INTRODUCTION: Elevated aspartate aminotransferase (AST) may not be associated with liver or muscle injury and can be caused by the presence of macroAST which results from unusual combination of molecules of AST with serum macroglobulins. MakroAST may be present in both healthy subjects and in the course of other diseases, including autoimmune diseases. Only few reports in limited number of patients described Macro AST and proposed diagnostic criteria.
AIMS & METHODS: The aim of this study was to evaluate the prevalence of macroenzymes in children with increased activity of aspartate aminotransferase and to compare two diagnostic methods- polyethylene glycol precipitation (PEG) and electrophoresis.
Methods: 247 children with mean age of 6.2 years (from 0.03 to 16.19 years) with isolated hypertransaminasemia were included in the study. The presence of macroenzymes was first based on polyethylene glycol precipitation (PEG), according to Levitt and Ellis [1]. Electrophoresis was used to confirm the presence of a macroAST.
RESULTS: In a group of 247 children with hypertransaminasemia (all with increased AST, 48 children presented with increased AST and ALT) we received the following results according to the different cut off values for precipitable activity (% PPA) of the PEG test:
1/ according to Davidson and Watson [2] with a cut-off point of 54% PPA macro AST was observed in 67 children (27.1% of the patients).
2/ according to Caropreso M, et al [3] with a cut-off point of 73.3% PPA macro AST was observed in 5 children (2.0% of the population studied).
Samples with AST activities > 50 U/l were analyzed with both PEG precipitation and electrophoresis. AST isoenzyme electrophoresis showed macroAST in 35 children which is 14% of the population studied.
CONCLUSION: MacroAST has to be considered in differential diagnosis of increased AST activity.
The cut off values for polyethylene glycol precipitable activity test need to be further evaluated and requires further confirmation with electrophoresis.
The cut off value of 54% PPA can be used as a screening test for macroAST.

INTRODUCTION: Primary sclerosing cholangitis (PSC), autoimmune hepatitis (AIH) and PSC/AIH overlap syndrome are three autoimmune liver diseases (AILD) of unknown origin.
AIMS & METHODS: Aim of this population-based observational case-control questionnaire study was to investigate the environmental risk factors associated with a paediatric onset AILD. All the patients (n = 85) with a paediatric onset (< 16 years) AILD diagnosed between 1985-2011 at Helsinki University Central Hospital (HUCS) were mailed a questionnaire, evaluating contact with environmental risk factors before the AILD diagnosis in 22 items, e.g., number of siblings, place of living (i.e., country/town, downtown/suburb), type of housing (i.e., block of flats, town house, terraced house, duplex), having pets or domestic animals (e.g., cat, dog, horse), smoking and other items. Two control groups -matched for sex, age and place of residence- were used: 1) as AILD are more frequent in patients affected by inflammatory bowel disease (IBD)[1] a paediatric group of patients with IBD without AILD (n = 91; selected from IBD Register of HUCS) was included and 2) a group of healthy subjects (n = 716; selected from Population Register Center). Univariate analysis (ORs; 95%CI) was performed using the two control groups separately. A logistic regression model for the multivariate analysis including (i) variables statistically significant in univariate analysis and (ii) confounders and interactive factors, was calculated; two models were constructed for controls: model 1 = IBD and healthy controls, model 2 = healthy controls.
RESULTS: Baseline characteristics (Percentage of respondents. F = female. Median age: range years) AILD cases: 51/85 (60%; F = 26; 22:8-36), IBD controls: 59/91 (65%; F = 34; 21:9-37), healthy controls: 292/716 (41%; F = 162; 21:8-38). No difference between respondents and non-respondents. Median age and range at AILD onset 10 years: 2-15. **Univariate analysis** Protective and risk factors are shown in Table 1; others factors were not associated with AILD. **Multivariate analysis** Children traveling abroad except those living in a block of flats seemed to be protected for developing AILD (Model 1 OR: 0.07; 95%CI: 0.02-0.2. Model 2 OR: 0.06; 95%CI: 0.02-0.2). Living with a cat or a dog was a risk factor (Model 1 OR: 2.7; 95%CI: 1.3-5.7. Model 2 OR: 2.1; 95%CI: 1.0-4.2). In models studying the effect of pet species individually, those living in a block of flats with a cat had the highest risk (e.g., Model 2 OR: 6.4; 95%CI: 1.8-22.7).**Table 1**

	IBD controls		Healthy controls	
	OR	**95%CI**	**OR**	**95%CI**
Traveling abroad	0.3	0.1-0.7	0.2	0.1-0.4
Having a pets (cat or dog)	3.4	1.5-7.8	2.5	1.2-5.0

CONCLUSION: In this postal questionnaire based survey of environmental risk factor of AILD, children traveling abroad and living in a town house, terraced house or duplex were less susceptible to develop AILD, suggesting a protective role of a higher socioeconomic status. Intriguingly, living in a close contact with a pet was a risk factor, suggesting an involvement of an unidentified agent (i.e., toxin or microbe) as a trigger of paediatric AILD.

INTRODUCTION: Alagille syndrome (AGS, OMIM #118450) is an autosomal dominant multisystem disorder affecting the liver, heart, face, eyes and skeleton. In early infancy AGS may mimic biliary atresia (BA) and extrahepatic bile ducts might not be visualised by endoscopic retrograde cholangiopancreatography (ERCP) or postoperative cholangiography.
AIMS & METHODS: Our aim was to confirm the diagnosis in patients with suspected AGS (n = 4) and to identify carriers of *JAG1* mutations among patients with BA (n = 72), all aged 2 months on average.
310 children with neonatal cholestasis were hospitalized at the Department of Peaditrics, Faculty Hospital Motol, Prague, between January 1998 and January 2012. ERCP was indicated in 127 patients with suspected BA based on clinical and laboratory examinations. Subsequent surgical revision was performed in 96 patients with pathological findings on the bile ducts. Mutational analysis of the *JAG1* gene was done in a subset of 72 living patients with isolated BA and in 4 patients with suspected AGS and normal extrahepatic biliary tree.
RESULTS: Sequence analysis of *JAG1* revealed seven novel mutations including one missense [c.401G > T (p. Leu135Phe)], one nonsense [c.1998T > A (p. Cys633*)] and five frameshift mutations [c.327_330delCAAG (p. Lys110Profs*50), c.1313_1314delGT (p. Cys438Serfs*10), c.879_880delTG (p. Cys293*), c.2913-2914delAC (p. Pro971Argfs*10), c.2050delG (p. Asp684Thrfs*59)], and one known nonsense mutation [c.960T > A (p. Tyr320*)]. All 5 patients with proven *JAG1* deficiency presenting initially as BA developed clinical signs typical for AGS before 3 years of age. By contrast, no *JAG1* mutation were present in the remaining 67 patients with isolated BA.
CONCLUSION: Biliary atresia is not associated with *JAG1* mutations in Central Europeans. In addition to liver histology, early molecular diagnosis of AGS could be useful in diagnosis of the "gray zone" AGS patients presenting as extrahepatic biliary atresia in early infancy.

P0657 STEATOSIS OF PANCREAS IN THE STRUCTURE OF METABOLIC SYNDROME IN OVERWEIGHT AND OBESE CHILDREN

M. Gurova[1,*], A. GusevA[2], V. Novikova[3]
[1]*Department of Pediatrics, Belgorod State National Research University, Belgorod,* [2]*Department of Pediatrics, Kursk Regional Children Hospital, Kursk,* [3]*Department of Pediatrics, Federal Centre of the Heart, Blood and Endocrinology, named after V. A. Almazof, Saint-Petersburg, Russian Federation*

INTRODUCTION: Involvement of pancreas in pathological process in case of obesity is caused by its important role in regulation of metabolic processes, of energetic balance and body weight.
AIMS & METHODS: This study is aimed at assessing frequency of detectability of ectopic fat deposition in the pancreas in obese and overweight children and at comparing this detection frequency of other components of metabolic syndrome (MS).
Methods: The cross-sectional study was conducted among 120 children aged 11-15 years, separated into 2 groups: 60 overweight children (1st group) and 60 obese children (2nd group). Diagnosis of the non-alcoholic fatty liver disease (NAFLD) and non-alcoholic fatty pancreas disease (NAFPD) was based on sonographic data. Peculiarities of carbohydrates and lipid metabolism and pancreatic exocrine function were investigated.
RESULTS: Complete MS was diagnosed only in 15% of children with obesity. Some components of MS according IDF recommendations (2005) were found in 88.3% of obese children and 66.7% of overweight ones ($p = 0.002$). The most common components were the following hyperinsulinemia (90% vs 66.7%, $p = 0.0027$), insulin resistancy according results of HOMA-index (51.7% vs 65%, $p = 0.12$), increasing triglycerides level (36.7% vs 6.7%, $p = 0.00l$), decreasing level of LPHD (78.3% vs 40%, $p = 0.001$). Sonographic data compatible with NAFLD were two times higher in children with obesity 56.7% vs. 30% ($p = 0.005$), whereas NAFPD data were found with equal frequency in overweight and obese children - 85% and 86.7% accordingly ($p = 0.88$). These results were associated with decreasing level of the elastase-1 in 23.3% children with obesity.
CONCLUSION: Sonographic results compatible with NAFPD were found more than in 2/3 cases in overweight and obese children and they had appeared earlier than sonographic results of NAFLD which were found only in 1/3 cases of overweight children and ½ cases of obese patients. These results were associated at first with carbohydrate metabolism disturbances (insulin resistancy), whereas atherogenic dyslipidemia in our study was not prominent. In 23% obese children with sonographic changes considered as pancreatic steatosis signs of mild exocrine insufficiency were found.

INTRODUCTION: Paediatric pancreatitis although reported has not emanated from developing world as a large single center study. More so, natural history of acute pancreatitis as a continuum of recurrent acute and chronic pancreatitis is not well established.
AIMS & METHODS: To look at prevalence, aetiologic categorization, dynamics, severity assessment and outcome in children with pancreatitis.
METHODS: From January 2002 to December 2013 consecutive children (≤18 years of age) diagnosed to have pancreatitis were included for analysis. Pancreatitis was classified as acute (AP), acute recurrent (ARP) and chronic pancreatitis (CP) as per standard definitions. Severity of acute pancreatitis was assessed by 2012: revised Atlanta classification. Follow-up data was assessed till March 2014.
RESULTS: Pancreatitis was diagnosed in 267 children (mean age of 11.29 ± 3.49 years). AP in 50% ($n = 133$), ARP in 22% (60) and CP 28% (74). The number of cases increased progressively from 18 in the 1st quarter of the study to 37 in 2nd quarter, 64 in 3rd quarter and 148 in the last quarter. Aetiology of AP was trauma in 22% ($n = 29$), biliary 10.5% (14), viral infection 7% (9), drugs 5% (7), others causes in 4.5% (6) and idiopathic 51% (68). Grading of pancreatitis was severe in 13% (17, 6 died), moderately severe (local complications) 55% (73) and mild 32% (43). Over a median follow-up of 12 (range, 3 to 96) months, 23.5% (27 / 115) developed either acute recurrent ($n = 9$) or chronic pancreatitis (18). Progression from acute to ARP/CP was observed mostly in idiopathic group (22/27). In ARP group, 10 were due to biliary causes (choledochal cysts 8, gallstones 2), pancreas divisum 3, duodenal diverticulum 1 and the remaining 46 (76.6%) were idiopathic. Over a median follow-up of 12 (range 3 to 120) months 31% (11/35) of idiopathic ARP cases developed CP. Almost half of CP (39 /74) were chronic calcific, 6 were familial, 4 had associated pancreas divisum and the remaining 64 (86%) were idiopathic. Among CP ($n = 63$), over a median follow-up of 13 (range, 3-120) months, 3 cases developed diabetes mellitus, one steatorrhoea, none had cancer and there was no mortality.
CONCLUSION: There is almost eight fold increase in the prevalence of pancreatitis over last 12 years. Among AP (mainly idiopathic subgroup) 23% progressed to ARP and chronic pancreatitis. The majority of ARP was idiopathic (77%) and a third of them progressed to CP. Thus a subset of pancreatitis seems to be a continuum of acute to ARP and CP.

P0659 EUS GUIDED NECROSECTOMY TEMPORARY CYSTOGASTROSTOMY WITH COVERED STENT FOR PANCREATIC NECROSIS

A. Krishnan[1,*], R. Ramakrishnan[1] on behalf of None
[1]*Fortis Malar Hospitals, Chennai, India*
Contact E-mail Address: *dr.arunkumarpillai@gmail.com*

INTRODUCTION: Pancreatic pseudocyst with infected necrotic tissue is associated with a high rate of complications and death. Standard treatment is open necrosectomy but is associated with significant morbidity, mortality, and prolonged hospital stay. Endoscopic cyst drainage with necrosectomy is an alternative and less invasive technique.
AIMS & METHODS: Aim: to evaluate pseudocyst drainage with cystogastrostomy and endoscopic necrosectomy for infected pancreatic necrosis with fully covered self-expanding metallic stents (CSEMS).
12 patients underwent endoultrasound guided endoscopic necrosectomy and temporary cystogastrostomy for infected pancreatic necrosis by using CSEMSs. Patient details, disease severity scores, scores for severity assessed at CT, treatment procedures, length of hospital stay, and outcome for patients undergoing endoscopic therapy were recorded. Patients proceed to intervention if infection is strongly suspected on clinical and radiological grounds or is confirmed bacteriologically. After the necrosis cavity had been accessed, with the assistance of endoscopic ultrasound, a large orifice was created and necrotic debris was removed using special short fully covered 15mm diameter SEMS with large flares was deployed across the tract under radiological control. Completeness of the necrosectomy procedure was ascertained by visualization of a clear pseudocyst cavity on endoscopy.
RESULTS: A total of 12 patients (10 men, 2 women; median age 39, range 19 - 76) were treated successfully. Median APACHE 2 score on presentation was 11 (range 3±18). Two patients presented with organ failure and needed intensive care. Necrosis was successfully treated endoscopically in all patients, requiring a median of 2 endoscopic interventions (range 1±4). The tissue samples obtained at the first necrosectomy confirmed infection in 12 patients. Complication included superinfection in patient who made an uneventful recovery. After median of 5 weeks the metal SEMS was extracted by endoscopy. The patients have remained asymptomatic and median follow-up was 4 (2±11) months.
CONCLUSION: Endoscopic necrosectomy and temporary cystogastrostomy with self-expanding metallic stent approach is feasible, safe, and effective in patient with infected pancreatic necrosis. The benefits of this endoscopic approach using fully covered self-expandable metallic stent in terms of less morbidity is conceivable and our report demonstrates that such an approach is feasible.

P0660 EUS-GUIDED PANCREATIC PSEUDOCYST DRAINAGE: AN ASSESSMENT OF EFFICACY, SAFETY, LONG-TERM FOLLOW-UP, AND TECHNICAL FEASIBILITY OF SINGLE-STEP APPROACH

A. Krishnan[1,*], R. Ramakrishnan[1] on behalf of None
[1]*Fortis Malar Hospitals, Chennai, India*
Contact E-mail Address: *dr.arunkumarpillai@gmail.com*

INTRODUCTION: Pancreatic pseudocyst is common complication of acute and chronic pancreatitis. While surgery is associated with significant complications and mortality, percutaneous drainage is associated with prolonged hospitalization and often times the need for other adjunctive treatment.
AIMS & METHODS: Assess the safety and efficacy of single-step EUS-guided pseudocyst drainage, evaluate the technical Feasibility.
69 patients who had undergone Single-step EUS guided drainage of pancreatic pseudocyst were included. Controlled radial expansion wire guided balloon dilation of the puncture tract was performed followed by insertion 10 Fr double pigtail stents were inserted into the pseudocyst from either the stomach or the duodenum in adults and 7F stents in children.
RESULTS: The mean age of 39 years. Median size was 12.5 cm in diameter. 56 patients had infected and rest had non-infected pseudocyst. Stent placement was successful in all. The technical success rate was 100%, and the treatment success rate was 98.5%. 54 patients had cystogastrostomy and rest of the patients had cystoduodenostomy with cyst drainage. There was one case with perforation and required an emergency operation. 98.5% patients had complete resolution of a pseudocyst. The double pigtail stent was removed in all cases after median duration of 10 weeks. Regarding long-term outcomes, recurrence of a pseudocyst was not observed over a median follow-up of 58 weeks.
CONCLUSION: Single-step EUS-guided transmural drainage is safe and associated with high success rate. It can be the first choice for therapy of pancreatic pseudocyst with good technical feasibility, efficacy, and safety with long-term results are acceptable.

P0661 EUS-GUIDED INTERVENTION IN WALLED-OFF PANCREATIC NECROSIS (WOPN): SINGLE CENTER EXPERIENCE WITH LONG TERM FOLLOW-UP

M.C. Sulz[1], **C. Meyenberger**[1,*]
[1]*Department of Gastroenterology and Hepatology, Kantonsspital St. Gallen, St. Gallen, Switzerland*
Contact E-mail Address: *michael.sulz@kssg.ch*

INTRODUCTION: Necrotising pancreatitis is associated with high morbidity and mortality [1-3]. Walled-off pancreatic necrosis (WOPN) is defined as a mature, encapsulated necrotic collection with well defined wall. Early intervention (< 4 weeks) should be avoided whenever possible [4, 5]. Compared to the traditional surgical necrosectomy, the endoscopic treatment shows significant reduction of major complications, of pancreatic fistula, and of pro-inflammatory response (IL-6). We present the largest prospective single-center experience regarding endoscopic treatment of WOPN in Switzerland with long term follow-up and add data to the increasing experience with this technique.
AIMS & METHODS: To evaluate the short- and long term outcome of patients with walled-off pancreatic necrosis (WOPN) after endoscopic treatment. This retrospective, observational study at a single center with tertiary care endoscopy in Switzerland included all patients with necrotising pancreatitis from 2002 until 2013 complicated by WOPN who underwent endoscopic treatment (two experienced interventionalists). Clinical short term success (<30 days) was defined as resolution of patient's symptoms requiring no further interventions. Clinical failure was defined as failure to either resolve the collection, or requiring other interventions, and/or complications requiring other therapeutic modalities (e.g. surgery), and/or death. Approval was obtained by the local Ethical committee.
RESULTS: 35 Caucasian patients with WOPN (median age 64.1 y, range 40-85 y; ASA II and III 51.3% and 35.9%; 73.1% males) underwent endoscopic treatment. The biliary disease was the primary cause of necrotising pancreatitis (57.1%). The median duration of pigtails was 52 days (range 8-552 days), the median duration of transpapillary stents was 82.5 days (range 5-563 days). The short- and long term results results are shown in Table 1.

