrate. The luminal surfaces of 2 biopsies were coated with 200 µl of either a sodium alginate solution (Gaviscon Advance, Reckitt Benckiser, Hull, UK) or a viscous control solution (of same viscosity, but without alginate). The biopsies were mechanically washed with 5 ml Krebs, then returned to the chambers then bathed in neutral solution for a further 1 hour. The luminal aspect of the biopsy was then exposed for 30 min to an acidic solution pH 2 + 1 mg/ml pepsin + 1 mM taurodeoxycholate. Percentage changes in TER from baseline at the end of exposure were recorded. For the 3rd biopsy sodium alginate solution containing fluorescein-labeled alginate was used, and after 1 hour bathing in neutral solution the biopsy was fixed for immunohistological examination of the location of the alginate.
RESULTS: Results.
Our previous experiments have demonstrated that exposure of *unprotected* biopsies to the acidic solution results in a -14.4±2.9% change in TER from baseline. I hour after protection with alginate solution the same exposure caused a -8.3 ± 2.2% change in TER compared to -25.1 ± 4.5% change after protection with the viscous control ($p<0.01$).
Labeled alginate could be seen coating the luminal surface in all cases.
CONCLUSION: Conclusion.
In vitro, alginate solutions can adhere to the esophageal mucosa for up to 1 hour and exert a topical protectant effect against acid, pepsin and bile acids. This suggests that durable topical protectants can be further explored and developed as first-line / add-on therapies for GERD, including refractory disease.

INTRODUCTION: Both SAGES and the American Gastroenteroloists Association (AGA) now recommend laparoscopic myotomy combined with anterior fundoplication for the treatment of achalasia. Peroral endoscopic myotomy (POEM TM) is a novel approach to performing esophageal myotomy through a long submucosal tunnel and rapprents a feasible, safe, and effective treatment for achalasia. Recently, FDA approved a method for transoral stapled anterior funduplicatio (SRSTM). SRS TM Endoscopic Stapling System (Medigus, Tel Aviv, Israel) is an advanced endoscope procedure to create an effective reflux barrier, like a laparoscopic anterior funduplicatio, using two or three quintuplets of standard 4.8mm titanium "B" shaped surgical staples.
AIMS & METHODS: The aim of this study was to test the feasibility of combining the two procedures, thereby achieving a completely transoral myotomy with anterior fundoplication, functinally equivalent to the standard laparoscopic operation for achalasia.
The feasibility experiment was performed on a swine model at a laboratory certified according to the Israeli Animal Welfare Act. After induction of general anesthesia. A standard gastroscope was inserted into the stomach, and an overtube was slided into the mid-esophagus. A submucosal tunnel, starting about 5 cm above the GE junction and extending to 2 cm below it, was created, and the circular layer of esophageal muscle was incised using the POEM electrode. Following the myotomy, the SRS stapler was inserted through the overtube, and the fundus of the stomach was stapled over the myotomy, using three quintuplets of staples, in a semi-circle. At the end of the procedure, the animal was sacrificied, and the stomach with the distal esophagus were dissected out carefully, and examined macroscopically.
RESULTS: Macroscopically, the resulting fundoplication covered the distal half of the myotomized muscle, including the gastric part. No perforation was observed. The macroscopic apearance was similar to that of a standard anterior fundoplicatio.
CONCLUSION: CONCLUSIONS / EXPECTATIONS:
It is feasible to combine the two procedures, at least in the swine model, and add a transoral reflux barrier to the submucosal myotomy. If the aganglionic segment is short (<3cm) it is possible to cover all the myotomized esophagus with the fundus, which may reduce the risk of perforation. It is probably easier to to ensure that the myotomy is on the side of the esophagus covered by the fundic flap perform the stapling first, and start the myotomy between the two topmost quintuplets,. Although further experiments are needed to optimize stapling location vis-a-vis the myotomy site, the combined procedure may enable the operator to achieve a result which is similar to the standard laparoscopic operation for achalasia, without violating the abodominal cavity, and without any incisions.

P1624 IN VITRO MODELLING OF THE POST-PRANDIAL ACID POCKET AND TESTING THE INFLUENCE OF ALGINATE ANTI-REFLUX SUSPENSIONS

J. Fisher[1], **V. Strugala**[1,*], P.W. Dettmar[1]
[1]*technostics Ltd, technostics Ltd, Cottingham, United Kingdom*
Contact E-mail Address: *vicki.strugala@technostics.com*

INTRODUCTION: The region of unbuffered acidity on top of the gastric contents after a meal, known as the 'acid pocket' was initially reported by Fletcher et al [1] and is well established. The acid pocket exists from 15 to 90 minutes after a meal and has a volume of 50-70ml and length of 2cm [2,3]. Post-prandial reflux is linked to this existence of this acid pocket.
Clinical studies utilise complex and invasive techniques including pH pull-through techniques and as a result only a few centres have the skills necessary to carry out such studies. It has been suggested that acidic gastric juice could partition on top of a homogenised fatty meal [1].
AIMS & METHODS: Aim: The aim was to develop a robust and fully validated in vitro model of the post-prandial acid pocket using physiologically relevant conditions stated in the literature. The in vitro model would then be used to investigate the impact of alginate anti-reflux suspensions and antacids on the acid pocket.
Methods: A standard refluxogenic meal (McDonalds double sausage and egg McMuffin + black coffee) was blended with simulated gastric acid and transferred to the model vessel (equilibrated to 37°C). An acid pocket layer was applied to meet the established clinically measured parameters. pH was recorded 2cm into the meal/acid homogenate and within the acid pocket every 5 min. A pull-through pH measurement was performed at 0.5cm intervals 30 minutes after addition of a test product ($n=6$).
RESULTS: The acid pocket had a volume of 70ml and was 2.5cm in depth with a mean pH of 1.08 (SD 0.04) at 1 cm into the acid pocket. On addition of a placebo product to the acid pocket the pH marginally increased to 1.33 (0.16). The addition of Antacid Liquid Supreme increased the acid pocket to 3.99 (1.99). The addition of raft forming alginate – antacid product Gaviscon Double Action (GDA) neutralised the acid pocket to pH 5.89 (0.30).
CONCLUSION: A robust in vitro model of the post-prandial acid pocket has been developed taking into account all relevant clinical literature. The model using a pH pull-though method, allows the evaluation of alginate raft forming products and antacids. Gaviscon Double Action formed an alginate raft which floated on the top of the acid pocket and significantly changed the pH compared to antacid and placebo ($P<0.001$). Whereas the antacid sank below the acid pocket similar to placebo.

INTRODUCTION: Progression of gastric premalignant conditions to cancer might warrant surveillance programmes. Recent guidelines suggested an endoscopic surveillance every 3 years for these patients (1).

AIMS & METHODS: Our aim was to determine the cost-utility of endoscopic surveillance of patients with extensive gastric premalignant conditions such as extensive atrophy or intestinal metaplasia to the corpus. A cost-utility economic analysis for the Portuguese population was performed from a societal perspective using a Markov model to compare two strategies: surveillance versus no surveillance. Clinical data was collected from a systematic review of the literature, costs from published national data and community utilities derived from a population study by the EuroQol questionnaire in terms of Quality Adjusted Life Years (QALY). Population started the model at the age of 50 and for a time horizon of 25 years. The threshold was set at € 36,575, corresponding to the proposed guideline limit of USD 50,000 (2) and an annual discount rate of 3% was used for both cost and effectiveness. The primary outcome was the incremental cost-effectiveness ratio (ICER) of a 3-yearly endoscopic surveillance versus no surveillance for a base case scenario and in deterministic and probabilistic sensitivity analysis. Secondary outcomes were ICER of 5- and 10-yearly endoscopic surveillance versus no surveillance.
RESULTS: Endoscopic surveillance every 3 years provided an ICER of € 18,336, below the adopted threshold and this strategy dominated surveillance every 5 or 10 years. In deterministic analysis, variables that most influenced the ICER were the proportion of males or females affected by the disease (ICER: 17.857-18.841), proportion of patients progressing to dysplasia (13.684-31.887), utilities for endoscopic treatment (12.326-42.875) and the cost of transportation (17,909-20,044), even more relevant than medical costs such as endoscopy (18,117-18,555), anaesthesia (18,223-18,449), surgery (18,302-18,370), chemotherapy (18,330-18,342) and radiotherapy (18,317-18,355). In probabilistic analysis the model remained cost-effective in 78% of simulations.
CONCLUSION: Endoscopic surveillance every 3 years of patients with extensive premalignant conditions is cost-effective for the Portuguese population.

INTRODUCTION: Primary gastrointestinal lymphoma (PGIL) is rare, and few studies have addressed it well, especially in China.
AIMS & METHODS: This study was to investigate its clinicopathological features and prognosis, and also to make comparisons between different locations of PGIL in South China. All patients with PGIL confirmed by histopathology between January 1991 and October 2012 in the First Affiliated Hospital, Sun Yat-sen University were included. Clinicopathological data were collected and prognostic factors influencing survival were analyzed.
RESULTS: The cohort included 160 males and 56 females, accounting for 0.02% of all hospitalized patients and 1.5% of hospitalized patients with GI cancers. Abdominal pain (75.9%) was the most frequent symptom. The percentage of tumor in Stomach group, Intestine group, and GI group was 38.5%, 55.1% and 6.4%, respectively. Patients in Stomach and GI group were older than Intestine group (Mean age: 54 and 53 years *vs*. 43 years, $p<0.001$). Histologically, intermediate-grade lymphoma was the most common (53.7%), but high-grade lymphoma almost occurred in Intestine group (82.5%). Five-year overall survival (OS) and event-free survival (EFS) was 56.4% and 49.3%, respectively. Univariate and multivariate analysis revealed that performance status, LDH level and histological type were independent prognostic factors for OS and EFS. Stomach group had better OS and EFS (72.3% and 48.4%) than Intestine group (43.1% and 23.6%), respectively ($p=0.003$ and $p=0.021$), but it lost the significance in the multivariate analysis.
CONCLUSION: PGIL is uncommon and lacks specific symptom in China. Intermediate-grade lymphoma is the most common histological type, while high-grade lymphoma almost occurred in the intestine. Patients with good performance status, normal LDH and non-high-grade phenotype may have better prognosis.

INTRODUCTION: Usually anatomical location and histological phenotype of gastric cancer (GC) is considered for selection of chemotherapy regime against GC. In other hand, genetic factors is also influence on out-come of GC and treatment. During recent years many researchers concentrate on molecular characteristics of cancer cell and it is believed that some molecular elements could have a prognostic value for therapeutic regimes. HER-2/neu over expression has proved to have predictive value in breast cancer patients, responding to Trastuzumab treatment. Some researchers also indicated the importance of this element in GC.
AIMS & METHODS: We investigated the frequency of HER-2/neu over expression in gastric carcinoma and its correlation with clinicopathologic variables.
101 paraffin embedded tissue blocks from the pathology archives of Firoozgar Hospital with established diagnosis of gastric carcinoma were used for the study of HER-2/neu over expression using immunohistochemistry (IHC) staining and using tissue microarray method (TMA).
RESULTS: Mean age of patients was 60.13 ± 11 (32-82) years. Male to female ratio was 2.4:1. HER2/neu over expression was positive in 13 cases (12.9%). The frequency of HER2/neuoverexpression in tumors ≥5cm was significant. There was no statistically significant correlation between HER2/neu over expression and other pathological features such as grade, stage, lymph node involvement, tumor location, histopathological type, as well as age and sex.
CONCLUSION: In conclusion, in our study the over expression rate of Her2/neu was reach to 13% which is same as other studies. We confirm that TMA could allow to determining the paten of biomarkers of GC and consequently can be used in clinical practices. Also this study can not confirm the association between Her2 and GC

INTRODUCTION: The problem of gastric carcinogenesis is closely connected with the concept of border epithelia. The structure and operation of border epithelia are based on the epithelial-stromal relations. The violations of the epithelial-stromal relations in gastric cancer (GC) are marked both in the intestinal (IGC) and diffuse (DGC) types. It results in the interest in GC with systemic non-differentiated dysplasia of connective tissue (DCT), that initially determines other character of "substrate" for the epithelium, or other epithelial-stromal relationship.
AIMS & METHODS: The aim is to study the peculiarities of GC in patients with systemic non-differentiated DCT. The analysis of the clinical data and morphological study (light microscopy) of surgical specimens were done in 76 patients with GC aged 29-79 years. Among them 41 (54%) patients with visceral signs of DCT amounted group 1; 35 patients without signs of DCT formed group 2. Comparative statistical analysis was performed by χ^2- criterion and Fisher' s exact test at $p<0.05$.
RESULTS: Groups did not differ in structure of histotypes GC: IGC was respectively diagnosed in 51.2 and 45.7% of cases, DGC - in 26.8 and 22.9%, mixed GC - in 22.0 and 31.4% of cases. The stigmatization of the genitourinary system (51.2%) and the gastrointestinal tract (41.5%) prevailed in group 1 among stigma. The nature of stigma was cysts in different organs (68.3%), but mostly in kidneys (41.5%). Peculiarities of GC with DCT were as following: high frequency of gastritic anamnesis (80.5 and 48.6% respectively, $p<0.05$) and chronic ulcers (41.5% and 17.1%, $p<0.05$) which prevailed in group 1 in IGC (52, 4%), but in general – in DGC (42.1%); localization of the tumor in the body of stomach (61.0%, in group 2 – 34.3%, $p<0.05$), in group 2 – in cardia (31.4%, in group 1 – 9.8%, $p<0.05$); greater (in 2.5 times higher than in group 2) proportion of patients aged under 40 years (14.6% in group 1 and 5.7% - in group 2); high frequency of combined lesion of gastric mucosa (GM) and other border epithelium – mucosa of urinary tract in particular (48.8%, in group 2 – 8.6%, $p<0.05$); combined lesion of GM and colonic mucosa (atrophic colitis, adenomatous polyps and in two cases - meta-and synchronous colorectal cancer) – 14.6 and 8.6% of cases in groups respectively (i.e. 1.7 times more frequently in patients of group 1); combined lesion of GM and bronchial mucosa (obstructive bronchitis, bronchial asthma, lung cancer) - by groups of respectively 24.4 and 14.3 % of cases (1.7 times more often in group 1). The features of epithelial «substrate» or system of connective tissue can be one of the basic mechanisms of combined lesions of the mucous membranes of various localizations.
CONCLUSION: The revealed features (stigmatization of gastrointestinal tract and urinary system, in particular cysts in kidneys, gastritic anamnesis, chronic ulcers) can have a marker value in patients with DCT for inclusion in group of risk of developing GC.

P1629 DETECTION RATES OF GASTRIC CANCER AT THE QUEEN ELIZABETH HOSPITAL BIRMINGHAM 2009-2013

N. Sagar[1,*], N. Bhala[1]
[1]*Gastroenterology, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom*
Contact E-mail Address: *dr.nidhisagar@gmail.com*

INTRODUCTION: Despite open-access endoscopy, previous series have suggested that between 8-20% of early gastric cancers (GC) are potentially missed at prior endoscopy1,2. Although upper gastrointestinal alarm symptoms are more frequently associated with malignancy, this may represent advanced cancer with poorer survival rates, as patients with early GCs may be asymptomatic. The false-negative rate for the diagnosis of GC may also be a measure of quality for endoscopy services. This is based on a reported median duration of 37

months between endoscopic diagnosis of early GC and progression to advanced GC2,3, so we assessed all oesophagogastroduodenoscopy (OGD) findings to assess detection of GC in a large tertiary hospital in the West Midlands.
AIMS & METHODS: Patients with histologically confirmed GC were identified from histopathology and endoscopy records. Patients who had undergone at least one OGD before the diagnosis were studied. Detection of GC within 3 years of a negative OGD was interpreted as a false negative.
RESULTS: Between September 2009 and September 2013, 16823 OGDs were performed. GC was diagnosed in 75 (0.45%) patients (male/female ratio 1.78; median age 74; 85% Caucasian). Sixty-seven (89%) of the 75 patients with GC presented with alarm symptoms. 33% (25) were done as inpatients, with 43% (at least 32 of 50 outpatients) being referred as urgent outpatients. Five of the 75 (7%) patients had previous OGDs within three years preceding diagnosis. Only one of these was planned because of a suspicious gastric ulcerative lesion at the same site, with other causes being gastric polyps (2); normal (1) and gastritis (1). There were 53 (71%) deaths in total, 47 (89%) of these patients had alarm symptoms at diagnosis of GC.
CONCLUSION: The absolute rates of GC are low (0.1%/OGD/year) and false-negative rates of 5% (within 3 years) for diagnosis of GC are reassuring with only a minority of preceding OGDs in this series demonstrating suspicious lesions. Whilst GC presents with alarm symptoms in the vast majority, the prognosis remains very poor, so continued quality measures in endoscopy will be required to ensure that early gastric cancers are not missed.

P1630 TRENDS AND RESULTS IN TREATMENT OF GASTRIC CANCER OVER LAST TWO DECADES AT SINGLE EAST EUROPEAN CENTRE

P. Ignatavicius[1,*], A. Mickevicius[1], Z. Dambrauskas[1], R. Markelis[1], A. Parseliunas[1], M. Kiudelis[1], Z. Endzinas[1], A. Maleckas[1]
[1]*Department of Surgery, Lithuanian University of Health Sciences, Kaunas, Lithuania*
Contact E-mail Address: *ignatavicius@gmail.com*

INTRODUCTION: A steady decline in gastric cancer mortality rate over the last few decades is observed in Western Europe. However it is still not clear if this trend applies to Eastern Europe where high incidence rate of gastric cancer is observed.
AIMS & METHODS: This was a retrospective non-randomized, single center, cohort study. During this period 557 consecutive patients diagnosed with gastric cancer in which radical operation was performed and who met the inclusion criteria were included in the study. The study population was divided into two groups according to two equal time periods: 01-01-1994 – 31-12-2000 (Group I – 273 patients) and 01-01-2001 – 31-12-2007 (Group II – 284 patients). Primary (five-year survival rate) and secondary (postoperative complications, 30-day mortality rate and length of hospital stay) endpoints were evaluated and compared.
RESULTS: Rate of postoperative complications was similar between the groups, except Grade III (Clavien-Dindo grading system for the classification of surgical complications) complications, where significantly ($p = 0.02$) less complications were observed in Group II (26 (9.5%) vs. 11 (3.9%)). Length of hospital stay was significantly ($p = 0.001$) shorter (22.6±28.9 vs. 16.2±17.01 days) and 30-day mortality was significantly (0.02) lower (15 (5.5%) vs. 4 (1.4%)) in Group II. In both groups similar number of patients died of cancer (92.3% vs. 90.7%). However survival analysis revealed significantly ($p = 0.02$) better overall 5-year survival rate in Group II (35.6%, 101 of 284) than in Group I (23.4%, 64 of 273). There was no difference in 5-year survival rate when comparing different TNM stages.
CONCLUSION: Despite positive changes in early postoperative mortality rate, hospital stay and overall survival over the time, gastric cancer treatment results in Eastern Europe remain poor. Prognosis of treatment of gastric cancer depends mainly on the stage of the disease. Absence of screening programs and lack of clinical symptoms in early stages of gastric cancer lead to circumstances when most of the patients presenting with advanced stage of the disease can expect a median survival of less than 30 months even after curative intent surgery.

P1631 PALLIATION OF INTRACTABLE VOMITING CAUSED BY INOPERABLE GASTROINTESTINAL MALIGNANCY: EFFICACY OF A VENTING GASTROSTOMY

S. Beg[1,*], R. Nathwani[2], M. Yalchin[2], M. Mensa[1], J. Deacon[2], I. Sargeant[2], D.L. Morris[2], S. Catnach[1], A. Leahy[1] on behalf of Hertfordshire and South Bedfordshire Network Cancer Group

INTRODUCTION: The insertion of percutaneous endoscopic gastrostomy (PEG) tubes for decompression of gastrointestinal obstruction in patients in whom a surgical option is not possible is well established. There is however, very little information on the safety or success of this intervention, which is usually performed in cohort of patients with poor baseline function and prognosis. The aim of this study is to assess the efficacy of a venting gastrostomy to relieve intractable vomiting in a palliative setting.
AIMS & METHODS: We retrospectively analysed our computer based endoscopy databases to identify all venting gastrostomies inserted over a four year period, between January 2010 and January 2014 in three NHS hospital Trusts within a Network Cancer Group (catchment population 1.4 million). Cases were analysed with respects to indication, complications, success at subsequent hospital discharge and survival.
RESULTS: Within a four year period a total of seven venting gastrostomies were inserted. The median age of this cohort was 68 years old (range 61 – 81 years), with a male to female ratio of 5:2. The most common indication for insertion was malignant obstruction (duodenal cancer $n = 2$, metastatic mesothelioma $n = 1$, colorectal adenocarcinoma $n = 2$, pseudomyxoma peritonei $n = 1$). One patient however, did not have evidence of active cancer, with instead multiple foci of fibrotic small bowel strictures secondary to pelvic radiotherapy from a previously treated gynaecological malignancy. Gastrostomy insertion was a palliative measure in five patients, whilst in two patients it was a temporising measure with concomitant total parenteral nutrition (TPN) support, whilst definitive complex surgery at a tertiary referral centre was considered.
The Corflo gastrostomy tube was used in all cases, with PEG size ranging from 16 fr ($n = 3$) to 20 fr ($n = 4$). At the time of insertion 57% had a American Society of Anesthesiology (ASA) score of 3, whilst 43% had an ASA score of 4. Successful placement was achieved in all patients, with no immediate complications. A single patient had several episodes of heamatemesis 22 days post insertion whilst an inpatient, a gastroscopy revealed gastritis only and confirmed normal appearances of the gastrostomy site. The median hospital stay after gastrostomy insertion was 12.4 days (range 1 – 29 days), with the longest continued hospital stay attributable to a patient awaiting transfer to a tertiary centre for home TPN. There were no PEG related readmissions or deaths, and the median survival after gastrostomy insertion was 37 days.
CONCLUSION: This study demonstrates the safety of venting gastrostomy insertion for gastrointestinal obstruction due to a variety of pathologies. Whilst patients undergoing venting gastrostomies may be expected to have a short post procedural survival, our data shows this procedure can lead to a successful palliation and a subsequent successful discharge home in the majority of cases.

P1632 THE ROLE OF RADIOLOGICAL STUDY AND ENDOSCOPIC ULTRASONOGRAPHY FOR PRE-OPERATIVE EVALUATION FOR EARLY GASTRIC CARCINOMA

S. Shimaoka[1,*], A. Matsuda[1], T. Nioh[1], S. Iifuku[1], Y. Baba[1], M. Toyoda[1], K. Iwaki[1], N. Nishimata[1], K. Tsukasa[1], K. Tashiro[1], T. Niihara[1], Y. Nishimata[1], M. Hori[1], H. Nishimata[1], S. Tanaka[2]
[1]*Gastroenterology,* [2]*Diagnostic Pathology, NANPUH HOSPITAL, Kagoshima, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is a developed EMR technique for reliable en bloc resection and is rapidly becoming standard of treatment for early gastric carcinoma.
AIMS & METHODS: The aims of this study is to clarify the role of radiological study and endoscopic ultrasonography for pre-operative evaluation for early gastric carcinoma. We investigated the 287 gastric carcinoma cases that had been treated by ESD or surgery. Endoscopic, Radiological, EUS findings that indicated SM2 carcinoma were set beforehand respectively. The accuracy of the diagnosis and the additional diagnostic value of radiological and EUS diagnosis were investigated.
RESULTS: The accuracy rates of endoscopic diagnosis were high enough to decide the indications of ESD in the lesions 30mm or less in size, differentiated type without Ul. However in the lesions larger than 30mm, differentiated type with Ul, the accuracy rates were lower than the lesions without Ul because of over-diagnosis. Even in such lesions, using radiological diagnosis, the accuracy rates rose enough to decide the indication of ESD. The accuracy rates of endoscopic diagnosis in the lesions larger than 30mm, differentiated type without Ul were lower than the lesions equal or less than 30mm because of under-diagnosis. The accuracy rates rose using radiological diagnosis in such lesions. In the lesions equal or less than 20mm, undifferentiated type without Ul, the accuracy rates of endoscopic diagnosis were high enough to decide the indications of ESD. EUS was useful in the upper gastric lesions that compression methods could not be used in radiological examinations.
CONCLUSION: Radiological examinations were useful in large lesions that were under-diagnosed in endoscopy to avoid unnecessary ESD and the lesions without Ul that were over-diagnosed in endoscopy to avoid unnecessary surgery. Even in ESD age, it is important to use endoscopy, radiological examination, EUS complementarily according to the lesions to get neither too much nor too little information for deciding treatment strategy.

P1633 SERUM C-REACTIVE PROTEIN CAN BE A PREDICTIVE MARKER FOR DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER

S. Yoshii[1,*], S. Yamamoto[2], M. Kato[1], K. Nagai[1], T. Fujinaga[1], Y. Tsujii[1], A. Maekawa[1], M. Hirao[2], T. Inoue[1], Y. Hayashi[1], M. Nishiyama[2], M. Komori[2], T. Nishida[1], H. Iijima[1], M. Tsujii[1], H. Yoshihara[2], T. Takehara[1]
[1]*Department of Gastroenterology and Hepatology, Osaka University Graduate School of Medicine, Suita-shi,* [2]*Department of Gastroenterology, Osaka Rosai Hospital, Sakai-shi, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has become a promising procedure as a therapeutic tool for early gastric cancer (EGC). However, delayed bleeding occasionally occurs and it sometimes leads to severe hemorrhage or shock. There has been no useful indicator to predict the risk of bleeding after ESD for EGC.
AIMS & METHODS: The aim of this study is to clarify the usefulness of the parameters of blood examination in addition to clinico-pathological factors for the prediction of delayed bleeding after ESD for EGC. A total of 548 subjects with EGC who underwent gastric ESD in Osaka University Hospital and Osaka Rosai Hospital between April 2007 and December 2013 were enrolled. Cases having intraoperative perforation (n = 16) or more than two lesions treated on the same day (n = 45) were excluded. Delayed bleeding was defined as bleeding from post-ESD ulcer with hematemesis, melena or massive blood retention in the stomach at an emergent endoscopy or planned follow-up endoscopy. Cases with bleeding before planned blood examination test on a day after ESD were excluded. We analyzed associations between delayed bleeding and the parameter of blood examination including white blood cell count, hemoglobin level, C-reactive protein (CRP) level (mg/dL), and blood urea nitrogen-to-creatinine ratio. In addition, we also analyzed the following clinico-pathological factors; age, sex, gross-morphology, location, size, presence of the ulceration, and the invasion depth of the tumor, procedure time, comorbidity (hypertension, cardiac disorder, liver cirrhosis, diabetes mellitus and dialysis) and the use of anticoagulants and/or antiplatelet drugs.
RESULTS: Of 26 (5.3%) post-ESD bleeding cases, 23 cases fulfilled the criteria of delayed bleeding and were included in the study. Univariate analysis revealed that presence of the ulceration in tumor, upper third location of the stomach, and the elevations of the serum CRP levels on post-ESD 1day (CRP-DAY1), were significantly associated with bleeding (p = 0.009, p = 0.04 and p = 0.007, respectively). Multivariate logistic regression analysis revealed that the presence of ulceration in tumor (OR, 4.1; 95%CI: 1.2-13.0, p = 0.02) and the elevation of the serum CRP-DAY1 (OR, 3.2; 95%CI: 1.1-9.9, p = 0.04) were independent risk factor for delayed bleeding. When classified the patients into 4 subgroups based on CRP-DAY1, the prevalence of the post-ESD bleeding gradually increased as CRP-DAY1 increased (p = 0.03, for trend, **table 1**).

	CRP level (mg/dL)	The rate of post-ESD bleeding
Q1	0.03-0.33	1.7% (2/117)
Q2	0.34-0.74	5.0% (6/121)
Q3	0.75-1.49	4.2% (5/118)
Q4	1.5-10.09	8.3% (10/120)

Table 1
CONCLUSION: A higher level of serum CRP on the next day of gastric ESD may serve as a predictor for delayed bleeding.

P1634 DISCRIMINATION OF EARLY GASTRIC CANCER FROM GASTRIC ADENOMA, BASED ON THE CHARACTERISTICS OF GASTRIC NEOPLASIA

T. Miike[1,*], Y. Miyata[1], S. Yamamoto[1], Y. Noda[1], T. Noda[1], S. Suzuki[1], S. Takeda[1], K. Maemura[1], K. Hashimoto[1], T. Yamaji[1], H. Abe[1], Y. Tahara[1], K. Yorita[2], H. Kataoka[2], K. Shimoda[1]
[1]*Gastroenterology and Hematology,* [2]*Oncopathology and Regenerative Biology, university of miyazaki, 5200 kihara kiyotake, Japan*

INTRODUCTION: Background and Aim: Chronic atrophic gastritis has received increased attention, in Japan, because the observed gastric mucosa characteristics have been reported to be associated with gastric neoplasia. However, chronic atrophic gastritis is caused by a *Helicobacter pylori* infection. In the present study, we aimed to discriminate between early gastric cancer (EGC) and gastric adenoma (GA) by analyzing the characteristics of gastric neoplasia.
AIMS & METHODS: Methods: We retrospectively examined the records of 211 patients who underwent endoscopic submucosal dissection for gastric neoplasia at the Miyazaki University Hospital between October 2009 and March 2014. Of these, 78 patients who had not previously undergone *H. pylori* eradication treatment were evaluated and assessed for the presence of pepsinogen and the degree of gastric atrophy. If the border of the atrophy was on the lesser curvature of the stomach, it was defined as a closed-type (C-type). These were subdivided into C0, Cl, C2, and C3 patterns. If the border was shifted orally and did not exist on the lesser curvature, it was defined as an open-type (0-type), subdivided into 01, 02, O3, and 0p patterns. Therefore, gastric atrophy was graded as C0-l, C2-3, 01-2, and 03-p, based on its severity. Statistical analyses were conducted using a chi-squared test, with $P < 0.05$ indicating statistical significance.
RESULTS: Results: In total, 78 patients had gastric neoplasia; of these, 64 were graded as having the 0-type (82%), and 14 with the C-type. EGC was diagnosed in 57 patients, including 13 patients were graded as C2-3, 37 as 01-2, and 7 as 03-p. Moreover, 21 patients had GA, including 1 graded as C2-3, 11 as 01-2, and 9 as 03-p. The degree of atrophy associated with GA was significantly higher than that associated with EGC ($P < 0.05$).
CONCLUSION: Conclusion: The current findings showed that gastric neoplasia was well correlated with severe atrophic gastritis. Based on the current findings, the degree of atrophy appears to be useful for discriminating between EGC and GA.