Short- and longterm outcome	%
Complete clinical success	62.3
Radiological success	75.3
complete/ partial	20.8/54.5
Short term mortality (<30d)	11.5
Complication rate Overall/related to endotherapy/to drainage	26.7/15.4/11.5
Rate of **additive radiological drainage**	15.4
Rate of **additive surgery**	23.1
Hospital stay, days, median (range)	41 (3-114)
Time of follow-up, months (median, range)	30.5 (1-180)
Longterm clinical well-being	76.9 %
Long term mortality (related to disease)	12.0 %
After endoscopic treatment/after surgery	4.0/8.0%
Secondary clinical failure (%)	21.7 %
Re-treatments (%)	14.3 %
Elective surgery	23.8 %

CONCLUSION: Our short term and long term follow-up data confirm that endoscopic interventions in WOPN are effective and safe. Future randomized prospective multicenter trials are needed to increase the generalizability.

INTRODUCTION: The natural history of acute pancreatitis(AP) is based on retrospective studies that elucidate the possible course of disease. The aim of this prospective, observational study was to evaluate the long-term occurrence of recurrent acute pancreatitis (RAP) and chronic pancreatitis (CP), in a cohort of patients affected by an initial episode of AP admitted to a single tertiary referral center.
AIMS & METHODS: 196patients admitted to our center for an initial episode of AP were consecutively enrolled and prospectively followed for 52.5 (26.8) months[mean (SD)]. Clinical characteristics,exogenously and endogenously associated-factors,and evolution to RAP and CP were analyzed.
RESULTS: 40patients developed RAP and 13 of these developed CP. The annual relapse rate was 5.4 (CI 95% 4.0-7.4) per 100 person-years. In univariate analysis, RAP was associated with idiopathic etiology ($p<0.001$), pancreas divisum (PD) ($p=0.001$), higher cigarettes and alcohol intake ($p<0.001$; $p=0.023$). CP was associated with severe AP first-episode ($p=0.048$), PD ($p=0.03$), and cigarettes smoking ($p=0.038$). By multivariate analysis,PD was an independent risk factor for RAP development (OR 11.5, 95% CI 1.6-83.3). Severe AP first episode increased the risk of progressing to CP by nine-fold (OR 9.3, 95% CI 1.8-47.2). Mutation frequencies of CFTR and SPINK-1 N34S were substantially higher compared to the general population but not statistically significant.
CONCLUSION: Understanding the factors that may predispose to RAP and CP holds important clinical implications for the prevention of disease progression. Special attention should be given to patients who experienced a severe first attack of AP, given the increased risk of developing CP.

P0663 A PROSPECTIVE MULTICENTER EVALUATION OF THE RADIOLOGICAL PERFORMANCE OF THE REVISED ATLANTA CLASSIFICATION

H. Sternby[1,*], R.C. Verdonk[2], A. Dimova[3], P. Ignatavicius [4], L. Ilzarbe[5], P. Koiva[6], A. Nieminen[7], T.L. Bollen[8] on behalf of Pancreas 2000 Atlanta Group
[1]*Dep of Surgery, ICS, Malmö, Sweden,* [2]*Dep of Gastroenterology, AZ, Nieuwegein, Netherlands,* [3]*Dep of Surgery, UHP, Sofia, Bulgaria,* [4]*Dep of Surgery, HLUHS, Kaunas, Lithuania,* [5]*Dep of Gastroenterology, HdM, Barcelona, Spain,* [6]*Dep of Gastroenterology, ETCH, Tallinn, Estonia,* [7]*Dep of Surgery, HUS, Helsinki, Finland,* [8]*Dep of Radiology, AZ, Nieuwegein, Netherlands*
Contact E-mail Address: *hannasternby@gmail.com*

INTRODUCTION: The Revised Atlanta Classification defines morphological features and descriptions of acute pancreatitis (AP) and its complications to enable standardized reports and communication. New computer tomography (CT) criteria are introduced to describe local complications in AP. However, these CT criteria have not yet been validated in an international setting.
AIMS & METHODS: The aim of this study was to analyze the interobserver agreement of the revised Atlanta criteria for CT findings in AP. Patients with a first episode of AP who obtained a CT were consecutively enrolled at six European centers. The CTs of each center were prospectively scored separately by a local radiologist at each center and an expert central radiologist (representing the reference standard) using the criteria stated in the Revised Atlanta Classification. No specific training was provided for the local radiologists before scoring. Interobserver agreement was determined using Kappa statistics. Clinical data was collected retrospectively.
RESULTS: 285 patients (56 % males) with a median age of 58 years with 388 CTs in total were enrolled. Aetiology of AP was gallstones in 36.6 %, alcohol in 35.9 %, and idiopathic in 27.5 % of the patients. AP was mild in 37,5 % of the patients, in 51.5 % moderately severe, and severe in 10.9 %. Overall interobserver agreement was moderate to substantial. However, the agreement differed substantially between the participating centers. The center independent kappa values for the different categories are shown in the table below.

Category scored	Kappa value - Agreement
Type of pancreatitis	0,370 - Fair
Parenchymal necrosis	0,539 - Moderate
Extrapancreatic necrosis (EXPN)	0,326 - Fair
Presence of Collections	0,756 – Substantial
Location of Collections	0,633 - Moderate
Characteristics of Collections	0,408 - Fair
Presence and Characteristics of Wall	0,675 - Substantial
Presence of gas/fluid level	0,764 - Substantial
Collection – most appropriate term	0,356 - Fair

In four categories agreement was merely fair. Detailed analysis showed that the low kappa values can be explained by discrepancies in the identification of extrapancreatic necrosis (EXPN). In most centers, the local radiologists identified EXPN less frequently than the expert central radiologist (126 vs 230 cases).
CONCLUSION: For most findings, interobserver agreement is moderate to good when CTs are scored according to the Revised Atlanta Classification even without prior training or instructions. However, the identification of EXPN remains problematic with poor interrater agreement. Previous studies suggest that EXPN might be considered a separate entity in acute pancreatitis. Given the results of this study, the definition and recognition of EXPN deserves further study.

P0664 ORAL UDENAFIL AND ACECLOFENAC FOR THE PREVENTION OF POST-ERCP PANCREATITIS IN HIGH-RISK PATIENTS: A RANDOMIZED, PLACEBO-CONTROLLED, MULTICENTER STUDY

H.-C. Oh[1,*], T.Y. Lee[2], J.S. Choi[3], T.Y. Park[1], J.H. Do[1], Y.K. Cheon[2], T.J. Song[4]
[1]*GASTROENTEROLOGY, CHUNG-ANG UNIVERSITY COLLEGE OF MEDICINE,* [2]*GASTROENTEROLOGY, Konkuk University, Seoul,* [3]*GASTROENTEROLOGY, Inje Univ Busan Paik Hosptial, Busan,* [4]*GASTROENTEROLOGY, Asan Medical Center, Seoul, Korea, Republic Of*
Contact E-mail Address: *ohcgi@cau.ac.kr*

INTRODUCTION: Acute pancreatitis is a common complication of ERCP. Combination therapy with oral udenafil and aceclofenac may reduce the occurrence of post-ERCP pancreatitis by targeting different pathophysiological mechanisms underlying acute pancreatitis. This study aimed to determine whether combining udenafil and aceclofenac reduces the rates of occurrence of post-ERCP pancreatitis.
AIMS & METHODS: A prospective, randomized, double-blind, placebo-controlled, multicenter study was conducted in four academic medical centers. Between January 2012 and June 2013, a total of 216 patients who underwent ERCP were analyzed for the occurrence of post-ERCP pancreatitis. Patients were determined to be at high risk for pancreatitis on the basis of validated patient and procedure-related risk factors.
RESULTS: Demographic features, indications for ERCP, and therapeutic procedures were similar in each group. There was no significant difference in the rate (15.8% [17/107] vs. 16.5% [18/109], p = .901) and severity of post-ERCP pancreatitis between the udenafil/aceclofenac and placebo groups. One patient in each group developed severe pancreatitis. On multivariate analyses, suspected sphincter of Oddi dysfunction and endoscopic papillary balloon dilatation without sphincterotomy were associated with post-ERCP pancreatitis.
CONCLUSION: Combination therapy with udenafil and aceclofenac was not effective for the prevention of post-ERCP pancreatitis.

P0665 NASOGASTRIC TUBE FEEDING VERSUS NASOJEJUNAL TUBE FEEDING IN SEVERE ACUTE PANCREATITIS

J.M. Rubio[1,*]
[1]*Section of Gastroenterology, Philippine General Hospital, Manila, Philippines*
Contact E-mail Address: *jowi5271@yahoo.com*

INTRODUCTION: Severe acute pancreatitis is a major cause of morbidity and mortality. Reviews have advocated enteral nutrition over parenteral nutrition in its management. Nasogastric tube is easier to insert than nasojejunal tube. The objective of this study is to determine the efficacy of nasogastric tube feeding in terms of exacerbation of pain, mortality, pancreatic infection and complications such as diarrhea in comparison to nasojejunal feeding.
AIMS & METHODS: RCT's among patients with severe acute pancreatitis comparing NGT feeding to NJT feeding were selected for inclusion. Search for randomized controlled trials was carried out using search engines such as PubMed, Ovid, Google scholar. Search terms were "severe acute pancreatitis", "enteral nutrition" and other synonyms listed in MeSH. The data were analyzed using Review Manager RevMan5.
RESULTS: 86 studies were found. Only 3 studies were included. NGT feeding did not result in an increase in exacerbation of pain as compared to NJT feeding (CI 0.31-3.22, p value 0.99). There was no significant difference between NGT and NJT feeding in terms of mortality (CI 0.38-2.06, p value 0.77). NGT feeding showed a trend towards benefit in reducing pancreatic infection (CI 0.17-1.76, p value 0.31). NGT feeding showed a trend toward causing diarrhea (CI 0.56- 4.05, p value 0.42).
CONCLUSION: NGT feeding is comparable to NJT feeding in exacerbation of pain, incidence of infection, complications such as diarrhea and mortality. NGT feeding can be used as an alternative to NJT feeding in institutions where an endoscopy guided NJT insertion cannot be done

P0666 CLINICAL PREDICTABILITY OF FLUID COLLECTIONS IN ACUTE PANCREATITIS USING INTERLEUKIN-6 LEVEL AND NOVEL APACHE-IL SCORE

S. Appasani[1,*], J. Basha[1], M. manrai[1], P. Siddappa[1], T. Yadav[2], V. Gupta[2], P. Sarotra[3], S.K. Sinha[1], R. Kochhar[1]

INTRODUCTION: Cytokine storm occurring in early phase of acute pancreatitis (AP) plays an important role in development of local & systemic complications. Fluid collections contribute significantly to the morbidity of this illness, hence its predictability in early phase could help in clinical triage.
AIMS & METHODS: AIMS
To prospectively evaluate the role of cytokine estimation at admission to predict the formation of fluid collections and correlate it with standard scoring systems.
MATERIALS AND METHODS
110 consecutive patients (69% males, age 17–70yrs) with AP were evaluated after an informed consent from Jan2012-March2013. Patients were stratified into mild, moderate & severe pancreatitis as-per revised Atlanta criteria and were treated with nutritional & organ support. Serum cytokine (Interleukin (IL) 6, 10, Tumor Necrosis Factor (TNF) Alpha) and fibronectin levels were analyzed quantitatively at admission (ELISA). APACHE, BISAP & SIRS scores were also calculated. Cytokine levels were compared with standard parameters while analyzing severity, development of fluid collections and outcome of AP using SPSS v17.0.
RESULTS: The median levels of IL-6 were higher in patients with severe pancreatitis (761.78pg/ml, n = 42) than in those with mild pancreatitis (277.80pg/ml, n = 40) and moderate pancreatitis (397.50pg/ml, n = 28, p = 0.038). At a cut off of 488pg/ml, IL-6 had a sensitivity of 85% & specificity of 75% in predicting severe pancreatitis (AUC = 0.702, p = 0.016). The median IL-6 levels were higher in patients with necrosis (635.0pg/ml) than in those without (372.5pg/ml, p = 0.008) as well in patients with organ failure than those without (540.35pg/ml vs. 406.42pg/ml, p = 0.046). Serum IL-10, TNF Alpha and fibronectin levels did not correlate with these events. Pearson & Spearman bivariate analysis revealed good correlation of IL-6 with CTSI (0.432, p = 0.001), APACHE score (0.354, p = 0.032), BISAP score (0.316, p = 0.019) and SIRS score (0.487, p = 0.007).
Patients who developed fluid collections had higher IL-6 levels than those who did not (524.28pg/ml vs 358.21pg/ml, p = 0.031). IL-6 levels also correlated with the type of collection (acute necrotic collection vs. acute peripancreatic fluid collection, p = 0.017). Standard APACHE score predicted only severity and necrosis but did not correlate with fluid collections. Hence we postulated a new APACHE-IL score by adding 2 points to standard APACHE score if IL-6 levels were elevated (> 488pg/ml). At a cut off of 6, APACHE-IL score had a sensitivity of 85% and specificity of 80% in predicting development of fluid collections (AUC = 0.746, p = 0.027).
CONCLUSION: IL-6 level at admission is an effective predictor of severity of acute pancreatitis (as per revised Atlanta) as well as of development of organ failure, necrosis and fluid collections. We recommend IL-6 to be measured for early risk stratification and APACHE-IL score for fluid collection prediction.

INTRODUCTION: Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) mutations are established risk factors for chronic pancreatitis (CP). CFTR variants increase disease risk by causing impairment of pancreatic ductal bicarbonate secretion. However, the role of genetic variations in the bicarbonate secreting SLC26A6 anion transporter has remained largely unexplored so far.
AIMS & METHODS: Our aim was to investigate the role of the *SLC26A6* gene in CP. 96 subjects with CP (cases) and 99 subjects with no pancreatic disease (controls) were recruited from the Hungarian National Pancreas Registry. In a discovery cohort of 30 idiopathic CP cases the entire *SLC26A6* coding sequence, including 21 exons and the exon-intron boundaries were amplified and sequenced. Further genotyping of p. V206M and p. P397P mutations in CP and controls was carried out by RFLP.

RESULTS: Sequencing analysis of the discovery cohort revealed four common mutations: intronic mutations c.23+71_23+103del, c.183-4C>A and c.1134+32C>A; and exonic missense mutation p. V206M. These four mutations were found in linkage disequilibrium indicating a conserved haplotype. We found this haplotype in 18 heterozygous and 2 homozygous cases, and in 24 heterozygous and 2 homozygous controls (allele frequency 11.4% and 14.1% respectively). A synonymous mutation p. P397P was also detected in a single case.
CONCLUSION: We found a novel, common haplotype in the *SLC26A6* gene, which did not show association with CP. Supported by TÁMOP and OTKA

P0668 PANCREATIC EXOCRINE INSUFFICIENCY IN PATIENTS WITH HIV AND CHRONIC DIARRHOEA

A. Jeevagan[1,*], M. AUSTIN[1], S. Soni[2]
[1]*Gastroenterology,* [2]*Sexual Health and HIV, Lawson Unit, Royal Sussex County Hospital, BRIGHTON, United Kingdom*
Contact E-mail Address: *arun.jeevagan@nhs.net*

INTRODUCTION: Chronic Diarrhoea (CD) in HIV-infected patients is an important cause of morbidity and has significant impact on their quality of life. Pancreatic exocrine insufficiency has been shown to be associated with HIV and has been suggested as an important non-infective cause of diarrhoea and fat malabsorption in these individuals.
AIMS & METHODS: HIV-positive patients undergoing investigation for CD between January 2011 and August 2013 were identified. Demographics and clinical data including measurement of faecal elastase were taken from the patients medical records.
RESULTS: 60 patients were referred by the HIV team to Gastroenterology clinic for investigation of CD. There were 55 (92%) male and mean age was 44 years. All were receiving antiretroviral therapy. No patients had a diagnosis of chronic pancreatitis. 31/60 patients had raised faecal calprotectin, one had stool culture positive for giardiasis, one had lymphocytic gastritis and so 34 patientswere excluded from the study. Out of these, 27 patients who had faecal elastase measurements and 9/27 (30%) had pancreaticin sufficiency.
CONCLUSION: In patients with HIV on antiretrovirals, in whom inflammation and infection had been excluded, approximately 30% of patients were confirmed to have pancreatic exocrine insufficiency. This prevalence is greater than that seen in HIV-negative individuals with chronic diarrhoea. HIV treatment with didanosine or stavudine-containing antiretroviral regimens used to be the main culprit but these drugs are seldom used in the management of HIV nowadays and other causes must be considered. Faecal elastase sampling should form part of the routine work-up for HIV-positive patients with chronic diarrhoea. Treatment with pancreatic enzyme supplementation is effective treatment of chronic diarrhoea in these patients.

INTRODUCTION: Serine protease inhibitor Kazal type 1 (SPINK1) provides an important line of defense against premature trypsinogen activation within the pancreas. The most common *SPINK1* mutation p. N34S seems to increase the risk of chronic pancreatitis (CP), but the precise pathophysiological mechanism of this mutation remains a subject of debate.
AIMS & METHODS: To determine the frequency of the p. N34S *SPINK1* mutation in Hungarian patients with alcoholic chronic pancreatitis (ACP) and idiopathic chronic pancreatitis (ICP) and to identify a possible pathogenic promoter variant linked with the p. N34S mutation. 70 subjects with CP (cases) (34 ACP and 36 ICP) and 70 subjects with no pancreatic disease (controls) were enrolled from the Hungarian National Pancreas Registry. Direct sequencing of the *SPINK1* proximal promoter region (~1 kb) was performed. The p. N34S *SPINK1* mutation was analysed by RFLP.
RESULTS: The p. N34S mutation was present in 3/70 patients, all with the diagnosis of ICP, while it was absent in healthy controls ($P = 0.24$). Two promoter variants (c.-253T>C and c.-807C>T) were found as common polymorphisms indicating no clinical significance. Additionally, three rare promoter variants (c.-14G>A, c.-108G>T, and c.-215G>A) were identified in cases. The c.-215G>A variant was linked with the pathogenic c.194+2T>C mutation. The clinical significance of the c.-14G>A and c.-108G>T variants is unclear so far.
CONCLUSION: We identified two novel variants in the proximal promoter region of *SPINK1* which will be further investigated to determine their possible association with CP. No associations were found between the p. N34S mutation and promoter region variants of the *SPINK1* gene.