P1635 SIGNET RING CELL EXISTENCE CAN BE A NEGATIVE PREDICTOR OF PACLITAXEL CHEMOTHERAPY EFFICACY FOR PATIENTS WITH UNRESECTABLE GASTRIC CANCER

T. Yamada[1,2,*], Y. Saida[1], T. Matsuura[1], S. Onoue[1], K. Sugimoto[2]
[1]*Department of Gastroenterology, Iwata City Hospital, Iwata,* [2]*First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan*

INTRODUCTION: The efficacy of chemotherapy is critical for quality of life (QOL) and prognosis of patients with unresectable gastric cancer. Cisplatin/fluoropyrimidine-based chemotherapy is commonly considered first line chemotherapy for gastric cancer, whereas taxian as well as CPT-11 is accepted for second line chemotherapy. However, clinicopathological parameters or biomarkers to decide second line chemotherapy regimen for gastric cancer remain to be elucidated.
AIMS & METHODS: We evaluated efficacy of weekly paclitaxel systemic chemotherapy (wPTX) for patients with unresectable gastric cancer using progress free survival (PFS) retrospectively. From 2008 to 2013, 32 unresectable gastric cancer patients were treated with wPTX as second line chemotherapy in two hospitals, a university hospital and a general hospital.
RESULTS: The mean PFS of all patients was 21.6 weeks (2 to 108 weeks). Three was no significant differences in sex (male; female, 9 cases; 23 cases), age (mean 69.4 years old, 16 cases are younger than 70, others are 70 or older), location of lesion (Upper 9 cases; Middle 16 cases; Lower 7 cases), peritoneal dissemination (18 cases), and clinical stage (IIIb 1 case, IV 31 cases). Microscopic morphology was classified into 4 groups (tubular 13 cases; poorly differentiated 16 cases; signet ring cell 8 cases; mucinous 2 cases). The cases consist of 2 or more types of cancer cell were counted in all their cell type groups. The mean PFS of tubular, poorly differenciated, signet ring cell (SRC), and mucinous were 28.1, 17.6, 8.5, and 12.0 weeks, respectively. There was signifincant difference of PFS only between SRC positive group (mean PFS 8.5 weeks) and negative (26.0 weeks) group (p = 0.006).
CONCLUSION: These results suggest that SRC existence can be a negative predictor of PTX efficacy for unresectable gastric cancer. Further investigation is needed to reveal the precise mechanism and development effective chemotherapies, including CPT-11, for SRC positive gastric cancer.

INTRODUCTION: Although the majority of gastrointestinal subepithelial tumors (SETs) are benign, some do have a malignant potential. Resection of SETs would aid in establishing the diagnosis and may be curative. So, we aim to present the feasibility and safety of a novel endoscopic submucosal tunnel dissection (ESTD) method for resection of upper gastrointestinal SMTs originating from the muscularis propria (MP).
AIMS & METHODS: In 8 patients who presented with an upper gastrointestinal SMT located in the stomach, we underwent submucosal tunnel endoscopic resection between August 2011 and February 2013. A submucosal tunnel was endoscopically created by starting approximately 4cm distant to the lesion. After careful submucosal dissection of the tumor from the surrounding submucosal tissue and the unaffected MP layer with making the tunnel, the SETs were completely removed by the technique of endoscopic submucosal dissection. Finally, the mucosal entrance of the tunnel was closed using endoclips after the tumor was removed.
RESULTS: SETs had a mean size of 21.5mm (range 17–25mm); 4 were located in the antrum,3 in the body and 1 in the cardia. SET resection was successful in all patients with en bloc resection 88% rate. 6 lesions affected the deep MP, so Full thickness resection including MP layer was performed; except ectopic pancreas partialy resected for the purpose of diagnosis. 2 lesions affected the superficial MP for a partial MP resection. The mean procedure time was 66.1 minutes (range 40–80 minutes). The endoscopic procedure was converted into laparoscopic surgery in three patients. Two patients had lost the full thickness resected samples in the peritoneal space. One patient had sustained abdomen pain and fever after successful procedure. The other five patients had no any complications such as delayed hemorrhage and chronic fistula after then. No residual tumor or tumor recurrence were detected during the follow-up period (mean: 4.5 months, range: 3–9 months). Pathological diagnoses of these tumors were low risk gastrointestinal stromal tumors (6/8), a schwannoma (1/8), and a etopic pancreas (1/8).
CONCLUSION: In this study, endoscopic submucosal tunnel dissection (ESTD) was appeared to be feasible endoscopic procedure to remove tumors originating from the muscularis propria layer in the stomach.

INTRODUCTION: Collagen type XI α1 (COL11A1) which plays important roles in carcinogenesis is increasingly recognized, including ovarian cancer and head and neck squamous cell cancer. However, the relation between COL11A1 and gastric cancer is still unclear.
AIMS & METHODS: The main purpose of this study is to investigate the expression levels and potential roles of COL11A1 in gastric cancer.
We examined the COL11A1 mRNA expression levels in fifty-three gastric cancer lesions and twenty normal gastric mucosa from endoscopy or surgery by qualitative real-time PCR. We also evaluated its expression level in seven gastric cancer cell lines by qualitative real-time PCR and western blotting. Furthermore, we established a stable cell line HGC-27 with COL11A1 gene knock-down to study its functional role in regulating cell proliferation, migration and invasion. To identify target candidates of COL11A1, we performed cDNA microarray.
RESULTS: Our qualitative real-time PCR results demonstrated that COL11A1 expression was significantly increased in tumor samples ($n = 53$) compared with that in normal tissues ($n = 20$) ($p < 0.01$). The up-regulation of COL11A1 was associated with T stage ($p < 0.01$). In addition, COL11A1 was highly expressed in the gastric cancer cell line HGC-27 as compared with other gastric cancer cells (SGC-7901, MGC-803, BGC-823, AGS, MKN-28, MKN-45) and a normal immortalized epithelial cells GES-1. We found that knockdown of COL11A1 significantly inhibited the migration ($p < 0.01$), invasion ($p < 0.01$) and proliferation ($p < 0.01$) of HGC-27 cells. Knockdown of COL11A1 also induced cell apoptosis ($p < 0.01$) and impaired cell cycles ($p < 0.01$). HGC-27 cells cDNA microarray showed that COL11A1 regulated multiple tumor metastasis-related genes such as CXCR4, CTSK, SET, KRAS, TPBG, MGAT5 and so on.
CONCLUSION: Our findings suggest that COL11A1 is overexpressed in gastric cancer, which may contribute to tumorigenesis and tumor aggressiveness. These results encourage the exploration of COL11A1 as a potential therapeutic target for gastric cancer.

INTRODUCTION: Doxorubicin (DOX) is a drug used in cancer treatment in wide ranges of tumors. More effectively DOX targeting into tumor foci can benefit a better therapeutic efficacy coupled with a lower drug dosage and minimized side effects. With the goal of improving the therapeutic utility of DOX, several forms of drug delivery vehicles to target cancer has been developed and characterized such as liposomes.
AIMS & METHODS: In our current work, we used gold nanoparticles (GNPs) as our drug carrier vehicles loaded with DOX to target MNK45-derived tumors in xenograft nude mice. To avoid the forming of GNPs aggregations and provide the bridges on GNPs to DOX, we formulated bovine serum albumin (BSA) to coat the surface of GNPs and then evaluate the therapeutic effects of DOX-GNPs in animals.
RESULTS: The results demonstrated that our synthesized GNPs after BSA modification with size ranged from 15 to 300nm and the average diameters is near to 76.1±57.6 nm. The peak absorbance of these BSA-decorated GNPs was measured at 534 nm wavelength of light. To determine the cytotoxicity of BSA-decorated GNPs, gastric cancer cells, MNK45, were cultured with medium containing GNPs from concentration of 10 to 100 μM and no cytotoxicity was measured. To evaluate the specificity in tumor targeting of BSA-decorated GNPs in animals, the fluorescein isothiocyanate (FITC) molecules were also directly tagged onto the BSA layers of GNPs for later in vivo real time detection and imaging. The results demonstrated that our BSA-decorated GNPs were more effectively targeting to tumors than other organs. To assess the therapeutic efficacy, DOX were covalently bound to the BSA-decorated GNPs and then was characterized *in vitro* and *in vivo* by intravenously administration into xenograft animals. It revealed that GNP vehicle-driven DOX uptaked by tumor cells *in vitro* was higher and also impact more severe cytotoxicity to tumors. We also observed a better therapeutic outcome *in vivo* therapy in the xenograft nude mice with intravenously injection of DOX driven by BSA-decorated GNPs by displaying the lower tumor volume after 24 days therapeutic period time.
CONCLUSION: It suggests that BSA is a good mediator to bridge chemotherapeutic drugs such as doxorubicin to GNPs for improving tumor targeting and therapeutic outcome with lower cytotoxicity, indicating that GNPs display as a good and safer vehicles for delivering antitumor drugs to tumors.

INTRODUCTION: microRNAs (miRNA) are functional molecules that control gene expression and are frequently dysregulated during carcinogenesis, in particular in gastric cancer (GC). miR-137 functions as a tumor-suppressor-miRNA through silencing various oncogenes. CpG island methylation of miR-137 is a common event in glioblastoma and colorectal cancer (CRC). In this study, we systematically characterize the miR-137 promoter methylation and miR-137 expression in gastric carcinogenesis and correlate these results with overall survival of gastric cancer patients.
AIMS & METHODS: Tissue specimens were prospectively collected in Kaunas, Lithuania and in Magdeburg, Germany. Overall, 287 tissues were included to the study. We analyzed 81 pairs of primary gastric cancer tissues (T-GC) with corresponding adjacent normal gastric mucosa (N-GC), 25 normal gastric tissues from controls (N), 44 tissues from patients with chronic/atrophic gastritis ± intestinal metaplasia (CG) and 28 pairs of primary CRC tissues (T-CRC) with corresponding adjacent normal colonic mucosa (N-CRC). We determined the methylation status of miR-137 using bisulfite pyrosequencing. TaqMan RT-PCR was used to analyze miR-137 expression. Survival differences were evaluated using Kaplan-Meier analyses.
RESULTS: Defined by the distribution of miR-137 methylation in normal mucosa (mean±2SD), methylation of miR-137 is rare in normal mucosa (5%, mean methylation ± SD: 7.47±0.89%), however, increased in CG patients (10.68±0.97%). In correlation, miR-137 methylation was more frequent in tumorous compared to non-tumorous conditions both in CRC and GC (T-CRC 75% vs. N-CRC 15.8% and T-GC 46.8% vs N-GC 42.3%). Quantitative miR-137 methylation analyses revealed higher methylation in T-CRC compared to N-CRC (30.12±17.37% vs. 11.12±9.07%, $p = 0.0009$) and in similar fashion in T-GC to N-GC (21.08±13.88% to 16.92±11.55%, $p = 0.015$). miR-137 expression is inversely correlated with miR-137 CpG methylation as tumors with low methylation level showed higher expression compared to tumors with intermediate or high miR-137 methylation ($p = 0.0006$). In subgroup analyses, miR-137 methylation was higher in GC with intestinal type compared to diffuse one and higher in antrum compared to cardia and corpus, while no association existed to *H. pylori* infection or TNM stages. Overall survival analyses revealed an association between miR-137 methylation and worse prognosis in diffuse type gastric cancer, but not in intestinal type.
CONCLUSION: miR-137 is frequently methylated in gastrointestinal cancers. Increasing methylation of miR-137 from normal mucosa, chronic gastritis to cancerous tissues suggests it is an early event in gastric carcinogenesis. The alterations of miR-137 may play probably a more considerable role in development of intestinal type GC; but also worse prognosis of patients with miR-137 methylation in diffuse type GC supports the need of further functional analyses in both types of GC.

INTRODUCTION: Existing, colon cancer (CC) markers lack sensitivity and specificity. KLKs present a new class of cancer biomarkers under investigation. KLKs are concomitantly expressed in various tissues participating in proteolytic cascades. KLK5 and KLK7 in human tumors facilitate metastasis by directly degrading components of the extracellular matrix in the area surrounding KLK5 or KLK7-producing cells. KLK5 activates its own pro-enzyme as well as proKLK7. Also, KLK5 promotes tumorigenesis by activating proteinase-activated receptors (PAR_2).
AIMS & METHODS: The aim of this study was to analyse the expression of KLKs 5 & 7 in colon cancer and to find out their clinical significance. In the present study we examined the concomitant expression of KLK5 and KLK7 in the cytosols of 121 CC tissues as well as their paired normal mucosa. We used a non-competitive ELISA methodology (monoclonal–monoclonal for both KLKs).
RESULTS: It was shown that whereas KLK7 protein of CC tissue is up-regulated in comparison to normal mucosa the same does not hold for KLK5. Both KLKs were significantly associated with overall survival in univariate analysis. Also, in multivariate analysis, after adjusting for age, TNM and differentiation stage, both proteins were shown to be significantly associated with overall survival ($p = 0.032$, $p = 0.015$ respectively).

CONCLUSION: KLK7 is up-regulated in colon cancer, whereas the KLK5 is not in comparison to normal mucosa. Both KLKs are associated with overall survival in univariate as well as in multivariate analysis using as parameters the patients age, the TNM and the differentiation stage.

INTRODUCTION: Colon cancer (CC) remains the third leading cause of worldwide cancer-related death in men and women. Currently, available prognostic and/or predictive markers for colon cancer lack specificity and sensitivity. Developing new biomarker for early detection, accurate diagnosis and therapeutic treatment for CC is of great importance in improving the clinical outcome of the disease. Cathepsin B (CB), a lysosomal cysteine protease, is expressed constitutively in lysosomes, however its expression and localization change in cancer. High levels of expression of CB at both gene and protein levels have been observed in different types of cancer.
AIMS & METHODS: The aim of this study was to analyze the CB expression in different stages of CC progression and to evaluate its clinical relevance. We examined for first time, using quantitative real time PCR, the expression of CB in 185 colonic tissue specimens from 130 patients; 50 were pairs of cancerous-normal tissues, 17 were cancerous tissues and 63 were adenomas for 5 of which normal paired mucosa were also available.
RESULTS: We proved that CB was up regulated in the cancer specimens in comparison to their normal paired mucosa ($p < 0.001$), as well as in the adenomas in comparison to normal tissue ($p < 0.001$). CB expression was found to be associated with histological grade ($p = 0.037$). Cox proportional hazard regression model using univariate and multivariate analysis revealed that high status CB expression is a significant factor for disease-free survival (DFS) ($p = 0.037$ and 0.0038, respectively) and overall survival (OS)($p = 0.003$ and $p = 0.0037$, respectively) of patients. Receiver-operating characteristic (ROC) analysis of our results showed that CB has discriminatory value between CC and adenomas tissues (area under the curve [AUC] = 0.711). Kaplan-Meier survival curves demonstrated that CB expression of low status is significantly associated with longer DFS ($p = 0.023$) as well as OS ($p = 0.002$).
CONCLUSION: Present results suggest that CB gene expression may represent a useful marker of unfavorable prognosis for CC patients with discriminatory power between CC and adenoma patients.

INTRODUCTION: LIM and SH3 protein 1 (Lasp1) is an actin-binding protein involved in numerous biological and pathological processes. The overexpression of Lasp1 has been described in many types of cancers[1-4]. But the role of Lasp1 in gastric cancer (GC) remains unclear. We sought to analyze the expression level of Lasp1 in GC, and the role of Lasp1 in the development of GC.
AIMS & METHODS: The mRNA level and protein expression of Lasp1 in 82 cases of gastric cancer tissues and the paired normal gastric tissues were detected by real-time RT-PCR, Western blots and immunohistochemistry (IHC) respectively. The relationship between the Lasp1 expression level and the various clinicopathological parameters were analyzed. Using gene transfection and RNA interference (RNAi) stratage, we investigated the effects of Lasp1 overexpression and depletion on tumor cellular behavior respectively.
RESULTS: The Lasp1 mRNA and protein expressionin cancerous tissues were both increased significantly as compared to the normal gastric tissues ($p < 0.05$). Though there was no significant correlation was found between Lasp1 expression and tumor size and pathological differential degree, Lasp1mRNA level was significantly higher in patients with lymph node metastasis (N1-3) ($P < 0.05$) and those with more advanced clinical stages ($P < 0.05$) respectively. Consistently, IHC revealed that patients with lymph node metastasis ($P < 0.05$) and those with more advanced clinical stages ($P < 0.05$) were prone to show higher Lasp1 protein level. Overexpression of Lasp1 was found in metastatic GC tissues ($p < 0.01$), and its expression level was closely correlated with overall survival of patients with GC ($p < 0.01$). RNA interference mediated silencing of the Lasp1 gene in BGC823 GC cells inhibited cell proliferation and migration significantly. Furthermore, gene transfection-mediated overexpression of Lasp1 in SGC7901 GC cells resulted in aggressive phenotypes of GC cancer cells and promoted cancer growth and metastasis.
CONCLUSION: Above results suggested that Lasp1 was overexpressed in gastric cancer tissues, and the increased expression of Lasp1 may contribute to cancerous progression and lymph node metastasis.

P1644 EPIGENETIC REGULATION OF SH2-CONTAINING PROTEIN TYROSINE PHOSPHATASE 1 (SHP1) IN GASTRIC CARCINOMA CELL LINES

H. Kim[1,*], M.K. Joo[1], J.-J. Park[1], H.S. Yoo[1], **J. Kim**[1], J.W. Choe[1], B.J. Lee[1], **J.S. Kim**[1], **Y.-T. Bak**[1]
[1]*Division of Gastroenterology, Department of Internal Medicine, Korea University Guro Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: The SH2-containing protein tyrosine phosphatase 1 (SHP1) is an important negative regulator in cytokine-mediated signal transduction and cell cycling. Recent studies demonstrated that promoter methylation of *SHP1* is frequently observed in gastric adenocarcinoma tissues. However, the functional effect of epigenetic silencing of SHP1 in gastric carcinogenesis has not been reported yet.
AIMS & METHODS: We tried in this *in vitro* study to reveal promoter hypermethylation of *SHP1* and to investigate the its carcinogenic effects in gastric carcinoma cell lines.
RESULTS: We observed that both gene and protein expression of SHP1 were negative in 8 of 10 gastric cancer cell lines (SNU-1, SNU-5, SNU-16, SNU-638, SNU-719, MKN-28, MKN-45, AGS), whereas KATO-III and NCI-N87 showed weakly positive protein expression by Western blot. Conventional methylation specific PCR (MSP) showed methylation-specific band only in all 10 gastric cancer lines. Bisulfite pyrosequencing revealed 96.5%, 97.3% and 94.8% of methylation frequency in AGS, SNU-719 and MKN-28 cells, respectively, whereas only 5.3% in peripheral blood mononuclear cells. When treating SNU-719, MKN-28 and AGS cells with 5 μM of 5-Aza-2'-deoxycytidine (5-Aza-dc) for 4 days, SHP1 was re-expressed in all three cell lines. SHP1 expression is known to be correlated with Janus kinase (JAK) and signal transducers and activators of transcription (STAT) signaling pathway. When introducing exogenous SHP1 in SNU-719 and MKN-28 cells by transient transfection, protein expression of phospho-JAK2 (Tyr 1007/1008) and phospho-STAT3 (Tyr 705) were substantially down-regulated, which in turn decreased the expression of target genes of phospho-STAT3, including Cyclin D1, MMP-9, VEGF and Survivin. Furthermore, induction of SHP1 significantly reduced cell proliferation and inhibited cell migration and invasion in SNU-719 and MKN-28 cells.
CONCLUSION: Epigenetic silencing of *SHP1* is frequently caused by promoter hypermethylation in gastric carcinoma cell lines. Exogenous expression of SHP1 down-regulates JAK2/STAT3 pathway to modulate various target genes and inhibit cell proliferation, migration and inhibition in gastric carcinoma cell lines, which suppports that epigenetic silencing of *SHP1* contributes various carcinogenic and progressive effects in gastric cancer cell lines.

P1645 THE CLINICOPATHOLOGIC SIGNIFICANCE OF EZRIN EXPRESSION IN GASTRIC CANCER

H.-M. Kwon[1,*], S.S. Kim[1], J.S. Kim[1], J. I. Kim[1], S.W. Han[1]
[1]*Department of Internal Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of*

INTRODUCTION: Ezrin belongs to the ezrin/radixin/moesin protein family, which acts as membrane organizer and link between the plasma membrane and the cytoskeleton. Recent studies have found that through the regulation of adhesion molecules and signal transduction pathways, the Ezrin protein might play an important role in the process of tumor cell invasion and metastasis. There have been reports on the relationship of Ezrin expression to clinical outcome in solid tumors. However, reports on Ezrin expression in *H. pylori* infection and gastric cancer have been rare.
AIMS & METHODS: In this study, we investigated the relationship of Ezrin expression to clinicopathologic parameters and prognosis in *H. pylori* infection and gastric cancer. 113 gastric cancer tissues and same numbers of adjacent non-tumor tissues were obtained from patients who received gastrectomy for curative resection. Prognosis and clinicopathlogic characteristics of patients according to the grade of Ezrin expression were assessed. Western blot was analyzed to reveal differences of expression according to presence of *H. pylori* infection and duration of infection in AGS and HS3C cell line. Thirty pre-eradication gastric mucosal tissues and the same numbers of post-eradication gastric mucosal tissues were obtained from peptic ulcer patients with *H. pylori* infection and immunohistochemical staining was conducted.
RESULTS: The expression rates and Ezrin score were significantly increased in gastric cancer tissue compared to adjacent normal tissue (81.4% vs 66.4%, $P = 0.015$, 4.51 ± 3.29 vs 3.18 ± 3.11, $p = 0.003$, respectively). The expression of Ezrin was also increased in cases of lymphatic invasion, progression of N and TNM staging. As to the analysis of survival and correlation with Ezrin, Ezrin expression score and rates were significantly correlated with survival. In western blot analysis of AGC and HS3C cell lines, the expression of Ezrin protein increased according to presence of infection and duration of infection. In vivo

study using gastric mucosal tissues, The expression rates and score of Ezrin was not significantly elevated in pre-eradication state.
CONCLUSION: Ezrin expression may be used as a marker of not only cancer progression and metastasis but also as a prognostic indicator in gastric cancer and the effect of *helicobacter pylori* on expression of Ezrin in normal gastric mucosa may be needed further study to conclude.

P1646 THE EXPRESSION OF MMPS IN GASTRIC CANCER IS NOT ASSOCIATED WITH THE ACTIVATION OF MTOR

J. Bornschein[1,2,*], T. Seidel[1], C. Langner[1], A. Link[1], T. Wex[1], D. Kuester[3], M. Vieth[4], P. Malfertheiner[1]
[1]*Gastroenterology, Hepatology & Infectious Dis., Otto-von-Guericke University of Magdeburg, Magdeburg, Germany,* [2]*MRC Cancer Unit, University of Cambridge, Cambridge, United Kingdom,* [3]*Institute for Pathology, Otto-von-Guericke University of Magdeburg, Magdeburg,* [4]*Pathologie Klinikum Bayreuth, University of Bayreuth, Bayreuth, Germany*

INTRODUCTION: Degradation of the extracellular matrix by matrix metallo proteinases (MMPs) enables invasive growth of gastric cancer. Regulation of MMP expression by activation of mTOR (mammalian target of rapamycin) and related signalling pathways has been demonstrated, although not thus far in gastric cancer.
AIMS & METHODS: We investigated the expression of MMP2, MMP7 and MMP9 in gastric cancer and their association to mTOR in its activated, phosphorylated form (p-mTOR). The study compromised 130 patients with gastric cancer resections; 72% male, mean age 74+12.4 years, 66.2% intestinal type. Quantitative real-time PCR was performed for MMP2, MMP7 and MMP9 in fresh frozen tissue in a pilot of 43 gastric cancer patients and 30 healthy controls. Following this, immune-histochemical (IHC) staining of the MMPs as well as mTOR and p-mTOR was undertaken in the complete study population (n = 130). A semiquantitative immune-reactivity score (IRS) was applied to assess the staining separately for the tumour centre as well as the invasion front. Groups were compared by Mann-Whitney U and Wilcoxon's signed rank test and expression between sites and targets correlated by Spearman's rank correlation test. mTOR-dependent regulation of MMP expression was furthermore assessed in MKN45 gastric cancer cells by rapamycin specific inhibition of mTOR signalling.
RESULTS: RT-PCR demonstrated an up-regulated expression of all MMPs in gastric cancer compared to both non-malignant tissue and gastric mucosa from non-cancer controls. IHC revealed only for MMP2 a higher expression at the invasion front compared to the tumour centre; MMP7 was more highly expressed in the tumour centre, there was no difference for MMP9 between tumour centre and invasion front (Table). There was a trend for higher expression of mTOR in the tumour centre and the IRS for p-mTOR was higher at the tumour centre when compared with the invasion front (Table). These effects were observed in intestinal type cancers but not in diffuse ones. IRS of tumour centre and invasion front correlated positively for all MMPs, mTOR and p-mTOR ($p < 0.001$). There was no correlation between mTOR or p-mTOR expression with any of the MMPs. However, MMP2 expression correlated with MMP9, and mTOR with p-mTOR staining. By treatment of MKN45 cells with rapamycin a reduction of p-mTOR in the Western blot was achieved; however, expression of MMPs was not affected by this.

Target	Tumorcenter		Invasion Front		p-value
	Positive staining	IRS (mean+SD)	Positive staining	IRS (mean+SD)	
mTOR	96%	10.36±7.34	78%	9.66±8.27	n.s.
p-mTOR	80%	2.98±3.76	50%	2.72±4.59	0.019
MMP2	60%	3.75±4.76	74%	6.75±7.36	<0.001
MMP7	42%	5.49±8.59	43%	4.70±7.77	0.003
MMP9	44%	4.97±7.43	41%	4.23±6.91	n.s.

CONCLUSION: Expression of MMP2, MMP7 and MMP9 in gastric cancer is not associated with mTOR activation.

INTRODUCTION: Patients with autoimmune atrophic gastritis (AAG) have an increased risk of carcinoid tumors whereas patients with chronic atrophic gastritis (CAG) carry an elevated risk of adenocarcinoma.
AIMS & METHODS: We evaluated whether AAG and CAG have distinct metaplastic and inflammatory phenotypes which might contribute to their different evolution. We studied 20 female patients with AAG (age 56.4 ± 9.8 yrs) and 6 patients with CAG (4M, 2 F, age 66.3 ± 16.5 yrs). Diagnosis of AAG was through histology and positivity to anti-parietal cell antibodies. We evaluated by immunohistochemistry the gastric body expression of TFF2 as a spasmolytic-polypeptide expressing metaplasia (SPEM) marker, MUC2 as an intestinal metaplasia marker, CD68 as a macrophage marker, myeloperoxidase (MPO) as a neutrophil marker, CD44 variant, a marker of SPEM in mice, DMBT1, a marker of IM in humans, and Ki67 as a proliferation activity marker.
RESULTS: 1) All AAG patients showed parietal cell loss and TFF2-staining SPEM; 2) 75% AAG patients (15/20) demonstrated MUC2-positive goblet cell intestinal metaplasia; 3) All CAG samples showed parietal cell loss and both TFF2-staining SPEM and MUC2-positive intestinal metaplasia; 4) CD44 variant was expressed in SPEM in both AAG and CAG patients, with weak or absent expression in IM in both groups. In contrast, DMBT1 labeled IM but not SPEM in both groups, although the intensity of staining for DMBT1 in IM was uniformally weaker in the IM associated with AAG; 5) AAG patients showed significantly fewer MPO-positive neutrophils (2.9/1000 cells) as compared to CAG patients (37.0/1000 cells) and significantly fewer CD68-positive macrophages (10.5/1000 cells) as compared to CAG patients (28.0/1000 cells); 6) AAG patients demonstrated significantly lower rates of proliferation as assessed by Ki67-immunostaining cells (3.8/1000 gland cells compared with 103.7/1000 gland cells in CAG patients).
CONCLUSION: Metaplasia in AAG patients has a low proliferative rate and low macrophage and neutrophil infiltration, suggesting that metaplasia in AAG lacks crucial pro-adenocarcinoma influences. This may explain the lower incidence of gastric adenocarcinoma in AAG as compared to CAG.

INTRODUCTION: Serum pepsinogen I:II ratio, a surrogate marker of atrophic gastritis, suggests that some adenocarcinomas at the gastroesophageal junction (GOJ) develop on a background of atrophic gastritis, similar to non-cardia gastric cancer, while others arise on a background of healthy, non-atrophic gastric mucosa similar to oesophageal adenocarcinoma (OAD). In this study, we compare background gastric body mucosa in patients with junctional adenocarcinomas, oesophageal adenocarcinomas and non-cardia gastric (NCG) cancers.
AIMS & METHODS: A total of 127 gastrectomy and oesophagectomy specimens for adenocarcinoma had clear topographic description allowing assignment to oesophageal, junctional (including cardia) and gastric non-cardia locations. In each case a block of gastric body mucosa was identified well clear of the carcinoma. Parietal and chief cells were immunostained for H+/K+ ATPase and pepsinogen-1, respectively. Secretory cells density was counted in 3 to 5 well-oriented fields (1 mm^2 each) and expressed as mean cell number per 1 mm^2 area in each patient. Reactive atypia (RA) and inflammation indicated by polymorphonuclear (PMN) and mononuclear (MN) cells were also scored. Non-parametric statistics were used to compare distributions.
RESULTS: Ten (8%) cases lacked well-orientated blocks of body mucosa. The remaining 117 patients included 34 oesophageal, 52 GOJ and 31 non-cardia gastric adenocarcinomas. Median (IQR) parietal cell densities were 836 (173), 602 (389) and 411 (334) per mm^2 in gastric mucosa of oesophageal, GOJ and gastric cancers, respectively (all differences $P < 0.001$). Using a parietal cell density of 630/mm2, 85% of oesophageal adenocarcinomas had a higher and 84% of non-cardia gastric cancers had a lower values. Applying the same cut-off, 50% of GOJ adenocarcinomas would be classified as gastric and the remainder oesophageal in origin. Parietal cell density was normally distributed in the non-cardia gastric cancer and oesophageal adenocarcinoma groups. In contrast, the junctional adenocarcinoma group showed a biphasic distribution with one peak corresponding to that of non-cardia gastric cancer and the other to that of oesophageal adenocarcinoma. Chief cells show density distributions closely similar to parietal cells in all samples.
Chronic inflammatory score expressed as median (IQR) was higher in non-cardia gastric cancer than in oesophageal adenocarcinoma [0 (IQR:1) vs. 3 (IQR:2), $p < 0.001$], but in junctional cancer [1 (IQR:2)] it was higher than oesophageal adenocarcinoma and lower than non-cardia gastric cancer ($P < 0.001$ for both).
CONCLUSION: This study shows marked differences in gastric mucosal phenotype in the patients with oesophageal versus gastric non-cardia cancer, with the former being healthy and uninflamed, but the latter atrophic and inflamed. The background gastric mucosa of GOJ cancer supports being two distinct aetiologies, one group resembling oesophageal adenocarcinoma and other gastric non-cardia cancer.

P1649 ABERRANT AMPLIFICATION OF RECEPTOR TYROSIN-KINASES (RTK) INVOLVED IN CELL CYCLE SIGNALING APPEARS TO DETERMINE PROGNOSIS OF GASTRIC CANCER PATIENTS

P. Minarikova[1,*], L. Benesova[2], B. Belsanova[2], T. Halkova[2], L. Dusek[3], M. Zavoral[1], **M. Minarik**[1,2]

INTRODUCTION: Gastric cancer, which ranks among the top malignancies worldwide, exhibits a notable variety in the course of the disease. Clinical factors, such as tumor stage and localization, are key in patient survival. Lauren histology type is used to discriminate levels of differentiation; however, it is not directly applicable in the anticancer treatment. With the recent rise of molecular targeted therapies, genomic signatures comprising of somatic mutations and gene copy number variations are essential in treatment prediction as well as in prognosis of patient survival. A study by Deng et al. (Gut 2012) has identified molecularly distinct subclones by evaluating aberrant deletions or amplifications of key receptor tyrosin kinases (RTKs).
AIMS & METHODS: In this work we have related survival of gastric cancer patients to molecular classes/clusters derived from comprehensive evaluation of gene amplification with special emphasis on cell cycle signaling. Tumor samples (FFPE or freshly acquired) from a total of 76 patients (all caucasians/Europeans) with clinically confirmed gastric cancer were included in this study along with relevant clinical data including disease stage, Lauren type and tumor localization. The panel of gene amplifications included multiple receptor tyrosin-kinases families as well as other genes involved in cell cycle and proliferation. A hierarchical clustering using Wards method was applied to cluster patients according to molecular profiles. Kaplan-Meyer survival analysis was then applied to test survival of the subgroups.
RESULTS: There was a significant difference in survival for tumor localization (210 days for cardia vs. 563 days for body+antrum, $p = 0.0154$). Amplifications were frequent at 5q, 8q, 10q, 17q and 20q chromosomal locations. Several transmembrane RTKs exhibited importance when related to the patient survival, including PDGFRB, EGFR, HER2 and RET along with of CCND1 (Cyclin D1), and important cell cycle regulator. A subgroup of patients whose tumors revealed amplification of at least one of the prior genes exhibited a significantly shorter survival compared to a group with none of the amplifications detected (904 days vs. 205 days, $p = 0.029$).
CONCLUSION: As reported previously receptor tyrosin kinases play a dominant role in initialization of gastric cancer and its subsequent progression. By using a panel of RTKs along with Cyclin D1 we have observed an effect of gene amplifications on patients prognosis. An independent validation on a separat patient cohort is now in progress. Supported by the Czech Ministry of Health grant no. 13640.

P1650 ANGIOTENSIN II TYPE 1 RECEPTOR BLOCKER SUPPRESS THE FIBROSIS AND PROGRESSION OF GASTRIC CANCER

S. Fushida[1,*], M. Okazaki[1], T. Tsukada[1], J. Kinoshita[1], K. Okamoto[1], K. Oyama[1], I. Ninomiya[1], T. Fujimura[1], T. Ohta[1]
[1]*Gastroenterological Surgery, KANAZAWA UNIVAERSITY HOSPITAL, Kanazawa, Japan*

INTRODUCTION: Peritoneal dissemination is the most frequent metastatic pattern of gastric cancer. The clinical outcome was poor prognosis because of the presence of rich stromal fibrosis and acquired drug resistance. Our previous study demonstrated that the epithelial-mesenchymal transition (EMT) of human peritoneal mesothelial cells (HPMCs) drives tumor fibrosis. In recent study, Angiotensin II type I (AT1) receptor blocker (ARB) has been attracted attention as drug with direct anti-fibrotic activity.
AIMS & METHODS: In this study, we examined whether ARB attenuates tumor proliferation and fibrosis, and explores the interaction between HPMCs and gastric cancer cells through the Angiotensin II / AT1 receptor / TGF-β1. The effects of ARB in vivo were evaluated in our established fibrotic tumor model, and the expression of fibrosis, E-cadherin and α-SMA was assessed by immunohistochemical staining. The effects of Angiotensin II and ARB on the proliferation of MKN45 were assessed by MTT assay. The AT1 receptor expression of gastric cancer cells was evaluated by western blotting. TGF-β1 expressions by the influence of Angiotensin II and ARB were evaluated by ELISA and western blotting. In addition, the effects of serum-free conditioned media (SF-CM) of MKN45 cells in HPMCs were examined by western blotting and immunofluorescence examination.
RESULTS: In fibrotic tumor model, the mean tumor volume of ARB treatment group was significantly reduced compared with that of absence of ARB. ARB treatment group was increased E-cadherin expression and decreased α-SMA expression and fibrotic area compared with absence of ARB. All gastric cancer cell lines showed AT1 receptor expression. The cell proliferation and TGF-β1 expression was significantly increased with 100nM of Angiotensin II compared with absence of Angiotensin II, and pretreatment with 1000nM of ARB showed significantly decreased compared with treatment of Angiotensin II. SF-CM of treatment with Angiotensin II caused the progression of EMT-like change. On the other hand, SF-CM of pretreatment with ARB suppressed this change.
CONCLUSION: ARB can significantly reduce TGF-β1 expression and EMT-like change, and suppress the tumor proliferation and stromal fibrosis. Targeting the Angiotensin II signaling pathway may be a novel, efficient strategy for treating the tumor proliferation and tissue fibrosis.

INTRODUCTION: We have previously shown a significant epidemiological association between CagA-positive strains of *H. pylori* and unstable angina or non ST-elevation myocardial infarction (n-STEMI).
AIMS & METHODS: Therefore, we have designed a study aimed at assessing the prevalence of CagA-positive strains in patients with ST-elevation myocardial infarction (STEMI) and of recurring acute coronary syndromes (ACS) as well as the usefulness of the assessment of serum levels of anti-CagA IgG as a predictor of the clinical outcome in patients with STEMI.
Methods: We enrolled 181 patients (155 males, mean age 64±13 years) with STEMI and 50 controls (38 males, mean age 63±10 years) without any history of coronary artery disease and matched for sex, age and socioeconomical status. In all patients, serum levels of IgG anti-CagA were assessed. Moreover, levels of IgG anti-HAV were also evaluated in all patients in order to exclude the presence of a bystander activation of the immune system. Finally, a previous history of ACS and the rate of major adverse cardiovascular events (MACEs) were evaluated in all STEMI patients with a 2 years follow-up.
RESULTS: Prevalence of CagA-positive strains was significantly higher in patients with STEMI compared to controls (33.1% vs 9%, $p = 0.026$). Moreover, anti-CagA antibody titer was significantly increased in patients with STEMI compared to controls (62.7±39 vs 25.6±42.7, $p = 0.02$). Interestingly, patients with STEMI and a previous history of ACS had an higher prevalence of CagA-positive strains (50% vs 29.3%, $p = 0.019$) and higher antibody serum levels (97.5±50.4 vs 55.2±25.3, $p = 0.001$) as compared with patients without previous history of ACS. Furthermore, MACEs rate was significantly higher in patients infected by CagA-positive strains compared to CagA-negative (LogPrank = 0.014). Finally, there was a negative correlation between levels of anti-HAV and anti-CagA IgG ($R = 0.271$, $p = 0.11$) thus excluding the presence of an aspecific bystander activation of the immune system.
CONCLUSION: CagA-positive strains of *H. pylori* may be involved in the pathogenesis of STEMI and in the recurrence of ACS. Moreover, serum assessment of IgG anti-CagA may be an useful tool for risk stratification in patients with STEMI as they may positively predict MACEs rate.

INTRODUCTION: A proton pump inhibitor (PPI), amoxicillin (AMPC), and clarithromycin (CAM) are recommended widely used as first-line therapy for *Helicobacter pylori* (*H. pylori*) eradication in Japan. The guideline of Japan Helicobacter Association recommends eradication about all patients infected by *H. pylori.* From 2013, national health insurance covered eradication therapy about all patients who were infected with *H. pylori.* Yet, a decline in eradication rate associated with an increase in the prevalence of CAM resistance is increasingly problematic.
AIMS & METHODS: To improve the outcome, we retrospectively analyzed the factors which influence the failure in eradication conducted multicenter from 1997 to 2013 (n = 2582).
RESULTS: By univariate analysis, young subjects (under 35 years), non-peptic ulcer history, non-PPI therapy before eradication, and CAM-resistance were detected as risk factors of eradication failure. Gastric mucosal atrophy, dose of CAM, and types of PPI had no influence on outcome of triple therapy. By multivariate analysis, young subjects (under 35 years), non-peptic ulcer history, non-PPI therapy before eradication, and CAM-resistance were risk factor of eradication resistance ([OR: 0.63, 95%CI: 0.481–0.944], [OR: 0.78, 95%CI: 0.641–0.948], [OR: 0.78, 95%CI: 0.0.626–0.977], and [OR: 0.16, 95%CI: 0.081–0.306], respectively).

CONCLUSION: Pretreatment of PPI may be a novel strategy improving eradication rate in triple therapy. Further prospective study is necessary to clarify about this.

P1653 HELICOBACTER PYLORI IN CHRONIC GASTRITIS: WHAT IS THE RELATIONSHIP BETWEEN THE GASTRIC COLONIZATION AND THE HISTOLOGICAL LESIONS?

S. Martin[1,*], A. Laila[1], S. Mouna[1], A. Mohamed[1], K. Nawal[1]
[1]*EFD, CHU Ibn Sina Rabat (Maroc), rabat, Morocco*

INTRODUCTION: Infection with Helicobacter Pyroli (Hp) is acquired in childhood and the prevalence increases with age. Hp is now recognized as the main etiologic factor of chronic gastritis. Indeed, this infection is responsible for the majority of inflammatory gastric lesions. The aim of our study was to analyze the relationship between the density of gastric colonization by Hp and different gastric histological lesions (inflammation activity, atrophy, intestinal metaplasia and dysplasia).
AIMS & METHODS: From January 2010 to March 2014, were included 336 patients infected with Hp histologically proven on gastric biopsies according to the Sydney system. Statistical analysis of data was performed by SPSS 20.0. The association between the density of Hp and the lesions of chronic gastritis was studied by the chi-square test of Pearson, $p < 0.05$ was considered statistically significant.
RESULTS: The mean age of patients was 44.5 years ± 15.34 with female predominance in 54.8%. The chronic gastritis was mild in 13.1 %, moderate in 44.9%, severe in 7.7% and follicular in 34.2%. The density of the Hp colonization was minimal (+) in 24.1 %, moderate (++) in 56% and high (+ + +) in 19.9 %. Gastritis was antrofundic in 80 % of cases and only antral in 20 % of cases. There is a statistically positive association between the density of Hp and activity of gastritis with ($P < 0.001$). In patients with a minimal density of Hp, chronic gastritis was slightly active in 43.2 % of cases. In patients with a moderate density Hp, gastritis was moderately active in 58.5 % of cases. In patients with a high density of Hp, gastritis was moderately to severely active in 98.8 % of cases. Patients with moderate density of Hp had moderate atrophy gastritis in 8.5 % of cases and patients with significant density of Hp, gastric atrophy was severe in 16.4%, but these differences were not statistically significant. Intestinal metaplasia was present in 3% of our patients, including patients with mild density HP and intestinal metaplasia in 4.93%, and those with a moderate density HP and intestinal metaplasia in 3.14% of cases, but these results were not statistically significant. There were no cases of dysplasia in our series.
CONCLUSION: The activity of gastritis was significantly correlated to the density of Hp. However, the relationship between gastric atrophy, intestinal metaplasia and the density of Hp was no statistically significant in this study.

P1654 IRON DEFICIENCY ANEMIA DUE TO HELICOBACTER PYLORI INFECTION IS RELATED TO HYPOCHLORHYDRIA IN THE PATIENTS WITH GASTRIC HYPERPLASTIC POLYP, AND RELATED TO THE SERUM PROHEPCIDIN IN THE PATIENTS WITH NODULAR GASTRITIS

Y. Sato[1,*], Y. Nishigaki[1], Y. Aoyagi[1]
[1]*Gastroenterology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*
Contact E-mail Address: *yuichi@med.niigata-u.ac.jp*

INTRODUCTION: *Helicobacter pylori* (*H. pylori*) is recognized as a causative agent for unexplained iron deficiency anemia (IDA). However, the mechanism by which *H. pylori* infection contributes to IDA remains unclear.
AIMS & METHODS: To clarify the association between *H. pylori* infection and IDA, we evaluated many background factors influencing an iron deficiency state in adult patients with various *H. pylori* infection-positive upper gastrointestinal tract diseases. **Study 1** *H. pylori*-infected 121 patients (those with nodular gastritis (NG) (n = 19), duodenal ulcer (DU) (n = 30), or gastric ulcer (GU) (n = 47), or gastric hyperplastic polyp (GHP) (n = 25)) were enrolled in the study. The red blood cell count and hemoglobin, serum ferritin, serum iron, serum pepsinogen (PG) I, PGII, serum gastrin, and anti-*H. pylori* antibody (Ab) levels were measured. **Study 2** *H. pylori*-infected 105 patients (NG, n = 19; DU, n = 43; GU, n = 32; GHP, n = 11) and non-*H. pylori* infected individuals (n = 35) were examined for the levels of prohepcidin, ferritin, and iron in the serum. We evaluated the relationship between the prohepcidin and ferritin or iron levels. In addition, we measured the data before and after the *H. pylori* eradication.
RESULTS: In the patients with GHP and NG, hypoferritinemia was observed in comparison to the GU and DU patients ($p < 0.05$). In the GHP patients, low levels of PG I (26.4 ± 5.1 ng/ml, $p < 0.01$ vs DU, GU, and NG) and a decreased PG I/ II ratio (1.6 ± 0.2, $p < 0.01$ vs DU, GU and NG) in the serum were observed, in addition to hypergastrinemia (469.5 ±78.4 pg/ml, $p < 0.01$ vs DU, GU and NG). The levels of serum prohepcidin in the patients with *H. pylori*-associated disease were higher than those in the uninfected adults ($p < 0.01$ vs NG, GU and GHP, $p < 0.05$ vs DU). In the patients with NG, the serum prohepcidin levels were higher than those in the other *H. pylori*–infected patient groups ($p < 0.01$ vs GU, DU), and decreased after the eradication. Moreover, there was a negative correlation ($p < 0.01$, $r = -0.59$) between the serum levels of prohepcidin and the serum iron levels in the NG patients.
CONCLUSION: There were differences the iron status among the patients with different *H. pylori*-associated diseases. Hypochlorhydria due to *H. pylori*-associated gastric mucosal atrophy would affect the hypoferritinemia in the GHP patients. While the production of prohepcidin is induced by *H. pylori* infection, the iron deficiency state in the NG patients appears to be strongly associated with the prohepcidin production.

P1655 EXPRESSION OF BH3 ONLY PROTEIN BIM IS ASSOCIATED WITH MUCOSAL INFLAMMATION IN GASTRITIS PATIENTS

Y. Akazawa[1,2,*], H. Isomoto[2], K. Matsushima [2], K. Matsuda [1], Y. Kido[2], T. Kanda [2], H. Minami[2], N. Yamaguchi[2], K. Shiozawa [2], K. Ohnita[2], K. Nakao[2], F. Takeshima[2], M. Nakashima[1]
[1]*Department of tumor and diagnostic pathology, Atomic bomb disease institute, Nagsaki University,* [2]*gastroenterology and hepatology, NAGASAKI UNIVERSITY HOSPITAL, Nagasaki, Japan*

INTRODUCTION: *H. Pylori* is a major cause of gastroduodenal diseases including gastritis, peptic ulcer, and gastric adenocarcinoma. Mechanisms by which *H. pylori* infection leads to persistent inflammatory responses are not completely understood. BH3-only protein Bim is known as a pro-apoptotic protein which participates in mitochondrial cell death (1, 2). Of note, recent study also indicated a paradoxical role of Bim in activating inflammatory cells (3). We have recently shown that Bim was up-regulated in *H. pylori*-infected mucosa (4). However, role of Bim in human gastritis remains unclear.
AIMS & METHODS: Our aim was to examine if Bim is associated with mucosal inflammation in gastritis patients. Patients who underwent upper gastrointestinal endoscopy from June 2007 to May 2013 were enrolled in the study (Total number; 36, *H. pylori* negative: n = 14, positive: n = 22). Biopsy specimens were obtained from the gastric antrum along the lesser curvature during endoscopic examinations, and samples were subjected to real time PCR to assess Bim mRNA expression. Localization of Bim was examined by immunohistochemistry. Correlation of Bim mRNA expression with the degree of gastritis was evaluated according to the updated Sydney system.
RESULTS: Expression of Bim mRNA was significantly elevated in *H. pylori*-infected mucosa compared to uninfected controls ($p < 0.01$). Immunohistochemistry revealed the localization of Bim in inflammatory cells at both lamina propria and submucosa. Double-staining confirmed co-localization of Bim and myeloperoxidase, but not with either B cell marker (CD20) or T cell marker (CD3), indicating that Bim was predominantly expressed by neutrophils. In accordance with the updated Sydney system, levels of Bim mRNA expression were positively correlated with degree of infiltrating neutrophils and monocytes. In contrast, Bim negatively correlated with degree of intestinal metaplasia. Other factors, such as degree of *H. pylori* colonization and atrophy, did not correlate with expression of Bim.
CONCLUSION: Bim is expressed by neutrophils and correlates with activity of gastritis. This study implied a possible link between Bim and pathogenesis of human gastritis. Further studies are awaited to determine the detailed role of BH3-only proteins in *H. pylori* infection.

P1656 HEPCIDIN WAS EXPRESSED NOT ONLY IN THE CYTOPLASM BUT ALSO IN INTRACELLULAR CANALICULI OF GASTRIC PARIETAL CELLS AND EXPRESSED IN LYMPHOCYTES IN THE DEEP LAYER OF THE LAMINA PROPRIA

Y. Nishigaki[1,*], Y. Sato[1], M. Iwafuchi[2], Y. Aoyagi[1]
[1]*Niigata University Graduate School of Medicine and Dental Sciences,* [2]*Division of Pathology, Niigata University School of Health Sciences, Niigata, Japan*

INTRODUCTION: Hepcidin is an antimicrobial peptide and the key hormone in iron homeostasis. In the stomach, hepcidin is located in parietal cells and is related to acid secretion. Moreover, serum hepcidin levels are upregulated by *Helicobactor pylori* infection; therefore, hepcidin is an important factor in iron deficiency anemia (IDA) during the course of *H. pylori* infection. However, the localization of hepcidin in the parietal cell and the distribution of hepcidin in the gastric mucosa are unclear. In addition, it is unclear whether *H. pylori* infection influences gastric hepcidin expression in the gastric mucosa.
AIMS & METHODS: We evaluated hepcidin expression and its distribution in the gastric mucosa of *H. pylori*-infected and non-infected patients by immunohistochemistry. We enrolled 20 patients with *H. pylori* infection (mean age 55.6 ± 7.2 years, M:F = 1:1.5) and 20 patients without *H. pylori* infection (mean age 51.6 ± 9.8 years, M:F = 1:1.5). All patients underwent esophagogastroduodenoscopy (EGD). During EGD, biopsy specimens were obtained from the greater curvature of the gastric antrum and corpus. Biopsy specimens were fixed in 10% formalin and embedded in paraffin. Immunohistochemical staining was performed using these sections using monoclonal antibodies against hepcidin (Abnova, Taiwan). The present study was approved by the ethics committee of our institution. Written informed consent was obtained from all patients.
RESULTS: Hepcidin was expressed not only in the cytoplasm but also in intracellular canaliculi of gastric parietal cells in the both groups. Hepcidin was not expressed in other cell types in gastric epithelia. Hepcidin was also expressed in lymphocytes in the deep layer of the lamina propria, and its expression in the *H. pylori*-infected group was stronger than that in the non-infected group.
CONCLUSION: Our study revealed the expression of hepcidin in intracellular canaliculi of gastric parietal cells. Schwarz et al. have reported that hepcidin was detected in human gastric juice (Gut 2012); therefore, our findings suggest that

gastric hepcidin is released into the gastric lumen with gastric acid concurrently from parietal cells. The strong expression of hepcidin in lymphocytes in the gastric mucosa of *H. pylori*-infected patients suggests its role in inflammation and in the etiology of IDA associated with *H. pylori* infection.

INTRODUCTION: First line empirical treatment, non bismuth quadruples either 10-day sequential therapy with omeprazole and amoxicillin 5 days followed by omeprazole clarithromycin, metronidazole for another 5 days or concomitant the same drugs for 10 days, in previous studies, in our area (southern Greece) achieve PP eradication 86% and 92% respectively (1,2)
AIMS & METHODS: Investigation in a prospective, randomized, pilot study whether prolonging the treatment duration of sequential therapy and/or continuing the amoxicillin throughout the 14 days (sequential-concomitant hybrid) could raise the PP eradication rate to >95%. METHODS: 3 years single centre study.130 naïve *H. pylori* infected patients were randomly assigned to receive either: Sequential (omeprazole 20 mg and amoxicillin1gr for 7 days followed by omeprazole 20 mg, clarithromycin 500 mg, and metronidazole 500 mg for 7 days; n = 65) or Sequential-Concomitant hybrid: (Sq-Con hybrid) (omeprazole 20 mg and amoxicillin 1 gr for 7 days followed by omeprazole 20mg, amoxicillin1 gr, clarithromycin 500 mg, and metronidazole 500 mg for 7 days; n = 65). All of them given twice daily. UBT or endoscopy was performed 4-8 weeks post treatment to assess the outcome.
RESULTS: 65% male, mean age 46.25 +/- 14.7 years, 55% endoscopic lesions (ulcer, erosions), 35% smokers. Eradication rate by intention to treat analysis was 84%; (95% CI, 76.7% - 90.9%) for 14 days sequential, 91% (95% CI, 86.5% - 97.3%) for sq-con hybrid therapy. Per-protocol analysis yielded 88% (95% CI, 82, 4% - 93.9%) for 14 days sequential and 93% (95% CI, 90.4% - 97.9%) for sq-con hybrid therapy. Both regimens exhibited similar adverse events (42% vs. 46%) and treatment compliance (95 % vs. 97%).
CONCLUSION: Our pilot study, apart from the number of tablets needed per day, is unable to support that extending the duration of sequential therapy to 14-days, neither adopting the hybrid regimen, as first line empirical treatment, will achieve better results than the obtained by either sequential 10 or concomitant in *H. pylori* eradication in our area.

INTRODUCTION: First-line triple therapy for *H. pylori* involves the use of a PPI with amoxicillin & clarithromycin or clarithromycin & Metronidazole in case of penicillin-allergy for one week. However, due to increased resistance to these commonly employed antibiotics, eradication has fallen considerably short of the 80% intention-to-treat (ITT) rates that are considered the minimal acceptable levels as recommended in the Maastricht guidelines. Despite these worrying trends, there are no centres routinely monitoring Irish resistance rates. Data which could help adapt new first line therapies and improve outcome.
AIMS & METHODS: To compare the efficacy of standard empirical triple therapy with tailored therapy based on antimicrobial susceptibility testing.
A prospective, multicentre, randomised controlled study was conducted after ethical approval in all participating hospitals. Treatment naïve *H. pylori*-infected patients (>18 years old), as assessed by a positive antral CLO-test at endoscopy, were invited to participate and informed consent was obtained. Information on age, gender, previous antibiotic use & smoking history was recorded. A single antral biopsy was processed for antimicrobial susceptibility testing employing both standard culture and E-testing & genotyping for antibiotic resistance associated SNPs. Patients were randomised to receive either standard empirical therapy with Amoxicillin, Clarithromycin & PPI or tailored treatment based on their antibiotic resistance profile which included standard triple therapy or if resistance was detected triple therapy with Amoxicillin, Levofloxacin & PPI or Denoltab, Tetracycline, Metronidazole & PPI based quadruple therapy. A follow up UBT was performed after 6-8 week to assess treatment success.
RESULTS: To date 247 consecutive patients had CLO tests assessed at endoscopy. Of these 52 (21%) were *H. pylori* positive. Infected patients tended to be younger men with a mean age of 47 versus 53 years, $p < 0.05$ and 56% versus 46% were male. In all 47 (90%) patients have been randomised to a treatment arm and 40 (85%) have completed the study. Of those 40, 15 (37.5%) and 25 (62.5%) received tailored and empirical therapy respectively. In the tailored arm 6 (40%) received quadruple and 4 (27%) Levofloxacin and 5 (33%) standard triple therapy. Eradication rates were higher for tailored versus empirical therapy, 87% (13/15) and 68% (17/25). This trend did not reach statistical significance. Only 1 (3%) patient had a severe side effect with mild anaphylaxis to amoxicillin. Overall 42% of strains were clarithromycin resistant and 7 of 8 (88%) patients who failed empirical therapy had resistant strains, $p < 0.001$. Of the 2 (13%) who failed tailored therapy neither treatment type nor resistance profiles were predictive.
CONCLUSION: Resistance levels to clarithromycin are high at 42%. Targeted therapy can enhance eradication rates. Larger numbers will be required before a new first line treatment can be recommended.

INTRODUCTION: In the era of increasing resistance of *Helicobacter pylori* against antibiotics, non-bismuth-containing regimens have been validated for the optimal treatment.
AIMS & METHODS: We aimed to identify the superb treatment option comparing concomitant and hybrid regimen as a first-line treatment for *H. pylori* infection. A total of 359 naïve *H. pylori*-infected patients from six hospitals in Korea were randomly assigned to concomitant and hybrid therapy groups. The concomitant regimen consisted of 20 mg of esomeprazole, 1 g of amoxicillin, 500 mg of clarithromycin, and 500mg of metronidazole, twice daily for 10 days. The hybrid regimen consisted of a 5-day dual therapy (20 mg of esomeprazole, and 1 g of amoxicillin, twice daily) followed by a 5-day quadruple therapy (20 mg of esomeprazole, 1 g of amoxicillin, 500 mg of clarithromycin, and 500 mg of metronidazole, twice daily).
RESULTS: Concomitant and hybrid eradication rates were 78.2% (161/206 patients, 95% CI 72.6-83.8) vs. 81.9% (163/199 patients, 95% CI 76.6-87.2) by intention-to-treat ($p = 0.841$) and 89.9% (151/168 patients, 95% CI 85.3-94.5) vs. 90.5% (153/169 patients, 95% CI 86.1-94.9) by per-protocol ($p = 0.841$), respectively. The incidence of adverse events was similar between the two groups.
CONCLUSION: Concomitant and hybrid therapy were proven to be equally efficient regimens as the first line treatment option for *H. pylori* infection.

INTRODUCTION: Since the efficacy of the standard triple therapies for *Helicobacter pylori* (*H. pylori*) eradication has decreased, novel antibiotic regimens have been introduced.
AIMS & METHODS: The aim of this study was to compare non-bismuth quadruple therapy with sequential therapy for the first-line *H. pylori* eradication.
One hundred and thirty-seven with proven *H. pylori* infection were randomly assigned to one of 2 regimens: amoxicillin 1000mg with clarithromycin 500 mg, metronidazole 500 mg, and pantoprazole 40mg twice daily for 10 days (non-bismuth quadruple therapy) or amoxicillin 1000mg with pantoprazole 40mg twice daily for 5 days followed by clarithromycin 500mg with metronidazole 500mg, and pantoprazole 40mg twice daily for 5 days (sequential therapy). The success of *H. pylori* eradication was evaluated 4-5 weeks after completing treatment.
RESULTS: Eradication rates were 93.4% in the concomitant therapy and 85% in the sequential therapy (per protocol), but the difference was not statistically significant ($P = 0.154$). Compliances were 97.2% in non-bismuth quadruple therapy and 97.1% in sequential therapy. Adverse events were generally mild in both groups.
CONCLUSION: Non-bismuth quadruple therapy led to a non-statistically advantage over sequential therapy, It is well tolerated and could be considered as the first-line empirical therapy for *H. pylori* in Korea.

INTRODUCTION: 10-day sequential therapy has been evaluated as the first line therapy for *Helicobacter pylori* eradication and studies of sequential therapy as a second line therapy has been scarce.
AIMS & METHODS: The aim of our study was to evaluate the efficacy of 10-day sequential therapy as second line treatment after failure of standard triple therapy.
Patients diagnosed as *H. pylori* infection by rapid urease test, giemsa staining, or ^{13}C-urea breath test and who failed from standard triple therapy for *H. pylori* eradication from January, 2010 to June, 2013 in Yeungnam university hospital were included. Post treatment *H. pylori* status was determined by rapid urease test, giemsa staining, or ^{13}C-urea breath test. Eradication rate, side effects were compared.
RESULTS: A total of 123 *H. pylori* infected patients were included and 39 patients were treated by bismuth based quadruple therapy and 84 patients, by 10-day sequential therapy. Age and sex were not significantly different between both groups. The per-protocol eradication rates were 82.1% (32/39) in quadruple group and 60.7% (51/84) in sequential group. Side effects were similar in both groups (quadruple group, 20.5% vs sequential group, 11.9%, p = 0.273).
CONCLUSION: For second line *H. pylori* eradication after failure of standard triple therapy, bismuth based quadruple therapy showed significantly higher *H. pylori* eradication rate than 10-day sequential therapy. Further prospective studies are needed to evaluate efficacy of 10-day sequential therapy as second line *H. pylori* eradication treatment.