P0670 QUANTIFICATION OF EXOCRINE DUCTAL PANCREATIC FUNCTION USING A SHORT ENDOSCOPIC SECRETIN TEST AND AUTOMATIC DUODENAL BICARBONATE MEASUREMENT

F. Erchinger[1,2,*], O.A. Gudbrandsen[2], T. Engjom[2,3], E. Tjora[4], D. Hoem[5], T. Hausken[2,3], O.H. Gilja[2,6], G. Dimcevski[2,3]

INTRODUCTION: A short endoscopic secretin test has recently been evaluated in different patient groups and provides useful information about exocrine ductal pancreatic function[(1-3)]. Bicarbonate in duodenal juice is an important parameter in direct pancreas function testing. Gold standard is measurement of bicarbonate by back titration right after endoscopy, but this is time consuming, and requires specialised equipment and highly skilled laboratory staff. A simplified method is warranted.
AIMS & METHODS: The aim was to determine if back titration can be replaced by an automated spectrophotometric method.
Patients examined with short endoscopic secretin test suspected to have decreased pancreatic function of various reasons. Bicarbonate in duodenal juice was analysed both by back titration and automatic spectrophotometry. In our short endoscopic secretin test duodenal juice is suctioned in three aliquots of 5 minutes. Both fresh and thawed samples were analysed.
RESULTS: 122 samples from 49 patients (25 men/24 women) were analysed. Correlation coefficient of all measurements was $r = 0.98$. Correlation coefficient of fresh versus frozen samples conducted with automatic spectrophotometry ($n = 27$): $r = 0.96$.
CONCLUSION: The measurement of bicarbonate in both fresh and thawed samples, by automatic spectrophotometric analysis correlates excellent with measurements made by back titration. This is a major simplification of direct pancreas function testing, and makes it possible to perform such tests standardised in all hospitals, in a time- and centre-independent way.

INTRODUCTION: To date, there is no standardized treatment for pain caused by chronic pancreatitis. Medical, endoscopic or surgical therapy are the currently available approaches. Antioxidants have been proposed on the rationale that they may slow down the damage of the gland produced by oxidative stress. Although several trials have been carried out over the years, no one of them showed convincing results.
AIMS & METHODS: Our aim was to systematically review the literature related to the efficacy of antioxidants in improving painful chronic pancreatitis. This systematic review was conducted in accordance with the PRISMA guidelines. All the original reports in which human subjects, both children and adults, with chronic pancreatitis were treated with antioxidants were considered for inclusion. Inclusion criteria also required the pain as endpoint, and the report of efficacy outcomes. No language restriction was set up. Animal model studies, studies presented only as abstracts, case reports and case series with less than 10 patients were excluded. The following databases were used to perform the literature search: PubMed, SCOPUS, Web of Science, the Cochrane Library. The last search was run on 27 February 2013. The following MeSH terms and keywords were used alone or in combination: antiox*; vitamin supplement; antioxidant supplement; vitamin A supplement; vitamin B6 supplement; vitamin B12 supplement; folic acid supplement; vitamin C supplement; vitamin D supplement; vitamin E supplement; selenium supplement; beta-carotene supplement; lycopene supplement; isoflavone supplement; chronic pancreatitis. A quality appraisal of the selected studies was performed.
RESULTS: The literature search retrieved 3590 studies; of these, 9 met our inclusion criteria. Six were blinded randomized clinical trials, 2 open trials, and 1 a prospective cohort study. Their comparability was severely limited because of

differences in the endpoints chosen, which include pain-free days, pain scores, quality of life scores, and supportive care needed; possibly severe selection bias and low statistical power due to small sample size were found in some studies. The few points of partial convergence include a potential reduction in the need of supportive therapies and inefficacy of antioxidants in alcoholic pancreatitis.
CONCLUSION: Available evidence is inconclusive: confirmation or refusal of the efficacy of antioxidant therapies against pain in chronic pancreatitis needs to be investigated by further randomized controlled trials, with adequate design and standardized outcome variables, so as to allow for comparison.

P0672 AUTOIMMUNE PANCREATITIS IN CHILDREN- SINGLE CENTRE EXPERIENCE

G. Oracz[1,*], B. Cukrowska[2], K. Wejnarska[1], E. Kolodziejczyk[1], J. Kierkus[1], J. Ryzko[1]
[1]*Dep. of Gastroenterology, Hepatology and Feeding Disorders,* [2]*Dep. of Pathology, The Childrens Memorial Health Institute, Warsaw, Poland*
Contact E-mail Address: *grzegorz_oracz@poczta.onet.pl*

INTRODUCTION: The etiology of chronic pancreatitis in children is varied and includes gene mutations, anatomic anomalies, and others. The reported paediatric experience with chronic pancreatitis (CP) is small and little is known about the role of autoimmune pancreatitis (AIP).
AIMS & METHODS: The aim of the study was to assess the frequency of autoimmune markers in children with CP**.**
136 children with CP hospitalized at the Department of Gastroenterology, The Children's Memorial Health Institute, between 2005 and 2014 were examined for the presence of AIP; the level of IgG4 was determined, and the tests for anti-tissue antibodies were conducted. AIP was diagnosed according to the IAP guidelines, i.e. on the basis of immunological criteria (presence of antibodies: IgG4 and autoantibodies), radiological criteria (swelling of the pancreatic head, and changes in the pancreatic duct), and response to corticosteroid therapy. Clinical data were recorded and analyzed.
RESULTS: Anti-tissue antibodies were detected in 85/136 children (62.5%), and 29/75 patients (38.6%) showed an increased IgG4 level. Based on the IAP criteria, a suspicion of AIP was raised in 8 patients. This diagnosis was definitely confirmed in 4 cases, based on clinical improvement observed after corticosteroid therapy. Due to the inactive phase of the disease, the immunosuppressive therapy was not implemented in the remaining suspected patients. In 41/85 (48.2%) patients with autoimmune markers we found gene mutations predisposing to CP. In 18/85 children (21.2%) anatomic anomalies were fund. There was no difference in the severity of the disease and clinical course between children with autoimmune stigmata and patients without autoimmune markers.
CONCLUSION: In children with CP, similarly to adults, there is a high frequency of biochemical markers of autoimmunity. AIP can be the cause of CP in children.

P0673 MATERIAL OBTAINED BY ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE BIOPSY IS NOT ADEQUATE FOR THE HISTOLOGICAL DIAGNOSIS OF EARLY CHRONIC PANCREATITIS

J. Iglesias-García[1,*], J. Lariño-Noia[1], I. Abdulkader[2], B. Lindkvist[3], J.E. Dominguez-Muñoz[1]
[1]*Gastroenterology,* [2]*Pathology, University Hospital of Santiago de Compostela. Foundation for Research in Digestive Diseases, Santiago de Compostela, Spain,* [3]*Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

INTRODUCTION: Diagnosis of early chronic pancreatitis (CP) is a clinical challenge and it is hampered by the lack of methods for histological confirmation. Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB), with the use of Procore™ histology needles provides adequate samples for the histological evaluation of solid pancreatic lesions, but the efficacy and safety of this technique for early CP is unknown.
AIMS & METHODS: We aimed at evaluating the efficacy and safety of EUS-FNB with Procore™ needles for the histological diagnosis of early CP.
Methods: A prospective, pilot study with consecutive inclusion of patients between January and September 2013 was designed. Inclusion criteria: Patients $>$ 18 years old submitted to our Endoscopy Unit to undergo EUS examination because of the clinical suspicion of chronic pancreatitis. Only patients with 3-4 EUS criteria of CP were finally included. EUS-guided FNB was performed by two experienced endosonographers in these patients under deep sedation after signing the informed consent. A linear slim Pentax echoendoscope (EG 3270 UK) attached to a Hitachi Ascendus ultrasound device was used for EUS. FNB of the body of the pancreas was performed with Procore™ needles of different sizes. Samples obtained were immersed into a Cytolit solution for cytohistological evaluation. All samples were evaluated by a single expert pathologist. The quality of the samples obtained and the histological findings (inflammatory cells infiltration and fibrosis) were evaluated. Complications were recorded.
RESULTS: The study was stopped after the inclusion of 10 patients (mean age 50.3 years, range 33-70 years, 6 male) due to unsatisfactory results. Pancreatic EUS-FNB was feasible in all cases. A 19G Procore™ needle was used in 5 cases, a 22G needle in 2 and a 25G needle in 3 cases. Sample quality was considered adequate for histological evaluation in only 3 cases (30%), (2 performed with a 19G needle and one with a 25G needle). Two out of these three biopsies revealed a normal pancreatic tissue and the diagnosis of CP could not be confirmed. The remaining biopsy revealed pancreatic tissue with some areas of fibrosis. Samples from the other seven patients (70%) were not adequate for cytohistological diagnosis due to the absence of tissue and a poor cellularity. There was one complication (10%), a mild acute pancreatitis requiring hospitalization for 48 hours.
CONCLUSION: EUS-FNB is feasible in the context of patients with EUS findings of early CP. Samples obtained by the commercially available needles are however not adequate for histological evaluation. In addition, the risk of complications exists. EUS-FNB for the diagnosis of early CP should be avoided unless new more appropriate needles are developed and can be evaluated for efficacy and safety in well-designed clinical trials.

INTRODUCTION: Pancreatic exocrine function insufficiency (PEI) is common in diabetes mellitus patients. Apparently, some patients with decreased exocrine function are type 3c diabetes mellitus (DM) and misdiagnosed as type 2 or type 1 DM. There are only few data about PEI in DM patients in Turkey. This study aims to investigate exocrine insufficiency among DM patients in Turkey.
AIMS & METHODS: The objective of the study is to assess the prevalence of pancreatic exocrine insufficiency among type 1 and type 2 diabetes mellitus patients in Turkey. The abstract aims to present preliminary results of the study. This is a cross sectional, non-interventional study which was conducted in Turkey between October 2013 and February 2014. Adult patients (older than 18 years) previously diagnosed type 1 or 2 DM, admitted to endocrinology department with or without symptomatic gastrointestinal problems, followed for more than five years were included to the study.
PEI was evaluated by measuring faecal elastase-1 concentration, level <100 μg/g stool was evaluated as severe PEI, whereas $\geq$100, <200 μg/g stool as mild-to-moderate PEI and $\geq$ 200 μg/g stool as normal (1). Upper detection limit of method used for faecal elastase-1 concentration was 500 μg/g stool.
RESULTS: Based on data of 211 DM patients [58.8% female, median (min-max) age 58.2 (18.5-85.7) years], 146 (69.2%) were previously diagnosed type 2 DM whereas others were type 1 DM. Median (min-max) DM duration of type 1 and 2 patients was 15.6 (5.0-43.6) and 13.5 (5.5-37.5) years, respectively.
Median (min-max) faecal elastase-1 concentration of type 1 and 2 DM patients was 465.5 (104.0-500.0) and 474.0(52.0-500.0) μg/g stool, respectively.
In entire study population, severe PEI prevalence was 1.9% (0.0% for type 1 DM, 2.7% for type 2 DM) whereas mild-to-moderate PEI prevalence was 12.3% (17.2% for type 1 DM, 10.3% for type 2 DM). Overall; 14.2% of patients (17.2 % of type 1 DM, 13.0% of type 2 DM patients) have reduced PEI.
CONCLUSION: Preliminary results of the study revealed that PEI prevalence among type 1 and type 2 patients was higher in Turkey and many DM patients might be misclassified. In conclusion, evaluation of pancreatic exocrine function in DM patients should be essential part of daily practice.

P0675 STUDY OF THE LIPID PROFILE AND THE OXIDATIVE STRESS OF DIABETIC PATIENTS WITH CHRONIC PANCREATITIS

M. Sliwinska-Mosson[1,*], S. Milnerowicz[2], W. Sajewicz[1], H. Milnerowicz[1]

INTRODUCTION: Smoking patients with chronic pancreatitis (CP) are at high risk for antioxidant deficiencies (1). Moreover, this disease may lead to the development of diabetes mellitus type II (DM2), which additionally enhances the oxidative stress (2). The main characteristics of DM2 are insulin resistance in muscle and liver cells accompanied by loss of β-cell function. However, adipose tissue and pancreatic cell activity, may be involved in disease development (3). Most recently a trend for positive correlation between HDL cholesterol and amylase in DM2 patients was shown.
AIMS & METHODS: In the present study we evaluated the lipid profile and total peroxyl radical trapping potential (TRAP), glutathione (GSH), thiobarbituric acid reactive substances (TBARS) in non-smoking and smoking patients with CP suffering from diabetes. The relationship between different parameters was examined. The blood was collected from 50 healthy persons and 63 patients

with diagnosed chronic pancreatitis (CP). Diabetes mellitus was diagnosed in 24 patients. The concentration of cotinine and lipid profile in plasma was estimated by the ELISA and diagnostic tests, respectively. Lipid peroxidation levels were assessed by TBARS, and TRAP was measured by using luminescence. Glutathione level was determined in blood hemolysates with the colometric method.

RESULTS: The concentration of HDL were statistically lower in smoking patients with CP with or without diabetes as compared to the control group, while the concentration of TG and LDL were statistically highest in smoking diabetics compared to all groups ($p < 0.001$). It was also observed that the concentration of TBARS was statistically significant increased in non-smoking and smoking patients with CP (3.5 ± 1.3 [μmol /l], 4.75 ± 1.0 [μmol /l]), and patients with CP and DM (5.3 ± 2.6 [μmol/l]) as compared with control group (3.4 ± 1.9 [μmol/l]). In smoking patients with DM, a statistical highest level of TRAP compared to all study groups was found ($p < 0.0001$). Statistical analysis of the results showed that the decline in the concentration of GSH is associated with cigarette smoking and diabetes. The lowest concentration of GSH was observed in smoking patients with CP and diabetes, the highest in non-smoking control group ($p < 0.0001$).

CONCLUSION: The lipid profile is altered in smoking patients with CP, particularly in those who also have DM. In these patients, a glutathione deficiency and an elevated plasma concentration of lipid peroxidation products were associated with significantly higher LDL. In the diabetic patients group, a positive correlation between TRAP and TBRAS was found, which points to the induction of the antioxidant potential on intensification of lipid peroxidation.

INTRODUCTION: Von Hippel-Lindau disease (VHL) is autosomal dominant disorder characterized by development of multiple tumors in central nervous system and visceral organs. There have been reported a few studies about clinical courses of pancreatic involvements of VHL.

AIMS & METHODS: In this study, we report clinical features of pancreatic involvements of VHL in Korea. We conducted retrospective cohort study of 55 patients who were diagnosed with VHL-associated pancreatic lesions from 1995 to 2013 in Asan Medical Center. Demographic, genetic, radiologic features and clinical features of VHL-associated pancreatic lesions were analyzed by medical record review.

RESULTS: 55 patients had VHL-associated pancreatic lesions (87.3%). Median onset of age was 33 years (12-67 years) and male and female ratio was 31:24. Median observation period was 1731 days (3-5077). Genetic test was performed in 35/55 patients (63.6%) and VHL gene mutations were confirmed in 28/35 patients (80%). VHL gene mutation was located on exon 1 in 13 patients (46.4%), exon 2; 4 (14.3%), exon 3; 9 (32.1%) and others 2 (7.2%). Mean involved number of organs was 2.51 ± 0.72. Most common subtype of VHL was type I as 44/55 patients (80%). Pancreatic involvements were included single simple cyst (n = 5, 9.1%), multiple simple cysts (n = 14, 25.5%), serous cystadenoma (n = 29, 52.7%) and neuroendocrine tumor (n = 17, 30.9%). Initial presented VHL-associated tumors as only pancreatic lesions were observed in only 2 of 55 patients (3.6%) and pancreatic symptoms were only 4 patients (7.3%). Of 55 patients, 11 patients received surgical treatment and 2 patients received EUS-guided ethanol ablation therapy as local treatment for neuroendocrine tumor and 42 patients were observed regularly without intervention (20%, 3.6%, 76.4% respectively). One patient received distal pancreatectomy as radiologic diagnosis of neuroendocrine tumor, however, final pathologic diagnosis was serous cystadenoma, which was thought to be solid microcystic serous adenoma (SMSA). One patient was died of pulmonary hemorrhage due to pulmonary metastasis of VHL-associated renal cell carcinoma.

CONCLUSION: Most common presentation of pancreatic involvement in VHL was serous cystadenoma. Pancreatic tumors as primary presenting lesion in VHL are relatively rare and most of pancreatic lesions were asymptomatic. Nationwide epidemiologic study is needed to verify natural course and prognosis of pancreatic involvement in VHL.

INTRODUCTION: Pancreatic insufficiency is a prevalent feature of cystic fibrosis (CF). The affected CF pancreas is dominated by fatty infiltration, atrophy and necrosis. Little is known about pancreatic perfusion in CF.

AIMS & METHODS: We aimed to evaluate pancreatic perfusion assessed by contrast-enhanced ultrasound (CEUS) in CF patients with known exocrine pancreatic function.

CEUS was performed in CF patients (n = 39) and healthy controls (n = 32). Exocrine pancreatic function was assessed by secretin-stimulated endoscopic short test and/ or faecal elastase. The CF patients were defined as pancreas sufficient through fecal elastase >200μg/g or duodenal bicarbonate >80mmol/L. Perfusion data was analyzed on stored DICOM-files using DCE-US software (http://www.isibrno.cz/perfusion/) and a dedicated perfusion model. Mean transit-time (MTT), blood flow (BF) and blood-volume (BV) was calculated. Exclusions due to image quality and image analysis in the CF group were made without knowledge of pancreatic function.

RESULTS: 26 CF patients and 20 controls were included. 13 CF patients and 12 controls were excluded due to poor image quality. Subjects were divided as follows: CF, pancreatic insufficient (CFI, n = 13), CF pancreatic sufficient (CFS, n = 13) and healthy controls (HC, n = 20). Results are displayed in the table (mean±SD) (s = seconds, ml = millilitre)

	CFI (n = 13)	*CFS (n = 13)*	*HC (n = 20)*	*P*
MTT (s)	8.0±3.2	4.0±1.9	2.9±1.4	$P < 0.001$
BF (ml/min/100ml)	18.4±10.5	76.8.0±54	117.4±70	$P < 0.001$
BV (ml/100mL):	2.3±1.3	4.1±2.5	4.8±2.5	$P < 0.05$

CONCLUSION: The pancreatic insufficient CF patients had significantly longer MTT ($p < 0.001$), lower BF ($p < 0.001$) and lower BV ($p < 0.05$) compared to healthy controls and pancreatic sufficient CF patients. CEUS can non-invasively differentiate between healthy pancreatic tissue and exocrine insufficient pancreatic tissue due to cystic fibrosis.

INTRODUCTION: The term "paraduodenal pancreatitis (PP)" was proposed as an umbrella for cystic dystrophy in heterotopic pancreas (duodenal dystrophy), paraduodenal cyst and groove pancreatitis, by reasoning that these conditions mimic pancreatic head tumors and share certain histological evidences. It is still unclear what organ "paraduodenal pancreatitis" originates of.

AIMS & METHODS: To assess the results of different types of treatment for "paradudenal pancreatitis".

1. Prospective analysis of 65 cases of PP (2004-2013), comparing preoperative and histopathological findings in 42 surgical specimens; 2. Assessment of clinical presentation and the results of DD treatment.