Contact E-mail Address: *michosp@hol.gr*

INTRODUCTION: The eradication rate of 1st line treatment with standard triple therapy in Greece remains persistently under 80% since 2007 and parallels Clarithromycin resistance of > 20%. Quadruple bismuth containing regimens were the standard of care as 2nd line treatments until 2010 when bismuth was withdrawn from the market.
AIMS & METHODS: The aim of our study was to evaluate the efficacy of 2nd line treatments over the periods before and after bismuth withdrawal.
Patients – Methods: Data from patients, who received 2nd line treatment for Helicobacter pylori, were collected retrospectively. Two periods were compared in terms of eradication success: period A (≤2010) and period B (≥2011). During period A patients received: {proton pump inhibitor bid + metronidazole 500mg tid + amoxicillin 1gr bid+ bismuth subcitrate 120mg qid} for 14 days while during period B: {proton pump inhibitor bid + levofloxacin 500mg bid + amoxicillin 1gr bid} for 10 days. Patients tested with urea breath test (UBT) 4-6 weeks after completion of treatment were analyzed. Susceptibility to levofloxacin was evaluated by E-test.
RESULTS: 159 patients (61 men), age (mean±SD = 51.7±12.3 years). Period A: 88 (34 men), and B: 71 (27 men). The 2 groups did not differ neither for age, gender, smoking and other demographic parameters nor for endoscopic lesions. Eradication rates according to UBT results for the 2 periods are shown in table 1. Eradication rates according to UBT results for period B ≥2011 are shown in table 2. For the years 2011-2013 the primary levofloxacin resistance rate as evaluated continuously in samples of our population remained stable (8-9%).
Table1

	UBT (+)	UBT (-)	Chi-square
<2010	13 (15%)	75 (85%)	p = 0.41
>2011	14 (20%)	57 (80%)	

Table2

2011	15	4	Fisher test
2012	19	4	p = 0.80
2013	18	6	
2014	5	0	

CONCLUSION: 1) 2nd line treatment with 10 days of levofloxacin-based treatment is equally effective to 14 days of quadruple bismuth-based treatment, with a levofloxacin resistance of <10% for the studied period. 2) During 4 years of levofloxacin use, the success rate did not change in this group and parallels the stability of levofloxacin resistance rates. However, increase of resistance is probable in the future and it may affect the efficacy of levofloxacin-based treatments.

P1663 TEN-DAYS CONCOMITANT THERAPY IS SUPERIOR TO SEQUENTIAL THERAPY FOR HELICOBACTER PYLORI ERADICATION

S.Y. Kim[1,*], J.W. Chung[1], D.K. Park[1], K.A. Kwon[1], **Y.J. Kim**[1], **K.O. Kim**[1]

INTRODUCTION: *Helicobacter pylori* (*H. pylori*) infection is the main cause of gastritis, peptic ulcer disease, gastric MALT lymphoma, and gastric cancer. The first-line international choice for treating *H. pylori* was consists of standard triple therapy, which includes two antibiotics (clarithromycin plus amoxicillin or metronidazole) plus proton-pump inhibitor for 7-14 days. Because the efficacy of the standard triple therapy for *H. pylori* eradication has declined, new regimens such as sequential therapy (ST) and concomitant therapy (CoCTx) have been introduced.
AIMS & METHODS: The aim of this study was to compare the efficacy of 10-days sequential therapy and 10-days CoCTx (non-bismuth quadruple drugs) for *H. pylori* eradication. We retrospectively reviewed the medical records of 316 patients with proven *H. pylori* infection. They were assigned to one of 2 regimens: (a) ST (n = 191): lansoprazole 30mg and amoxacillin 1g for 5 days followed by lansoprazole 30mg, metronidazole 500mg, and clarithromycin 500mg for 5 days; (b) CoCTx (n = 125): lansoprazole 30mg, amoxicillin 1g, metronidazole 500mg, and clarithromycin 500mg for 10 days. All drugs were administered twice a day. Bacterial eradication was checked by using a ^{13}C-urea breath test, at least 4 weeks after treatment. Side effects and compliances were evaluated with interview and more than 90% of drug administration.
RESULTS: The mean age and male to female ratio was 51.74 and 1.03. Baseline characteristics (age, gender, smoking) were not different in both groups. Ten days CoCTx group (94.4%, 118/125) showed better eradication rate than ST group (82.2%, 157/191) ($p = 0.002$). The difference was statistically significant. Drug compliances were not statistically different between both groups (ST: 96.3%, 184/191; CoCTx: 92.8% 116/125) ($p = 0.19$). Side effects were more frequently reported in the CoCTx group (42.4%) than in the ST group (29.8%) ($p = 0.03$). The most common side effect was taste disturbance.
CONCLUSION: Ten-days CoCTx was superior to ST in terms of eradicating *H. pylori* infection. Although the CoCTx was producing more side effects than ST, CoCTx is thought to be a promising alternative to ST as a treatment regimen for *H. pylori* eradication.

Contact E-mail Address: *yoshimasa.saito@gmail.com*

INTRODUCTION: Esomeprazole is the proton pump inhibitor (PPI) that was developed as the S-isomer of omeprazole. Although extensive metabolizer genotype of CYP2C19 metabolizes omeprazole rapidly, it is believed that esomeprazole is not affected by CYP2C19 genotype and is more effective for suppression of gastric acid secretion. However, there is no evidence for clinical advantage of esomeprazole in first-line *Helicobacter pylori* (*H. pylori*) eradication therapy.
AIMS & METHODS: In the present study, we investigated influence of CYP2C19 genotype and serum pepsinogen level on first-line eradication therapy with esomeprazole for patients with *H. pylori*-positive gastritis. Patients with gastritis who were diagnosed as positive for *H. pylori* were included in this study between January and September 2013. They were treated by first-line eradication therapy with esomeprazole 40 mg/day, amoxicillin 1500 mg/day and clarithromycin 400 mg/day for 7 days. Three-months after eradication, *H. pylori* infection was validated by ^{13}C-urea breath test. Correlation between *H. pylori* eradication and CYP2C19 genotype and serum pepsinogen level was analyzed. This study is registered with the UMIN Clinical Trials Registry, number UMIN000009642.

RESULTS: *H. pylori* eradication rate of first-line therapy with esomeprazole was 68.3% (54/79), which was similar to that of first-line therapy with lansoprazole (69%; 80/116). Eradication rates of first-line therapy with esomeprazole in three different CYP2C19 genotypes, extensive metabolizer (EM), intermediate metabolizer (IM) and poor metabolizer (PM) were 50% (11/22), 72.7% (32/44) and 84.6% (11/13), respectively. Eradication rate of EM group was significantly lower than that of PM group ($p = 0.043$) and IM+PM group ($p = 0.03$). Serum pepsinogen I level and pepsinogen I/II ratio were significantly increased after eradication of *H. pylori* ($p = 0.007$), suggesting that gastric atrophy was improved by eradication therapy.
CONCLUSION: These findings suggest that EM genotype of CYP2C19 metabolizes esomeprazole more rapidly, and therefore plasma concentration of esomeprazole become lower, resulting in higher gastric acid secretion and lower *H. pylori* eradication rate. Evaluation of CYP2C19 genotype and serum pepsinogen level is important to develop effective personalized therapy of first-line eradication with esomeprazole for patients with *H. pylori*-positive gastritis.

INTRODUCTION: Diagnosis of gastric *mucosa-associated lymphoid tissue* (MALT) lymphoma (G-MALT) is frequently established after an upper gastrointestinal endoscopy (UGE) with biopsies, for investigation of nonspecific digestive symptoms. Described endoscopic changes of this rare neoplasia are heterogeneous.
AIMS & METHODS: The aim of this study was to characterize endoscopic findings of G-MALT in diagnosis and follow-up endoscopies.
We performed a retrospective study of all G-MALT cases, in a single tertiary center, over a 14-year period (2000-2013). Data regarding patients' demographics and clinical factors and endoscopic findings were collected.
RESULTS: Sixteen patients were included, with a mean age of 60.8±2.7 years and 9 (56.3%) were male. Indications for UGE were: epigastric pain in 8 (57.1%) patients, postprandial fullness in 6 (26.1%), heartburn in 2 (8.7%), asthenia in 2 (8.7%), hematemesis in 2 (8.7%), anorexia and weight loss in 2 (8.7%) and anaemia in 1 (4.3%). G-MALT was located in the (gastric) body in 9 (56.3%) cases, antrum in 5 (31.3%) and both in 2 (12.4%). According to endoscopic findings, changes were classified as: erosions of gastric folds in 3 (18.8%) patients, gastric ulcer in 3 (18.8%), nonspecific areas of irregular mucosa in 3 (18.8%), structural modifications in gastric folds in 2 (12.5%), hypertrophic gastric folds in 2 (12.5%), erythematous mucosa in 2 (12.5%) and exophytic tumor in a single case (6.3%). The mean follow-up time was 5.6 ± 0.9 years, with no mortality. On follow-up endoscopies in non-gastrectomized patients, gastric ulcers only maintained an area with a scar and there were no gastric folds erosions. The remaining changes persisted similar to the first UGE, regardless disease evolution.
CONCLUSION: Endoscopic findings of G-MALT are nonspecific and, most of the times, apparently benign. Given this, histological characterization of these lesions is preponderant to its diagnosis and follow-up.

INTRODUCTION: Gastric mucosa associated lymphoid tissue (MALT) lymphoma, is an indolent cancer, that occurs in the presence of pre-existing prolonged lymphoid proliferation in mucosal sites. In that instance, the most well established trigger is the gastric *Helicobacter pylori* (Hp) infection.
AIMS & METHODS: Evaluation of clinical and laboratorial factors, and the effect of therapy in achieving Complete Remission (CR) in 1 year of patients with gastric MALT lymphoma. Multicentric study, in which clinical and pathological features of patients with gastric MALT lymphoma, according Dawson criteria for primary gastrointestinal lymphoma, were evaluated retrospectively.
RESULTS: A total of 34 cases were identified, 23 men, and 11 women, with an average age of 59 years. The most common symptom was epigastric pain (74%), six patients presented Gastrointestinal Bleeding and three patients had type B symptoms. The most prevalent localization was gastric body and 18 patients had ulcerative pattern at presentation. At diagnosis, 91% and 94% were classified has limited disease (Lugano I-II and Ann Arbor IE-IIE respectively) and 94% had an International Prognostic Index (IPI) <3. A total of 20 patients (59%) had histologic evidence of Hp infection. One year rate of CR was 77% (70% in the Hp-positive versus 86% in the Hp-negative), with an average remission time of 8.5 months. Using Lugano Staging System, CR was achieved in 77% of patients with limited disease versus 67% in those with advanced disease. In the Hp-positive group, isolated antibiotic therapy led to a CR in 60% of the cases, including a CR in a patient with advanced disease. There was achieved a CR in a patient of the Hp-negative group treated only with isolated antibiotic therapy. The variables Limited Disease, IPI score <3, age, histologic evidence of HP, serum LDH, Albumin and Beta2-microglobuline levels, were not associated with one year rate of CR ($P < 0.05$). At one year there was 1 death (Hp-positive patient).
CONCLUSION: The results confirm the good prognosis and the indolence of MALT lymphoma. The variables studied couldn't predict CR in 1 year, but enhances the idea that patients with early stage Hp-negative MALT lymphoma and with advanced disease, might still benefit from antibiotic treatment.

INTRODUCTION: *Helicobacter pylori* (*H. pylori*) is a risk factor for gastric cancer. We investigate the incidence for gastric cancer development in peptic ulcer patients with *H. pylori* infection.
AIMS & METHODS: This was a retrospective study created from chart review for patients who diagnosed by gastric cancer in peptic ulcer patient with *H. pylori* infection between 2003 and 2013. They consisted of 86 gastric ulcer patients and 15 duodenal ulcer patients. Gastric and duodenal ulcer patients were excluded from the analysis because of their limited number.
RESULTS: The prevalence rates of gastric cancer in gastric ulcer with *H. pylori* infection were 3.60% (86/2387) and in duodenal ulcer with *H. pylori* infection were 0.84% (15/1775). Kaplan-Meier analysis showed that the incidence of gastric cancer in duodenal ulcer patients was lower than that in gastric ulcer patients, and the prognosis of gastric cancer in duodenal ulcer patients was poorer than that in gastric ulcer patients (log-rank test, $p = 0.191$). Cox's proportional hazard model denotes the relative risk for duodenal ulcer against gastric ulcer adjusted by pathologic differentiation as 1.71 (95% CI: 1.09-2.70, $p = 0.02$). In univariate and multivariate analysis, pathologic differentiation, stage and cell type were related to gastric cancer in peptic ulcer patients with *H. pylori* infection ($p < 0.05$).
CONCLUSION: In duodenal ulcer patients with *H. pylori* infection, the risk of gastric cancer development was less and the prognosis was poorer than that of gastric ulcer patients with *H. pylori* infection. The prevalence rates of gastric cancer were 3.60% in gastric ulcer with *H. pylori* infection and 0.84% in duodenal ulcer with *H. pylori* infection. The relative risk for duodenal ulcer against gastric ulcer adjusted by pathologic differentiation as 1.71 (95% CI: 1.09-2.70, $p = 0.02$).

P1668 THE EFFECT OF *H. PYLORI* ERADICATION ON METACHRONOUS GASTRIC NEOPLASMS AFTER ENDOSCOPIC RESECTION OF GASTRIC DYSPLASIA

S.H. Shin[1,*], D.H. Jung[1]
[1]*Department of Internal Medicine, Institue of Gastroenterology, Yonsei University College of Medicine, Seoul, Korea, Republic Of*
Contact E-mail Address: *earth-peace@yuhs.ac*

INTRODUCTION: *Helicobater pylori (H. pylori)* infection was closely related in gastric atrophy, intestinal metaplasia (IM), and a progression to dysplasia or cancer. Furthermore, some studies showed that the eradication of *H. pylori* after endoscopic resection (ER) of early gastric cancer (EGC) was helpful to prevent the development of metachronous gastric cancer.(1.2) However, there are no sufficient data about the role of eradication of *H. pylori* after ER for gastric dysplasia.
AIMS & METHODS: The aim of this study was to investigate the effect of *H. pylori* eradication would affect the development of the metachronous gastric neoplasms after ER in patients with gastric dysplasia.
We retrospectively reviewed 1850 patients who underwent endoscopic resection of gastric dysplasia from January 2007 to February 2012 at Severance hospital. We excluded patients with follow-up period of < 2 years and who had not undergone tests for active *H. pylori* infection at the time of endoscopy. Total of 289 patients were enrolled in this study. Then divided them into three groups: those without active *H. pylori* infection (Hp negative group, $n = 131$), those who successfully underwent *H. pylori* eradication (eradicated group, $n = 119$), and those who failed or did not undergo *H. pylori* eradication (non-eradicated group, $n = 39$). The rate of metachronous recurrence after ER was compared.
RESULTS: Metachronous reccurence was diagnosed in 42 patients, including 25 in the Hp negative, 8 in the eradicated, 9 in the non-eradicated group. Median time to metachronous recurrence was 36 months (range, 6-85 months). The incidence of metachronous recurrence was 5.13 cases per 1,000 person-years in the Hp negative group, 1.57 cases per 1,000 person-years in the eradicated group, and 6.07 cases per 1,000 person-years in the noneradicated group. Patients in non-eradicated group had a higher risk of developing metachronous gastric neoplasms than eradicated group (hazard ratio [HR] 3.974, $p = 0.005$).
CONCLUSION: The successful *H. pylori* eradication may reduce the development metachronous gastric neoplasms after ER in patients with gastric dysplasia. Also regular follow-up of test for *H. pylori* infection is important to prevent the metachronous recurrence in those high-risk patients.

INTRODUCTION: Before the introduction of capsule endoscopy and double-balloon endoscopy, there were no effective modalities for reliable evaluation of the small bowel. Evans D F reported the measurement of gastrointestinal pH profiles in normal ambulant human subjects by using pH sensitive radiometry capsule in 1988 (Evans D F et al. Gut 1988;29:1035-41). Recently, the SmartPill, a wireless pH, temperature and pressure recording capsule, has been utilized to measure the whole gut transit time. This modality can record gastrointestinal pH, but could not record correct gastrointestinal location, especially ileum into cecum. Evans reported that the pH in the normal gastrointestinal increase in pH from the duodenum to the terminal ileum, decrease in the cecum by using sensitive radiometry capsule. Recently we have designed a new noninvasive modality "pH capsule" for recording sequential images and the pH of the gastrointestinal tract (Iida H, et al. Hepatogastroenterology 2011;59:114).
AIMS & METHODS: The aim of this study was to investigate the pH changes from the terminal ileum to cecum by using the "pH capsule". Ten healthy male volunteers swallowed the "pH capsule" with 50cc water. The "pH capsule" transmitted the acquired images and pH to a recorder unit located outside the body for about ten hours while the subject was fasting.
RESULTS: Ten male subjects completed this study. The intragastric pH was low, and the pH in the small intestine ranged from 7.2 to 8.1 (mean of 7.61). The pH in the terminal ileum (mean of 8.15) significantly decreased in the cecum (mean of 6.60).
CONCLUSION: We could noninvasively monitor sequential images and the pH of the gastrointestinal tract, especially terminal ileum to cecum, with the "pH capsule". Thus, the "pH capsule" is expected to become a valuable tool for the assessment of gastrointestinal pH abnormalities in various kind of diseases with the accurate location and mucosal images of gastrointestinal tract.

P1670 A NOVEL GENE TRANSDUCTION SYSTEM INTO SMALL INTESTINAL ORGANOID ENABLED THE IDENTIFICATION OF THE STEM CELL SUBPOPULATIONS IN A CRYPT

N. Horita[1,*], K. Tsuchiya[2], R. Hayashi[1], K. Fukushima[1], S. Hibiya[1], M. Watanabe[1]

INTRODUCTION: Recently, two kinds of stem cell population are advocated; +4 quiescent stem cell and Lgr5+ crypt base columnar (CBC) cell by the progress of stem cell research using small intestinal organoids that was generated from a single stem cell by the 3-dimentional culture method. However, single stem cell dynamics in a crypt remains not to be fully elucidated, because plural stem cells exist in a crypt. We therefore hypothesized that the identification of a single stem cell by fluorescent labeling might enable to explore the dynamics and relationship between plural stem cells in a crypt.
AIMS & METHODS: Lentivirus encoding mCherry gene was mixed with matrigel to directly infect the small intestinal organoids. The localization of mCherry positive cells in whole organoids was analyzed by confocal microscope and time-lapse imaging microscope. The cell types of mCherry positive cells were identified by the immunostaining with OLFM4 and Lysozyme.
RESULTS: We have established a lentiviral transduction system into the intestinal organoids to detect mCherry protein expression for a long time, 50 weeks after transduction. Three-dimensional analysis using confocal microscope showed both mCherry -positive and -negative cells in a crypt, which suggested that both mCherry-positive and -negative stem cells might be long lived in the same crypt. Moreover, we found a single mCherry positive cell in a crypt, which was co-localized with stem cell marker: OLFM4. Furthermore, Paneth cells in a crypt were differentiated from both mCherry-positive and -negative stem cells. Time-lapse imaging showed that a single mCherry-positive stem cell in a crypt divided and supplied cells to both crypt base columnar cells and transit amplifying cells. These results suggested that epithelial cells in a crypt might be permanently supplied from independent different stem cells in a crypt but not single stem cell.
CONCLUSION: Our original lentiviral transduction system to mark stem cells might be useful to elucidate the subpopulation of intestinal stem cells in a crypt. Live imaging of single cell in a crypt is useful for the analysis of the stem cell division and maintenance.

P1671 NOTCH SIGNALING REGULATES EXPRESSION OF GELSOLIN SUPERFAMILY GENES, GELSOLIN AND SCINDERIN, AND PROMOTES RE-ASSEMBLY OF ACTIN CYTOSKELTON IN HUMAN INTESTINAL EPITHELIAL CELLS

INTRODUCTION: In our previous study, we have shown that activation of Notch signaling plays an indispensable role in differentiation and proliferation of human intestinal epithelial cells (IECs). Dynamic change of the actin cytoskeleton is regulated by actin-binding proteins, including Gelsolin superfamily proteins, and is critically involved in fundamental cellular processes such as cell adhesion or cell migration. However, the role of Notch signaling in regulation of actin cytoskeleton dynamics remains completely unknown.
AIMS & METHODS: The present study was planned to identify whether Notch signaling may also regulate the dynamic changes or reassembly of actin cytoskeleton in human IECs. To analyze the cellular effect of Notch activation, tetracycline-dependent overexpression of the Notch intracellular domain (NICD) was induced in LS174T or DLD1 cells. Microarray analysis was performed to compare the expression of genes encoding actin-binding proteins, before and after activation of Notch signaling in IECs. Change in gene expression was further confirmed by quantitative PCR or immunoblot analysis. Also, the dynamic change of actin-based cell structures was visualized by phalloidin staining. Finally, assembly of focal adhesion, a cell structure indicating actin- and integrin-mediated cell adhesion to the extracellular matrix, was examined by double staining of phalloidin and paxillin.
RESULTS: Microarray analysis of LS174T cells showed a significant increase in expression of two Gelsolin superfamily genes, Gelsolin and Scinderin, upon Notch activation. Validation of the data by quantitative PCR confirmed significant increase of Gelsolin and Scinderin mRNA expression by Notch activation, in both LS174T and DLD-1 cells. Significant up-regulation of the Gelsolin protein expression was also clearly confirmed by immunoblot analysis. However, in sharp contrast, expression of other Gelsolin family genes, such as Villin or Supervillin remained completely unchanged. Consistent with the up-regulation of Gelsolin and Scinderin expression, phalloidin staining clearly revealed promotion of actin cytoskeleton reassembly by Notch activation, resulting in significant increase of lamellipodia and filopodia formation, but decrease of actin stress fiber formation. Futhermore, double staining of phalloidin and paxillin showed a significant decrease in formation of focal adhesions upon activation of Notch signaling in DLD-1 cells, suggesting decreased cell adhesion, as well as increased cell motility of those cells.
CONCLUSION: Activation of Notch signalling up-regulates expression of Gelsolin superfamily genes, Gelsolin and Scinderin, in human IECs. Such an up-regulation of actin-binding proteins may mediate the promotion of actin reassembly by Notch activation, and subsequently regulate the behavior of IECs, such as cell adhesion or cell migration.

INTRODUCTION: Enterohemorrhagic *Escherichia coli* (EHEC) are food-borne pathogens associated with diarrhea, hemorrhagic colitis and life-threatening complications such as hemolytic-uremic syndrome. EHEC interact preferentially with the Follicule-Associated Epithelium (FAE) of Peyer's patches (PPs) regions of the distal ileum in humans and translocate across the intestinal epithelium *via* M cells. The Long Polar Fimbriae (LPF), encoded by two *lpf* operons, contribute to epithelial cells adhesion and intestinal colonization.
AIMS & METHODS: To investigate the involvement of LPF in the ability of EHEC strain EDL933 to target PPs, we generated the D*lpfA1,* D*lpfA2,* D*lpfA1*-D*lpfA2* isogenic mutants and trans-complemented them with *lpf*operons.
In vivo interactions with murine PPs were analyzed in ileal loop assays. Mice were infected with a mixture of two bacterial strains, and the numbers of PPs-interacting bacteria were determined using a competitive index analysis. LPF interaction with M-like cells was investigated using the *in vitro* model of specialized M cells.
RESULTS: *Lpf* isogenic mutants (i) were not able to interact with ileal biopsies containing PP compared to the wild type strain in competitive colonization assays, and (ii) did translocate across M cells at levels significantly lower than those observed for the wild type strain. Trans-complementation of the mutants

with the cloned *lpf* operons restored their ability to interact with PPs and M cells, indicating that expression of *lpfA1* or/and *lpfA2* operons is required for interactions with PPs.
CONCLUSION: We conclude that LPF are involved in the interaction of EHEC with murine PPs and are needed for an active translocation across M cell monolayer.

P1673 LACTOBACILLUS PARACASEI SUBSPECIES PARACASEI F19 PREVENTS BOWEL SYMPTOMS IN PATIENTS AT LONG-TERM PPI TREATMENT: A RANDOMIZED DOUBLE-BLIND PLACEBO CONTROLLED CROSS-OVER MULTICENTER STUDY

D. Compare[1,*], A. Rocco[1], C. Sgamato[1], P. Coccoli[1], A. Martino[1], S.M. A. Campo[2], I. Nazionale[3], T. Larussa[3], F. Luzza[3], G. Nardone[1]
[1]*Clinical Medicine and Surgery, University Federico II of Naples, NAPOLI,* [2]*Gastroenterology Unit, Nuovo Regina Margherita Hospital, Roma,* [3]*Health Science, University Magna Grecia, Catanzaro, Italy*

INTRODUCTION: Proton pump inhibitors (PPIs) may foster intestinal dysbiosis and related-bowel symptoms.
AIMS & METHODS: Aim of this study was to evaluate the effect of Lactobacillus paracasei subspecies paracasei F19 (LP-F19) on bowel symptoms' onset in patients at long-term PPIs. Patients with typical gastroesophageal reflux disease symptoms were screened. Enrolled patients received pantoprazole 40mg/d for 6 months and were randomly assigned to: 1) LP-F19 for 6 months (LP-F19); 2) placebo for 6 months (PBO); 3) LP-F19 for the first 3 and placebo for the following 3 months (LP-F19→PBO); 4) placebo for the first 3 and LP-F19 for the following 3 months (PBO→LP-F19). Bowel symptoms (bloating, flatulence, abdominal pain) and bowel habit were assessed baseline and monthly.
RESULTS: 100/312 patients were enrolled, 84 of whom completed the study. The percentage of patients who developed at least one bowel symptom at 3-month checkpoint was 4% in the LP-F19 group and 27% in the PBO group ($p = 0.04$). At 6-month checkpoint, the percentage of symptomatic patients increased up to 18% in the LP-F19 and 57% in the PBO group ($p = 0.01$). In details, only the percentage of patients who complained of bloating and flatulence, were significantly higher in PBO group in respect to LP-F19 group. In the LP-F19→PBO group the percentage of patients who developed at least one bowel symptom was 20% during active treatment and increased up to 55% during placebo treatment ($p = 0.05$). Opposite, in the PBO→LP-F19 group, the percentage of symptomatic patients was 48% during placebo treatment and progressively decreased to 14% during active treatment ($p = 0.04$). In details, in the LP-F19→PBO group, the percentage of patients who complained of bloating, flatulence and abdominal pain did not significantly differ in respect to baseline during active treatment. Opposite, during placebo treatment, 40% of patients developed bloating ($p = 0.003$) and 35% flatulence ($p = 0.008$). In the PBO→LP-F19 group, 14% of patients complained of bloating ($p = 0.003$) and 33% of flatulence ($p = 0.008$) during placebo treatment in respect to baseline. Opposite, during active treatment, only 5% of the patients still complained of bloating ($p = 0.02$) and none of flatulence ($p = 0.008$). At multivariate analysis, LP-F19 treatment was the only covariate independently associated with absence of symptoms (OR 0.2; 95%CI 0.09-0.46; $p = 0.0001$). Mean stool frequency/week and stool form significantly changed only during placebo treatment in both standard and cross-over groups.
CONCLUSION: LP-F19 supplementation prevents the onset of bowel symptoms in patients at long-term PPI treatment. In view of the growing number of patients requiring long-term, high-dose PPIs, our results provide evidence for new treatment strategies to reduce the burden of PPI-related intestinal diseases. Further studies to define the best strain, dose, and timing of probiotics are needed.

INTRODUCTION: Intestinal bacterial translocation is usually increased in inflamed tissues. Postbiotics (probiotic-produced soluble factors) have been proposed to specifically manipulate intestinal functions[1]. We have previously shown that pathogen bacteria-induced release of the enteroglial derived S100B protein plays an active role in nitric oxide (NO)-dependent gut inflammation[2].
AIMS & METHODS: We aim to study the effects, in human intestinal biopsies, of the probiotic *Lactobacillus Casei DG* (LC) and of the postbiotics derived from LC (LC-PB), on *Enteroinvasive Escherichia Coli* (EIEC)-induced NO and S100B secretion and iNOS protein expression. To achieve this goal, rectal biopsies, without macroscopic signs of inflammation, obtained from 7 healthy subjects undergoing screening for colorectal cancer, were stimulated with EIEC and/or with LC or LC-PB, as the following experimental scheme: A) stimulation with EIEC from 0h to 5h (0-5h); B) LC or LC-PB 0-5h; C) [LC or LC-PB] 0-5h + EIEC 2.5-5h; D) EIEC 0-5h + [LC or LC-PB] 2.5-5h; E) EIEC + [LC or LC-PB] 0-5h. After 24 h, S100B release was evaluated by ELISA and NO release and iNOS expression were evaluated by nitrite assays and Western Blot analysis respectively, in stimulated compared to un-stimulated biopsies (control). Data are expressed as mean±SD.
RESULTS: EIEC, but not LC or LC-PB, significantly increased S100B secretion (+3.7±1.1 fold increase vs control; $p < 0.05$). When LC or LC-PB were added to biopsies before, after or together EIEC, S100B secretion was not increased respect to control and, interestingly, LC-PB were significantly more effective in reducing S100B expression (-8.1±0.6, -3.7 ±0.4, -19.1±1.1 fold decrease vs viable LC; $p < 0.05$). In parallel, incubation with EIEC led to a significant increase of iNOS protein expression (+5.6±1.6 fold increase vs control; $p < 0.05$) and of NO secretion (+2.4±0.3 fold increase vs control; $p < 0.05$), that was not observed with LC or LC-PB. When LC or LC-PB were added to biopsy before, after or together EIEC, iNOS expression and NO secretion were similar to control.
CONCLUSION: We showed that both LC and LC-PB are able to decrease EIEC-induced S100B and NO secretion in human biopsies and that LC-PB was more effective in reducing S100B expression than viable LC. Since probiotics may be detrimental in those pathologies where bacterial translocation is increased, with this preliminary report we propose postbiotics as a safer and effective alternative to probiotics.