RESULTS: Preoperative diagnosis was correct in all the cases except one, when cystic tumor of the pancreatic head was suspected (1.9%). Patients were presented with abdominal pain (100%), weight loss (76%), vomiting (30%) and jaundice (18%). CT, MRI and endoUS were the most useful diagnostic modalities. Ten patients were treated conservatively, 26 underwent pancreaticoduodenectomies (PD), pancreatico- and cystoenterostomies(8), Nakao procedures(4), duodenum-preserving pancreatic head (DPPH) resections(5), and 12 pancreas-preserving duodenal resections (PPDR). No mortality. Full pain control was achieved after PPRDs in 83%, PDs in 85%, and after PPPH resections and draining procedures in 18% of cases. Diabetes mellitus developed thrice after PD.

CONCLUSION: 1. The diagnosis of PP can be confidently determined by modern methods prior to surgery; 2. PD is the main surgical option for PP treatment at present; 3. Early diagnosis makes pancreas-preserving duodenal resection the treatment of choice for PP; 4. The effectiveness of PPDR provides compelling proof that "paraduodenal pancreatitis" is an entity of duodenal origin.

INTRODUCTION: Recently it has been shown that low prediagnostic plasma adiponectin levels are associated with an elevated risk of pancreatic cancer (PC). However, no studies exist in which association between adiponectin levels and pancreatic tumor stage were tested.
AIMS & METHODS: The aim of the study was to analyze plasma concentrations of adiponectin in PC patients and to compare these concentrations to clinicopathological parameters. Baseline levels of adiponectin were determined in 40 consecutive patients with newly diagnosed pancreatic adenocarcinoma and 40 healthy control subjects. The association between adiponectin and tumor stage (TNM classification) and tumor grade were evaluated using nonparametric Spearman's correlation test. Control subjects were matched to case patients by smoking status, age and BMI.
RESULTS: Overall median adiponectin concentrations were lower in PC patients versus control subjects (7.1 vs 9.3 mg/mL, $p<0.001$). In PC patients with TNM stage III-IV ($n=21$) median adiponectin concentrations were significantly lower than in PC patients with TNM stage I-II ($n=19$) (5.7 vs 7.3 mg/mL, $p<0.001$). Mean adiponectin concentrations were lower in high grade intraepithelial neoplasia tumors ($n=18$) compared to low grade tumors ($n=13$) (5.1 vs 6.5 mg/mL, $p<0.05$). Adiponectin concentrations were inversely correlated with tumor size and tumor TNM stage ($r=-0.834$, $p<0.01$) and tumor grading ($r=-0.615$, $p<0.01$) of pancreatic adenocarcinoma patients.
CONCLUSION: This study identified, for the first time, an inverse correlation between adiponectin levels and tumor size and TNM stage suggesting a potential role for adiponectin in progression of pancreatic adenocarcinoma.

P0680 PREOPERATIVE ENDOSCOPIC BILIARY DRAINAGE PROCEDURES INFLUENCE SURVIVAL FOLLOWING RESECTION FOR AMPULLARY CARCINOMAS

K. Urbonas[1], **A. Gulbinas**[2,*], J. Pundzius[1], G. Barauskas[1]
[1]*Surgery,* [2]*Institute for Digestive Research, Lithuanian University of Health Sciencies, Kaunas, Lithuania*
Contact E-mail Address: *kestasu@gmail.com*

INTRODUCTION: Carcinoma of Papilla of Vater has the best survival rate of all periampullary carcinomas. Patients typically manifest symptoms early in the course of the disease with abdominal pain, jaundice, and weight loss. This may account for early diagnostic and relatively high resection rate. Aim of our study was to identify the independent factors influencing a long term survival for patients who underwent pancreatodudenectomy for ampullary adenocarcinoma.
AIMS & METHODS: of our study was to identify the independent factors influencing a long term survival for patients who underwent radical surgical treatment for ampullary adenocarcinoma.
Methods. Data of 64 patients with ampullary adenocarcinoma who underwent major surgery was prospectively collected and analyzed. Demographic, clinical and histopathological examination data were assumed to have the impact on survival. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to indentify prognostic factors that were independently associated with survival.
RESULTS: The mean of survival time was 109 months, whereas five years cumulative survival was 62 percent. Univariate analysis revealed preoperative endoscopic biliary drainage (stenting) ($p<0.001$), microvessels infiltration ($p<0.001$), patients' age over 70 years ($p<0.005$), lymphonodes infiltration ($p<0.021$) and T stage ($p<0.048$) as a factors influencing survival. Preoperative endoscopic biliary drainage (HR 5.25; CI (1.94-14.21)), microvessels infiltration (HR 3.85; CI (1.09-13.51)) and patients' age >70yrs (HR 2.35; CI (1.03-5.39) were independent factors influencing survival in multivariate analysis.
CONCLUSION: Preoperative endoscopic biliary drainage seems to have the most significant influence on survival, therefore necessity of procedure should be carefully assessed before the operation.

P0681 HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) THERAPY FOR LOCALLY ADVANCED PANCREATIC CANCER

A. Sofuni[1,*], F. Moriyasu[1], T. Sano[1], M. Fujita[1], T. Tsuchiya[1], K. Ishii[1], N. Ikeuchi[1], J. Umeda[1], R. Tanaka[1], R. Tonozuka[1], S. Mukai[1], K. Kamata[1], S. Tsuji[1], F. Itokawa[1], T. Itoi[1]
[1]*Gastroenterology and hepatology, TOKYO MEDICAL UNIVERSITY, Tokyo, Japan*
Contact E-mail Address: *a-sofuni@amy.hi-ho.ne.jp*

INTRODUCTION: Even with recent advances in the diagnostic imaging technology, most cases of pancreatic cancer (PC) are diagnosed at an unresectable stage. The results of chemotherapy and chemo-radiotherapy for the condition were not satisfactory. However, locally advanced PC can expect the possibility of additional therapy including the surgical treatment and the prolongation of the prognosis by the strategy of combination therapy. HIFU therapy being promoted as a new method to ablate the tumor is expected for locally advanced PC.
AIMS & METHODS: We have evaluated the therapeutic effect of HIFU therapy for locally advanced pancreatic body cancer (PBC). We treated PBC patients using HIFU therapy as optional local therapy as well as systemic chemo / chemo-radiotherapy, with whom an agreement was obtained in adequate IC, from the end of 2008 in our hospital. This study took approval of member of ethic society of our hospital. HIFU device used is FEP-BY02 (Yuande Bio-Medical Engineering, Beijing, China). The subjects were 20 locally advanced PBC patients.
RESULTS: The mean tumor size after HIFU therapy changed to 36.5 (15-57) mm from 39.5 (20-57) mm at pre-therapy. There were no significant changes in tumor size. The mean treatment data was the following; mean number of treatment sessions, 2.7 (2-5); mean total treatment time, 2.3 (1.8-4.7) hours, and mean total number of ablation: 2852 (760-6420) shots. The effects of HIFU therapy was the following; the rate of complete tumor ablation was 75%, the rate of symptom relief effect was 82%, the effectiveness of primary lesion was CR:0, PR: 3, SD:14, PD:3, and primary disease control rate (DCR) more than SD was 83.3%. There was no adverse event. The following therapy after HIFU therapy was; operation 2, chemotherapy 15, and BSC 3 cases, respectively. Mean survival time (MST) after diagnosis was 41.5 months, and MST after HIFU therapy was 19.1 months. Mean duration time from diagnosis till HIFU therapy was 16.3 months. MST after diagnosis in HIFU with chemotherapy or chemo-radiotherapy and chemotherapy alone (10 patients in our hospital) was 41.5 vs 23.1 months, respectively ($p<0.05$, $p=0.04$, Log-rank). Combination therapy with HIFU was better result than common chemotherapy alone.
CONCLUSION: This study suggested that HIFU therapy has the potential of new method of combination therapy for locally advanced pancreatic body cancer.

P0682 EVALUATION OF UPFRONT SURGERY AS CURATIVE-INTENT THERAPY CONCEPT IN LOCALLY ADVANCED PANCREATIC CANCER

C. Ansorge[1,*], G. Saliba[1], M. Karimi[2], N. Kartalis[3], L. Lundell[1], M. Del Chiaro[1], J. Blomberg[1], R. Segersvärd[1]
[1]*Department of Surgical Gastroenterology, Karolinska University Hospital,* [2]*Department of Oncology, Karolinska University Hospital, Division of Surgery, Department of Clinical Science, Intervention and Technology (CLINTEC), Karolinska Institutet,* [3]*Department of Radiology, Karolinska University Hospital, Division of Medical Imaging and Technology, Department of Clinical Science, Intervention and Technology (CLINTEC), Karolinska Institutet, Stockholm, Sweden*

INTRODUCTION: Representing the 4th most common cancer mortality, pancreatic cancer remains an unsolved health problem. The majority of patients are diagnosed at an advanced disease stage with limited therapy options. Currently, in addition to the limitations, the treatment of non-metastatic locally advanced pancreatic cancer (LAPC) is characterized by substantial methodological heterogeneity among pancreatic centers due to variation of applied definitions, regimes and surgical procedures. Based on radiological criteria of mesenteric vessel involvement, the radiological assessment of technical resectability in our institution distinguishes between primarily resectable LAPC (B-tumors, superior mesenteric/portal vein involvement >50% of the circumference, <2cm length) and primarily unresectable LAPC assessed as potentially resectable after neoadjuvant chemoradiotherapy (NACRT, C-tumors, SMV/PV >50%, >2cm and/or superior mesenteric artery involvement <50%, <2cm).
AIMS & METHODS: The aim of the present study was to evaluate the performance of primary resection and neoadjuvant treatment followed by attempted resection as curative-intent concepts in LAPC. A single-center prospective cohort study was conducted including patients with B- and C-tumors in the pancreatic head between 2008 and 2013. Histological confirmation preceded NACRT (Gemcitabine and Capecitabine). Toxicity, therapy response and postoperative complications were recorded according to established classifications. Overall (OS) and progression-free survival (PFS) was analyzed; OS was calculated from date of decision until death, PFS either from date of surgery or date of confirmed stable disease/partial remission (SD/PR) after NACRT until date of tumor progression. Patients with specimen histology other than ductal adenocarcinoma were retrospectively excluded.
RESULTS: Ninety-nine patients with histologically confirmed pancreatic cancer were included. Of 30 patients with B-tumors, 22 underwent curative-intent resection (CIR). Of 69 patients with C-tumors, 64 underwent NACRT, 22 had SD/PR, and 15 underwent CIR. The resection rate in B-tumors was significantly higher (73%) than in C-tumors (22%); however, both groups had comparable median OS rates (B-tumors 10.5, C-tumors 11 months). In B-tumors, median OS in intra-operatively confirmed unresectability was 8, in CIRs 11.5, and if followed by adjuvant treatment 14 months (median PFS in CIRs 9.6 months). In C-tumors, median OS in patients with discontinued NACRT was 4, with post-NARCT tumor progression 11, and with confirmed SD/PR 19 months (median PFS after CIR 21 months).
CONCLUSION: In patients with technically resectable LAPC, primary resection was not proven to be a sustainable therapy concept, and the preoperative radiological resectability assessment does not seem to have prognostic significance. Provided that a timely histological confirmation can be guaranteed, the indication for NACRT, and followed by attempted resection in SD/PR cases, should be extended to patients with technically resectable LAPC.

P0683 STENT ON DEMAND IS SAFER THAN PROPHYLACTIC DOUBLE BYPASS SURGERY WHEN A PLANNED RESECTION FOR PANCREATIC CANCER CANNOT BE PERFORMED

J. Wennerblom[1,*], C. Williamsson[2], B. Tingstedt[2], C. Jönsson[1]
[1]*Dept. of Surgery, Gothenburg University, Gothenburg,* [2]*Dept. of Surgery, Lund University, Lund, Sweden*

INTRODUCTION: For decades routine use of prophylactic hepaticojejunostomy and gastroenterostomy has been advocated when a curative intention must be abandoned due to peroperative findings of locally advanced or metastatic disease in pancreatic cancer (1). The development of Self Expanding Metal Stents (SEMS) has challenged this routine.
AIMS & METHODS: The aim of the present study was to retrospectively compare the results for patients operated 2004-2013 from two Swedish referral centres with local guidelines for different surgical strategies when signs of irresectability were discovered during surgery.
At Lund University Hospital, Lund the abdomen was closed immediately in patients without gastric outlet syndrome (GOS) and if the patient later developed jaundice and/or GOS a SEMS was inserted (n = 74). At Sahlgrenska University Hospital, Gothenburg prophylactic double bypass surgery (DBS) was performed when the patient was found to have a non-curable disease (n = 77).
RESULTS: There was no difference between the cohorts regarding age, sex and ASA-class. The need for immediate reoperations did not differ between the two groups. However, delayed gastric emptying (DGE) as well as other complications according to the Clavien-Dindo system (2) was significantly more frequent after DBS than when using the stent strategy. These findings probably explain the longer post operative hospital stay in the DBS group (11 vs. 9 days (p = 0.001). The long term survival after surgery was not better in the DBS-group than for the SEMS patients (318 vs. 380 days, p = 0.075).

	Double Bypass	SEMS	P-value
Survival ¤	318 (23-808)	380 (15-1151)	0.075
Length of Stay ¤	11 (6-66)	9 (4-42)	***0.001***
Removal nasogastric tube ¤	2 (1-17)	1 (1-22)	***0.046***
Fluid intake ¤	4 (1-18)	2 (1-23)	***0.005***
Food intake ¤	6 (3-19)	4 (1-31)	***0.0001***
DGE (A,B or C)*	27 (35%)	14 (19%)	***0.03***
Reoperations *	5 (6.5%)	7 (9.4%)	0.55
Complications*	42 (55%)	25 (34%)	***0.013***
Overall Clavien-Dindo Score			***0.001***

CONCLUSION: The more conservative approach to primarily close the abdomen and to treat the patient with SEMS on demand seems safer and results in a shorter initial hospital stay and does not seem to impair the long time survival for the patients compare to the DBS-routine.

INTRODUCTION: Due to the poor prognosis of advanced unresectable pancreatic cancer (PC), predicting response to palliative chemotherapy is essential to avoid adverse events of otherwise unnecessary treatments. The majority of studies on expression of tumor proteins have been performed on surgical specimens of resectable PC. We hypothesize that the expression of some tumor proteins may predict prognosis and response to gemcitabine in patients with unresectable PC.
AIMS & METHODS: Aim of the present study was to analyze the role of several tumor proteins evaluated in EUS-FNB samples as biomarkers of progression and response to treatment in patients with unresectable PC.
Patients diagnosed with unresectable PC by EUS-FNB, who received palliative treatment with gemcitabine were retrospectively included. Availability of EUS-FNB tissue samples embedded in paraffin block was required for final inclusion. Candidate proteins (collagen-I, annexinA1, FAK, FAS, HSP70, SSH and MMP) were evaluated by specific immunohistochemistry. Statistical analysis was performed by Mann-Whitney U and McNemar test.
RESULTS: From 277 EUS-FNB samples of patients with unresectable PC, an adequate sample for ancillary studies in patients who received palliative treatment with gemcitabine was available in 37 patients (65.1±11.7 years, 62.2% men). Mean survival time was 220 days (range 16 to 519 days). Tumor size was 41.2±12.8mm. Frequencies of protein expression in tumor areas were AnnexinA1: 96.9%; SSH: 93.6%; FAK: 59.4%; collagen-I: 32.3%; FAS: 28.6%; MMP: 12.9; HSP70: 14.3%. Expression of collagen-I was associated with a shorter survival (150.8±98.2 vs 285.4±147.2 days, p = 0.029). FAK expression was associated with a smaller tumor size (36.1±9.5 vs 48.2±14.2, p = 0.02). Finally, lack of SHH was associated with normal serum Ca19.9 levels.
CONCLUSION: Some tumor proteins expressed in unresectable PC can be evaluated by immunohistochemistry in EUS-FNB samples to predict survival and response to palliative chemotherapy. Expression of collagen-I is associated with a shorter survival in patients receiving palliative therapy with gemcitabine. Further prospective studies including a larger number of patients are required to confirm these data.

INTRODUCTION: Pancreatic juice cytology (PJC) is considered optimal for the differential diagnosis of pancreatic masses and is thought to be the most exact diagnostic modality for intraductal papillary mucinous carcinoma (IPMC). However, the accuracy of PJC has been unsatisfactory, ranging from 46.7% to 93.0%. Therefore, to improve the accuracy of diagnosis for pancreatic malignancy, alternative modalities are needed. MUC1, a membrane-associated mucin widely expressed in gastrointestinal tissues, has a variety of types based on different glycoforms in its extracellular domain. Many investigations have shown that aberrant expression of MUC1 in gastrointestinal cancer tissue has clinicopathological and biological importance in cancer. KL-6 mucin, one kind of MUC1, has also been investigated; it appears to have a significant relationship with malignant tumor behavior, especially cancer cell invasion and metastasis in various gastrointestinal cancers.
AIMS & METHODS: The aim of this study was to evaluate the clinical impact of the KL-6 concentration of pancreatic juice for diagnosing pancreatic masses. This study comprised 70 consecutive patients with pancreatic masses (34 pancreatic ductal adenocarcinomas [PDACs], 5 intraductal papillary mucinous carcinomas [IPMCs], 12 pancreatic inflammatory lesions and benign stricture of the main pancreatic ducts [MPDs] and 19 intraductal papillary mucinous adenomas [IPMAs]). All patients underwent PJC and measurement of the KL-6 concentration of pancreatic juice, which was obtained from the pancreatic duct. After pancreatic juice was centrifuged at 1000 rpm for 5 minutes, cytological examination of the cell pellet was performed. The supernatant (10 μL) was used to measure the KL-6 concentration. Human KL-6 levels were assayed in duplicate using a PICOLUMI KL-6 kit (EIDIA, Tokyo, Japan) an electrochemiluminescence immunoassay (ECLIA) specific for human KL-6.
RESULTS: The average KL-6 concentration of pancreatic juice was significantly higher for PDACs (167.7 ± 396.1 U/mL) than for pancreatic inflammatory lesions and benign MPD strictures (17.5 ± 15.7 U/mL $P = 0.034$). Furthermore, KL-6 was significantly higher in IPMCs (86.9 ± 21.1 U/mL) than in IPMNs (14.4 ± 2.0 U/mL $P = 0.026$). The cut-off level of KL-6 concentration was 16 U/mL for differentiating PDACs and IPMCs from pancreatic inflammatory lesions and IPMNs. The sensitivity, specificity, positive predictive value, negative predictive valu, and accuracy of KL-6 concentration alone were 79.5%, 64.5%, 73.8%, 71.4% and 72.9%, respectively, whereas those of PJC alone were 82.1%, 96.8%, 97.0%, 81.1% and 88.6%, respectively. Adding the KL-6 concentration to PJC diagnosis increased the sensitivity and accuracy of PJC by 15.3% ($P = 0.025$) and 8.5% ($P = 0.048$), respectively.
CONCLUSION: The KL-6 concentration of pancreatic juice may be useful for diagnosing PDAC, as well as PJC.