P1675 XYLOGLUCAN: A NEW AGENT TO PROTECT THE INTESTINAL MUCOSA AND TO PREVENT BACTERIALLY- MEDIATED ALTERATION OF TIGHT JUNCTION PERMEABILITY

L. Bueno[1,*], V. Theodorou[1], S. Sekkal[1]
[1]*NGN Unit, INRA, Toulouse, France*
Contact E-mail Address: *lbueno@toulouse.inra.fr*

INTRODUCTION: Xyloglucan (XG) is a water-soluble hemicellulose from vascular plants, indigested by digestive enzyme. This polysaccharide has various application areas like drug-delivery technology, food technology and textile industry. It has also been suggested that it may act as a film-forming barrier distributed on the intestinal mucus layer able to protect the mucosa from chemical or bacterial aggression. However until now, no data has yet been published to confirm such hypothesis.
AIMS & METHODS: Aims: Our studies aimed to evaluate both in vitro and in vivo the potency of xyloglucan to prevent the bacterial toxin- induced -increase permeability and the subsequent epithelial cell bacterial invasion.
Methods: A first series of experiments performed *in vitro* on co-cultured CaCo2/ Goblets cells submitted to *E. coli* inoculation, XG was added on the apical site of the bath both preventively and curatively. Changes in tight junction (TJ) permeability was measured by TEER, Lucifer yellow transfer, E. coli adhesion and epithelial cell invasion were counted. In a second series performed in vivo, Wistar rats received orally XG (12.5mg/kg) and 2 h. later were injected IP with LPS from *E. coli*. Jejunal strips were collected 6 hours later for in vitro TJ permeability measurement using FITC-dextran and mucosal myelo-peroxidase (MPO) activity as a marker of inflammation. In a last series, XG was given orally associated or not with gelatin or co-administered with cholera toxin (CT) into isolated jejunal loops in anesthetized rats. Evaluation of CT-induced water secretion was performed 2hours later.
RESULTS: *In vitro,* given preventively XG (2.5mg/200ml), reduced significantly by 78% the degree of *E.coli* mucosal colonization after 30min. Added curatively, 1after *E.coli* inoculation, XG attenuated by 87% the decrease in TEER measured 3h. later. Administered orally 2 hours before LPS, XG (12.5mg/kg) reduced significantly ($P \leq 0.01$) by 81.8% the LPS-triggered increase in permeability and subsequently by 63.2% the increase in mucosal MPO activity. When administered orally 4h earlier (12.5mg/kg) or 12h earlier with gelatin (250mg/kg), XG suppressed CT-induced water secretion. Co-administered locally with CT at dose of 0.75 and 1.25mg/loop, XG reduced (67%) or suppressed respectively, the secretory effects of CT.
CONCLUSION: Both in vitro and in vivo data indicate that xyloglucan has protective effects on intestinal bacterial invasion, alterations of gut permeability and CT-induced intestinal secretion reaching 12h when associated with gelatin. These data support that this compound may be of therapeutic interest in the treatment of infectious diarrhea.

INTRODUCTION: Small intestinal bacterial overgrowth (SIBO) is defined by the presence of an excessive concentration of bacteria in the small intestine. Lactose intolerance (LI), fructose intolerance (FI) and sorbitol intolerance (SI) and SIBO share many gastro-intestinal (GI) symptoms usually attributed to patients diagnosed with irritable bowel syndrome (IBS).
AIMS & METHODS: To evaluate the role and effect of SIBO in the formation of LI, FI and SI symptoms in affected patients. A total of 348 patients with suspected IBS underwent SIBO and LI, FI and SI diagnosis by hydrogen breath test (HBT). 15 gr of lactulose dissolved in 50 ml of water and 50 gr of lactose, 25 grams of fructose and 15 grams of sorbitol dissolved in 250 ml of water were used for SIBO and LI, FI and SI HBT respectively. The test results were considered positive when hydrogen concentration acceded 10 PPM for SIBO and 20 PPM for LI, FI or SI above baseline.

RESULTS: Out of the 348 patients tested for SIBO and LI, 101 (29%) were positive for both tests. Out of the 197 patients tested for SIBO and FI, 17 were positive for both tests. And finally, out of the 196 patients tested for SIBO and SI, 45 were positive for both tests. Out of the 101 SIBO and LI, 17 SIBO and FI and 45 SIBO and SI positive patients, 82 (81%), 14 (82%) and 23 (53%) respectively had an increase of hydrogen measurement above threshold between 30-90 minutes during their LI/FI/SI-HBT, implying SIBO.
CONCLUSION: The fermentation of lactose, fructose or sorbitol in the small bowel due to SIBO may increase the likelihood of LI, FI and SI incorrect diagnosis. We suggest that all symptomatic patients will undergo SIBO testing and eradication if diagnosed positive, prior to LI, FI or SI HBT evaluation.

P1677 IS A GLUTEN CHALLENGE REQUIRED TO DIAGNOSE ADULT COELIAC DISEASE IN EQUIVOCAL CASES: A SINGLE CENTRE EXPERIENCE OF 'REAL' CLINICAL PRACTICE

S. Raju[1], P.D. Mooney[1], **M. Kurien**[1,*], D.S. Sanders[1]
[1]*Regional GI and Liver Unit, Royal Hallamshire Hospital, Sheffield, United Kingdom*
Contact E-mail Address: *peter.mooney@sth.nhs.uk*

INTRODUCTION: Coeliac disease (CD) is under diagnosed which may result in significant morbidity. The gold standard for diagnosing CD is the demonstration of villous atrophy. However in some cases there is a strong suspicion of CD but histology is normal or equivocal. In these cases the gold standard is a 6 week gluten challenge and repeat duodenal biopsy. To date there is little clinical data reported in the adult literature for outcomes or effectiveness of a gluten challenge outside of research studies. This study aims to determine the clinical utility of gluten challenge and predictive factors that could be used to aid diagnosis.
AIMS & METHODS: We undertook a prospective analysis of all patients who were asked to undertake a gluten challenge over a 5 year period. Data were recorded from referral to outcome. Presenting characteristics, baseline haematinics, tissue transglutaminase (tTG) and endomysial antibody (EMA) and HLA type were recorded prior to gluten challenge. Repeat coeliac serology and biopsy results were then recorded post gluten challenge. CD diagnosis required an appropriate HLA phenotype, positive coeliac serology and deterioration in duodenal histology.
RESULTS: 64 patients (46 female, mean age 48.8, SD 16.5) were reviewed. 4 (6.3%) declined gluten challenge. 42/60 (70.0%) of patients challenged were HLA DQ2 or DQ8 positive (6 homozygous). 21/60 (35.0%) patients were diagnosed with CD and 32/60 (53.3%) had CD excluded. 7/60 (11.7%) patients were diagnosed with potential CD based on an HLA type compatible with CD and positive serology but a normal duodenal biopsy on gluten challenge.
6/60 (10%) were unable to complete the full 6 week challenge (median 14.5 days) due to gluten induced symptoms. A conclusive diagnosis was made in all 6 of these patients.
Gluten challenge caused an increase in tissue tTG of 50.6% ($p = 0.034$) in patients with CD. No cut off for tTG prior to gluten challenge could be used to diagnose CD. Of 30 EMA negative patients prior to endoscopy 6 (20%) became positive on gluten challenge all of whom were diagnosed with CD. A combination of tTG > 20 times the upper limit of normal and a positive EMA prior to challenge ($n = 7$) had a positive predictive value of 85.7%.
There was no difference in presenting characteristics, baseline bloods or demographics between those diagnosed with CD, potential CD or those who had CD ruled out.
CONCLUSION: No presenting characteristics, blood results or genotype could reliably predict a diagnosis of CD. Increased tTG or new EMA positivity on gluten challenge were associated with CD diagnosis. A gluten challenge will ensure the best chance of recognition or exclusion of patients with CD. A 2 week gluten challenge may be sufficient to make conclusive diagnosis. A shortened gluten challenge could reduce the length of distress to patients with significant gluten induced symptoms and ensure prompt diagnosis.

INTRODUCTION: It was reported that involvement of the pancreas, liver and biliary tract, including the gallbladder is rare in patients with celiac disease (CD).
AIMS & METHODS: Our aim to find the prevalance of these involvements by using transabdominal ultrasound (US). Additionally, we further characterized pancreas parancyhmal changes by echoendoscopy (EUS). We evaluated our CD clinic's records which includes 198 patients. We used US to show pancreas, liver and biliary tract abnormalities. Then, patients with pancreas abnormalities were further examined by EUS. Patients with recent onset dyspepsia were used as a control group.
RESULTS: Of the 198 patients with CD, 102 had documented US results. There were 102 patients without CD as a control group. All of the patients, 25% in CD and 33% in control were male ($p > 0.05$). The prevalence of abnormalities as follows: liver steatosis, 46% in CD vs 48% in controls ($p > 0.05$); gallbladder polip, 3.9% in CD vs 6.9% in controls ($p > 0.05$); gallbladder sludge&stone, 4.9% in CD vs 11.8% in controls ($p > 0.05$); hepatomegaly, 2.9% in CD vs 28.4% in controls ($p < 0.001$); gallbladder operation, 5.9% in CD vs 8.8% in controls ($p < 0.001$); gastric antrum wall tickness, 4.9% in CD vs 2.0% in controls ($p > 0.05$); hepatic simple cyst, 3.9% in CD vs 2.9% in controls ($p > 0.05$); hemangioma, 3.9% in CD vs 2.9% in controls ($p > 0.05$); chronic liver disease findings, 5.9% in CD vs 0% in controls (p: 0.014); hepatoportal sclerosis 1.0% in CD vs 0% in controls ($p > 0.05$); pancreas parancyhmal changes, 5.9% in CD vs 0% in controls ($p = 0.029$). EUS investigation was performed in all of the patients with paranchymal changes that were found by US. EUS showed major B or minor findings according to the Rosemont classification. None was autoimmune pancreatitis (AIP). Echoendoscopy findings as follows: main duct and side branch dilation, small cysts, pancreas atrophy, hyperechogen stria and foci. Further analysis of the 6 patients with chronic liver disease showed that none had autoimmune or viral serology. One of them showed grade 1 eosephageal varices with portal hypertensive gastropathy findings.
CONCLUSION: Our results showed that chronic type involvement of the pancreas and liver is significantly frequent in patients with CD. Even, cirrhosis with varices was seen. So, CD might be a cause of cryptogenic cirrhosis. Thus, we consider that pancreas and liver abnormalities were underestimated in clinical practice and should be followed to detect progression.

P1679 DEVELOPMENT OF NOVEL T CELL BASED ASSAYS TO IMPROVE THE DETECTION OF COELIAC DISEASE

M.X. Ma[1,*], G.M. Forbes[1,2], J. Jessica[3], N.M. Keane[3], M. John[3,4]

Contact E-mail Address: *michael.ma@health.wa.gov.au*

INTRODUCTION: Coeliac disease (CD) is an immune disorder characterized by intestinal pathology with systemic manifestations. Accuracy of CD diagnosis is limited by need for continued ingestion of gluten. Unlike antibodies, memory CD4 T cells can be stimulated to proliferate after low levels of antigen exposure *in vivo* (1,2).
AIMS & METHODS: We developed and compared four *in vitro* assays to detect peripheral blood GSTCs in newly diagnosed CD patients. Subjects on a gluten-containing diet had CD diagnosed by positive anti-tissue transglutaminase (tTG) antibody, appropriate histology and expressed HLA alleles DQ2/DQ8. Whole blood (WB) and/or peripheral blood mononuclear cells (PBMCs) were stimulated with coeliac associated antigens (whole gliadin [WG], deamidated gliadin [DG] and tTG) after which cells and supernatants were analysed for: CD4 T cell expression of lymphocyte activation markers (CD134/CD25), soluble Ox40 ligand (sOx40L) by ELISA, Th1, Th2 and Th17 cytokines (IL-6, TNFα, and IL-17α) by Cytokine Bead Array (CBA) and CD antigen specific cytokine secreting cells from cryopreserved PBMCs by TNFα ELISpot assay.
RESULTS: Six patients with CD and three patients without CD were studied. Detection of % CD4+CD134+CD25+ T cell levels above baseline were present to at least one CD antigen (medians: WG 0.09%, DG 0.04%, tTG 0.11%) in four patients with CD and one patient without CD to antigens DG (0.11%) and tTG (0.13%). sOx40L levels were detected in three patients with CD and one patient without CD. The CBA assay showed increased levels of TNFα to DG antigen in four CD patients (baseline 6.9 pg/ml; stimulated median 13.8 pg/ml, range 7.0-24.2 pg/ml), increased levels of IL-6 to WG antigen in three CD patients (baseline 98.5 pg/ml; stimulated median 130.7 pg/ml, range 101.8-226.1 pg/ml), and increased levels of IL-17α to WG antigen in two CD patients (baseline undetectable; stimulated median 26.6 pg/ml, range 23.9-28.6 pg/ml). However in patients without CD, increased IL-6 and IL-17a levels were also detected whereas TNFα was not, suggesting it may be a more suitable cytokine marker for patients with CD. DG stimulated T cell secretion of TNFa was detected in three CD patients by TNFa ELISpot assay (baseline 6.7 SFU/million cells; stimulated median 49.7 SFU/million cells, range 4.7-55.8 SFU/million cells), whilst no patient without CD had detectable responses.
CONCLUSION: GSTCs can be detected in the peripheral blood of patients with CD using methods to measure memory T cell responses to coeliac associated antigens. Such assays have potential for implementation into future CD diagnostics, but will need improved performance characteristics to be clinically useful.

INTRODUCTION: Coeliac disease (CD) is a genetically determined autoimmune condition, with an estimated worldwide prevalence of 1%. It is believed to be the result of an abnormal autoimmune response in susceptible individuals to dietary gluten derived from wheat, rye and barley. Disease phenotype can be

mainly classiffied as typical and atypical. Typical CD patients are defined as patients having diarrhea as predominant symptom.
AIMS & METHODS: The evidence for reduced bone mineral density (BMD) in CD is well known although it is not known whether there is a difference between disease phenotypes. This study has aimed to compare bone mineral densities of typical and atypical CD patients.
Between February 2008 and April 2014, 102 patients with CD were prospectively included into the study. After serologic screening of CD by antigliadin antibody (AGA) IgA, AGA IgG and antiendomysium antibody (EMA), duodenal biopsies were obtained once a positive serology has been reported to confirm the diagnosis. Typical CD patients are patients presenting with diarrhea and patients referring with complaints other than diarrhea are classified as having atypical CD. Both groups are evaluated in terms of BMD results and routine biochemistries.
RESULTS: A total of 102 patients with CD were included in this study. Patients were assigned into two groups as atypical and typical form of CD. Comparision of mean biochemistry parameters and bone mineral density in patients with typical and atypical celiac patients are shown in Table 1.
Table 1: Comparision of mean biochemistry parameters and bone mineral density in patients with typical and atypical celiac patients.

	Typical (n = 38)	Atypical (n = 64)	P
Age (years)	35.42±11.31	34.76±12.15	NS
Body Mass *I*ndex kg/m^2	21.36±4.02	23.38±4.64	NS
Hip T score	-1.26±1.04	-0.89±1.05	NS
Vertebral body T score	-1.64±1.34	-0.99±1.17	<0.05
Serum Calcium (mg/dl)	9±0.62	9.09±0.71	NS
Serum Phosphorus (mg/dl)	3.57±0.55	3.39±0.636	NS
25-hydroxyvitamin D (ng /ml)	16.04±11.8	15.96±8.68	NS
Parathyroid Hormone (pg/ml)	100.92±78.6	68.4±46	<0.05

CONCLUSION: Low BMD, osteopenia, and osteoporosis are frequent complications of CD. In this study vertebral T score was found to be significantly lower and parathyroid hormone levels significantly higher in typical CD patients. Calcium malabsorption seems to play an important role in low bone mineral density in CD but the apparent difference between typical and atypical CD patients suggest there should be another mechanism in typical CD.

INTRODUCTION: BACKGROUND: Several studies have shown that weight changes are common in patients affected by coeliac disease (CD) after the adoption of a gluten-free diet (GFD). However data on the prevalence of metabolic syndrome (MS) and hepatic steatosis (HS) in patients with CD on free diet and after GFD are still scarce.
AIMS & METHODS: 1) to assess the prevalence of MS in CD patients at time of diagnosis and 1 year after starting GFD 2) to evaluate the prevalence of HS in CD patients before and after GFD. Between January 2011 and March 2013, we enrolled all consecutive patients with newly diagnosed CD who were referred to our third-level CD Unit. All patients were investigated about waist circumference with BMI, blood pressure, lipid profile (HDL cholesterol, triglycerides), levels of glucose, aspartate (AST, U/l), alanine aminotransferase (ALT, U/l) and HS. MS diagnosis was made according to International Diabetes Federation criteria (IDF) for European countries. HS diagnosis was performed by ultrasonography (US) in accordance to the current literature. The prevalence of MS and HS was revaluated after 12 months of GFD. Statistical analysis was performed by using X^2, Mann-Whitney U test, Wilcoxon signed-rank test and odd ratio (O. R.) when indicated. The differences were considered significant with a $p < 0.05$.
RESULTS: Finally, 98 CD patients (29 men, 69 women; mean age: 35.7 years) were analysed at diagnosis and after 1 year of GFD. At diagnosis, only 2 CD patients (2%) fulfilled the criteria for MS while 29 patients (29.5%) met the diagnostic criteria of MS after 12 months of GFD ($p<0.01$; O. R. 20). The comparison of MS sub-categories 1 year after GFD respect to the baseline showed that 72 *vs* 48 patients exceeded waist circumference cut-off ($p<0.01$; O. R. 2.8), 18 *vs* 4 patients showed high values of blood pressure ($p<0.01$; O. R. 5.2), 25 *vs* 7 patients exceeded glycemic threshold ($p=0.01$;O. R. 4.4), 34 vs 32 CD patients had reduced levels of HDL cholesterol ($p=0.7$) and 16 *vs* 7 patients had high levels of triglycerides ($p=0.05$). Mean BMI increased after GFD initiation (22.9 kg/m^2 *vs* 24.1 kg/m^2; $p=0.01$). At time of CD diagnosis, 18 out of 98 patients showed HS at US (18%). One year after starting GFD, 28 out of 98 patients showed HS (18% vs 28.5%; $p=0.1$); HS was present in 19 out of 29 patients with MS and 9 of 69 CD patients without MS (65% vs 13%;$p<0.01$;O. R.19).
CONCLUSION: CD patients show a high risk of MS and HS 1 year after starting GFD. We suggest a deep nutritional assessment at diagnosis and during the follow-up of patients affect by CD.

P1682 LEVEL OF ANTI-TRANSGLUTAMINASES IN PREDICTING THE MARSH GRADE FOR THE DIAGNOSIS OF ADULT CELIAC DISEASE

R. Tortora[1,*], N. Imperatore[1], P. Capone[1], G. De Stefano[1], G.D. De Palma[1], N. Caporaso[1], A. Rispo[1]
[1]*Clinical Medicine and Surgery, Federico II University of Naples, Naples, Italy*

INTRODUCTION: The new ESPGHAN guidelines for diagnosis of pediatric celiac disease (CD) suggest to avoid intestinal biopsy in genetically predisposed and symptomatic individuals with positive anti-endomysial antibodies (EMA)/ anti-tissue transglutaminases (a-tTG). On the other hand, duodenal biopsy (in combination with positive a-tTG and EMA) remains the *gold standard* in adults with suspected CD.
AIMS & METHODS: To assess the cut-off values of a-tTG able 1) to predict the presence of a duodenal histology (Marsh ≥2) diagnostic for CD; 2) to predict the presence of villous atrophy (Marsh 3) in CD. From September 2011 to March 2014 we performed an observational prospective study including all consecutive adult patients referred to our third-level centre for suspected CD. All subjects were tested for EMA (absent/present) and a-tTG (U/ml). All patients with positive antibodies underwent upper endoscopy with duodenal biopsies/histology. CD diagnosis was made in presence of Marsh ≥ 2 histology associated with both a-tTG IgA > 7 U/ml and positive EMA. Furthermore, a ROC curve was constructed in order to detect the best cut-off of specificity of a-tTG level able to predict the presence of Marsh ≥ 2 and Marsh 3 on duodenal histology. Sensitivity, specificity, PPV and NPV of a-tTG level were calculated by using SPSS statistical software. In addition, the presence of any disease other than CD found on upper endoscopy was recorded.
RESULTS: The study included 310 patients with suspected CD (M/F: 35%/ 65%; mean age 33.6 years) in presence of both positive EMA and a-tTG. Final histology showed: Marsh 1 in 27 patients (8.7%), Marsh 2 in 11 subjects (3.5%) and Marsh 3 in 272 cases (87.7%). The best cut-off value of a-tTG in predicting Marsh ≥2 histology was 45 U/ml (sensitivity 70%; specificity 100%; PPV 100%; NPV 79%) while the best cut-off in predicting villous atrophy (Marsh 3) was 62.4 U/ml (sensitivity 69%, specificity 100%; PPV 100%; NPV 31%). In addition, we found other endoscopic findings: reflux-related esophagitis in 38 patients (12%), hiatal hernia in 45 cases (14%), mild/superficial gastritis in 113 subjects (36%), atrophic gastritis in 5 cases (1.6%).
CONCLUSION: CD diagnosis could be performed without biopsy/histology in adult patients with positive EMA and a-tTG levels > 45 U/ml. A a-tTG level > 62.5 is diagnostic for villous atrophy. These results could improve the diagnostic work-up of CD with a significant reduction of diagnosis-related costs.

P1683 PERSISTENCE OF VILLOUS ATROPHY AND IRON-DEFICIENCY ANEMIA IS FREQUENTLY OBSERVED IN ADULT PATIENTS WITH CELIAC DISEASE AFTER AT LEAST ONE YEAR OF GLUTEN FREE DIET

R. Saadi[1,*], G. Malamut[1], G. Rahmi[1], E. Samaha[1], C. Cellier[1]
[1]*gastroenterology, hôpital européen georges pompidou, Paris, France*
Contact E-mail Address: *saaderoula@hotmail.com*

INTRODUCTION: Iron-deficiency anemia is a frequent manifestation of celiac disease (CD), often leading to the diagnosis of the disease. Few studies look at the evolution of anemia after a gluten free diet (GFD). The persistence of villous atrophy (VA) and its connection to the improvement of anemia was also rarely studied.
Goal of our work: to describe the incidence of anemia with hypoferritinemia after at least a year of GFD in patients with CD, depending on the presence or absence of persistent VA.
AIMS & METHODS: In a cohort of 655 patients with a diagnosis of CD, followed at the Hôpital Européen Georges Pompidou in Paris, France between the year 2000 and 2012, we have analyzed 262 patient records, (40% of the cohort), of which 158 had duodenal biopsies after at least a year of GFD (after excluding all patients with refractory celiac disease) and 120 patients had a hemoglobin level before and after a GFD.
RESULTS: Among the 120 patients with available hemoglobin levels before and after GFD (98 women, 22 men, mean age of diagnosis 28 yrs.), 46 (38.3%) had anemia at the time of diagnosis (40.8% of women and 27.27% of men). After a year of GFD, 27 (22.5%) had persistent anemia.
Among the 158 patients with available duodenal biopsies after at least a year of GFD (122 women, 36 men, mean age of diagnosis 28 yrs.), 70 (44%) had persistent VA, varying from partial to subtotal, after GFD, and 88 (56%) showed no more atrophy. Anemia was found in 20 patients (28.57%) with persistent VA, and in 11 patients (12.5%) who had villous regrowth ($p=0.015$; OR: 2.78). Hypoferritinemia was found in 23 patients (33%) with persistent atrophy, and in 21 patients (24%) with villous regrowth ($p=0.217$; OR: 1.55). Consistent observance of GFD was found in 48 patients (69%) with persistent VA, and in 62 patients (71%) without atrophy (NS). Among the 20 patients with residual atrophy and anemia, 9 patients (45%) had inadequate GFD observance.
CONCLUSION: After at least a year of GFD, 22.5% of the patients in our series had iron-deficiency anemia, and 44% had persistence of VA (after excluding refractory CD). Some involuntary errors in GFD might explain this finding in 30% of cases, but there seem to appear a subgroup of patients who have no villous regrowth and have more frequent iron-deficiency anemia in spite of strict

GFD. These patients might beneficiate from intravenous iron therapy. The future and follow-up of these asymptomatic patients, but with no villous regrowth, needs to be evaluated, particularly regarding concerns of lymphomatous complications (1).

P1684 RAISED INTRAEPITHELIAL LYMPHOCYTES IN THE PRESENCE OF NORMAL SMALL BOWEL MUCOSA: CONFIRMATION OF COELIAC DISEASE IN CLINICAL PRACTICE

S. Subramaniam[1,*], A. Joshi[2], K. Besherdas[1]
[1]*Department of Gastroenterology,* [2]*Department of Histopathology, Barnet & Chase Farm Hospitals NHS Trust, London, United Kingdom*
Contact E-mail Address: *sharmila.subramaniam@nhs.net*

INTRODUCTION: Raised intraepithelial lymphocytes (IEL) (>30-40 IEL/100 enterocytes) in small bowel (SB) mucosa is most commonly associated with coeliac disease (CD) when accompanied by distorted villous architecture. In addition to CD, there are various other causes of raised IEL including NSAIDs, autoimmune conditions, tropical sprue, H pylori associated gastritis, parasitic or viral infections and intestinal lymphoma. It is recommended that patients who have raised IEL without distorted villous architecture (Marsh classification Stage 1 criteria) undergo further serological testing along with HLA DQ2/DQ8 genotyping to assist in the diagnosis of CD.

AIMS & METHODS: The aim of the study was to determine the further assessment in clinical practice of patients with raised IEL in otherwise normal SB biopsies to confirm the diagnosis of CD.

A single centre, retrospective analysis of patients with the histological finding of raised IELs on distal duodenal (D2) biopsies in a district general hospital in north London over a two year period between March 2012 and March 2014 was performed. A database of patients with raised IEL was obtained from the hospital histology database and data on the patients coeliac antibody result, symptoms, diagnosis and management was scrutinized using the hospital's electronic patient record system.

RESULTS: 121 patients had raised IEL on D2 biopsy specimens. 58 of these patients had a confirmed diagnosis of CD with villous atrophy. The remainder (63) had raised IEL with preserved villous architecture. 48/63 patients were negative for coeliac antibodies, 1 was positive and 14/63 (22.2%) were not tested. 15/63 (23.8%) were initiated on a gluten free diet and of this, 4 did not report an improvement in their symptoms despite adherence to the diet. Only 2 patients had HLA DQ2/DQ8 testing to aid in the diagnosis of CD. A final diagnosis of CD was made in 11/63 (17.5%) patients meeting Marsh 1 criteria. 32/63 (50.8%) patients had a diagnosis of gastrooesophageal reflux disease (GORD) including 10 patients (15.9%) with H pylori associated gastritis. H pylori was not tested in 13/32 patients with GORD (40.6%). A third of patients (20/63 = 31.7%) with raised IEL and normal SB mucosa did not undergo any further specific investigation to elucidate the cause of the raised IEL.

CONCLUSION: We conclude that there is marked variability in management of patients following the findings of raised IEL with normal SB mucosa. A fifth of patients did not have coeliac antibody tested and only 2 patients had HLA DQ2/DQ8 genotype assessment to affirm or deny association with CD. Latent CD was diagnosed in almost a fifth (17.5%) of patients with raised IEL and preserved villi. GORD and H pylori gastritis were present in half of the patients with this histological finding. We recommend that all patients in whom raised IEL is identified have coeliac serology and HLA DQ2 DQ8 testing to exclude CD prior to entertaining other diagnoses in clinical practice.

INTRODUCTION: Whipple's disease (WD) is a rare chronic systemic disorder caused, in genetically predisposed subjects, by *Tropheryma whipplei*, a common bacterium widespread in the environment [1]. The relevance of genetic predisposition in WD is shown by the association with HLA alleles DRB1*13 and DQB1*06 and by the demonstration that in patients with WD the cytokine genetic profile is skewed toward a Th2 and Treg response [2,3]. Since IL-16 is involved in hampering the development of a protective macrophagic response against *Tropheryma whipplei* [4], we investigated whether the genetic background of IL-16 is different between patients with WD and controls.

AIMS & METHODS: Thanks to the European Consortium on WD (QLG1-CT-2002-01049), rs 4778889, a polymorphism of the promoter region of IL-16 gene, was studied in 80 patients with WD and in 74 healthy controls using the PCR-real time technique; the frequencies of alleles and genotypes were then compared. Levels of serum IL-16 protein were also tested by means of an ELISA technique in samples from the same 74 healthy controls; a possible relationship between genotype and levels of serum IL-16 was investigated.

RESULTS: The wild type T allele was found in 138/160 (86%) patients with WD and 114/148 (77%) controls (p = NS for Chi squared test). TT genotype was found in 58/80 (72.5%) patients with WD and 44/74 (59.5%) controls (p = 0.08 for Chi squared test); no relationship was found between levels of serum IL-16 and genotypes.

CONCLUSION: IL-16 gene polymorphisms have already been found associated with different diseases [5]. Despite this, a relationship has not yet been found between types of polymorphism and serum levels of IL-16 protein. Although TT genotype seems to be more frequent in patients with WD than in controls, our results did not reach statistical significance and do not support an association. These very preliminary results need to be expanded to hopefully reach statistical significance.

INTRODUCTION: Bile acid diarrhoea (BAD) is a common and less acknowledged cause of chronic watery diarrhoea. The 7-day radiolabled ^{75}Selenium homocholic acid taurine (SeHCAT) test is not generally available, and it is cumbersome and expensive. Patients suffering from undetected BAD have a poor quality of life and are withheld effective therapy with sequestrants. New insight into the regulation of bile acid physiology have identified fibroblast growth factor FGF19 as one possible marker of BAD and demonstrated a correlation with SeHCAT. FGF19 concentrations are easily measurable but subject to diurnal variation and postprandial increase. Further studies of FGF19 as a test for BAD therefore are warranted.

AIMS & METHODS: To confirm the association between SeHCAT and FGF19 in a prospective patient series, to examine the inter- and intra-individual variation and effect of cholecystectomy on FGF19 levels, and to explore whether the overlap between normal and individuals with BAD could be reduced by measuring the meal induced change in FGF19. FGF19 was measured by commercially available quantitative sandwich enzyme immunoassay technique before and one hour after meals and after 1 week in healthy volunteers, in patients with previous diagnosed BAD or cholecystectomy, and in consecutive patients referred to SeHCAT. The median (range) FGF 19 values are given as pg/mL. No correction for cholesterol values or weight was performed. The interassay variation was 9.6 % in our laboratory.

RESULTS: The results are depicted in the table. The median FGF19 was lower for patients with BAD with a wide overlap. The least squares linear correlation coefficient r = 0.5 for the relation between SeHCAT and FGF19 in the prospective series in which the breakfast induced increase in FGF19 did not differ significantly (Mann-Whitney). Neither single values nor meal induced changes in FGF19 could predict or rule out BAD. The inter-individual variation of fasting FGF19 values in all 56 participants was large.