INTRODUCTION: Detection of pancreatic cancer (PC) at an early stage with curative surgery is the approach with the potential to significantly improve long-term patient outcome. However, the rate of tumor detection of computed tomography (CT) in the case with small pancreatic cancer was not satisfied. For the diagnoses of PC less than 10mm, the rate of tumor detection was higher for endoscopic ultrasonography (EUS) than for CT or other modalities, and the histologic diagnosis with EUS guided fine needle aspiration (EUS-FNA) was helpful in confirming the diagnosis. For the diagnosis of PC in situ, EUS and magnetic resonance pancreatocholangiography (MRCP) played important roles in detecting of the local irregular stenosis of the pancreatic duct. Endoscopic retrograde pancreatography (ERP) and sequential cytodiagnosis of pancreatic juice using endoscopic nasopancreatic drainage (ENPD) multiple times were useful in the diagnosis of PC in situ.
AIMS & METHODS: In 2007, Onomichi Medical Association tried to start a social program for diagnosis of the small pancreatic cancer. Specialized doctors for pancreatic cancer (SDPC) in medical centers enlightened practicing doctors about risk factors of PC, abnormal findings of US, or elevated serum pancreatic enzymes. Simultaneously, if practicing doctors experienced the patient with these previous problems, they actively consulted SDPC.

RESULTS: From January 2007 to June 2013, a total of 4969 cases were consulted with SDPC in Onomichi General Hospital. Methods of image diagnosis of CT, MRI, and EUS were performed in 4157, 2303, and 1692 cases. Among these cases, ERP was performed in 550 cases. ENPD and the repeated cytology using pancreatic juice were performed in 59. EUS-FNA was performed in 257. As a result, 338 cases were proved as adenocarcinoma histocytologically. There were 13 cases with stage 0, and 28 cases with stage Ia and Ib histopathologically.
CONCLUSION: To detect of early stage of PC, the relationship between SDPC in medical centers and practicing doctors is very important. ENPD and repeated cytology using pancreatic juice also may play important roles in diagnosis of the early stage of PC.

P0688 A COMPARATIVE STUDY BETWEEN A 22-GAUGE ASPIRATION NEEDLE AND A 25-GAUGE BIOPSY NEEDLE FOR EUS-GUIDED SAMPLING OF PANCREATIC MASS LESIONS

Y.S. Moon[1,*], J.H. Kim[2], M.J. Yang[2], J.C. Hwang[2]
[1]*Gastroenterology, Haeundae Paik Hospital, Busan,* [2]*Gastroenterology, Ajou Unversity School of Medicine, Suwon, Korea, Republic Of*

INTRODUCTION: EUS biopsy needles have recently been developed in order to obtain both histologic and cytologic specimens.
AIMS & METHODS: We conducted this study to compare 22-gauge (G) aspiration needles (FNA) and 25G biopsy needles (FNB) for EUS-guided sampling of solid pancreatic masses. Thirty-four patients with solid pancreatic masses underwent EUS-guided sampling with a 25G FNB from June 2012 to April 2013, and thirty-four patients with solid pancreatic masses, who underwent EUS-guided sampling with a 22G FNA from June 2011 to May 2012, served as the historical control group. EUS-guided sampling was performed using the standard technique without an on-site cytopathologist.
RESULTS: The diagnostic rates of cytology were 97.1% (33/34) with 22G FNA needles and 85.3% (29/34) with 25G FNB needles ($P=0.197$). The diagnostic rates of histology were 23.5% (8/34) with 22G FNA needles and 41.2% (14/34) with 25G FNB needles ($P=0.194$). There was no significant difference in the mean number of needle passes (5.09 vs 5.76, $P=0.089$) or needle malfunctions (2.9% vs 11.8%, $P=0.356$) between 22G FNA and 25G FNB needles, respectively. No complications were identified in either group.
CONCLUSION: The 25G FNB needle was not superior to the 22G FNA needle in the diagnostic yield of histology for EUS-guided sampling of pancreatic mass lesions, as the diagnostic yield, technical performance, and safety profiles were comparable between both of them.

INTRODUCTION: Anastomotic leakage after gastrectomy is an important determinant of early and late morbidity and mortality. Various methods for postoperative leakage are used including conservative, endoscopic or surgical treatment.
AIMS & METHODS: We aimed to evaluate the effectiveness and safety of endoscopic intervention for the management of leakage after gastrectomy. We retrospectively reviewed 57 patients with anastomotic leakage after gastrectomy for gastric cancer that was treated with endoscopic interventions between December 2007 and March 2014. Clinical aspects of leakages and endoscopic managements, closure rates and treatment related complications were evaluated.
RESULTS: Anastomotic leakages were found at esophagojejunostomy (n = 26), duodenal stump (n = 14), gastroduodenostomy/gastrojejunostomy (n = 10), wedge resection (n = 3), esophagogastrostomy (n = 2) or jejunal stump (n = 2). Median size of leak was 8mm (range, 2 - 40mm). The leakages were treated by endoclips (n = 13), endoclips with detachable snare (n = 31) or stent (n = 13). Simultaneously, abscess around the leak was drained by external drains (n = 32). After endoscopic treatment, complete closure was achieved in 42 patients (73.7%) and partial closure in 13 patients (22.8%). In all patients with partial closure, final closure of leak was achieved by continuing conservative treatment. Among remaining two patients, one with failed endoscopic treatment went on to receive surgery and the other died due to septic shock during endoscopic treatment. Treatment related complication (esophageal fistula) occurred in one patient who was treated with stent. The complete closure rate of the leaks at duodenal or jejunal stump was significantly lower than that of leaks at other sites ($P=0.027$), whereas the size of leak and the method of endoscopic management were not associated with the complete closure rate.
CONCLUSION: Endoscopic management using clips or stent represents an effective and safe method for anastomotic leakage after gastrectomy in gastric cancer and it can be an easily available minimally-invasive option which may reduce leakage related mortality and morbidity.

P0691 RISK FACTORS OF DELAYED ULCER HEALING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

J.H. Lim[1,*], S.G. Kim[1], J. Choi[1], J.P. Im[1], J.S. Kim[1], H.C. Jung[1]
[1]*Departement of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Post-endoscopic submucosal dissection (ESD) iatrogenic ulcer is known to have specific histologic features and heal faster than peptic ulcer. However, some iatrogenic ulcers show delayed healing.
AIMS & METHODS: The aim of this study is to clarify risk factors of delayed ulcer healing after gastric ESD. For this, we reviewed medical records of patients who had ESD for gastric high-grade adenoma or early gastric cancer between January 2005 and February 2012. Delayed ulcer healing was defined as sustaining unhealed iatrogenic ulcer at 3 months after the ESD. To find potential risk factors we reviewed following parameters: age, sex, comorbidity that might influence mucosal healing, history of peptic ulcer, history of abnormalities, antiplatelet or NSAID usage, size of the specimen, location and histologic type of lesion, *Helicobacter pylori* status, and hot biopsy.
RESULTS: Among 2,140 subjects, 11 were excluded because of anticoagulation, 3 because of emergency for post-ESD bleeding, and 346 were excluded because of loss of 3 month follow-up endoscopy. Out of the total 1680 patients enrolled, 95 had delayed ulcer healing. In multivariate analysis, diabetes (OR 1.743; 95% CI: 1.017-2.989, $p=0.043$), coagulation abnormality (OR 3.195; 95% CI: 1.535-6.650, $p=0.002$), specimen size greater than 4cm (OR 2.999; 95% CI 1.603-5.611, $p=0.001$), and hot biopsy (OR 7.149; 95% CI 1.738-29.411, $p=0.006$) were revealed to be independent risk factors of delayed ulcer healing. Meanwhile, persistent *Helicobacter pylori* infection was not shown to be related to the delayed ulcer healing.
CONCLUSION: Patients those who undergo ESD for large gastric lesions and massive hemostasis, especially with diabetes or coagulation abnormalities, tend to have delayed healing of iatrogenic ulcer. For such patients initial dosage increment of PPI or addition of other anti-ulcer agents after ESD should be considered.

INTRODUCTION: *Helicobacter Pylori (HP)* negative gastric cancer is rare. Recently, we experienced *HP* negative early gastric cancer.
AIMS & METHODS: The purpose of this study is to evaluate the clinical characteristics of *HP*-negative Early Gastric Undifferentiated adenocarcinoma. We examined 35 cases (19 males and 16 females) with 36 lesions of Helicobacter Pylori (*H.pylori*)-negative Early gastric undifferentiated adenocarcinoma. All cases were treated by Endoscopic Submucosal Dissection. All cases had no history of *H.pylori* eradication, no inflammatory changes on the resected specimen, and no sign of atrophy on endoscopy, with negative results for pepsinogen and urea creath tests.
RESULTS: Of the 36 lesions, 35 were diagnosed as signet-ring cell carcinoma, with only 1 case of poorly differentiated adenocarcinoma. The mean lesion size was 7.4mm. The macroscopic type was 0-IIc in 30 (83%) lesions and 0-IIb in 6 lesions. 33 (92%) lesions showed pale lesion in color. The depth classification was intramucosal in 36 lesions. Of the 36 intramucosal lesions, 3 (8%) were limited to the proliferative of the mucosa, 22 (61) invaded from the proliferative zone to the upper side, and only 1 (2%) case invaded the lower mucosa. With respect to the background mucosa, 25 (69%) lesion originated from the fundic gland area, 5 (14%) originated from the intermediated zone, and 6 (17%) originated from the pyloric glands. The incidden of HP-N-UEG was 2.3% of all ESD cases.
CONCLUSION: *HP* negative early gatric cancer was rare. However, we experienced HP negative early gastric undifferentiated adenocarcinoma. These cases may have considerable relevance in the near future.

P0693 CHROMOENDOSCOPY WITH INDIGO CARMINE DYE ADDED TO ACETIC ACID FOR DELINEATING EARLY GASTRIC CANCERS IS USEFUL AND EASIER THAN MAGNIFYING ENDOSCOPY WITH NARROW BAND IMAGING

K. Nagao[1,*], H. Noda[1,1], N. Ogasawara[1], T. Shimura[2], M. Ebi[2], S. Izawa[1], Y. Kondo[1], Y. Ito[1], Y. Tamura[1], M. Sasaki[1], K. Kasugai[1]
[1]*Gastroenterology, Aichi Medical University School of Medicine, Nagakute,* [2]*Gastroenterology and Metabolism, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) was developed to improve the rate of en bloc resection for early gastric cancer (EGC). Although a clear diagnosis of EGC demarcation is important for proper treatment, demarcations are often obscure. To achieve a successful ESD outcome, it is very important to accurately determine the lateral extent of the tumor. The determination of EGC demarcation has traditionally been performed with conventional endoscopy and chromoendoscopy (CE) using indigo carmine dye. However, it is sometimes difficult to identify the margins of the tumors, especially those of superficial or flat-type tumors. Various techniques using magnifying endoscopy

(ME) have been developed to enhance images of EGC demarcations. Magnifying endoscopy with narrow band imaging (ME-NBI) has reportedly been useful in overcoming this problem but the use of ME–NBI is limited by the technical difficulties in manipulating the scopes. Therefore, easier methods are required that make it possible to accurately determine the lateral extent of these tumors. Chromoendoscopy with indigo carmine dye added to acetic acid (CE-IA) has recently been reported to improve the diagnostic yield in terms of recognizing the tumor borders in patients with EGC. Our purpose was to compare the diagnostic performance of CE-IA with that of ME-NBI and conventional ME (CME). We investigated three methods to determine which is more effective in enhancing the recognition of EGC demarcations.

AIMS & METHODS: The study group included 266 lesions of consecutive 259 patients with differentiated EGC who underwent ESD at Aichi Medical University Hospital between January 2006 and March 2014. The recognition of demarcations were evaluated using CME (n = 193), ME-NBI (n = 43) and CE-IA (n = 30). All observations were made on optimal foci and at the highest magnification ratios possible. For CE-IA, 20–30 mL of 1.5% acetic acid was sprinkled onto the lesion and 10-20 mL of 0.2% indigo carmine dye was similarly sprinkled 30-60 seconds later using a washing pipe. The recognition of demarcations between the lesion and the normal mucosa were classified as distinct or indistinct by observation of CME, ME-NBI and CE-IA.

RESULTS: The demarcations of the lesions were distinct in 64.8% (125/193) with CME, in 81.4% (35/43) with ME-NBI and in 90.0% (27/30) with CE-IA. ME-NBI and CE-IA clarified the demarcation in a significantly higher percentage compared with CME ($P < 0.05$). However, the determination rate of EGC demarcation did not differ between ME-NBI and CE-IA. The mean duration of determination procedure for demarcation with CE-IA was significantly shorter than that with ME-NBI (6.97±3.75 min vs. 8.57± 4.33 min, $P < 0.05$).

CONCLUSION: CE-IA and ME-NBI are useful in determining the lateral extent of EGCs. The mean duration of determination procedure for EGC demarcation was significantly reduced using CE-IA compared with ME-NBI. The demarcations of EGDs were recognized most easily using CE-IA.

INTRODUCTION: The advent of endoscopic ultrasonography (EUS) has significantly improved the preoperative diagnosis and staging of gastric cancers. EUS is the most reliable nonsurgical method available for assessing primary tumor with a high diagnostic rate of accuracy in staging gastric cancer. This assessment is an important factor in choosing a proper treatment such as endoscopic resection or surgery. Especially in early gastric cancers (EGC), the size, gross appearance, histologic diagnosis, degree of differentiation, and depth of invasion are very important factors to be considered for therapeutic decision making. Endoscopic submucosal dissection (ESD) currently is widely accepted as a standard treatment strategy for EGC without any risk of lymph node metastasis because the ESD procedure facilitates en bloc resection even in patients with large or ulcerous lesions. Therefore, it has become more important in treatment planning to determine the depth of invasion accurately before treatment. The aim of this study was to evaluate the clinicopathological factors affecting the diagnostic accuracy of EUS and to compare the diagnostic accuracy evaluated by endoscopic findings with that by EUS in EGCs.

AIMS & METHODS: During the period from April 2009 to January 2014, 136 patients (94 men and 42 women; age range, 44-88 years; mean age, 72.1 years) with an endoscopic diagnosis of EGCs underwent EUS to define pretreatment staging. Diagnoses of invasion depth by EUS or endoscopic findings were divided into intramucosal (M) and submucosal invasion (SM). All patients underwent curative treatment by either ESD or standard surgical intervention, and all lesions were evaluated by histopathological examination. Both EUS-determined diagnosis and conventional endoscopy-determined diagnosis were compared with the final histopathological evaluation of resected specimens, and the impact of various clinicopathological parameters on diagnostic accuracy was analyzed.

RESULTS: The accuracy of invasion depth were 83.0 % for EUS and 74.5 % for conventional endoscopy, respectively. There was significant difference related with the accuracy of invasion depth between EUS and endoscopic findings ($p < 0.01$). The diagnostic accuracy of EUS for predicting tumor invasion depth was significantly affected by the tumor location and the tumor size. Lesions located in the posterior wall of the stomach larger than 3 cm were significantly associated with lower diagnostic accuracy in predicting the tumor invasion. These lesions had higher probability of overstaging estimated by EUS. However, no significant differences were found in histopathological differentiation, tumor gross appearance and ulceration. Unexpectedly, the observation time for EUS was the same as that for conventional endoscopy (6.8±3.1 minutes vs. 6.1±4.2 minutes).

CONCLUSION: EGCs larger than 3 cm located in the posterior wall of the stomach should be cautiously considered in the decision on treatment modality by pretreatment EUS staging. Moreover, observation time for EUS was so short that a sedation was not considered to be required during EUS investigation.

P0695 ADDITORY RISK FACTORS FOR PYLORIC STENOSIS AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION, AND VARIOUS MANAGEMENTS

K.S. Lee[1,*], M.J. Yang[1], S.J. Ahn[1], S.J. Shin[1]
[1]*Department of Gastroenterology, Ajou University School of Medicine, Suwon, Korea, Republic Of*
Contact E-mail Address: *kiseong@hotmail.com*

INTRODUCTION: Endoscopic mucosal dissection (ESD) is useful method for local resection of early gastric neoplasia. [1,2] But, ESD can cause early and late complications commonly known as bleeding, perforation, and stricture formation. [3] In previous study, Coda S, et al., circumferential extent of a mucosal defect > 3/4 and longitudinal extent > 5 cm were each significantly related to the occurrence of post-ESD stenosis in both cardiac and pyloric resections. And endoscopic balloon dilatation can be an effective treatment of them. [4]

AIMS & METHODS: The aim of this study is to clarify the previous risk factors and determine the additory risk factor. And we report another management methods for pyloric stenosis after ESD. Retrospectively a total of 1621 early gastric neoplasia resected by ESD at a single institution between 2005 and 2012. Pyloric stenosis is defined when a 1 cm diameter endoscope could not passed through the pyloric ring.

RESULTS: Among 126 cases which resected from the pylorus, stenosis occurred in six cases. Significant differences were found between longitudinal diameter of resected specimen (≥5cm) and the others (<5cm) (odd ratio = 15.362, $p = 0.037$), circumferential mucosal defect over the half (≥270°) and the others (<270°) (odd ratio = 23.840, $p = 0.015$). Also the number of repeated ESD was significant different between the single lesion and the others (≥2 times) (odd ratio = 26.169, $p = 0.040$). Six patients of pyloric stenosis received endoscopic balloon dilatation for treatment of post-endoscopic resection stricture and 4 patients has improved symptoms. But two patients received an additional procedure for treatment of pyloric stenosis. One of them underwent subtotal gastrectomy and other was treated with metallic pyloric stent.

CONCLUSION: The risk factors of pyloric stenosis were the longitudinal diameter of resected specimen (>5cm) and circumferential mucosal defect over 75% of pyloric ring in this study. In addition, repeated ESD limited pylorus also caused pyloric stenosis. We thought the diameter of specimen and circumferential defect are important factors as previous study. [4] And this study revealed another risk factor: repeated procedure is additional risk factor of pyloric stenosis after ESD. In treatment of post-endoscopic resection stricture, balloon dilatation is effective treatment. But, according Coda S, et al., procedure is needed more than nine times on average. [4] Frequent the procedures decrease quality of life. Therefore more confident short-term treatment is needed. Pyloric stent is useful management of pyloric stricture. But it is too expensive and has complications like stent-migration. This is must be resolved first.

P0696 ULTRA THIN ENDOSCOPE WITH NARROW BAND IMAGING (NBI) IN DIAGNOSTIC OF GLUTEN DEPENDENT AND INDEPENDENT SMALL INTESTINAL ATROPHY IN INFANT AND UP TO 36 MONTHS AGE CHILDREN

K. Marakhouski[1,*]
[1]*Endoscopy, RSPC "Mother and child", Minsk, Belarus*

INTRODUCTION: Using high-resolution endoscopy is sharply limited at this age. It remains unclear whether there are differences in the high-resolution endoscopic assessment of the small intestinal mucosal pit pattern at congenital intestinal atrophy (non gluten) and atrophy at a gluten sensitivity enteropathy.