Before lunch	**134** (86 – 236)	**75** (21 – 210)	**108** (69 – 1102)	n.a.	n.a.
Change after lunch	**26** (-15 – 105)	**8** (-71 -51)	**7** (-143 – 76)	n.a.	n.a.
Diff. between fasting values	**44** (-211 – 294)	**13** (183 – 593)	**10** (-150 – 245)	**4** (-21 – 135)	**4** (-220 – 245)

CONCLUSION: While the overall results confirm that FGF19 is lower in patients with BAD, the inter- and intra-individual variation of FGF19 is large. Neither fasting nor single postprandial values of BAD could identify patients with BAD. The utility and timing of FGF19 values as a diagnostic test for BAD using a more powerful and uniform stimulation of the bile acid transporter should be tested. Analysis of area under the curve of FGF19 values following stimulation and combination with other markers such as C4 should be included.

INTRODUCTION: Food intolerances are a major complaint in IBS. Fructose intolerance prevalence in IBS is up to 70%, but the causative mechanism is unknown (1). Fructose is transported across the intestinal epithelia by glucose transporters 5 (GLUT5, Slc2a5) and 2 (GLUT2, Slc2a2) in the apical and basolateral membranes, resp.(2). In mice, deletion of GLUT5 resulted in malabsorption of dietary fructose and typical signs of intolerance (3). Several of the postulated underlying mechanisms in IBS, e.g. inflammation and stress, reduce GLUT5 expression (2) Recently, no group differences in GLUT5 and GLUT2 protein and mRNA expression in IBS patients with fructose intolerance and controls were shown (4).
AIMS & METHODS: To further analyze the relationship between fructose-associated symptoms in IBS patients with malabsorption, a correlative analysis with GLUT5 and GLUT2 protein and mRNA expression levels was performed. Duodenal biopsies were obtained in 11 male or female IBS patients with fructose malabsorption and intolerance, diagnosed by breath testing after 8h fasting and ingestion of 35g fructose. Malabsorption was characterized by an increase of $H2 > 20$ppm or $CH4 > 10$ppm in breath and intolerance was defined by a positive GI-symptom index within 5h of fructose ingestion. 15 matched healthy subjects aged between 18 and 60 years were used as controls. Coeliac's disease and IBD were excluded. mRNA for GLUT5 and GLUT2 was quantified by multiplex RT-qPCR, and expressed as a ratio of β-actin. GLUT5 and GLUT2 protein expression level were determined by Western Blot relative to alpha-tubulin. Analysis was by Spearman Rank correlation and Mann-Whitney test for group comparisons.
RESULTS: The maximum H2 and CH4 concentrations across all individuals did not correlate with either GLUT5 or GLUT2 mRNA or protein expression levels ($r < 0.14$, $p > 0.48$). There were no significant group differences in GLUT5 mRNA expression levels between fructose intolerant IBS patients (median: 0.18 (IQR 0.13-0.21)) and controls (0.17 (0.12-0.19))($p > 0.05$). Respective GLUT2 mRNA expressions were 0.26 (0.20-0.31) and 0.26 (0.19-0.31)($p > 0.05$). There were also no significant group differences in GLUT5 protein expression between patients (0.95 (0.52-1.68) and controls (0.95 (0.59-1.15))($p > 0.05$). Respective GLUT2 protein expression levels were 1.56 (1.06-2.14) and 1.35 (0.96-1.79)($p > 0.05$).
CONCLUSION: Duodenal GLUT5 and GLUT2 mRNA and protein expression did not correlate with fructose malabsorption characterized by classic breath testing, and did not differ significantly between fructose-intolerant IBS patients and healthy controls. Our results suggest that human fructose intolerance or malabsorption may not be associated with marked changes in GLUT5 and GLUT2 mRNA and protein expression.

P1688 HEADACHE DURING LACTOSE BREATH TEST: IS THERE ANY RELATIONSHIP?

F. Del Zompo[1,*], F. Mangiola[1], D. Feliciani[1], T.A. Di Rienzo[1], G. D'Angelo[1], A. Gasbarrini[1], V. Ojetti[1]
[1]*Department of Internal Medicine, Gastroenterology Division, Policlinico A. Gemelli, Rome, Italy*

INTRODUCTION: Lactose malabsorption (LM) consists of the incomplete absorption of lactose, mainly due to lactase deficiency on the brush border. While generally well-tolerated, a certain rate of lactose malabsorbers may experience symptoms (diarrhoea, abdominal pain, bloating, and flatulence) characterizing the so-called lactose intolerance (LI). Therefore, LI commonly shows a clinical overlap with Irritable Bowel Syndrome (IBS). Headache affects IBS patients with an estimated OR of 2.66 according to previously published studies, showing a range of similar comorbidities such as fibromyalgia, depression, insomnia. Thus, several authors support the idea that both headache and IBS are central pain-related disorders. We investigate the onset of headache during the LBT, and a possible correlation with lactose malabsorption.
AIMS & METHODS: We enrolled 93 (74 F/19 M; mean age 42±15 yrs) outpatients who perform a LBT in our Gastroenterology Unit according to the guidelines. Patients were asked to report on a Visual Analogue Scale the intensity of usual headache, before lactose administration and after the end of the test. We considered as significant an increase of headache in VAS peak during the test > 10 mm (dVAS). A positive LBT was considered with a peak > 20 ppm in H_2 excretion over baseline. Statistical analysis was performed with Pearson's correlation test and with χ^2 test.
RESULTS: 67 out of 93 (72%) patients result lactose malabsorbers, while 53% (49 out of 93) referred a headache worsening. Within the group of lactose malabsorbers, headache worsened in 50.7% patients compared to 57.7% in non-malabsorber subjects ($p = 0.36$). More interestingly, we observed that in the subgroup of patients with a habitual headache (VAS > 30 mm; 41 subjects) there is a significant worsening of headache during the test compared to the subgroup with a non habitual headache VAS ≤30 mm (70.7% vs 38.5%; $p = 0.003$), regardless of the breath test result. A significant correlation was observed between habitual-headache VAS and headache-during-the-test VAS ($r = 0.313$; $p = 0.02$). No significant correlations were observed between the VAS increase and H_2 nor CH_4 excretion.
CONCLUSION: We did not find any correlation between headache and lactose malabsorption. Although, we observed that the majority of patients undergoing a LBT complain of headache and the rate dramatically increases among the patients usually suffering from headache. We are not able to determine whether the onset of headache or its deterioration are linked to the load of lactose or prolonged fasting. We think that this data should be taken into account, since we suppose that the onset of clinically relevant headache during a LBT could affect compliance in the correct execution of the test and maybe lead to an overestimation of classic LI symptoms. Moreover, the onset of headache might be a cause of premature suspension of LBT.

P1689 PERCEPTION OF LACTOSE INTOLERANCE IMPAIRS HEALTH RELATED QUALITY OF LIFE

F. Casellas[1,*], A. Aparici[1], P. Rodríguez[1]
[1]*Digestive System Research Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

INTRODUCTION: Changes in health impacts well-being, which is perceived as an impaired health related quality of life (HRQOL). It is debated whether adult lactose malabsorption is a normal situation or a pathological condition. In any case, the symptoms that people attribute to lactose intolerance or malabsorption have great relevance as they are associated with a lower consumption of calcium/vitamin D and a lower bone density. In addition, it is not known if malabsorption or intolerance to dairy products is associated with a loss of HRQOL.
AIMS & METHODS: Our aim was to determine the HRQOL based on the perception of tolerance to lactose and on the objective determination of the absorption of lactose. METHODS: Prospective, observational, cross-sectional study in a cohort of patients referred to assess absorption of lactose. After signing the informed consent, patients completed a validated questionnaire to determine the perception of symptoms of intolerance during their regular consumption of dairy products at home and a visual analogue scale 0-100 generic measure of quality of life (VAS). Afterwards, a standardized hydrogen breath test with 50 g lactose was performed. At the end of the breath test, the questionnaire was administered again to determine the intensity of symptoms after the lactose overload in the lab.
RESULTS: 173 patients were included (median age 42 y, F/M 132/41). 77 (44 %) of patients considered themselves lactose intolerants and that perception was associated with avoidance of dairy consumption (56 % of self-defined intolerants avoid dairy intake vs only 6 % of self-defined tolerants). Self-perception of intolerance was associated with lower scoring of the VAS (median of 60 vs 70 scored by tolerant, $p < 0.01$). In contrast, lactose malabsorption established by a positive hydrogen lactose test was not associated with dairy avoidance (36 % of malabsorbers avoid dairy vs 32 % of absorbers). However, scoring of VAS was also significantly lower in malabsorbers than in absorbers (60 vs 70 respectively, $p < 0.001$).
CONCLUSION: Subjective perception of lactose intolerance affects the decision to avoid dairy even more than objective malabsorption. However, both the self-perception of lactose intolerance and the objective lactose malabsorption are associated with poorer perceived quality of life.

INTRODUCTION: Cholelithiasis, is defined as the presence of stones in the gallbladder, is one of the most common digestive diseases, affecting 9-19 % of the general population, with a female prevalence. The most common symptom is postprandial biliary colic, characteristic for localization, duration and intensity. Cholecystectomy, usually laparoscopic, is the definitive treatment of choice. The altered composition and excretion of bile in the duodenum is very irritating to the lining of the intestines, altering the brush border with a possible interference on the lactose absorption.
AIMS & METHODS: The aim of this study was to assess the prevalence of lactose malabsorption through a H2/CH4 lactose breath test (LBT) in subjects affected by gallstones.
Twenty (4M/16F; mean age 55±8 yrs) subjects, which would undergo cholecystectomy in the following month for gallstones, have performed a H2/CH4 LBT in our Gastroenterology Unit according to the guidelines. We have considered a positive LBT when there was a peak > 20 ppm over baseline.
RESULTS: 14 out of 20 (70%) pts resulted lactose malabsorbers with a mean peak value of H2 of 73±23 ppm.

The most interesting data was that 90% (18/20) of these pts produced high levels of CH4, with a mean basal value of 8±5 ppm and a mean peak value of 28 ± 12 ppm.
CONCLUSION: We found a high prevalence of lactose malabsorption in pts affected by gallstones, confirming the hypothesis that an alteration of bile composition could destroy the lactase enzyme on the brush border.
The high prevalence of methanogenic flora observed in these pts could be a cause or a consequence of the formation of gallbladder stones. Further studies are needed to better understand this interesting findings.

INTRODUCTION: Gluten is the main protein complex of wheat and represents a complex substance on both chemical and genetic grounds. The exposure to gluten in genetically predisposed subject determines the onset of celiac disease, a frequent condition characterized by increased comorbidity and mortality. However, gluten exposure may cause a spectrum of disorders, involving different organs and recently it was suggested to be responsible for a condition characterized by a complex clinical presentation involving both the intestinal tract and extraintestinal organs defined non celiac gluten sensitivity (NCGS) (1). Besides un unblinded evaluation of intestinal fermentation (2), in healthy volunteers (HV) the response to a gluten-containing (GCM) in comparison to a gluten-free meal (GFM) was not yet evaluated.
AIMS & METHODS: Therefore, in a group of HV, we analyzed the effect of a GCM and a GFM on gastric and gallbladder emptying time and intestinal fermentation.
In a group of 40 HV a preliminary evaluation of gluten recognition in the meal was performed. Then 18 HV (6 female, median age 25.7±2.4 ys, range 21-29) on separate days at least ten days apart, underwent ultrasonographic measurement of gastric and gallbladder emptying time after a GCM and a GFM. In 16 HV (11 female, median age 24.5±3.2 ys, range 21-30) measurement of breath hydrogen excretion (sampling every 15 min for 7 hours) after a GCM, a GFM and after a GFM added of powdered gluten was performed in order to evaluate intestinal fermentation. All the evaluations were performed in a random order, according to a crossover protocol. Presence and severity of symptoms were monitored during all the tests with VAS (0-10).
RESULTS: The recognition of GCM and GFM was similar (21/40 versus 23/4, p = NS). After GCM, presence and severity of symptoms was similar than after GFM. After both meals, the mean parameters of gastric and gallbladder emptying were similar. Hydrogen peak (12.5±7.3 vs 6.5±5.1 ppm, $p<0.01$) and cumulative breath excretion (2139±1720 vs 989±680 ppm x min, $p<0.01$) was significantly higher after GCM than after GFM. Adding gluten powdered to GFM did not modify intestinal fermentation (peak of breath H2 4.4±1.8 ppm, AUC 984±342 ppm x min).
CONCLUSION: Gluten doesn't modify gastric and gallbladder kinetics, but induces differences in the fermentation process at colonic level even if it didn't increase the symptoms. It is possible that, at least in a subgroup of patient, alterations of visceral sensitivity may represent a co-factor in the pathophysiology of symptoms after gluten ingestion.

INTRODUCTION: Olmesartan is an angiotensin-II antagonists use in the treatment of arterial hypertension. In 2012 it was described the first case of spruelike enteropathy related to this antihypertensive.
AIMS & METHODS: To present 4 cases that are clinical and histological compatible (figure 1) with spruelike enteropathy related to olmesartan. The clinical characteristics and evolution of patients are summarized in table 1.
RESULTS: The 4 cases presented the clinical features of the entity described as olmesartan spruelike enteropathy, with chronic diarrhea, associated clinical manifestations, injury to the duodenal mucosa and especially by clinical and histopathologic improvement after the removal of olmesartan.
Clinicians should be aware of olmesartan as a potential drug than can cause severe chronic diarrhea and severe spruelike enteropathy.

INTRODUCTION: Bile acid diarrhoea (BAD) associated to diseases other than those of the ileum is known as BAD type 3. A variety of diseases are known to be associated with bile acid diarrhoea type 3, though the mechanisms are not always well understood. There is a degree of awareness of BAD in the context of post-cholecystectomy diarrhoea and microscopic colitis, and these predisposing conditions have been included in previous studies. However, where BAD is not idiopathic, there is less information as to the prevalence of reduced bile acid turnover rate (as measured by the ^{75}SeHCAT test) in other diseases.
AIMS & METHODS: Our aim was to study a population with BAD, with special consideration for bile acid turnover rates of those with amyloidosis, pancreatic disease, upper gastrointestinal (GI) resection (not including the ileum) and GI radiotherapy. These represent conditions known or suspected to be associated with BAD, but where the investigation by the ^{75}SeHCAT test is not commonly considered. Medical records in patients investigated with ^{75}SeHCAT for chronic diarrhoea at a large tertiary hospital since 1989 were reviewed, and any patients with the diagnoses above noted. The ^{75}SeHCAT of these patients was compared to 29 previously published healthy controls, both as a unified group and as individual diagnostic groups using Mann-Whitney U. ^{75}SeHCAT retention on day 7 (S7) < 10% was considered abnormal.
RESULTS: Despite the small number of patients referred with the aforementioned diagnoses, all diagnoses showed significantly lower ^{75}SeHCAT retention than controls. Median S7 values were significantly lower in all groups other than amyloidosis. However, the patients with amyloidosis exhibited universally low retention.

Table to abstract P1692
Table 1 Clinical characteristics and evolution. VA, villous atrophy; CH, crypt hyperplasia; IEL, intraepithelial lymphocytes

Age	Sex	Weight loss (kg)	Doses (mg)	Years of treamtent	Evolution after drug withdrawal	HLA	Duodenal histology at diagnosis	Duodenal histology after drug withdrawal	Colon histology
78	F	22	40	2	Improvement	DQ2 DQ8	Total VA total and IEL	Partial VA and few IEL	Nonspecific inflammation
59	M	20	40	5	Improvement	DQA1 DQB1	Total VA, IEl, CH, eosinophilia and lymphoid follicular hyperplasia	Remission of atrophy	Collagenous colitis
69	M	15	40	3	Improvement	DQA1 DQB1	Partial VA	Histological improvement	Not performed
53	F	12	40	1,5	Improvement	DQA1 DQB1	Partial VA, IEL, CH	Pending outcome	Pending outcome

Diagnosis	Number of patients with 75SeHCAT < 10%	Median 75SeHCAT (10th, 90th percentile)	Mann-Whitney U	Median age at investigation (years)	RR (95% CI)
Upper GI surgery (n = 41)	14	15.0* (3.6, 48.2)	266 (Z = -3.917)**	53	5.0 (1.2-20.1)
GI radiotherapy (n = 29)	17	7.0* (0.1, 30.0)	82.5 (Z = -5.258)**	69	8.5 (2.2-33.5)
Pancreatic disease (n = 25)	14	9.0* (0.6, 43.8)	102 (Z = -4.520)**	54	8.1 (2.0-31.3)
Amyloidosis (n = 6)	5	1.7 (0.01, n/a)	172 (Z = 3.722)**	54	12.1 (3.0-48.2)

CONCLUSION: Patients with amyloidosis, chronic pancreatitis, upper GI surgery and GI radiotherapy showed significantly lower ^{75}SeHCAT retention than healthy controls. These predisposing conditions remain rare causes of referral for the ^{75}SeHCAT test, and bile acid diarrhoea may be underdiagnosed in the context of these diseases.

INTRODUCTION: Recently, a new test has been integrated for the noninvasive diagnosis of hypolactasia disease. This test analyze urine D-xylose after lactase cleavage of a lactose analogue 4-galactosylxylose (Gaxilose).
AIMS & METHODS: Evaluate the diagnostic performance of the method compared to the most widely accepted, hydrogen breath test with lactose. Genetic testing of hypolactasia was also assessed. Determinate the clinical tolerance of these methods and the patient acceptance.
A prospective study of patients with clinical symptoms suggesting lactose intolerance was performed. Hydrogen breath test was carried out after 50 g of oral lactose. Malabsorption was considered as an increase of 20 ppm over the basal level. A Gaxilose test was performed by the measure of five hours urine D-xylose after 0.45 g of oral Gaxilose. Hypolactasia was considered when the level of D-xylosa was lower than 37.87 mgr. The study was completed with the analysis of the polymorphism of the gene 13910 (CC associated with hypolactasia).
Furthermore, every patient fulfilled a previously validated symptom score, that consist of a 5 items-scale from 0 to 10, in relation with milk intake and analyzed by both diagnostic tests. Finally, each patient chooses their preferred test.
RESULTS: In our study, 31 patients were included (24 women, average age: 34.5 years). Twenty-eight patients who meet all the requirements were analyzed. According to the hydrogen test, 50% of the patients (14/28) were diagnosed of malabsorption. The rest of them were negative for the test, five patients were non-hydrogen producers. A lower percentage of hypolactasia was achieved with Gaxilose test, 35.7% of the patients (10/28). The same conclusion was obtained in 22 patients (78.6%) using both tests. Gaxilose test could detect hypolactasia in one of the five non-hydrogen producer patients and it excluded this possibility in the other. The results were different in the other five patients (17.9%): two of them were probably a false positive of the hydrogen test. The other three patients were false negative of Gaxilose test, with urine D-xylosa level above and close to the cut-off (39.2-40.2 and 41.9 mg). In our experience the cut-off 41.9 mg improves the result (100% Sensitivity, 87% Specificity, 87% PPV and 100% NPV). All the patients who had the 13910 CC genotype, showed malabsorption in the hydrogen test except one, non-hydrogen producer.
In terms of the clinical expression, every patient had symptoms after drink milk (average 24 points), 90% while performing the hydrogen test (average 14 points) and only 33% during Gaxilose test (average 10 points). Gaxilose test was selected by 89% of patients.
CONCLUSION: Urine Gaxilose test offers an efficient tool for hypolactasia diagnosis, as well as the hydrogen test. However, this test is inaccurate when urine xylose level is near over the cut off. In our experience increase the cut-off would improve the efficacy of the test. Furthermore, the Gaxilose test allows diagnosis of the non-hydrogen producing patients. It is a well-tolerated test and the most accepted by the patients.

INTRODUCTION: The majority of intestinal follicular lymphomas (intestinal FL) have some distinct clinical features different from those of nodal follicular lymphomas.
AIMS & METHODS: In this study we compared the clinical course of 33 cases of FL-GI patients with 70 cases of nodal FL patients both treated by watch and wait (W&W) strategy in order to evaluate W&W strategy in the era of rituximab being introduced as a treatment option for intestinal FL. Thirty-three cases of intestinal FL diagnosed as low-tumour-burden follicular lymphoma (LTB-FL) according to GELF criteria for LTB, M/F = 18/15, age 49-82, clinical stage (CS), Ann Arbor staging system I: 16, II: 7, IV: 9, WHO grade 1: 32, 2: 1, 3: 0, were followed for over 12 months by W&W, median time period of 46 months. Seventy cases of nodal FL, M/F = 36/34, age 36-92, CS (Ann Arbor) I: 6, II: 10, III: 21, IV: 30, WHO grade 1: 32, 2: 30, 3: 4, followed by watch and wait strategy for median period of 57 months were compared. The clinical stage at diagnosis was confirmed by blood test, bone marrow (BM) aspiration, positron emission tomography (PET), contrast-enhanced CT scan (from neck to pelvis), esophagogastroduodenoscopy (EGD), colonoscopy, double balloon enteroscopy. During the period of W&W, EGD and blood test were performed every four months and PET, colonoscopy and capsule endoscopy were performed every year.
RESULTS: There was no difference in the age and sex in the patients between intestinal FL and nodal FL. CS, WHO grade, follicular lymphoma international prognostic index (FLIPI) grade and the value of sIL-2R were significantly lower in intestinal FL. The proportion of BM involvement was significantly low in the patients of intestinal FL. No patient died of disease in intestinal FL while 2 patients of nodal FL died after treatment. The overall survival showed no difference between intestinal FL and nodal FL. The discussion of progression free survival (PFS) showed significantly better result in intestinal FL compared with nodal FL. The factors causing the difference in PFS were considered to be BM involvement, the existence of bulky mass and FLIPI. In all the 28 nodal FL patients with the progression of the disease, LTB turned into high-tumor-burden and they were treated by chemotherapy, rituximab-chemotherapy combinations or peripheral blood stem cell transplantation. Only 6 patients of intestinal FL showed progression of the disease. Out of these six patients, 2 patients deviated from the category of LTB-FL and received rituximab-chemotherapy combinations and 4 patients, although the CS progressed (I to II in 3 patients and II to IV in one), remained in the category of LTB-FL and were followed by 'W&W'.
CONCLUSION: The treatment modality of LTB-FL comprising large proportion of intestinal FL is 'watch and wait' in the era of rituximab as a choice of treatment.

INTRODUCTION: Recently, many papers showed that ultrasonography (US) is a conventional and non-invasive modality for the examination of abdominal cavity. The aim of this study was to evaluate the usefulness of US for the detection of small bowel tumors (SBTs).
AIMS & METHODS: The aim of this study was to evaluate the usefulness of US for the detection of SBTs. Five hundred and fifty eight consecutive patients (295 male, 263 female, mean age 71.1) who underwent capsule endoscopy (CE) and/or balloon assisted endoscopy (BAE) were enrolled in this study. All patients underwent US prior to CE and BAE. The sensitivity and specificity of US in detecting SBTs, size of detected SMTs, detection rate of SBTs by US were evaluated.
RESULTS: Ninety three tumors (benign 48, malignant 45) detected by CE and/or BAE were retrospectively analyzed. The sensitivity and specificity of US in the detection of SBTs were 50.5% (47/93) and 100% (465/465). Tumor size in patients with SBTs detected by US (mean 33.2 mm) were significant larger than those undetected by US (mean 8.7 mm). The ratio of SBTs located in the ileum was significantly higher in SBTs detected by US (12/17) compared to those undetected by US (5/17). Body mass index was irrelevant to the detection rate. Of all patients with SBTs undetected by US, 91.3% (42/46) were benign tumors with good clinical prognosis.
CONCLUSION: US examination is considered to be a useful modality for detecting small bowel lesions. We consider that US examination is the first choice modality for examining SBTs because it is a conventional and non-invasive procedure.

INTRODUCTION: GISTs are known as the most common tumor originated from gastrointestinal (GI) mesenchyme. In 1998, we firstly reported gain-of-function mutations of the c-*kit* gene in GISTs which appear to originate from interstitial cells of Cajal (ICC)[1]. As we and others have already reported, some families with multiple GISTs carry a germline gain-of-function mutation of the c-*kit* gene. The c-*kit* gene mutations are reported in approximately 90% of all sporadic GISTs, and are located most frequently in exon 11. In patients with familial GISTs, most of the mutations are located in exon 11 as well. We have experienced a family who has a germline gain-of-function mutation of the c-*kit* gene in exon 11 (Del-Val560). Notably, one of the patients has shown fair response to imatinib. To our knowledge, there are few reports describing the response to imatinib in familial GISTs. We report here the clinicopathological features of the patients together with a review of literature.
AIMS & METHODS: A 40-year-old female (case 1) with a history of rheumatoid arthritis treated with infliximab, complained right lower abdominal dull pain and underwent contrast enhanced abdominal computed tomography (CT). It revealed a large mass lesion with the size of 50 x 30 mm at the small intestine. Single balloon enteroscopy showed a jejunal protruding submucosal tumor with ulceration on the surface. Partial resection of the jejunum was performed. Immunohistocheical analysis revealed the tumor was positive for KIT and CD34 and was diagnosed as GIST. The father of this patient (case 2) had a previous history of small bowel operation for small bowel perforation due to mass lesion. He underwent an abdominal CT which revealed multiple mass lesions at the duodenum and small intestine. EUS-guided fine needle aspiration (EUS-FNA) biopsy was performed. The tumor showed positivity for KIT and CD34 and was diagnosed as GIST. To identify germline gain-of-function mutation of the c-*kit* gene, blood samples were obtained and analyzed for c-*kit* gene sequencing.
RESULTS: After obtaining informed consent, blood samples from case 1 and 2 were analyzed. In case 1 and 2, germline c-*kit* gene mutation was identified in exon 11, resulting in deletion of codon 560 valine, and they were diagnosed as familial GIST patients. Imatinib treatment for GISTs was considered in case 2 because of previous history of intestinal perforation. Considering his age, the dose of imatinib was reduced in half. All GISTs were markedly reduced in size in one year.
CONCLUSION: Multiple GISTs were more frequently observed in patients with type 1 neurofibromatosis (NF-1) than in familial GISTs with germline c-*kit* gene mutation. Patients who have multiple GISTs without classical symptoms of NF-1 have the possibility of such familial GISTs. Therefore, detailed familial history should be taken. In patients with sporadic GISTs harboring exon 11 KIT mutations, the partial response rate of imatinib was 83.5%[2]. In our case, half dose of imatinib was effective. Even in the patients with familial GISTs, imatinib can become an encouraging therapeutic option.

P1698 RAPID GASTRIC AND INTESTINAL TRANSIT IS A MAJOR DETERMINANT OF CHANGES IN BLOOD GLUCOSE, INTESTINAL HORMONES, GLUCOSE ABSORPTION AND POST-PRANDIAL SYMPTOMS AFTER GASTRIC BYPASS

INTRODUCTION: Gastric emptying usually regulates the rate of small intestinal (SI) nutrient entry to 1-4 kcal/min. It is hypothesized that Roux-en-Y gastric bypass (RYGB) augments distal gut hormone release and modifies glycaemia by uncontrolled transit of liquid nutrients, which should be normalized if nutrient delivery were controlled.
AIMS & METHODS: To determine the contribution of rapid gastrointestinal transit of nutrient liquid on blood glucose, incretin hormones, glucose absorption and gastrointestinal (GI) symptoms after RYGB. 10 RYGB patients were studied twice in random order, separated by at least a week, with either: (i) an oral glucose drink (50g glucose/ 150ml water with 3g 3-O-methyl-D-glucopyranose (3-OMG) and 20MBq 99mTc-sulfur colloid) over 3 min or (ii) the same solution (without 99mTc-sulfur colloid) infused via an endoscope into the proximal Roux-limb over 50 min (4kcal/min). 10 healthy control subjects were studied with the latter solution infused into the duodenum (4kcal/min). GI transit of the glucose drink was assessed by scintigraphy. On each study, blood glucose, and plasma 3-OMG, insulin, glucose-dependent insulinotropic polypeptide (GIP), and glucagon-like peptide-1 (GLP-1) concentrations, and GI symptoms, were measured over 270 min.
RESULTS: In RYGB subjects, the glucose drink emptied rapidly into the distal SI (pouch emptying (PE), $t50 = 3 \pm 1$min; caecal arrival time (CAT) $= 26 \pm 10$min). CAT, but not PE, was inversely correlated with peak plasma GLP-1 ($r = -0.73$, $p = 0.01$). Compared to oral glucose, 4kcal/min SI glucose infusion in RYGB subjects was associated with substantially lower plasma GLP-1, GIP, insulin and GI symptoms, similar to those observed in healthy subjects. Both plasma 3-OMG and blood glucose were higher in RYGB subjects during SI glucose infusion than after oral glucose, and higher than in healthy subjects. Peak plasma 3-OMG correlated closely with peak blood glucose ($r = 0.94$, $P < 0.0001$) in RYGB subjects during SI infusion, but not after oral glucose or in healthy subjects.
CONCLUSION: After RYGB, reducing intestinal glucose delivery to 4kcal/min is associated with higher blood glucose, greater glucose absorption, lower incretin responses and less GI symptoms, supporting rapid transit contribution to the exaggerated incretin responses and "dumping symptoms".