AIMS & METHODS: Inclusion criteria were: child wasn't older 36 month and has low weight gain (WHO criteria) and non bloody diarrhea. Investigation performed with permission and control of the local ethic committee. We analyzed endoscopy results of 32 cases (13 girls).

Endoscopy: the EXERA III with an endoscope GIF - N180 4.9 mm in diameter was used Evaluation of duodenal mucosa was done with narrow band imaging (NBI, more brightly than in EXERA II light source) and for additional sign of atrophy water flow with addtion of semethicon was done too. Two biopsy specimens were taken minimally. The description of a biopsy was carried out by a standard technique with special orientation biopsies specimens, by two independent pathology experts. Four criteria were used for endoscopic and histological (HYS) intestinal atrophy assessment: definitely yes, probably yes, probably no, definitely no. The main group was divided on two subgroups: A - age up to 6 months (group of strictly non gluten enteropathy) and B - 6 - 36 months (probably gluten dependent enteropaty).

RESULTS: Age in group A (N = 17) was: mean – 2.9 (CI 95% = 2-4), median - 3.0 (CI 95% = 1-4). Frequency of the HYS definitely yes atrophy was in 5, probably yes- 1. Atrophy rate was 35% (Exact 95% C. I. (Fisher's) = 14.2-61.7). Frequency of the endoscopic definitely yes atrophy was in 6, probably yes- 2. Endoscopy sensitivity 0.67(CI 95% = 0.35 - 0,88, specificity 1,00 (CI 95% = 0.68 - 1,0), odds ratio (Fleiss)- 33(CI 95% = 1,6 - 151,23). If endoscopy negative, expected HYS negative will definitely to no atrophy.

Age in group B (N = 15) was: mean – 23,5 (CI 95% = 18,5-28,4), median - 21,0 (CI 95% = 17-33). Frequency of the HYS definitely yes atrophy was in 4, probably yes- 0. Atrophy rate was- 26,7% (Exact 95% C. I. (Fisher's) = 7,8-55,1), and not different significant from group A. Frequency of the endoscopic definitely yes - atrophy was in 4, probably yes - 1case. Sensitivity 0.8 (CI95% = 0.38 - 0,96; specificity 1,00 (CI95% = 0.72 - 1,00), odds ratio (Fleiss) 63 (2,22 - 313,23), and LR (Test = Negative) = 0.2.

CONCLUSION: In infant and up to 36 months age children with low weight gain and non bloody diarrhea small intestinal atrophy rates are from 14.2% to - 61.7%. We found no difference in the two groups (gluten associated or not) used to assess ultra thin with NBI endoscopy sensitivity, specificity, and it has value as a good standard for visual endoscopic evaluation of duodenal villi changes as a method for exclusive intestinal atrophy.

INTRODUCTION: Propofol sedation is widely used, mainly in Europe and the US, not only as an induction agent for general anesthesia but also in the field of gastroenterological endoscopy. Especially in the US, the certified registered nurse anesthetists perform general and local anesthesia for many endoscopic procedures under anesthesia management, independently from doctors. However, quite a few states prohibit individuals other than anesthetists from performing propofol sedation from the safety aspect. Propofol sedation, which is "easy to give and wean off," by nurse-administered propofol sedation (NAPS) is quite meaningful, and could thereby reduce labor costs and charges for recovery rooms and curb medical expenses.

AIMS & METHODS: We prospectively examined the safety of propofol sedation at the time of esophagogastrodudenoscopy (EGD). Between July 2013 and January 2014, EGD was performed under NAPS in outpatients, and time to arousal and safety were prospectively assessed. Propofol was administered manually in a prespecified regimen, and, before the test and at 10 and 60 min after the test, the mean blood pressure, $Sp0_2$, grasping power of both hands, visual acuity of both eyes, Mini Mental State Examination (MMSE) score, and reflex nerve test were assessed and compared.

We hypothesized that "MMSE score recovers to the pretest value 60 min after the completion of EGD under propofol sedation." To prove this hypothesis, we tested non-inferiority of MMSE at 60 min after the test against that before the test. We calculated that 87 eligible patients were needed to obtain a significant difference, and estimated the number of patients to be included at 104, expecting 20% of the patients to be ineligible. Quantitive variables were evaluated by *t*-test, and the significance level of <0.05 was considered statistically significant.

RESULTS: 95 patients (mean age: 55.5 ± 14.9 years; male/female ratio: 37/58 cases; mean examination time: 315.6 ± 115.8 s; mean induction dose of propofol: 0.097 ± 0.019 mL/kg; and mean total dose: 0.129 ± 0.027 mL/kg) were included for analysis. All patients could be successfully sedated and opened their eyes immediately after the test. Before the test vs. 10 min after the test, the mean blood pressure (mmHg) was 95.19 ± 13.20 vs. 90.13 ± 12.34 ($p < 0.01$); grasping power of right hand (kg) was 27.7 ± 8.08 vs. 26.2 ± 8.49 ($p < 0.01$); grasping power of left hand (kg) was 26.4 ± 8.08 vs. 25.3 ± 8.22 ($p < 0.01$); and MMSE (points) was 27.3 ± 2.2 vs. 26.8 ± 2.4 ($p < 0.05$); all of which showed significant differences. Before the test vs. 60 min after the test, the mean blood pressure (mmHg) was 95.19 ± 13.20 vs. 91.80 ± 11.88 ($p < 0.01$), showing a significant decline. No occasional symptoms were observed in all patients.

CONCLUSION: EGD under NAPS was performed safely and all factors other than mean blood pressure returned to the pretest condition 60 min after the test. Blood pressure was also in an acceptable range as per discharge criteria, and the patients were considered to be allowed to be safely discharged from hospital after 60 min.

P0698 DEVELOPMENT OF PROPOFOL SEDATION FOR THERAPEUTIC ENDOSCOPY UNDER DEEP SEDATION WITH SPONTANEOUS RESPIRATION

K. Matsumoto[1,*], **K. Matsumoto**[1], A. Nagahara[1], Y. Nakagawa[1], H. Ueyama[1], Y. Shimada[1], D. Asaoka[1], M. Hojo[1], S. Watanabe[1]
[1]*gastroenterology, juntendo univ., bunkyo-ku, Japan*

INTRODUCTION: In recent years, propofol sedation has attracted attention for use during therapeutic endoscopy under deep sedation with spontaneous respiration. However, a standard protocol for propofol sedation has not yet been established.

AIMS & METHODS: Our aim was to establish a simple and safe protocol for propofol sedation during therapeutic endoscopy. This study retrospectively investigated 89 patients (67 male, 22 female; mean age 71.2 years) who underwent endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR) of the esophagus and stomach under anaesthesia with 1.0% propofol. Patients were assigned to 1 of 5 groups (phases 1 – 5) each corresponding to a different dosing protocol. After beginning phase 1, when it was deemed that the dose of propofol was insufficient or excessive, the dose was adjusted and the next phase was begun in a different group of patients. In all phases, the initial dose of 1.0% propofol was administered after bolus injection of pethidine hydrochloride (0.5 mg/kg), and 1.0 mL of propofol was added every minute until anaesthesia to level 6 on the Ramsey Sedation Scale was achieved. Subsequently, continuous drip infusion was performed to maintain the depth of sedation. Induction and maintenance doses in each phase are shown in the table below. When the patient showed movement, a bolus injection of 1.0 mL propofol was repeated every minute until suitable sedation was obtained, and continuous drip infusion was increased to a dose of 5 mL/h. Oxygen saturation and blood pressure were monitored during all procedures. A BIS monitor was used at phase 5. Continuous drip infusion was stopped temporarily under the following conditions: SpO_2 <90%, BP <80 mm Hg, or BIS score <60 (5 seconds or more). Following recovery, the rate of continuous drip infusion was decreased to 5 mL/h. We calculated the dose of propofol at the time of induction and during the maintenance phase, the number of additional bolus injections, and the average total dose of propofol. The incidence of cardiorespiratory suppression was evaluated for each phase. The incidence of BIS below 60 was also evaluated in phase 5.

RESULTS: During induction, no cardiorespiratory suppression occurred in any of the phases. During the maintenance phase, circulatory suppression occurred more frequently in phases 1-4 than in phase 5. In contrast, no respiratory suppression occurred in any of the phases.

Table: Propofol dosing and the incidence of adverse events during each phase of study

CONCLUSION: This newly developed propofol anesthesia protocol (phase 5) could be safe for therapeutic endoscopy under deep sedation with spontaneous respiration.

P0699 MAGNIFICATION ENDOSCOPY WITH ACETIC ACID-ENHANCEMENT AND NARROW-BAND IMAGING FOR PREDICTING HISTOLOGIC CHARACTERISTICS OF GASTRIC MUCOSAL NEOPLASMS

K. Shibagaki[1,*], Y. Amano[2], N. Ishimura[3], H. Taniguchi[4], H. Fujita[1], K. Kobayashi[5], Y. Kinoshita[3]
[1]*Gastroenterology, Tottori Municipal Hospital, Tottori,* [2]*Gastroenterology, Kaken Hospital, International University of Health and Welfare, Ichikawa,* [3]*Gastroenterology, Faculty of Medicine, Shimane University, Izumo,* [4]*Tottori Municipal Hospital, Tottori, Japan,* [5]*Pathology, Tottori Municipal Hospital, Tottori, Japan*

INTRODUCTION: Magnification endoscopy with narrow-band imaging (NBIME) that visualizes the capillary patterns of gastric surface structure is useful for predicting the histologic characteristics of superficial gastric neoplasms. NBIME with acetic acid-enhancement (A-NBIME) clearly visualize the microstructure pattern of gastric mucosal surface.

AIMS & METHODS: We performed a prospective study to compare the diagnostic reliability of white light endoscopy (WLE), NBIME, and A-NBIME for the histologic characteristics of gastric mucosal neoplasms. Consecutive 220 gastric neoplasms (49 adenomas, 144 differentiated adenocarcinomas, and 27 undifferentiated adenocarcinomas) were photographed with WLE, NBIME and A-NBIME.

Macroscopic patterns by WLE, capillary patterns by NBIME and microstructure patterns by A-NBIME were respectively classified into type M1/M2/M3, type C1/C2/C3/C4 and type S1/S2/S3, by referring to the previously reported

Table to abstract P0698

	Phase1 (n=27)	Phase 2 (n=11)	Phase 3 (n=7)	Phase 4 (n=14)	Phase 5 n=30)
Dose of initial bolus injection (mg/kg)	0.5	0.33	0.5	0.5	0.5
Dose of continuous drip infusion (mg/kg/h)	5	3.3	3.3	2.5	2.5
Average number of additional bolus injections at introductory phase	1.07 (0∼6)	4.0 (1∼13)	1.6 (0∼5)	3.8 (0∼7)	3.6 (0∼17)
Average number of increasing maintenance dose	0.7 (0∼5)	1.5 (0∼2)	1.3 (0∼5)	2.6 (1∼5)	1.9 (0∼7)
Average total dose (mL)	48.5(17∼109)	60.1 (24∼135)	49.6 (16∼133)	44.4 (12∼95)	52.1 (7.5∼170)
SpO_2 < 90%	0	0	0	0	0
Blood pressure < 80 mm Hg	11 (40.7%)	3 (27.3%)	3 (42.9%)	4 (28.6%)	3 (4.8%)
BIS score < 60 (>5 seconds)	NA	NA	NA	NA	1 (1.6%)

classifications as described below. Macroscopic pattern; Type M1: the protruded and whitish lesions with roundish edge and smooth or often nodular surface. Type M2: the irregular-shaped and depressed, flat, or elevated lesion in red or similar color to the surrounding mucosa. Type M3: the depressed and whitish lesions often with variously sized nodules on the lesion. Capillary pattern; Type C1: capillaries with homogenous diameters and distributions. Type C2: capillaries with heterogeneous diameters and irregular distributions. Type C3: capillaries grow in disorder with unclear mucosal microstructure. Type C4: capillaries are invisible or obviously decreased. Microstructure pattern; Type S1: glandular crypts present, homogeneously sized, shaped and arranged foveolae or grooves. Type S2: glandular crypts present, heterogeneous. Type S3: glandular crypts are absent or severely decreased.
Endoscopic images were independently reviewed by three expert endoscopists. Type M1/M2/M3 in WLE, type C1/C2/C3 in NBIME, and type S1/S2/S3 in A-NBIME were used as the indicator of adenoma/differentiated adenocarcinoma/undifferentiated adenocarcinoma, respectively. Type C4 in NBIME was excluded from the analysis of histologic diagnostic accuracy. The histologic diagnostic accuracy and interobserver diagnostic agreement was compared among modalities.
RESULTS: The kappa values of interobserver agreement for WLE, NBIME, and A-NBIME diagnosis were 0.33(0.31-0.36), 0.58(0.55-0.61), and 0.61(0.54-0.67), showing an insufficient diagnostic agreement for WLE and a statistically good diagnostic agreement for both NBIME and A-NBIME. Adenomas/differentiated adenocarcinomas/undifferentiated adenocarcinomas were statistically related to type M1/M2/M3 in WLE, type C1/C2/C3 in NBIME and type S1/S2/S3 in A-NBIME, respectively ($P<0.01$). Type C4 of capillary pattern by NBIME did not show a statistical correlation to the specific histologic characteristics. The diagnostic accuracy of WLE, NBIME, and A-NBIME were 79.0%, 74.1%, and 90.5%, showing statistical superiority of A-NBIME ($P<0.01$). No additional effect of NBIME to WLE.
CONCLUSION: A-NBIME is superior to WLE and NBIME in the predictive histological diagnosis of gastric mucosal neoplasms with good clinical feasibility.

INTRODUCTION: Curative endoscopic submucosal dissection (ESD) of early gastric cancers requires accurate determination of the horizontal extent of invasion. A number of studies have since reported superior diagnostic ability for magnifying endoscopy with narrow-band imaging (ME-NBI) over conventional endoscopy (CE) in delineating the lateral extent of early gastric neoplasias. However, there are few studies that have reported the actual magnifying ratio used when performing ME. The added benefits of ME-NBI over CE in terms of the difference in magnification level have yet to be elucidated.
AIMS & METHODS: The aim of this study was to investigate the improvement in diagnostic accuracy for tumor delineation obtained with different magnification levels of ME-NBI following CE. This study comprised a series of 161 consecutive early gastric cancers resected *en bloc* using ESD in 158 patients between July 2008 and June 2012. Each patient underwent sequential CE, LM-NBI and HM-NBI examinations during the same procedure as preoperative diagnostic examinations 1 to 2 weeks prior to ESD. On the day of the ESD procedure, or the preceding day, using HM-NBI we again identified the lesion margin, and made markings 3-5 mm outside the DL. After ESD with reference to the pathohistological findings, we identified the markings, and reconstructed the lateral extent of the cancer on the each endoscopic image (CE, LM-NBI, HM-NBI). The histologically determined cancer margins were used as the gold standard. The primary endpoint was the added benefit, as measured using the successful delineation rate, for the delineation of gastric cancer margins using CE+LM-NBI *vs* CE, and for CE+LM-NBI+HM-NBI *vs* CE+LM-NBI. We derived the successful delineation rate with 95% confidence intervals (CI) for early gastric cancers using each examination method, CE, CE+LM-NBI, and CE+LM-NBI+HM-NBI and used McNemar's test with Bonferroni's multiple comparison correction to calculate p values.
RESULTS: The clinical characteristics were as follows: average age 71 years; 116 males and 45 females; mean lesion diameter 19.2 mm (±14.4 mm, range 5-120 mm); and macroscopic type using the Paris classification type 0-I 4 lesions (2.5%), type 0-IIa 64 lesions (39.8%), type 0-IIb 38 lesions (23.6%), and type 0-IIc 55 lesions (34.2%). The location of the lesion was the upper part of the stomach in 46 cases (28.6%), middle part in 41 (25.5%), and lower part in 74 (46.0%). The successful delineation rates (95% CI) using CE, CE+LM-NBI and CE+LM-NBI+HM-NBI were 72.7 (68.5-79.9%), 88.9 (83.9-93.7%), and 98.1 (95.8-100%). The diagnostic accuracy improved significantly for CE+LM-NBI compared with CE ($P<0.001$) and for CE+LM-NBI+HM-NBI compared with CE+LM-NBI ($P<0.001$).
CONCLUSION: ME-NBI is an extremely useful modality for the delineation of the margins of early gastric cancers. HM-NBI is superior to LM-NBI in improving the successful delineation rate, following CE.

P0701 GASTRIC ATROPHY WAS A RISK FACTOR FOR THE PRESENCE OF MISSED SYNCHRONOUS LESION AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION

K.H. Kim[1,*], S. I. Seo[1], B.Y. Choi[1]
[1]*Department of Internal Medicine, Division of Gastroenterology & Hepatology, Kangdong Sacred Heart Hospital of Hallym University Medical Center, Seoul, Korea, Republic Of*
Contact E-mail Address: *minsoksumin@naver.com*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been widely accepted as a minimally invasive therapy for gastric adenoma or early gastric cancer (EGC). However, the risk of secondary gastric neoplasms developing during the surveillance period after ESD has become a important medical problem. In particular, there is a high possibility that ESD can miss synchronous gastric neoplasms compared with surgery.
AIMS & METHODS: In the present study, we aimed to investigate predictive factors associated with the presence of missed synchronous gastric neoplasms after ESD for gastric adenoma or EGC. We performed ESD in 370 patients with EGC or gastric adenoma from January 2008 through December 2012 at our institution. The patients with endoscopic surveillance interval less than 1 year, patients without curative resection, and patients with additional surgery were excluded from the study. Missed synchronous gastric neoplams were defined as any gastric neoplasms detected within one year after ESD, but initially unidentified. We compared clinical, endoscopic, and pathological factors between patients with missed synchronous gastric neoplasms and patients without missed synchronous gastric neoplasms.
RESULTS: Missed synchronous gastric neoplasms were found in 4.3% (16/370) of the patients. Among the 16 missed synchronous gastric neoplasms, three (18.8%) cases were carcinomas. In the univariate analysis, open-type gastric atrophy, gastric atrophy and intestinal metaplasia more than moderate degree were significantly associated with the presence of missed synchronous gastric neoplasms. In multivariate logistic regression analysis, only gastric atrophy more than moderate degree was the independent risk factor for the presence of missed synchronous gastric neoplasms (Exp (B) = 8.608, 95%CI: 1.036–45.549).
CONCLUSION: Gastric atrophy could be an independent risk factor for the presence of missed synchronous lesion after ESD. Careful endoscopic surveillance should be performed after ESD for patients with severe gastric atrophy.

P0702 EFFECT OF ELECTRICAL CURRENT MODE ON CLINICAL COURSE AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

K.H. Song[1,*], S.M. Kim[1], J.H. Park[1], K.C. Huh[1]
[1]*Konyang University, Deajon, Korea, Republic Of*
Contact E-mail Address: *postit2@daum.net*

INTRODUCTION: Several modes of electrical current are available for endoscopic submucosal dissection (ESD) of gastric epithelial tumor. There has been no data regarding whether the electrical current mode effects on clinical course after gastric ESD, including incidence of post ESD coagulation syndrome, ulcer healing rate.
AIMS & METHODS: AIM Clinical courses were surveyed according to the setting of two different dissecting mode: endocut or swift, to provide relating data on optimal adoption of mode for gastric ESD.
METHODS Among 286 consecutive sessions of gastric ESD, 200 lesions were surveyed after excluding cases: usage of endoknives other than IT2 knife, tumor with nearby scar, synchronous tumor, subepithelial tumor. Only one of endocut or swift mode was adopted for submucosal dissection in eaach session of ESD. All the procedure were performed using an electrosurgical unit, VIO 300D (ERBE, Germany). The ESD pathology, location of tumor, procedure and resection time, incidence of post ESD syndrome were assessed with demographic data. Patients with pyrexia (body temperature $>38.3\_C$) and upper abdominal pain or tenderness after ESD, with or without symptoms of peritoneal irritation were defined as having post ESD coagulation syndrome. Follow up endoscopy was performed at 3 months after the endoscopic therapy and rated as ulhealed if the ulcer was in A1 to H2 rated by Sakita-Miwa stage.
RESULTS: In total of 200 sessions, we applied endocut mode for 116 cases (58%) and swift mode at for 84 cases (42%). The demographic data between the two groups were not significantly different. Total of 16 post ESD coagulation syndromes were notified. Multivariate analysis revealed adoption of swift mode (OR 6.90, 95%CI: 1.83-25.92) and malignant pathology (OR 5.93, 95%CI: 1.46-24.02) was related post ESD coagulation syndrome. Ulcer healing rate judged at 3 months after ESD tended to be delayed for endocut mode, even though it was not statistically significant.
CONCLUSION: Mode of electrical current may be related to the incidence of post ESD coagulation syndrome or ulcer healing after gastric ESD. Randomized and controlled studies are warranted.

P0703 TRANASAL VERSUS PERORAL PERCUTANEOUS ENDOSCOPIC GASTROSTOMY: A PROSPECTIVE CASE CONTROL STUDY

L.-F. Lin[1,*]
[1]*Gastroenterology, Pingtung Christian Hospital, Pingtung, Taiwan, Province of China*
Contact E-mail Address: *lin.lian.feng@gmail.com*

INTRODUCTION: Percutaneous endoscopic gastrostomy (PEG) is a challenge in patients with difficult oral intubation. Some cases of successful transnasal insertion of PEG were reported. But no any case control study was conducted to compare transnal and oral insertion of PEG.
AIMS & METHODS: This work is to investigate the difference between transnasal and peroral insertion of percutaneous endoscopic gastrostomy in clinical outcome. A prospective, case-control study was conducted to compare transnasal (T-PEG) and peroral (O-PEG) placement of a 20 Fr PEG tube in dysphagic patients without conscious sedation. Additional spraying lidocain solution and epinephrine solution to the nasal cavity and using ultrathin 5 mm endoscope (Olympus GIF-N-260) were applied to the T-PEG. The other premedication and procedure are same as conventional pull-method PEG. Neither the nasal cavity nor the oral cavity were decolonized in all patients. The success rate, operation time, occurrence of choking during PEG, nasal bleeding, stomal site infection, post-PEG complication were recorded and analyzed.
RESULTS: Thirty-nine insertions of T-PEG and thirty-eight insertions of O-PEG were attempted in 77 chronic dysphagic patients form home or nursing home. Mean age is (T-PEG vs O-PEG) 76.3±10.3 vs 79.5±6.9 years, male gender 67% vs 48%, operation time 14.6 ± 4.0 vs 11±3 minutes (p: 0.028), choking occurred in 3 vs 5 patients. One failed insertion and two nasal bleeding occurred in T-PEG. There are nine stomal site infection (8 pseudomonas aeruginosa infection including one systemic infection) in T-PEG and 14 stomal site infects (8 pseudomonas aeruginosa) in O-PEG ($p < 0.001$). One systemic infection of urinary tract, one buried bumper, and one soiling of stoma were observed respectively in T-PEG and O-PEG. No PEG related mortality occurred within 3 months after all PEG procedures.
CONCLUSION: Transnasal insertion is feasible in placing a 20 Fr PEG but it causes rare nasal bleeding rate and needs longer operation time. Stomal site infection is less but more dominant pseudomonas infection occurred in T-PEG. In conclusion, T-PEG is an alternative for patients who had difficulty in oral intubation. It needs more studies to concern the prophylaxis of pseudomonas infection.

INTRODUCTION: Numerous studies support the efficacy and safety of propofol in digestive endoscopy in which propofol is administered by non-anesthesiologist during endoscopic procedures. There is literature on the safety of sedation with propofol in elderly patients. However, there are no clear guidelines regarding the dose of propofol to be used in this group of patients in which comorbidity can make them more fragile, making the standard dose/kg of weight excessive to achieve a safe sedation.
AIMS & METHODS: The aims of this study were to establish the dose of propofol in patient ≥75 years compared with patients <75 years and to evaluate the safety of propofol when is administered by non-anesthesiologist. Between June 2012 and March 2014, we prospectively recorded all endoscopic procedures and safety data. Only diagnostic procedures were included for this study. We excluded: patients <18 years, not sedated by endoscopist, therapeutic and incomplete procedures, and also patients with two endoscopies performed on the same day. To reduce variability and determine whether the differences between the doses of propofol in both groups were related to age, all patients ≥75 years were matched on a 1:1 basis with the <75 years group in terms of weight, body mass index (BMI) and endoscopic procedure. All esophagogastroduodenoscopies (EGDs) and colonoscopies received an initial dose of propofol 0.5-1 mg/kg. Colonoscopies also received a fixed dose of 50 mcg of fentanyl. Subsequently, boluses of 10-20 mg propofol were administered to maintain an adequate level of sedation. Vital signs were recorded before, during and after the procedure. A statistical analysis was performed with the SPSS v20.0 program.
RESULTS: There were 439 diagnostic EGDs and 307 diagnostic colonoscopies performed in patients ≥75 years. When compared with patients <75 years, there were significant differences between groups in mean propofol dose, and mild adverse events. No serious adverse events occurred. Patients ≥75 years required significantly less propofol than patients <75 years, 72.99± 37.4mg vs. 120.54± 4.8mg for EGDs ($P < 0.001$) and 80.59±34mg vs 129.12± 55.9mg ($P < 0.001$) for colonoscopies (39.4% less in EGDs and 37.5% in colonoscopies). Table 1 shows the demographic, endoscopic procedures, propofol dose and adverse events in both groups.

Table 1. Demographic, endoscopic procedures, propofol dose and adverse events in both groups
Table to abstract P0704

	Age	Weight	ASA I/II/III (%)	EGD n	Colonoscopy n (%)	Propofol dose EGD / Colonoscopy	AE (%) Desaturation/ Bradycardia
≥75 years	81 ± 4	68.56 ± 12,4	17.3/70.3/12.4	439	307	72.99± 37.4/ 80.59±34	2.6/0.3
<75 years	51.3± 13	68.55 ± 12,4	62.8/34.9/2.3	439	307	120.54± 4.8**/ 129.12± 55.9**	0.8/0.3*

Data are presented as mean ± SD (range: 95% CI of the mean). Abbreviations: ASA (American Society of Anaesthesiology); EGD (Esophagogastroduodenoscopy). AE: adverse events. *$P < .005$; **$P < .001$
CONCLUSION: Propofol is safe when administered by non-anesthesiologists. Patients ≥75 years globally require almost 40% less propofol than patients <75 years. These results support the use of a lower dose of propofol in the elderly.

INTRODUCTION: Gastric Intestinal Metaplasia (GIM) is a precancerous condition potentially leading to gastric cancer. However, this occurs in a limited number of cases and, therefore, the need of endoscopic surveillance and follow-up is controversial. Moreover, there is no universal consensus regarding which patients should be better investigated and followed-up in the long-term period. Most of the experts among pathologists and gastroenterologists recommend to perform an upper endoscopy with multiple biopsies every three-year only in patients with extensive GIM, but no studies have validated the effectiveness of this protocol, so far.
AIMS & METHODS: Our aim was to investigate whether changes in extension and/or progression of GIM occur during a strict yearly endoscopic follow-up program. Between November 2011 and December 2013, we prospectively evaluated consecutive patients with an histologically defined diagnosis of GIM by means of Narrow Band Imaging with Magnification Endoscopy (NBI-ME) and multiples gastric biopsies (2 antrum +1 angulus +2 corpus). Helicobacter pylori infection was excluded. Patients with a GIM extension higher than 20% were offered to repeat the endoscopic examinations every year and, to date, 20 out of 121 accepted and were included in the follow-up program. Endoscopic examinations have been performed by experienced endoscopists (each of them with more than 1000 NBI-MEs performed). Biopsies were taken at sites suggestive for GIM based on NBI-ME appearance (i.e. presence of light blue crests on the surface of gastric mucosa) or randomly if no evident mucosal alterations were seen. Biopsies were assessed by two expert and blinded pathologists, who evaluated the percentage of extension of GIM at both times.
RESULTS: The median time between the two observations was 13 months (range 11-18). As shown in the Table, patients were divided in three categories, according to the changes in GIM extension, which was considered stable if there were tiny variations (0-5%) between the two observations, or raised/lowered otherwise. At 1-year, in all patients, the second evaluation confirmed the presence of GIM. In patients with worsened extension, the mean percentage of GIM increase was 20%, whereas the mean percentage of GIM lowering was 26%in patients with a reduced GIM extension.

	N	MEDIAN AGE	AGE RANGE	GIM EXTENSION LOWERED	STABLE GIM EXTENSION	GIM EXTENSION RAISED
Females	13	67	56-71	3 (23%)	3 (23%)	7 (54%)
Males	7	64	53-85	4 (57%)	1 (14%)	2 (29%)
OVERALL	20	64	53-85	7 (35%)	4 (20%)	9 (45%)

CONCLUSION: Our results demonstrate that already at 1-year the extension of GIM and, therefore, the risk of developing a gastric cancer GIM-related, worsens in about 45% of the patients. Thus, these data seem to support a more close follow-up in patients with a GIM extension higher than 20% at histologic assessment.

P0706 DOES MAGNIFYING ENDOSCOPY WITH NARROW BAND IMAGING IMPROVE DIAGNOSTIC ACCURACY FOR DEPTH OF INVASION IN ESOPHAGEAL SQUAMOUS CELL CARCINOMA?

M. Imajoh[1,*], T. Yano[1], T. Kadota[1], T. Kato[1], S. Osera[1], H. Morimoto[1], T. Odagaki[1], Y. Oono[1], H. Ikematsu[1], K. Kaneko[1]

INTRODUCTION: While accurate estimation for the depth of invasion in esophageal squamous cell carcinoma (ESCC) is essential to indicate relevant treatment methods, it is difficult to evaluate conventional endoscopy alone. Microvascular patterns identified using magnifying narrow band imaging (M-NBI) have been reported to be useful for the diagnosis in the depth of invasion for superficial ESCC. Recently, a classification regarding the microvascular patterns of superficial ESCC using M-NBI was advocated from the Japan Esophageal Society, however, it is not clear whether the depth of invasion can be estimated more accurately according to this classification compared with estimation using conventional white light endoscopy (WL) alone.
AIMS & METHODS: The aim of this study was to evaluate whether the diagnostic accuracy of in M-NBI is higher than that in WL alone. In this study, we enrolled patients with superficial ESCC who had undergone pretreatment evaluation using both WL and M-NBI, and who received endoscopic resection or surgery in our institution from June 2012 to December 2013. The patients who had been previously treated with chemotherapy or chemoradiotherapy were excluded. The microvessels of tumor surface observed by M-NBI were classified into 3 groups; type B1 consisted of loop-like vessels with atypia, including dilatation and meandering; type B2 were non-loop vessels; and type B3 were large vessels 3 or more times larger than type B2. Type B1, B2, and B3 vasculatures were correlated with lesions invading to EP/LPM, MM/SM1, and SM2 or deeper, respectively. Investigators who were blinded to the pathological diagnosis estimated retrospectively the depth of invasion in the endoscopic pictures by WL alone, and then using the pictures by M-NBI. We sorted the lesions into 3 groups (EP/LPM, MM/SM1, and SM2/SM3) and the diagnoses for individual modalities were compared to the pathological results. Finally, sensitivity, specificity, and positive predictive value (PPV) were analyzed.
RESULTS: A total of 198 lesions were examined. Sensitivity, specificity, and PPV of WL-alone were 92%, 85%, 90% for EP/LPM; 63%, 89%, 51% for MM/SM1; and 74%, 97%, 90% for SM2/SM3, respectively. Sensitivity, specificity, and PPV of M-NBI were 85%, 71%, 81% for EP/LPM; 50%, 75%, 28% for MM/SM1; and 39%, 100%, 100% for SM2/SM3, respectively. The concordance rate for diagnoses between both modalities was 87% in EP/LPM, 59% in MM/SM1, and 45% in SM2/SM3. In cases of a concordance between WLE and NBI-ME, the PPV was 90% for EP/LPM, 61% for MM/SM1, and 100% for SM2/SM3.
CONCLUSION: While the concordance rates between WL and M-NBI was unfavorable in MM/SM1, and SM2/SM3, PPV was high in the diagnosis was concordant cases between both modalities. However, the difficulty of evaluating the invasion depth for MM/SM1 lesions remains unsolved.

INTRODUCTION: Good quality of biopsy specimen is required for reliable diagnosis of early neoplasia in patients with Barretťs esophagus (BE). Studies comparing large capacity vs. jumbo forceps have shown inconsistent results. The aim of this study was to assess the quality of biopsy specimen obtained by 2 different-sized biopsy forceps (Radial Jaw 4 large capacity (outer diameter 2.4 mm) vs Radial Jaw 4 jumbo (outer diameter 2.8 mm) in patients with BE. We hypothesized that RJ4 ''jumbo'' forceps if used with a standard diagnostic endoscope (channel 2.8 mm) provides a better quality of biopsy specimen as compared to the large capacity forceps.
AIMS & METHODS: A single center, randomized (forceps order), prospective and single blind (pathologist) study. Twenty-one patients with BE (5 women, 16 men) were enrolled. All patients underwent an upper GI endoscopy with trimodal imaging. Targeted or random biopsies with both types of forceps used in random order were obtained from each patient during a single endoscopy with a diagnostic endoscope. Main outcome measurement was specimen adequacy (defined as a well oriented biopsy specimen 2 mm in diameter or greater with mucosa present).
RESULTS: A total of 288 biopsy specimen were analyzed (large capacity: 159, jumbo forceps: 129). A significantly higher proportion of biopsy samples obtained with jumbo forceps was adequate as compared to large capacity forceps (54.3 % vs. 18.9 %, $p < 0.0001$).
Biopsies with jumbo forceps had a larger diameter (median 2.4 mm vs. 2 mm; $p < 0.001$). Muscularis mucosae was detected in 67.4 % of specimen with jumbo forceps vs. 31.4 % with large capacity forceps ($p < 0.0001$). Excellent or good specimen orientation was present in 79.8 % of samples with jumbo forceps and in 59.1 % with large capacity forceps (not significant). Intestinal metaplasia was present in 69.8 % with jumbo forceps vs. 78.6 % of samples with large capacity (not significant). The diagnostic yield of both types of forceps was comparable.
CONCLUSION: Radial Jaw 4 Jumbo biopsy forceps, if used with diagnostic endoscope, provides more adequate biopsy specimen as compared to Radial Jaw 4 large capacity biopsy forceps. The diagnostic yield seems to be comparable.

P0708 OPTIMIZED IMPEDANCES OF INJECTION SOLUTIONS LEAD TO IMPROVED CUTTING RESULTS IN ENDOSCOPIC RESECTION

N. Al-Dayaa[1], M. Lösle[1,2], **K.-E. Grund**[1,2,*]

INTRODUCTION: The endoscopic resection of large (ø > 20 mm) lesions in the gastrointestinal tract is a high challenge for interventional endoscopy and radiofrequency surgery. There is no easy, fast and safe way to remove large lesions en-bloc. An important reason is the interaction between submucosal injection, tissue and high-frequency parameters in respect to electrical impedances. This interaction is only partly understood and poorly investigated. Preliminary studies led to the conclusion that problems in the cutting process like cutting delay, perforation and thermal artifacts are due to unsuitable impedances.
AIMS & METHODS: Our aim was to improve the cuttings results (avoiding of cutting delay and high thermal load of the intestinal wall) by optimizing the impedances of the tissue. Therefore we analyzed various submucosal injection solutions in respect to impedances (surface and tissue) and rf-cutting.
With standardized gold probes (1 mm/15 mm) and a special RF-impedancemeter ($f = 100$ kHz, 10 Ω - 1 MΩ) the specific impedances of various solutions and the impedances on the surface and in the tissue after submucosal injection of 3 ml were measured in a standardized bio-model (porcine stomach). Additionally the elevations during 30 min were observed. The following solutions were injected into the submucosa: 0.9% saline, 4% gelatin, 6% hydroxyethyl starch, 10% glycerol/5% fructose in 0.9% saline, 10% glucose and aqua destillata. Additionally 5% albumin, 20% albumin, human blood and blood plasma and a new experimental substance.
RESULTS: Aqua destillata and 10% glucose showed a highly significant higher ($p \leq 0.0001$) specific impedance compared to the standard 0.9% saline (factor 360). After injection also the impedances on the surface and in the tissue were significantly higher ($p \leq 0.01$, resp. $p \leq 0.0001$). The elevation showed no significant difference between the tested solutions. Cutting experiments in a standardized setting showed the expected improvements: no cutting delay, less thermal load of the intestinal wall, smooth cut without carbonization but with adequate zone of hemostasis.
CONCLUSION: Clinically used injection solutions show a highly significant difference of specific impedances. After injection they lead to different impedances on the surface and in the tissue. Better cutting results (avoidance of delayed cut, high thermal load and thermal artifacts) obviously depend on an optimized impedance of the tissue. Therefore injection solutions with optimal (i.e. higher) impedances should be further investigated and preferred to conventional agents.