INTRODUCTION: Gastroesophageal reflux disease (GERD), affecting up to 20% of the general population in Western countries, develops when the reflux of gastric contents causes troublesome symptoms and/or complications. Behaviors changes and lifestyle modifications are considered the first line treatment for GERD with the least possibility of side effects.
Although few data are available on eating habits, in clinical practice different foods (i.e., chocolate, peppermint, wine, tomato, spicy food, coffee) and, generally, high-fat diet are indicated as triggering reflux symptoms. However, the role of dietary behavior, mainly in terms of specific dietary components, in influencing GERD clinical manifestations remains controversial.
AIMS & METHODS: By means of impedance and pH monitoring, we aimed to evaluate the effect of two meals with a bromatological-balanced composition: one with a prevailing component of animal food protein and the other with vegetable food protein.
We enrolled 30 consecutive patients with typical reflux symptoms and negative endoscopy, who had been proposed for esophageal manometry and 24-h impedance and pH monitoring (MII-pH) (OFF-therapy) during their scheduled diagnostic program.
All patients were allocated to receive a scheduled diet with a caloric intake of about 1200 Kcal, divided into two meals of 600 Kcal: one with a prevailing component of animal protein and the other with vegetable protein. Breakfast was free and not considered during the 1-h postprandial analysis.
According to MII-pH analysis, we evaluated total reflux number, acid exposure time (AET) and symptom-reflux association. Moreover, during the first postprandial hour (both lunch and dinner), we evaluated: total reflux number, number of acid and weakly-acidic refluxes, AET, presence of symptoms.
A student t-test for paired data was performed and the differences were considered significant when p values were < 0.05.
RESULTS: Male/female ratio was 0.5 (10/20). Mean age was 53.4 ± 12.7 yrs. All patients had heartburn. Twenty-four hour MII-pH analysis showed that 14/30 patients had pathological AET (non-erosive reflux disease, NERD), and 16/30 had normal AET but positive symptom-reflux association (hypersensitive esophagus, HE). The comparison between the first postprandial hour analysis showed a higher total reflux number (7.6 ± 3.9 vs 4.7 ± 3.1) and acid reflux number (4 ± 2.7 vs 1.9 ± 2.2), and greater AET (3 ± 3 vs 0.7 ± 1.3) after the animal protein meal than after the vegetable protein meal. Moreover, more symptoms were reported after the animal protein meal (2.3 ± 1.8 vs 0.8 ± 0.7) ($p < 0.05$).
CONCLUSION: Vegetable proteins are associated with a lower number of refluxes, particularly acid refluxes, and thus with a reduced number of symptoms during the first postprandial hour. This is a pilot study and future investigations are warranted to confirm these results.

INTRODUCTION: Micronutrient deficiency including B12, Folic Acid (FA) and Iron (Fe) are frequent in Inflammatory Bowel Diseases (IBD). Laboratory manifestations of these deficiencies are evident on blood count. B12 and/or FA may present as macrocytosis, and Fe as microcytosis. Combined deficiencies can present as normo/macro or micro-cytosis with a large Red Cell Distribution Width (RDW). These laboratory abnormalities should lead to investigation of these deficiencies.
AIMS & METHODS: The aim of this study is to check the awareness for investigation of these deficiencies.
Data regarding all IBD patients hospitalized for exacerbation during 2010-3.2014 with mean corpuscular volume (MCV) ≤ 75 fL; MCV ≥ 100 fL; RDW $\geq 17\%$

was retrieved from the electronic files. Deficiencies were defined in accordance to our local laboratory values.
RESULTS: Three hundred and seventy-three patients; 46% males; age 38.9+/-17.7 years. Relevant abnormal laboratory results were found in 90 (24%) patients. 28 and 22 of 56 patients with low MCV had high and normal RDW respectively. Four and three of ten patients with high MCV had normal and high RDW respectively. 41/56, 4/7 and 11/27 of patients with laboratory findings mandating investigation for Fe, B12 and Folic acid, and combined deficiencies according to the above criteria had complete evaluation. A stratified tendency towards higher awareness for investigation was noted as highest for Fe, and lowest for combined deficiencies (p = NS). 55/59; 2/7 of patients who underwent investigation for Fe and B12 and FA, were found to be deficient. Almost 40% did not undergo full evaluation. 86% of investigated patients were found to be deficient. 56% of patients diagnosed with Fe deficiency were prescribed treatment.
CONCLUSION: Deficiency of Fe and/or B12 and/or FA is suggested in almost a quarter of hospitalized IBD patients, but is far too often overlooked. Untreated deficiencies can cause significant morbidity. Measures to increase awareness are needed.

P1701 DIETARY MANIPULATION OF GASTROINTESTINAL FUNCTION CAN MODIFY POSTPRANDIAL ENDOTHELIAL DYSFUNCTION IN HEALTHY HUMANS

S.S. Thazhath[1,2,*], T. Wu[1,2], M. Bound[1,2], H. Checklin[1,2], K. Jones[1,2], S. Willoughby[1,3], M. Horowitz[1,2], C. Rayner[1,2]

INTRODUCTION: Endothelial function, measured by flow-mediated dilatation (FMD), predicts cardiovascular events, and is known to be impaired after meals. The rate of gastric emptying and nutrient delivery to the small intestine has a substantial influence on postprandial glycaemic excursions in health and type 2 diabetes, but its impact on endothelial function is unclear.
AIMS & METHODS: Our aim was to evaluate the effects of dietary modifications designed to slow gastric emptying and/or small intestinal nutrient exposure on postprandial endothelial function in healthy humans.12 healthy subjects (6 male, 6 female: 33 ± 5.6 years) were studied on 3 occasions each, in a randomised, crossover design. After an overnight fast, subjects consumed a mashed potato meal (meal 1) or the same meal mixed with 9 g guar (meal 2) within 10 min, or the mashed potato meal divided into 12 equal portions over 60 min (meal 3), each labelled with ^{13}C-octanoic acid. Brachial artery FMD was measured every 30 min for 120 min. Blood glucose and serum insulin concentrations, and gastric emptying (breath test), were evaluated for 240 min. Data are means ± SE.
RESULTS: Addition of guar to the meal ('meal 2' vs 'meal 1') slowed gastric emptying (half-emptying time 285 ± 27 vs. 208 ± 15 min, $p < 0.05$), lowered postprandial glycaemia and insulin ($P < 0.001$ for each), and was associated with a delayed but sustained suppression of FMD ($P < 0.005$). With 'meal 3', the glycaemic excursion was modestly suppressed ($P < 0.001$), but the insulin response was more marked after the first 30 min ($P < 0.001$) compared with 'meal 1', while the reduction in FMD was markedly attenuated ($P < 0.05$). The magnitude of reduction in FMD at t = 30 min was inversely related to the cumulative $^{13}CO_2$:$^{12}CO_2$ ratio ($r = -0.53$ $P < 0.01$), suggesting a relationship to small intestinal nutrient delivery, but FMD did not correlate with postprandial glycaemia.
CONCLUSION: These observations indicate that gastrointestinal function can be manipulated by dietary means to regulate postprandial endothelial function. The underlying physiology potentially reflects interplay of multiple factors including gastric volume, rate of small intestinal nutrient exposure, and insulin secretion. Further studies are warranted to develop therapeutic strategies to reduce postprandial endothelial dysfunction in high-risk populations (eg. type 2 diabetes).

INTRODUCTION: The effects of alcoholic beverages such as small amount of wine have been proposed for keeping healthy conditions.
AIMS & METHODS: The aim of this study was to investigate the effect of consuming small amounts of beer or a non-alcoholic beer taste beverage (non-beer) on internal organ functions, including gastric motility.
The subjects included 20 male healthy volunteers. All subjects were questioned regarding their alcohol consumption status. Blood was collected for DNA extraction prior to the test, and the genetic polymorphisms in ADH1B (rs1229984, Arg47His) and ALDH2 (rs671 Glu487Lys) was analyzed using the TaqMan assay method. The subjects consumed 150 ml of beer (5.0 % v/v contain ethanol) or non-beer once per week, followed by the ingestion of 200 ml of the test nutrient containing 13C-acetate 15 min later, after which the subjects' exhalations were collected in a breathing bag at 0, 5, 10, 15, 20, 30, 40, 50, 60, 90, and 120 min. The concentration peak of 13C was measured as Tmax. The volunteers was measured their body weight, height, body mass index (BMI), body surface area (BSA), basal metabolic rate. Diamine oxidase activity (DAO) for the marker of small intestinal function activity was measured in a fasting blood sample collected the day after the test. Statistical analyses were performed with Wilcoxon signed-rank test, and F-test.
RESULTS: Gastric motility was significantly slower in the group that consumed a small amount of beer (Tmax = 49.0 vs. 38.3, respectively, $p = 0.00137$). Similar results were found in the ADH1B *2/*2, ALDH2 *1/*2, and daily beer consumption groups. BMI, BSA were not related with gastric empting time. DAO values were significantly variable in beer drinking group compared with non-alcoholic beer drinking group ($P < 0.0001$).
CONCLUSION: The consumption of even a small amount of beer affects gastric motility and small intestinal function. And the polymorphisms in alcohol metabolism-related enzyme-encoding genes are related to gastric motility and small intestinal function.

P1703 THE ROLE OF PROPHYLACTIC PERCUTANEOUS ENDOSCOPIC GASTROSTOMY TUBE PLACEMENT IN PATIENTS WITH HEAD-AND-NECK CANCER TREATED WITH DEFINITIVE CHEMORADIATION THERAPY

R. **V. Rodrigues**[1,*], S. Faias[1], J. Moleiro[1], M. Serrano[1], M. Femenia[1], S. Severiano[1], V. Machado[1], A. Dias-Pereira[1]
[1]*Gastroenterology, Instituto Portugues de Oncologia de Lisboa, Franscisco Gentil, Lisboa, Portugal*

INTRODUCTION: Head-and-neck cancer (HNC) patients have a high-risk of malnutrition and swallowing dysfunction, particularly during chemoradiation therapy (CRT) that justifies prophylactic percutaneous endoscopic gastrostomy (PEG) placement for nutritional support.
AIMS & METHODS: Evaluate the utility, duration of use and nutritional outcome of prophylactic PEG tube placement in patients with HNC undergoing definitive CRT, with a follow-up longer than 1 year.
Prospective analysis of consecutive patients with HNC refered for prophylactic PEG placement in a 6-month period, between July/2012-December/2012, in a single center. Demographic data, tumor location and stage, body mass index (BMI), duration of PEG usage (exclusive and complementary) and weight evaluation before, during and after treatment were assessed.
RESULTS: PEGs were placed in 47 patients with HNC (41M/6W), mean age = 58 year old (40-76). TNM: T1/2 = 11, T3/4 = 36 N0/1 = 20, N2/3 = 27. BMI = 24kg/m^2 (15-33). Of the 47 PEGs placed, only 2 were not used. Average length of PEG usage: 7 months (0.1-20 months). After one-year of follow-up, of the 45 patients who used PEG: 27 were in remission, 3 had persistent disease, 15 died (13 of disease progression; 2 of respiratory infection). Of the 27 in remission: 22 removed PEG on average after 7 months (3-15) and 5 still use PEG on average after 17 months (14-20). Of the 15 deceased patients only 2 removed PEG. Average length of exclusive use of PEG: 3 months (0-18). Use of PEG (exclusive/partial/null): during treatment (15/29/2); after treatment (6/26/9); six months after treatment (7/5/23). Mean weight (before/during/after treatment): 65/62/60Kg. Weight reduction occurred in 31 patients during treatment and in 24 after treatment even using PEG for nutritional support.
CONCLUSION: Enteral nutritional support is essential in patients with HNC during and after treatment with definitive CRT. Prophylactic PEG placement allowed enteral intake but did not prevent weight loss. Almost all patients required PEG not only during but also after treatment. One fifth of the patients in remission required long-term PEG usage for nutritional support.

P1704 TRANSNASAL PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (TN-PEG) IN HEAD AND NECK CANCER PATIENTS: COMBINED APROACH WITH GASTROENTEROLOGY AND PNEUMOLOGY

S. Faias[1,*], D. Costa[2], J. Dionísio[2], P. Mota[2], I. Rosa[1], J. Pereira Silva[1], S. Ferreira[1], S. Mao Ferro[1], A. Dias Pereira[1]
[1]*Gastroenterology,* [2]*Pneumology, INSTITUTO PORTUGUÊS DE ONCOLOGIA DE LISBOA, Lisboa, Portugal*
Contact E-mail Address: *sandrarfaias@hotmail.com*

INTRODUCTION: Head and neck cancer patients (HNCP) are prone to malnutrition due to malignancy and side efects of treatment. The placement of a percutaneous endoscopic gastrostomy (PEG) is necessary for most of these patients. In some situations, oropharyngeal obstruction or trismus preclude a transoral aproach and a transnasal (TN) route with a thin scope is the available option. Adaptation of a bronchofiberoscope for PEG placement in this context has been previously described.
AIMS & METHODS: Retrospective analysis of all TN-PEG tubes placed in HNCP in a single institution, over a 5-year period, using the "pull" method, in a combined aproach by a gastroenterologist in the abdominal side and a pneumologist in the head side, employing an adapted bronchofiberscope.
Demography, indication (prophylatic versus palliative), TN-PEG procedure outcome, complications and treatment, and overall survival were reviewed.
RESULTS: Between 2009-201, 23/649 (3,5%) consecutive HNCP patients referred for PEG placement, underwent a TN-PEG procedure. TN-PEGs were successfully placed in 22/23 patients, 17 men and 6 women, with a mean age of 56 years old (26-74) and a mean BMI = 20 (15-27). Only one TN-PEG technical failure due to missing transillumination. Palliative TN-PEGs in 14/23 and

prophylatic in 9/23 patients. TN-PEG route due to trismus (22/23) and oropharyngeal obstruction (1/23), in patients with tumors of oropharynx (8), oral cavity (7), tongue (5) e maxillary sinus (3). TN-PEG was the only way of nutrition in the 22 patients for a mean time of 242 days (31-1115). On follow-up, 15 patients died of disease progression, 2 died of other causes and 5 are alive in remission. None of the patients removed TN-PEG. The 5 patients in remission were using TN-PEG for exclusive enteral nutrition for a mean time of 378 days (110-730). Minor complications ocurred in 8/22: 1 burried bumper syndrome; 1 PEG extrusion; and 6 infections, 3 early ($<=7$ days after TN-PEG placement) and 5 late (>7 days after TN-PEG placement). Neither immediate, major complications ocurred nor mortality associated with the procedure.

CONCLUSION: Combined TN-PEG placement by a Gastroenterologist and a Pneumologist using an adapted bronchofiberoscope is a safe and useful option for HNCP in witch transoral PEG placement is not possible.

INTRODUCTION: Chronic intestinal failure (CIF), mostly caused by short bowel syndrome (SBS), frequently - through malabsorption - leads to malnutrition which requires parenteral nutrition (PN). PN, particularly long-term PN, is frequently complicated by a form of hepatopathy (intestinal failure associated liver disease, IFALD), which is not well understood in pathogenesis, diagnosis and consequences for CIF-patient-management.

AIMS & METHODS: The incidence, severity and outcome of IFALD were studied in a retrospective fashion in a cohort of 142 patients with CIF from an interdisciplinary team at an acedemic referral center. Statistical analysis was performed using SPSS 19.0.

RESULTS: 142 patients from 2004 - 2013 with CIF due to SBS were analyzed; 88 (62%) of them had a non-malignant cause of CIF due to venous (11%) or arterial (28%) mesenteric ischemia, Crohn's disease (14%), adhesions or volvlus (23%), radiation enteritis (2%) or other causes. 80 (91%) patients of non-malignant CIF required PN. 52% had a type I (end-jejunostomy), 24% a type II (jejunocolostomy) and 24% a type III (ileocolostomy) SBS-anatomy. Elevated liver enzymes were detected in all patients during the initial 24 months (hypersecretive and adaptive period) of SBS and in 90% beyond 24 months (during stabilization period). After stabilization period was reached, an elevation of ASAT, ALAT and total bilirubin (but not AP or GGT) indicated a significantly worse prognosis by Cox regression analysis. A combined score considering a more than 2-fold elevation of at least two of these 3 parameters indicated a statistically worse long-term outcome as indicated by decreases overall survival by Kaplan-Meier analysis ($p<0.001$); this was idependent from other statistically significant prognostic factors such as type of SBS or presence and number of catheter-related blood stream infections.

CONCLUSION: In CIF-patients IFALD as defined by elevated liver enzymes ASAT, ALAT and elevated total bilirubin is highly prevalent even after intestinal stabilization has been achieved independently from type of SBS and other complications. A simple assessment score based on these lab values may indicate poorer long-term outcome and should thus direct medical and surgical CIF- and PN-management.

INTRODUCTION: Different techniques for direct insertion of a gastric feeding tube (g-tube), are reported. Advantages are:easy and safe positioning in upper tract stenosis;reduced incidence of peristomal infections;possibility to place, as first choice, a balloon type g-tube, which is easy to be changed at bed-side.

AIMS & METHODS: To compare the push/pull endoscopic method (PEG) to the MIC introducer kit (KIT; Kimberly-Clark Corporation, Roswell, GA, USA) for placing g-tubes. From September 2010 to April 2013,206 consecutive patients (age:18-85) without upper tract stenosis randomly received a 20 French g-tube by push/pull PEG method (106), or by direct insertion using the KIT (100). Primary enpoints were complication rates during tube placement and at 30-days and Jain score-based[1] peristomal infection severity. Secondary endpoints were time necessary for the placement, longevity of the g-tube until first change and the need of endoscopic substitution. Patients were planned to be followed for 13 months. Data were analysed using the Mann-Whitney test, while frequencies were analysed by the Chi-squared test with Yate's correction or Fisher exact test, when appropriate. Significant differences between means were indicated by $p \leq 0.05$.

RESULTS: Placement was successful in 106/106 PEG and in 99/100 KIT patients. Complication rates were not significantly different in the two arms. Major complications were 2 fistulas and 1 death in PEG,1 respiratory arrest in KIT. Minor complications were only in KIT patients (2 superficial lesion of gastric mucosa;2 pneumoperitoneum;1 deformation of dilator device). Complications at 30-days included infection (4 cases in both groups), death (PEG:10;KIT:11) minor bleeding (PEG:2;KIT:1), leakage (PEG:1), and ab-ingestis pneumonia (KIT:1). Peristomal infection severity scores were similar at 30-days (0.28 vs 0.31). G-tube substitutions occurred in 62% and 95% ($p<0.01$) of PEG and KIT patients, with a greater incidence of these procedures occurring in endoscopy unit for PEG (58% vs. KIT:22%; $p<0.01$). The mean time required to place tube was shorter by PEG (10.4 ± 4.5 min vs. KIT: 14.8 ± 5.2; $p<0.001$). Time prior to first change exceeded 90-days (PEG:230 vs KIT:124).

CONCLUSION: These results suggest that KIT is a feasible and safe alternative to PEG. Furthermore, patients with g-tubes placed using the KIT were significantly less likely to require a second endoscopic procedure to have their g-tubes removed, whith a reduction of endoscopic suite costs.

INTRODUCTION: Nutrition is an important biological factor in the holistic approach towards management of the surgical patient. The MUST (Malnutrition Universal Scoring Tool) is a tool used in many studies to assess the nutritional status of patients. In 2012, we performed an audit of the MUST scoring tool, comparing it with with a trust devised tool. In 2013, we repeated the audit to complete the audit cycle, following recommendations implemented from the previous audit.

AIMS & METHODS: Aims: We aimed to assess the accuracy of these assessment tools, and the value of the concerted education of our nursing staff regarding the use of these tools.

Methods: Data was prospectively collected over a 2 month period, including both elective and acute admissions to surgical wards. The same audit tool was used this year, as was used in the previous year, to allow for comparative analysis. Education was given to the nurses on how best to implement the MUST tool.

RESULTS: The 2013 cohort included 140 patients (32 elective and 108 acute admissions) as compared with 120 patients in the 2012 cohort (24 elective and 96 acute admissions). In 2012 86% of patients had nutrition assessment completed on admission, compared to 94% in 2013. 52% of patients assessed by MUST were deemed to have low, 12% had moderate and 36% had high risk of malnutrition in 2012, compared to 54% low, 13% moderate and 40% high respectively in 2013. 56% of these were reviewed by dietitian/ had appropriate nutritional support started by their medical team in 2012, compared to 76% in 2013. Higher re-admittance rates were also reflected in different MUST score groups. Low risk group readmission rates were 7.9% (8.6% in 2013), moderate 33.3% (33.3% in 2013) and 14.2% (14.8% in 2013) in high risk MUST groups. Wound infections occurred in 8.6% of patients in 2012, and 7.2% of patients in 2013.

CONCLUSION: Conclusions: Both years audits reveals a direct correlation between MUST scores and the length of stay in hospital, readmission rate, risk of wound infection and risk of death. Promisingly, after the education of nursing staff on the wards, there appears to have been an increase in the number of surgical patients receiving adequate care in regards to nutrition/ nutrition assessment.

P1708 SAFETY OF UNSEDATED PEG PLACEMENT USING TRANSORAL ULTRATHIN ENDOSCOPY IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS

Y. Sato[1,*], Y. Nishigaki[1]
[1]*Gastroenterology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*
Contact E-mail Address: *yuichi@med.niigata-u.ac.jp*

INTRODUCTION: In patients with amyotrophic lateral sclerosis (ALS), percutaneous endoscopic gastrostomy (PEG) placement under sedition often causes apnea or hypoventilation. To prevent complications of sedation, unsedated transnasal PEG placement using small diameter endoscopy (SDE) has been

performed. However, even with SDE, transnasal intubation sometimes fails due to the impossibility of crossing the nasal cavity or results in epistaxis and/or nasomucosal injury. Moreover, a recent study revealed that transoral insertion using SDE is superior to transnasal insertion using SDE in endoscopy procedures.
AIMS & METHODS: The aim of the present study was to assess whether unsedated PEG placement in ALS patients using ultrathin endoscopy (UTE) via the transoral route can improve safety. Between 2003 and 2012, PEG placement was identified and reviewed in 42 patients with ALS. PEG was performed in 11 patients using transoral UTE without sedation (UTE group), 17 patients using conventional normal-diameter esophagogastroduodenoscopy (C-EGD) without sedation (unsedated C-EGD group) and 14 patients using C-EGD with sedation (sedated C-EGD group). We compared the clinical features, cardiopulmonary data before and during PEG placement, and complications related to PEG placement among the three groups.
RESULTS: There were no significant differences in age, M/F ratio, forced vital capacity (FVC), blood pressure, oxygen saturation before and during PEG or major complications among the three groups. With regard to complications, no major complications such as adverse events requiring surgery, permanent adverse sequelae or death, were observed in any patient. However, among the three groups, there were differences in the incidence of minor complications, including apnea and/or hypoventilation, aspiration pneumonia and peristomal infection. No minor complications were observed in the UTE group, whereas, aspiration pneumonia was observed in the unsedated C-EGD group (3/17, 7.6%) and apnea and/or hypoventilation were observed in the sedated C-EGD group (3/14, 21.4%). The proportion of patients whose BP was elevated by more than 20% compared with that observed before the PEG procedure was 7.1% (1/14) in the UTE group, 23.5% (4/17) in the unsedated C-EGD group and 14.2% (2/14) in the sedated C-EGD group. In the UTE group, PEG placement was successfully performed in all patients, and no patients required sedation during the procedure. However, among the three patients complicated with apnea and/or hypoventilation due to sedation in the sedated C-EGD group, PEG placement could not be successfully performed due to apnea and/or hypoventilation in two patients.
CONCLUSION: Unsedated PEG placement using transoral UTE in ALS patients is a safe method.

INTRODUCTION: Regulatory T cells are critical to maintain the immune system homeostasis in the gut and Treg malfunctioning is associated with chronic colitis. At the same time, accumulating evidence indicates that proinflammatory stimuli can downregulate the Treg lineage commitment transcription FoxP3 leading to Treg phenotype instability. Although Tregs have been shown to accumulate in the stroma of sporadic colorectal cancers suppressing the intratumoral immune response, the role and functional stability of Tregs in colitis associated colorectal cancer is unknown.
AIMS & METHODS: Aim of the study was to characterize Treg phenotype and stability in a model of colitis-associated colorectal cancer. To address this issue a Tregs fate mapping reporter mouse was generated where Tregs and ''ex-Tregs'', which have lost FoxP3 expression are identified by the emission of specific combinations of green and red fluorescences. Treg fate mapping reporter mice underwent the Azoxymethane/Dextrane Sulphate Sodium model of colitis-associated colorectal cancer. At the end of the experiment, the expression of Th1- and Th17-specific markers (i.e. Tbet and IFN-gamma for Th1 and RORgamma-t and IL17A for Th17) were analyzed by flow cytometry in Treg and ''ex Treg'' cells isolated from tumors and tumor-surrounding lamina propria.
RESULTS: The frequency of both Tregs but not ''ex-Tregs'' among CD4+ T cells isolated from the lamina propria of treated mice was higher as compared to untreated mice (45% vs 28% Tregs treated vs untreated respectively) while the absolute number of both Tregs and ex-Tregs was increased in treated as compared to untreated mice. In inflammatory conditions, in the peritumoral areas, both Tregs and ex-Tregs upregulated the transcription factors Tbet and RORgamma-t and expressed the proinflammatory cytokines IL17A and IFN-gamma. However in the tumor Tregs and ex-Tregs were characterized by the expression of Th17- but not Th1-related markers.
CONCLUSION: Tregs and ex-Tregs characterized by the expression of Th1 and Th17 effector molecules represent a sizable fraction of CD4+ T cells accumulating in the peritumoral lamina propria and in the tumor stroma. The exclusive expression of Th17 markers by Tregs and ex-Tregs infiltrating the tumor stroma suggest that Tregs phenotypic plasticity might enhance rather than suppress the intratumoral Th17 immune response.

INTRODUCTION: A strong body of evidence supports the role of environmental influence in the development of Inflammatory Bowel Diseases (IBD). The increase in incidence of IBD during the 50's in Europe and United States and since about 10 years in developing countries parallel the modification of alimentary habits and in particular, the consumption of refined food.
Acrylamide is a chemical compound considered a potential carcinogen in humans. Acrylamide is produced naturally in food as a result of cooking starch rich food at high temperature (>120°C, baking, frying or grilling). High amounts of acrylamide are present in Western diet (in potato chips, pizza, French fries or pastries) with unknown effects on intestinal inflammation.
AIMS & METHODS: The aim of our study was to determine the effects of acrylamide on intestinal homeostasis in mice. C57bl6 mice were given increasing doses of acrylamide in their drinking water (25; 50 et 100µg/kg of body weight/day) for 9 months, control mice receiving water only. Colon was then harvested and assessed for macroscopic, structural and histological modifications. Markers of intestinal barrier, inflammatory and immune responses were also quantified.
RESULTS: No macroscopic lesions were observed in mice receiving acrylamide. However, the 3 doses of acrylamide induced structural abnormalities of the colon with a modification of the intestinal permeability compared to control mice. Crypts depth (148µm for control mice, 215µm for 25µg of acrylamide, and 211µm for 50µg, $p=0.0317$), number of goblet cells per crypt (respectively x3 for 25µg and 50µg, and x2 for 100µg, $p=0.0195$) and Muc 2 expression (+75% for 100µg, $p=0$ .04) were higher in mice receiving acrylamide. Acrylamide also induced expression of inflammatory markers; a significant increase of myeloperoxidase activity (+48%, $p=0.03$ for 50µg, and +50%, $p=0.04$ for 100µg), and of oxidative stress (+103% for 50µg, $p=0.03$ and +52% for 100µg, $p=0.009$ for iNOS expression, and +32% for 25µg, $p=0.04$ and +37% for 100µg, $p=0.009$ for NADPH oxydase expression) were observed in mice receiving acrylamide compared to control mice. The immune response was also disturbed; with an increased expression of Th1 cytokines (+57% for 50µg, $p=0.02$, for TNF expression, and +477%, $p=0.009$, +443%, $p=0.01$, and +408%, $p=0.009$, for 25µg, 50µg and 100µg of acrylamide respectively for IFNg expression), Th2 cytokines (+291%, $p=0.02$, +81%, $p=0.03$, and +82%, $p=0.03$ for 25µg, 50µg et 100µg respectively for IL-4 expression) and a decreased expression of Th17 cytokines (-24% for 100µg, $p=0.02$ for IL17f) in mice receiving acrylamide compared to control mice.
CONCLUSION: At low doses, acrylamide disturbed intestinal homeostasis with architectural modifications, altered permeability, increased inflammation and mucosal immune response. More studies are now needed to evaluate the role of acrylamide in IBD.

P1711 LIVING WITH CROHN'S DISEASE: EXPECTATIONS, EXPERIENCES AND DECISION-MAKING IN RELATION TO BEST CONVENTIONAL AND AUTOLOGOUS STEM CELL TREATMENT-THE DECIDES STUDY

J. Cooper[1,*], I. Blake[1]
[1]*Nottingham University Hospitals, Nottingham, United Kingdom*
Contact E-mail Address: *joanne.cooper3@nuh.nhs.uk*

INTRODUCTION: The DECIDES study involved an in-depth qualitative investigation into experiences of living with severe Crohn's Disease (CD), exploring expectations, decision-making and perceived risk within the context of the Autologous Stem Cell Transplantation International Crohn's Disease (ASTIC) trial. The ASTIC trial examines the role of haematopoietic stem cell treatment (HSCT) for Crohn's sufferers. Although the study examines quality of life and disease-specific measures of patient response, feedback from participants indicated other important issues impacting on their experiences of CD and specifically on decision-making and experience of trial participation.
AIMS & METHODS: The DECIDES study used semi-structured interviews to investigate the experiences, expectations, decision-making and perceptions of risk taking of participants who, a) took part in the ASTIC trial, b) considered participation by did not take part, and c) patients with matched severity of CD. Research questions investigated the impact of CD on life, attitudes towards current best conventional treatment, expectations, risk taking, perceived decision making towards radical treatments, and information needs. Interviews were analysed using thematic analysis informed by a framework analysis approach.
RESULTS: 1. **'Running out of options and time'**. The majority of participants described having exhausted all available treatment options prior to considering ASTIC, often stating they had 'nowhere else to go'. This decision making process was driven by a sense of limited time and options, but with the knowledge of possible randomisation to delayed or early treatment arms.
2. **Fertility**- Decision-making about fertility emerged as an important and emotive factor to consider for participants. Perceptions varied on how this issue was initially mentioned in consultations. Regardless, a number of participants reported that fertility and family planning was an unexpected, unconsidered, yet important issue to consider during the decision making process.
3. **Shared decision-making and control-** Participants described the relationship with their specialist IBD consultant and research nurse as essential factors in their decision making process, valuing expert opinion and advice. The majority of participants stated that the recommendation to participate in the trial by their

IBD Consultant strongly influenced their decision, in addition to media/internet resources.
4. **Balancing risks and benefits-** Perceived benefits of the ASTIC trial such as 'buying more time' or being a 'potential lifeline' outweighed the risks of the trial. With the understanding that the treatment procedure was very severe and there was a realistic risk of death, the risks were negated by the potential enhancement of their quality of life.
CONCLUSION: This research provides new insights into the decision making processes of patients with severe Crohn's disease faced with potential participation in a trial of a radical treatment option. The research indicates a variety of external influences and critical moments or 'touch points' in the decision making journey, providing opportunities for additional support, information and a suite of decision making support tools.

P1712 IMPROVEMENT OF ULCERATIVE-COLITIS-ASSOCIATED MICROBIOTA DIYSBIOSIS AFTER TREATMENT WITH MESALAZINE-MMX (MEZAVANT™) USING MUCOSAL F. PRAUSNITZII/E. COLI INDEX AS A MARKER

J.O. Miquel Cusachs[1,2,*], D. Busquets Casals[2], M. Serra Pagès[3], J. Garcia-Gil[4], X. Aldeguer Mantè[2]

Contact E-mail Address: *uriolmiquel@gmail.com*

INTRODUCTION: Microbiota (MI) in Cohn's disease's (CD) and Ulcerative Colitis (UC) are structurally different from healthy ones. We assume that the inflammation on colon mucosa may disrupt the normal MI ecosystem. Thus, any treatment given to curb the inflammation process has to be expressed by a recovery of the lost healthy equilibrium. In this study, our research group has developed a bacterial marker to evaluate treatment effectiveness on UC. We designed a specific index of Fp/Ec (FEI), based on the disappearance of *Faecalobacterium prausnitzi (Fp)* and the different abundance of *E.coli* (Ec). In previous studies, it has been established that the lower the value the more disturbed is the MI ecosystem.
We designed a study to assess Mesalazine-MMX (MZX) clinical response on mild/moderate UC and how that correlates on MI dysbiosis changes by examining FEI, previous (T0) and after (T1) treatment (TM).
AIMS & METHODS: We obtained rectal biopsy from mild/moderate UC patients on MZX (4,8 gr once daily) given with intention to treat and re-sample them 4 wks after. We included 8 patients in total. Biopsies are obtained from first 5 cm of rectum by flexible gastroscope with standard procedures.
Inclusion criteria were: Patient >18yo. UC diagnosed histologically, naïve to treatment, with a mild/moderate flare (Mayo index ≤ 5) and histological criteria; and signed informed consent. We excluded patients with previous antibiotic and/or any concomitant drugs aimed to IBD TM given in the previous 6 months. All samples were analyzed using DNA real-time PCR methods.
RESULTS: All patients but one (number 5) in this study showed an improvement on disease activity as measured by Mayo Index. At T0, patients showed an FEI under 2,6 (previously established cut-off point, COP, for major dysbiosis) and in T1 the median was 3,150. That increase on value is related to the improvement on MI dysbiosis. In T1, the number of EC was reduced (in average 55%) of patients. There were no differences in the total number of Fp after TM. MZX is able to significantly ($p = 0.035$) change the FEI above the COP. The FEI detects, with 83% of accuracy, the MI dysbiosis improvement. Coefficient of variation after TM of the FEI is 0.34%.
CONCLUSION: TM on mild/moderate UC flare with MZX contributes to an improvement on dysbiosis situation as shown by a clear increase in the FEI. FEI looks as a good marker to measure MI dysbiosis and thus, it is a promising new tool to assess response to TM on UC. *This study has been supported by Shire, Inc.*

P1713 USE OF MELATONIN IN THE TREATMENT OF EXPERIMENTAL DSS-DEPENDENT COLITIS IN RATS

K. Celinski[1,*], G. Czechowska[1], A. Korolczuk[2], T. Dworzański [1], A. Mądro[1], E. Dworzańska[3], P. Konturek[4]
[1]*Gastroenterology,* [2]*Pathomorphology,* [3]*Pediatric Neurology, MEDICAL UNIVERSITY OF LUBLIN, Lublin, Poland,* [4]*Internal Medicine, Thueringen-Clinic, Saalfeld, Germany*

INTRODUCTION: Melatonin is known as a factor regulating daily activity, but it is also a powerful antioxidant and a substance with an anti-inflammatory properties. Significant amounts of melatonin is produced in the mucous membrane of the digestive tract and liver. Melatonin has a protective effect on oxidative stress dependent damage of proteins, lipids and DNA. Melatonin reduces the inflammatory response by blocking the NF-κB signal pathway which is responsible for the expression of proinflammatory cytokines. These mechanisms are involved in the pathogenesis of ulcerative colitis.
AIMS & METHODS: Evaluation of Melatonin possible influence on severity and the course of rats' large intestine inflammation induced DSS.
Methods: The study was performed on 40 Wistar rats. Animals were divided into 4 groups. Group 1 received saline intraperitoneally (1ml/kg), group 2 - received saline and Melatonin 100mg/kg/day, groups 3 and 4 were given 1% DSS in the drinking water for 14 days. In group 3 during last seven days of DSS administration rats were receiving saline intraperitoneally. Group 4 during last seven days of DSS administration were receiving saline intraperitoneally and melatonin in dose of 100mg/kg/day. Histological changes in all goups were evaluated. Level of Il-1β, Il-6, Il-10, TNF-α, paraoxonase (PON-1), reduced glutathione (GSH) and oxidized glutathione (GSSG) in intestinal homogenate was determined in enzyme – linked immunosorbent (ELISA) assay.
RESULTS: Melatonin administration to rats with DSS-dependent colitis significantly reduced the severity of histopathological inflammation features. The use of melatonin resulted in a reduction in the level of IL-1β (7.53 in group 1) from (17.86 pg/mg in the group 3) to the (9.24 pg/mg group 4), IL-6 (8.39 in group 1) from (16.92 pg/mg in the group 3) to the (8.66 pg/mg in the group 4) and TNF-α, (7.21 in the group 1) from (14.57 pg/mg in the group 3) to the (6.76 pg/mg group 4), and had no significant effect on the level of anti-inflammatory IL-10 ($p > 0.05$). Experimental colitis resulted in reduced levels of antioxidant agents (GSH and PON-1), melatonin reversed this adverse event ($p < 0.05$).
CONCLUSION: Melatonin by anti-inflammatory and antioxidant effect reduces the severity of experimental colitis in rats.

P1714 REMISSION IN CROHN'S DISEASE AND THE MANAGEMENT OF RELAPSES: A REVIEW OF REAL WORLD PATIENT CASES

L. Chanroux[1,*], J. Casellas[1]
[1]*The Research Partnership, London, United Kingdom*
Contact E-mail Address: *laurentc@researchpartnership.com*

INTRODUCTION: Biologic agents have improved the outlook for many patients with moderate to severe Crohn's disease (CD). However, clinical data suggest that many patients may still not be attaining remission.
AIMS & METHODS: Our aim was to better understand disease remission in CD by reviewing "real-world" patient cases and assessing the management of relapses. We used patient data collected as part of an online treatment survey conducted among a panel of gastroenterologists between November 2012 and December 2013 across the five largest EU countries (France, Germany, Italy, Spain and the UK) and analysed the treatment history of 4284 patients (2879 bio pts and 1405 pts receiving immunosuppressants). We then analysed the characteristics of 1229 patients who at their most recent visit were not experiencing any flares in their disease. We also examined the records of 1064 biologic experienced patients who were currently in remission or had experienced it in the past.
RESULTS: 29% of patients were said to be experiencing no flares in their CD at the time of their visit, with the highest levels seen in France and Spain where 37% and 35% of patients were free from flares, respectively. There were no statistically significant differences in the age or gender of these patients compared to all "other" patients (pts with an increase, decrease or stabilisation of flares) though they were more likely to have a CDAI < 150 (97% vs. 45% for "other" pts). Patients in remission were also less likely to have fistulising disease (19% vs. 28% for all "other" pts) although the proportion of patients with mucosal lesions remained similar in all groups (55% - 57%). Patients in remission were less commonly treated with steroids and biologics although use of the latter stayed high. 3% of patients received a steroid (22% for "other" pts) and 60% received a biologic (70% for "other" pts). Among current biologic patients, 41% had experienced remission in the past with an average of 3 episodes and 36% experiencing remission for > 12 months. At relapse doctors immediately initiated biologic therapy in 57% of patients and in 71% of cases elected to re-start the biologic the patient had been receiving prior to remission. There was little correlation between these decisions and the number or duration of remission episodes. However, 90% of patients who had experienced ≤ 3 remissions had undergone 0-1 surgical interventions for their disease vs. 76% for those who had experienced ≥ 4. 9% of all patients cases reviewed had discontinued biologic therapy and disease remission was the most common reason for this change (52%, no statistically significant differences between bios). However, while 66% of patients had been in remission for > 12 months, 57% had experienced remission before (average of 3 episodes).
CONCLUSION: Our data show that both the induction and maintenance of remission are common but also highlight that while patients may see a reduction in the number of drugs they receive and an improvement in their CDAI and fistulae, drug-free remission and deep-remission with mucosal healing are not guaranteed. Additional analysis is required to assess how treatment strategies may optimise outcomes by maximising the duration of remission and minimising relapses, delaying or halting the progression of CD to increasing damage and disability.

P1715 REDUCED MONOCYTE ACTIVATION AND RECRUITMENT TWO WEEKS AFTER TREATMENT START REFLECT EARLY INFLIXIMAB THERAPY RESPONSE IN PATIENTS WITH ULCERATIVE COLITIS

M.K. Magnusson[1,2,*], H. Strid[2], S. Isaksson[1,2], A. Lasson[3], K.-A. Ung[4], A. Bajor[2], L. Öhman[1,2]

Contact E-mail Address: *maria.magnusson@microbio.gu.se*

INTRODUCTION: The cellular mechanisms leading to infliximab therapy response in patients with ulcerative colitis (UC) are still incompletely known. Also, it is difficult to assess early therapy response during treatment.
AIMS & METHODS: The aim was to determine effects of infliximab therapy on monocytes and monocyte related chemokines in UC patients during their first 4 months of therapy, and to evaluate early immunological effects linked to therapy response.
Blood, biopsies and stool samples were obtained before treatment (baseline), 2 weeks and 4 months after infliximab therapy start from 42 previously anti-TNF therapy-naïve UC patients. Therapy response was defined as decreased Mayo score ≥ 3 after 4 months (20 responders and 22 non-responders). The expression of CD86 and CD14 on monocytes in serum and in lysed biopsies was measured by FACS and ELISA, respectively. Expression of the chemokines CCL2, CCL3, CCL4, CX3CL1 and CXCL10 in serum and biopsies was determined by cytokine bead array. Data are presented as median (range).
RESULTS: At baseline there were no differences in monocyte phenotype, chemokine secretion, CRP levels, fecal calprotectin or Mayo score between therapy responders and non-responders. However, in therapy responders, infliximab reduced blood monocyte expression (median fluorescent intensity) of CD86 (2904 (2043-9862) *vs*. 2826 (1351-5618), $p = 0.02$) and CD14 (4004 (1492-23164) *vs*. 3008 (798-9872), $p = 0.02$), 2 weeks after therapy start, relative to baseline. In contrast, therapy non-responders showed increased levels of CD86 (2628 (1420-4848) vs. 3828 (1527-7568), $p = 0.01$) and similar levels of CD14 (3518 (1151-11631) vs. 5312 (3530-17163), $p = 0.1$) at 2 weeks post therapy start, relative to baseline. In intestinal tissue, CD14 (0.36 ng/ml (0.14-0.57) *vs*. 0.63 ng/ml (0.54-0.85), $p = 0.006$) and CD86 (0.43 ng/ml (0.23-0.89) *vs*. 1.35 ng/ml (1-3.09), $p = 0.01$) was lower in therapy responders compared to non-responders 4 months after therapy start.
Two weeks after therapy start, serum CCL2 decreased in therapy responders (169 pg/ml (69-663) vs. 132 pg/ml (43-241), $p = 0.03$) but not in non-responders (118 pg/ml (34-637) vs. 133 pg/ml (44-364), $p = 0.22$), relative to baseline. At 4 months after therapy start, serum CCL2 was still decreased in therapy responders (169 pg/ml (69-663) vs. 126 pg/ml (49-403), $p = 0.009$) but not in non-responders (118 pg/ml (34-637) vs. 128 pg/ml (60-174), $p = 0.16$) relative to baseline. This correlated with lower levels of CCL2 in intestinal tissue in responders as compared to non-responders after 4 months of treatment (12.6 pg/ml (1.4-56.9) vs. 755 pg/ml (465-862), $p = 0.006$). Serum CCL3, CCL4 and CX3CL1 were not linked to therapy response while CXCL10 was only decreased in therapy responders after 4 months (241 pg/ml (75-552) vs. 157 pg/ml (68-608), $p < 0.05$), relative to non-responders.
CONCLUSION: Infliximab therapy response in UC patients is associated with reduced monocyte expression of CD86 and CD14 and serum levels of CCL2 two weeks after therapy start. A similar pattern was observed in intestinal tissue 4 months after therapy start. Thus, reduced monocyte activation and recruitment two weeks after treatment start may reflect early infliximab therapy response in UC patients.

INTRODUCTION: Intestinal dendritic cells (DCs) and macrophages (MQs) have pivotal roles in intestinal homeostasis, and disruption of this balance can culminate in ulcerative colitis (UC). Relatively little is known about human DC and MQ subsets in the intestinal mucosa in health versus disease. Also, not much is known about retinoic acid, a vitamin A metabolite that can influence the generation of tolerance, and its role in UC.
AIMS & METHODS: Our aim was to study the population dynamics and retinoic acid production of DC and MQ subsets in UC patients with active inflammation and in clinical remission compared to non-inflamed control tissue. Colonic biopsies and surgical samples were collected from patients with active UC (inflamed tissue, $n = 28$), UC in remission (non-inflamed tissue, $n = 6$) and non-inflamed control subjects (non-inflamed tissue, $n = 28$). Blood samples were collected from UC patients in remission ($n = 6$) and non-inflamed control subjects ($n = 7$). Characterization of DCs and MQs was performed by flow cytometry. Lamina propria DCs were grouped into lin-HLADR+CD14-CD1c+ cells (CD1c+DCs) and lin-HLADR+CD14-CD141+ cells (CD141+DCs) and studied for their expression of CD103. Lamina propria MQs were grouped into lin-HLADR+CD14+HLADRint MQs (DRintMQs) and lin-HLADR+CD14+HLADRhi MQs (DRhiMQs). Blood monocytes were grouped into classical (CD14++CD16-), intermediate (CD14++CD16+) and non-classical (CD14+CD16++) monocytes. The ability of cells to produce retinoic acid was analyzed using the Aldefluor assay, which measures aldehyde dehydrogenase (ALDH) activity. Data are presented as median (range).
RESULTS: The inflamed intestinal mucosa of UC patients is characterized by an increased number per 10^5 lamina propria cells of DR^{int}MQs (1472 (160-4066) *vs*. 138 (1-1947), $p < 0.0001$) and a decrease in CD103+$CD1c^+$DCs (4 (1-26) *vs*. 19 (2-59), $p = 0.002$) and $CD103^+CD141^+$DCs (7 (1-38) *vs*. 24 (4-54) $p = 0.0009$) compared to non-inflamed controls. The frequency of $ALDH^+$ cells was reduced in $CD1c^+$DCs (13 % (6-28) *vs*. 47 % (18-61), $p = 0.003$), $CD141^+$DCs (16 % (7-29) *vs*. 33 % (14-64), $p = 0.006$), DR^{int}MQs (8 % (7-24) *vs*. 24 % (21-33), $p = 0.002$) and DR^{hi}MQs (18 % (9-33) *vs*. 56 % (47-69), $p = 0.0002$) from the inflamed lamina propria of UC patients compared to healthy controls. Interestingly, when studying ALDH activity in lamina propria of UC patients in remission, the frequency of $ALDH^+$ cells was also lower among $CD1c^+$DCs (18 % (8-30) *vs*. 47 % (21-61), $p = 0.005$), $CD141^+$DCs (18 % (13-26) *vs*. 41 % (17-64), $p = 0.003$) and DR^{hi}MQs (33 % (19-56) *vs*. 57 % (45-69), $p = 0.01$), compared to controls. In contrast, no difference in the frequency of $ALDH^+$ cells among classical, intermediate or non-classical blood monocytes was detected between UC patients and controls.
CONCLUSION: The inflamed intestinal mucosa in UC is characterized by an influx of DR^{int}MQs and reduced numbers of $CD103^+CD1c^+$DCs and $CD103^+CD141^+$DCs. Colonic myeloid cells of UC patients are imprinted by the intestinal environment to display low ALDH activity, regardless of disease activity, which may influence the delicate balance between inflammation and tolerance.

P1717 OSTEOPATHY IMPROVES THE SEVERITY OF IBS-LIKE SYMPTOMS ASSOCIATED WITH CROHN DISEASE IN REMISSION

D. Pishvaie[1], D. Tirouvaziam[1], R. Dainese[1], A. Setien[1], J.L. Payrouse[1], X. Hébuterne[1], **P. Thierry**[1,*]
[1]*CHU Nice, Université de Nice Sophia Antipolis, Nice, France*

INTRODUCTION: Osteopathy may improve the severity of the irritable bowel syndrome (IBS) (1). About 35% of patients with quiescent Crohn Disease (CD) continue to suffer from IBS-like symptoms (2).
AIMS & METHODS: We aimed to evaluate the effect of osteopathy on the severity of IBS-like symptoms in CD patients on remission. We prospectively assigned 38 patients with CD on remission over 12 months while receiving infliximab every 8 weeks. Twenty-five patients received 3 sessions of standardized osteopathy 15, 30 and 45 days after the last infusion of infliximab. Ten patients were followed at same interval for clinical interview. IBS-like symptoms were evaluated according to Rome III criteria. The impact of IBS-like and abdominal pain associated with CD on quality of life was evaluated using the Francis score and the Inflammatory Bowel Disease Questionnaire (IBDq). The severity of psychological factors was appreciated by evaluating anxiety, depression and fatigue with HAD, Beck and Fatigue Impact scale questionnaires. All patients were evaluated at day 0, 30, 45 and 60. Comparisons from baseline values were performed between groups and during time in each group.
RESULTS: Compared with baseline, the severity of IBS-like symptoms was significantly reduced in patients receiving osteopathy. Compared with controls, this decrease was significantly more pronounced in patients treated with osteopathy at day 30 (-38.4±43.9 vs 37.7±49.1, $p = 0.005$) and day 45 (-38.4±43.9 vs 37.7±49.1). Compared with controls, the clinical benefit of osteopathy was not sustained at day 60 (-30 ±43.3 vs -13±36.8, $p = 0.4$). The quality of life was significantly greater during osteopathy ($p = 0.09$ at day 30, $p = 0.02$ at day 45), being not significantly different at day 60 ($p = 0.3$). The severity of fatigue was significantly improved in patients receiving osteopathy with a persisting effect at the end of the study. The effect of osteopathy on depression scores was less marked, being statistically significant only at day 30. However, anxiety was not affected by osteopathy.
CONCLUSION: Three sessions of osteopathy improve the severity of IBS-like symptoms and quality of life associated with CD in remission, with no sustained clinical benefit after stopping treatment. Osteopathy improves fatigue and depression traits whereas anxiety is not changed. Osteopathy should therefore be considered in future clinical trials aimed at reducing the severity of abdominal pain and discomfort in patients with CD considered in remission.

P1718 ANTI-TNF THERAPY RESPONSE IS ASSOCIATED WITH LOWER MUCOSAL EXPRESSION OF INFLAMMATORY CYTOKINES BEFORE THERAPY START IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

R. Dahlén[1,*], M.K. Magnusson[2], H. Strid[1], A. Bajor[1], A. Lasson[3], K.-A. Ung[4], L. Öhman[1]

INTRODUCTION: The mechanisms of action of therapy response to anti-TNF treatment in IBD patients are currently not completely known. Therefore, we aimed to determine the mucosal immunopathology in IBD patients before anti-TNF treatment and four months after therapy start, in therapy responders and non-responders, respectively.
AIMS & METHODS: Mucosal biopsies from 37 IBD patients (UC = 27, CD = 7, unclassified = 3), (28 males, median age 36) were collected before anti-TNF antibody (infliximab or adalimumab) treatment start and at evaluation of therapy response, four months after therapy start. Therapy response was evaluated by comparing one or several of the following parameters before treatment start and after four months of therapy; CRP, fecal calprotectin, partial or complete Mayo score (UC) and HBI (CD). Biopsies were obtained from 24 therapy responders (UC = 17, CD = 5, unclassified = 2) before therapy start, and at four months post therapy start from 11 of these patients. Among non-responders, biopsies were obtained from 13 patients (UC = 10, CD = 2, unclassified = 1) at baseline, and at four months post treatment start from five of these patients. Total mRNA from biopsies was analyzed with real-time PCR. Expression of TNF, IL-1b, IL-17A, IFN-γ, IL-6, IL-13, FOXP3, TNFR1, and TNFR2 was determined. Results were normalized to the expression level of GAPDH and expressed as $2^{\text{-Target-GAPDH}}$. Data are shown as median arbitrary units, 25-75 percentile.
RESULTS: At baseline, there was no difference between UC and CD patients in any of the targets analyzed; therefore patients were not subdivided according to UC or CD-phenotype in subsequent analyses. At baseline, patients responding to therapy had lower levels of TNF (responders $36*10^{-5}$($24*10^{-5}$-$56*10^{-5}$) vs. non-responders $59*10^{-5}$ ($45*10^{-5}$-$76*10^{-5}$); p = 0.046)), and IL-1β ($200*10^{-5}$ ($110*10^{-5}$-$510*10^{-5}$) vs. $510*10^{-5}$ ($370*10^{-5}$-$800*10^{-5}$); p = 0.03) as compared to non-responders. Similar trends were seen for the expression of IL-17A, IFN-g and FOXP3. Among anti-TNF therapy responders, a reduced expression of TNF, IL-1b, IL-6 and FOXP3 was demonstrated, comparing baseline to four months post treatment start (Table 1). Among the patients not responding to the therapy, four out of five patients had reduced expression of IL-17A, IFN-g and IL-1b (p = n.s.) at baseline as compared to after four months of therapy.
Table 1. Mucosal RNA expression in therapy responders at baseline and four months after therapy start.

Target gene	Baseline (x10-5)	4 months post treatment start (x10-5)	p-value
TNF	54 (33-91)	19 (11-72)	0.03
IL-1β	360 (180-1200)	93 (49-180)	0.006
IL-6	130 (66-240)	11 (4.7-40)	0.03
FOXP3	37 (19-70)	18 (8.7-40)	0.007

CONCLUSION: The expression of several mucosal cytokine RNA decreases after four months of anti-TNF therapy among both responders and non-responders, although the cytokines regulated by the therapy may differ between the two groups. Before therapy start, therapy responders have lower mucosal cytokine expression of TNF and IL-1b than non-responders, indicating that non-responding patients might have a more severe immunopathology than responders.

P1719 CHARACTERIZATION OF APPENDICEAL LYMPHOCYTES IN ULCERATIVE COLITIS PATIENTS

S. Sahami[1,*], J. Bernink[2], A. te Velde[2], P. Tanis[1], W. Bemelman[1], C. Buskens[1]
[1]*Surgery,* [2]*Tytgat Institute for Liver and Intestinal Research, AMC, Amsterdam, Netherlands*

INTRODUCTION: An increasing body of literature reported on the negative correlation between an appendicectomy and the development of ulcerative colitis (UC). Extensive infiltration of CD4+ T cells has been observed in the inflamed mucosa of UC patients, and it has been suggested that aberrant activation of T-lymphocytes in the appendix could serve as a priming site. Furthermore, appendiceal mucosal tissue of UC patients showed an increased CD4/CD8 ratio that correlated with the disease activity in the colon. However, which T helper subsets accumulated in the appendix that might account for the enhanced susceptibility to develop UC, remains to be investigated.
AIMS & METHODS: In this study we aimed to characterize the T cell populations in appendiceal mucosal tissues of UC patients with inactive and active disease and compared them to Crohn's disease (CD) and acute appendicitis (AA).
Surgical samples of the appendix were obtained from UC patients and compared to patients with Crohn's disease (CD) and acute appendicitis (AA). UC patients were either in remission (inactive, median mayo score 1) or therapy refractory (active, median mayo score 3). The appendix was histologically evaluated by assessing the degree of inflammation and compared to a retrospective cohort of patients with unaffected appendices (operated upon for cancer). In order to determine the T-cell composition of the appendix in these patients, we took the advantage of multicolour flow cytometric analysis. Both freshly isolated mucosal appendix resection specimens and peripheral blood were stained with a cocktail of antibodies to discriminate between the cytotoxic T cells and T helper subsets.
RESULTS: In contrast to the transmural infection seen in appendices of CD and AA patients, resection specimens of UC patients appeared macroscopically normal. However, histological evaluation showed increased mucosal lymphocyte infiltration, which was not significantly different between inactive and active disease.
We observed in the appendix of UC patients a significantly lower proportion of pro-inflammatory CCR6+ CD4+ T helper cells when compared to CD.
Furthermore, although no significant difference was observed in CCR6+ CD4+ T helper cells between inactive and active UC resection specimens, the proportion of CCR6+ CD4+ T helper cells in peripheral blood of UC patients was significantly higher for inactive disease when compared to active disease.
CONCLUSION: Our results demonstrate that despite a macroscopically normal appearing appendix, there is an increased infiltration of T lymphocytes in appendices of UC patients, irrespective of disease activity. Although no difference was seen between inactive and active UC, the lower frequency of pro-inflammatory CD4+ CCR6+ T cells in the appendix of UC patients compared to CD patients is possibly a result of enhanced efflux of these cells to the affected colon.

P1720 NARROW SPECTRUM KINASE INHIBITORS (NSKI) TARGET KINASES INVOLVED IN BOTH INNATE AND ADAPTIVE IMMUNE RESPONSES LEADING TO POTENT AND HIGHLY EFFICACIOUS EFFECTS IN EXPERIMENTAL MODELS OF INFLAMMATORY BOWEL DISEASE

S. Sirohi[1,*], Y. Solanke[1], M. Butler[1], M. Foster[1], M.C. Fyfe[1], P. Biancheri[2], T.T. MacDonald[2], S. Webber[1], C.A. Walshe[1]

INTRODUCTION: Inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), is a complex disease involving both the adaptive and innate immune responses. Here we demonstrate that NSKI TOP1210 can modulate kinases (P38α & Lck) leading to inhibition of pro-inflammatory cytokine release from cells involved in both arms of the immune response. Furthermore, in vitro, in vivo, and patient explants demonstrate the potent and efficacious effects of NSKIs and their superiority to corticosteroids in these models.
AIMS & METHODS: Inhibition of phospho- P38α (pP38α) & phospho-Lck (pLck) were assessed *in vitro* in either an ATP-based biochemical assay or in human T cells and macrophages by flow cytometry or spectrophotometry methods. *In vivo* efficacy and target engagement of TOP1210 was investigated in an adoptive T cell transfer colitis model with modulation of pP38 and pLck in the mucosal tissue assessed by immunohistochemistry (IHC). Biopsies and cells isolated from IBD patients were cultured *ex-vivo* in the presence or absence of TOP1210 or Budesonide and assessed for pro-inflammatory cytokine release. Cytokine release for all models was assessed by ELISA.
RESULTS: In the *in vitro* assays, TOP1210 exhibited sub-100nM IC_{50} against both pP38α and pLck. Inhibition of pP38α was linked to a reduction of IL-8 release from stimulated human macrophages and inhibition of pLck correlated with a similar inhibition profile of IFNγ release from stimulated human T cells. Oral administration of TOP1210 (5 mg/kg) in an adoptive transfer T cell colitis model led to down modulation of pP38α and pLck in the mucosa of these animals and linked to a reduction in IL-8 and IFNγ release in colon homogenates. Furthermore, TOP1210 was superior compared to a maximum tolerated dose of Budesonide (1 mg/kg) in efficacy end points in the model (histopathology scores). Consistent with the *in vitro* and *in vivo* data, TOP1210 was also found to be a highly efficacious and a potent inhibitor of pro-inflammatory cytokine release from IBD patient biopsies and isolated cells (LPMC and myofibroblasts) with effects comparable, and in some cases superior, to Budesonide.
CONCLUSION: TOP1210 targets key kinases involved in the inflammatory signalling cascades of IBD pathogenesis. Down-modulation of these kinases in both a mouse *in vivo* colitis model and UC patient explants led to a significant reduction in pro-inflammatory cytokine release. TOP1210's efficacy, relative to budesonide, suggests NSKIs may provide an important alternative to corticosteroids in the treatment of IBD.

P1721 GENETIC POLYMORPHISM IN TRAF3IP2 GENE COULD BE PREDICTIVE FACTOR OF LONG-TERM EFFECT OF INFLIXIMAB AGAINST CROHN'S DISEASE

S. Urabe[1,*], H. Isomoto[1], K. Maeda[2], T. Ishida[3], Y. Fukuda[4], C.C. Chen[1], F. Takeshima[1], H. Machida[1], K. Nakao[1], K. Tsukamoto[2]

INTRODUCTION: Infliximab (IFX) is a TNF-α monoclonal antibody which have substantial effects for remission induction and maintenance for Crohn's disease (CD). However, there are primary failure patients who could not get remission and secondary failure patients who once got remission but the effect of IFX was lost later. In this regard, the identification of biomarkers to predict the therapeutic effect is important. The present study was conducted to elucidate the association of genetic polymorphisms in IL17RA, IL17RC, TRAF3IP2, IL17A, and IL17F in interleukin-17 signaling pathway with therapeutic effects of IFX against CD.

AIMS & METHODS: CD patients who were treated with infliximab in Oita Red Cross Hospital, Nagasaki University Hospital and Nagasaki Harbor Medical Center City Hospital were enrolled in this study. The study was approved by each ethics committee and informed consent was obtained from each subject. For correlation analysis of the short-term treatment effect, we extracted 112 patients who have been assessed treatment effect of 10 weeks after infliximab administration, and for analysis of long-term effect, extracted 104 patients assessed 1 year after, and 93 patients assessed 2 years after administration, and in each treatment period, the patients were divided into two groups whether the treatment was effective or not. In each period, significance tests were performed between sensitive group and resistance group about the frequency of occurrence of genetic polymorphism of IL17RA, IL17RC, TRAF3IP2, IL17A and IL17F.

RESULTS: There were significant differences in the frequency of occurrence of rs10872070 which is single nucleotide polymorphism (SNP) in TRAF3IP2 between the sensitive group and the resistance group two years after IFX administration ($p = 0.022$, $OR = 0.068$). Sensitivity as a biomarker to predict the treatment-resistance was 16.7%, and the specificity was 98.7%. In addition, the positive predictive value was 75.0%, and negative predictive value was 83.1%.

CONCLUSION: We for the first time found that TRPF3IP2 could be the treatment-resistant gene in IFX therapy for CD. This gene polymorphism could be a biomarker to predict the treatment-resistance and secondary failure of IFX. Moreover, IL-17 signaling pathway suggested that participating in the treatment-resistance of IFX would involve the pathogenesis of CD, and it could be a target molecule for novel therapeutics combined with a TNF-α monoclonal antibody.