INTRODUCTION: Percutaneous transesophageal gastrotubing (PTEG) was developed as an alternative route to access the gastrointestinal tract for patients where Percutaneous Endoscopic Gastrostomy was contraindicated with conditions such as prior gastrectomy, gastric anterior wall malignancies, or massive ascites. PTEG was originally developed to be performed under fluoroscopy without endoscopy. However, endoscopy may enhance the safety of the procedure.
AIMS & METHODS: The aim of this study is to evaluate the clinical usefulness of PTEG supported by endoscopy. A rupture-free balloon (RFB) catheter is inserted into the lower esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient's neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed. We started to perform PTEG under

endoscopy without fluoroscopy in a total of 99 patients (63 men and 36 women, mean age 74.0 years) in whom PEG was not feasible. PTEG was performed for nutrition in 53 patients and for decompression in 46.
RESULTS: Satisfactory results were achieved in all 100 patients. Median follow-up was 60.5 days in patients who received decompression because of the obstruction due to malignancies and 231.0 days in those who received nutrition. Two of the 99 patients in the endoscopic assistance required fluoroscopy because of the tube insertion into the jejunum. There were no major complications, but one patient had tracheal penetration, which was managed conservatively. Other complications were minor oozing bleeding in six patients that did not require blood transfusion, subcutaneous emphysema in two patients, which were managed conservatively. Nine accidental (four self) tube removals occurred more than 2 weeks after the procedure, without any problem in reinsertion. The overall complication rate associated with endoscopically assisted PTEG was 14.1%. No patient required surgical treatment or died after PTEG.
CONCLUSION: PTEG supported by endoscopy is as feasible, safe, and useful as PTEG supported by fluoroscopy, the original procedure. The use of endoscopy enhances the safety of the procedure and allows better confirmation of each step involved.

INTRODUCTION: Various narrow band imaging (NBI) pattern classifications in Barrett's oesophagus (BO) have been proposed, but are not readily applied to routine clinical practice due to their multiplicity or complexity.
AIMS & METHODS: We evaluate inter- and intra-observer agreement as well as accuracy of a new simplified NBI pattern classification using NBI magnifying endoscopic images.
A simplified binary classification is based upon NBI mucosal and vascular patterns: 1) regular pattern (non-neoplastic BO) 2) irregular (Barrett's neoplasia, BN). Four endoscopists consisting of 2 experts and 2 non-experts assessed 248 NBI magnifying endoscopic images (neoplasia 72, non-neoplasia 176) based on a simplified binary NBI pattern classification. The endoscopists assessed two times a randomly-arranged NBI magnifying endoscopic image sequence. The interval between the 1st and the 2nd assessment was 6 weeks. Primary endpoint was inter-observer agreement among endoscopists. Secondary endpoints were intra-observer agreements in each endoscopist and diagnostic accuracies of sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) in predicting BN as well as scores of diagnostic confidence level and image quality.
RESULTS: A median score for image quality was 5 (excellent) in both the 1st and 2nd assessment. Inter-observer agreement (multi-kappa value) among endoscopists for BN prediction was calculated as 0.79 (substantial) and 0.86 (almost perfect) for the 1st and 2nd assessment. Intra-observer agreement (kappa-value) which were 0.95, 0.94 (experts) and 0.83, 0.83 (non-experts), respectively, were all almost perfect. Mean sensitivity and specificity of NBI patterns for predicting BN were 92.7% (experts, 90.3%; non-experts, 95.1%) and 95.9% (experts, 99.4%; non-experts, 92.3%) in the 1st assessment as well as 95.5% (experts, 95.8%; non-experts, 95.1%) and 95.7% (experts, 99.1%; non-experts, 92.3%) in the 2nd assessment, respectively, with high confidence level in both assessments. NPV was 98.9% (experts, 96.2%; non-experts, 97.9%) and 99.3% (experts, 98.3%; non-experts, 97.9%) in the 1st and 2nd assessment, respectively.
CONCLUSION: A simplified binary NBI pattern classification for BO showed substantial to almost perfect inter- and intra-observer agreement and significantly high diagnostic accuracies in both experts and non-experts. A simplified binary NBI pattern classification seems applicable to routine clinical practice.

P0711 PREDICTIVE FACTORS FOR LYMPH NODE METASTASIS AFTER NONCURATIVE ENDOSCOPIC RESECTION FOR EARLY GASTRIC CANCER

M. Inoue[1,*], T. Omori[1], R. Nakamura[1], T. Takahashi[1], N. Wada[1], H. Kawakubo[1], H. Takeuchi[1], Y. Saikawa[1], Y. Kitagawa[1]
[1]*Department of Surgery, School of Medicine, Keio University, Shinjyuku-ku, Tokyo, Japan*

INTRODUCTION: Endoscopic resection (ER) is widely accepted as an appropriate treatment modality for early gastric cancer. The indication criteria for ER is established, and additional treatment, including gastrectomy with lymph node dissection, is recommended when pathological examination of resected specimens do not meet the criteria. In some non-curative ER cases, pathological examination after additional surgery reveals lymph node metastasis which have not been detected before ER. There is a possibility that the discovery of risk factors of LN-metastasis in non-curative ER case can expand the indications of endoscopic treatment for early gastric cancer.
AIMS & METHODS: The aim of this study is to examine the predictive factors of LN- metastasis which could not be detected before ER in non-curative ER cases. The indication criteria for ER in Japan is as follows; the lesion clinically diagnosed as intramucosal differentiated cancer which is ≦2 cm in size with no ulceration findings. Expanded indications for some differentiated cancers (intramucosal cancers either ≦3 cm in size with ulceration findings or with no ulceration findings regardless of tumor size) and some undifferentiated cancers (intramucosal cancers ≦2 cm in size with no ulceration findings) have been accepted by high volume ER centers like our institution. If the pathological examination of resected specimens show that they do not meet the criteria including expanded indications, we diagnose them as non-curative. From Apr 2000 to Jul 2013, 75 patients underwent ER as the expanded indication lesion, and were diagnosed as non-curative by pathological examination in our hospital. They underwent additional gastrectomy and their pathological findings in ER and surgical specimens were retrospectively analyzed. And the cases with pathological LN- metastasis, which have not been detected before ER, were picked up and their characteristics were analyzed.
RESULTS: LN- metastasis was found in 9 cases (12%). 7 cases were primary gastric cancers, and 2 cases were residual gastric cancers. In the 7 primary cases, 5 cases had no residual cancer in surgical specimen, while LN- metastases existed. Focus on these complete endoscopic resection cases, 1 case was pathologically undifferentiated type and 5 cases were mixed type. The depth of invasion was SM1 in 1 case, and SM2 in 4 cases. Lymphatic-vascular capillary involvement was found in all cases. In these cases, LN- metastases were found only in local D1 lymph node lesion. Lymph node relapse was found in 2 SM2 cases in the complete endoscopic resection cases at an early date, one case was in 5 months and another in 6 months after surgical resection. Both of them had not only lymphatic capillary involvement but also vascular one.
CONCLUSION: Our data indicate that SM1/SM2 gastric cancer with pathologically mixed type, regardless of predominant type, have high risk of LN- metastasis even if complete endoscopic resection of local lesion has been performed. Lymphatic-vascular capillary involvement also may be a predictive factor of LN-metastasis and risk factor of recurrence. In these cases, we should perform gastrectomy with appropriate LN- dissection keeping the risk of recurrence in mind and consider adjuvant chemotherapy according to the risks.

P0712 HIGH DEFINITION (HD) ENDOSCOPY WITH I-SCAN FOR THE DETECTION OF MARKERS OF COELIAC DISEASE: A FEASIBILITY STUDY

P.D. Mooney[1], **M. Kurien**[1,*], S. Wong[1], D.S. Sanders[1]
[1]*Regional GI and Liver Unit, Royal Hallamshire Hospital, Sheffield, United Kingdom*
Contact E-mail Address: *peter.mooney@sth.nhs.uk*

INTRODUCTION: Coeliac disease (CD) remains underdiagnosed. Previous studies have shown that up to 13% of patients with CD have undergone a previous gastroscopy where the opportunity to take duodenal biopsies and make a diagnosis had been missed. Clinicians may rely on the presence of endoscopic markers of CD to guide biopsy however these have been shown to lack the required sensitivity. A routine duodenal biopsy approach may solve this problem but this is time consuming and expensive. Methods to improve the macroscopic detection of CD at endoscopy to guide biopsy would seem advantageous. A single trial on I-Scan, a commercially available digital enhancement technique, has shown promising results in identifying markers of villous atrophy (VA)[1]. However this was an uncontrolled, unblinded trial in high prevalence population (35% CD). We aimed to assess the utility of I-Scan in a lower prevalence population in a randomised controlled trial.
AIMS & METHODS: Patients on a single coeliac enriched endoscopy list were randomised into 2 groups. Group 1 standard HD white light endoscopy (WLE) and group 2 WLE plus I-Scan. The presence of endoscopic markers of CD, scalloping, mosaic pattern, nodularity, loss of duodenal folds or increased vascularity was noted throughout the duodenum. All patients received 4 biopsies from the second part of the duodenum and at least 1 biopsy from the bulb. Coeliac serology was taken at the time of endoscopy. Macroscopic markers of CD are compared VA on histology as the gold standard. 3, 10-point likert scales for pain, discomfort and distress were used to assess tolerability.
RESULTS: 253 patients (149 female, mean age 53.3 SD 18.2) have been recruited to date (127 into group 1 and 126 in group 2). In total 27 (prevalence 10.7%) new diagnoses of CD have been made (14 in group 1 and 13 in group 2). I-Scan appears to enhance the appearance of markers for CD and in 2 patients in group 2 CD markers that were not noted to be seen on WLE became apparent. Preliminary results show that endoscopic markers of CD across both groups currently have a sensitivity of 78.6% (58.5 – 91.0), specificity 87.6% (82.4 – 91.5), positive and negative predictive values of 44.0% (30.3 – 58.7) and 97.1 (93.4 – 98.8). Median tolerability scores were good in both groups but better in the I-Scan group than WLE alone (4/30 versus 8/30 p0.005)
CONCLUSION: The addition of I-Scan to standard endoscopy to aid the diagnosis of CD is well tolerated and is feasible. I-Scan appears to enhance the markings of coeliac disease, however a larger study is required to truly evaluate the effectiveness of I-Scan as an adjunct to standard endoscopy to increase CD diagnosis.

INTRODUCTION: As ESD has been widely used as a minimally invasive treatment for EGC, opportunity to perform it for elderly patients is increasing. However, there are few reports about safety and efficacy of ESD for them. We evaluated the effect of aging on complications of ESD for EGC.
AIMS & METHODS: We perform a prospective study of the expanded indication of ESD for EGC (Soetikno, et al. J Clin Oncol. 23(20):4490-8). ESD was performed in 891 patients from April 2006 to March 2013 according to the indication. Patients were divided into elderly group (75 years or older; 344 cases) and non-elderly group (the rest; 547 cases). We compared the incidence of complications such as post-ESD bleeding, perforation, pneumonia, and delirium between the groups.
RESULTS: No emergent surgery was experienced in all cases. One patient in non-elderly group died of pneumonia. The incidence of pneumonia and delirium were significantly higher in elderly group than in non-elderly group (7.0% in elderly group vs 1.7% in non-elderly group; $P<0.01$, 10.2% in elderly group vs 1.0% in non-elderly group; $P<0.01$, respectively). There was no significant difference between two groups in the incidence of post-ESD bleeding and perforation (3.8% in elderly group vs 4.9% in non-elderly group; $p=0.42$, 7.0% in elderly group vs 5.7% in non-elderly group; $p=0.57$, respectively). Among the elderly group, the incidence of delirium was significantly higher in patients who have dementia than in those who haven't (79.2% in dementia patients vs 5% in non-dementia patients; $p<0.01$), and pneumonia was observed relatively more often in patients who have a history of chronic obstructive pulmonary disease (COPD) than in those who haven't (10.9% in COPD patients vs 6.1% in non-COPD patients; $p=0.17$).
CONCLUSION: ESD for EGC were safely performed even in elderly patients without critical complications. However, pneumonia and delirium would be more encountered after ESD in elderly patients, so we have to take care additionally about them.

Contact E-mail Address: *emara_20007@yahoo.com*

INTRODUCTION: A variety of endoscopic methods are available to achieve hemostasis from an actively bleeding ulcer and reduce the risk of rebleeding e.g. endoscopic injection of diluted epinephrine, applications of endoscopic clips and argon plasma coagulation. Preliminary report showed that autologous blood through tamponade effect, cellular components and its viscosity is effective and easy applicable technique that can control bleeding from the actively bleeding gastroduodenal ulcers.
AIMS & METHODS: The aim of this study was to test if endoscopic injection of autologous blood is superior to endoscopic injection of diluted epinephrine in controlling bleeding from gastroduodenal ulcers. One hundred patients with actively bleeding gastroduodenal ulcers were randomly assigned to autologous blood injection (Group A, $n=50$) or diluted epinephrine (group B, $n=50$) along the edges of the ulcers. Groups were compared for rates of initial hemostasis, rebleeding and complications.
RESULTS:

	Group A (Autologous blood) N = 50 (No & %)	**Group B (Diluted epinephrine) N = 50** (No & %)	**P**
Ulcer size			**0.523**
Small (<2 cm)	**32(64.0)**	**35(70.0)**	
Large (>2 cm)	**18(36.0)**	**15(30.0)**	
Ulcer site			**0.424**
Bulbar	**20(40.0)**	**20(40.0)**	
Antral	**15(30.0)**	**20(40.0)**	
Corporal	**15(30.0)**	**10(20.0)**	
Ulcer type			**1.0**
Forest Ia (spurting)	**30(60.0)**	**30(60.0)**	
Forest Ib (oozing)	**20(40.0)**	**20(40.0)**	
Volume/cc (blood/epinephrine)			**0.022***
Mean±SD	**7.4±1.8**	**8.9±4.1**	
Range	**(5-10)**	**(5-21)**	

All patients initially achieved hemostasis (100%). Rebleeding occurred in 4 cases of group A (8%) and 5 cases of group B (10%) but this difference was not statstically significant. Two cases in group B developed cardiovascular complications (arrhythmia and ischemic heart attack) while none of group A developed complications. Ulcer characteristics showed no difference regarding ulcer size, site and Forrest classification (the table). There was a significant difference in the amount needed for injection, little amounts of blood were needed to achieve hemostasis in group A than the amounts of epinephrine needed in group B ($p=0.022$)
CONCLUSION: Autologous blood is effective, comparable to diluted epinephrine in achieving initial hemostasis from actively bleeding gastroduodenal ulcers, associated with 8% rebleeding rate and had no complications.

P0715 ENDOSCOPIC RESECTION AS A DIAGNOSTIC THERAPY FOR BORDERLINE LESION OF GASTRIC CANCER; A MULTICENTRE PROSPECTIVE OBSERVATIONAL STUDY

M. Kato[1,2,*], A. Maekawa[2], S. Egawa[3], M. Komori[4], T. Yamada[2,5], K. Yamamoto[6], H. Ogiyama[7], M. Nakahara[8], N. Kawai[9], T. Yabuta[10], A. Mukai[11], Y. Hayashi[2], T. Nishida[6], M. Tsujii[2], T. Takehara[2]

INTRODUCTION: It is often difficult to discriminate between gastric adenocaricinoma and dysplasia/adenoma using endoscopic forceps biopsy. Endoscopic resection (ER) is, therefore, applied for "borderline malignant" lesions for the purpose of total biopsy in clinical practice. We have reported that about 40% of patients with borderline lesion were diagnosed as adenocaricinoma after ER from a multicenter retrospective analysis (*M. Kato, et al. J Gastroenterol. 2010*). However, true incidence rate of adenocarcinoma is still unknown due to its retrospective study design.
AIMS & METHODS: The aim of this study is to confirm the feasibility of ER for gastric borderline malignant lesions.
This is a multi-centre prospective observational study from 10 hospitals (UMIN Clinical Trials Registry: UMIN000007476). Patients were included if they were diagnosed as Category 3.1 or 4.1 based on Vienna classification using endoscopic forceps biopsy specimen. After inclusion, patients underwent ER in each hospital and data was prospectively collected concerning macroscopic findings (size and morphological type based on Paris classification), findings of magnified endoscopy with narrow band imaging (NBI-ME), outcomes of ER, and pathological findings. Primary endpoint was cancer-bearing rate in patients diagnosed as adenocarcinoma after ER. Secondary endpoints were the association between final diagnosis and findings of macroscopic appearance and NBI-ME, and the short-term outcomes of ER.
RESULTS: A total of 105 patients were included from April 2012 to February 2014. Among them, 48 patients were diagnosed as adenocarcinoma after ER and cancer-bearing rate was 46%. Larger ($\geq$ 20mm) and smaller ($<$ 20mm) lesions were not significantly different in cancer-bearing rates (43% vs 57%, $p=0.2589$). Similarly, depressed and elevated lesions were not significantly different (50% vs 55%, $p=0.7469$). NBI-ME could predict accurately the pathological diagnosis after ER in 52% of the patients. En bloc margin negative resection was achieved in 103 patients (98.1%). Perforation and post-procedural bleeding occurred in 3 patients (2.9%) and 2 patients (1.9%), respectively. All these adverse events were managed conservatively and no patients required emergent operation or blood transfusion.
CONCLUSION: The present study showed that diagnostic ER for gastric borderline malignant lesion is clinically safe and useful because of acceptable complication and high cancer-bearing rate.

INTRODUCTION: Endoscopic procedures for patients taking aspirin were recently reported[1,2]. However, there was not enough evidence to support these procedures. We evaluated the safety of endoscopic procedures in Asian patients with a high risk of bleeding without perioperative discontinuation of aspirin.
AIMS & METHODS: A multicenter prospective cohort study was conducted at six high-volume endoscopy centres in Japan (UMIN000009176). Patients regularly taking antiplatelet agents and with a high risk of thromboembolism upon discontinuation of administration were enrolled in this study. All patients underwent endoscopic procedures with a high risk of bleeding while continuing aspirin including endoscopic submucosal dissection (ESD), endoscopic mucosal resection (EMR), and endoscopic polypectomy of the upper and lower

gastrointestinal tracts. The primary endpoint was the rate of major bleeding complications after endoscopic procedures.
RESULTS: This study was terminated in accordance with predetermined criteria because seven of 28 consecutive patients experienced major bleeding complications (25.0%; 95% confidence interval, 10.7%–44.9%). All major bleeding complications occurred after ESD (stomach n = 6; colon, n = 1). Univariate analysis revealed that postoperative administration of a thienopyridine derivative was the only significant factor associated with postoperative bleeding ($p = 0.04$). Subanalysis of gastric ESD of 23 lesions in 19 patients also confirmed that administration of a thienopyridine derivative was the only significant factor through multivariate analysis ($p = 0.01$). All complications of postoperative bleeding (postoperative day 11.2 ± 3.5; range, 7–17) occurred after resuming administration of thienopyridine derivatives postoperatively (postoperative day 2.3 ± 2.4; range, 1–7). No patients experienced thromboembolic events during the course of the study.
CONCLUSION: Endoscopic procedures with a high risk of bleeding require careful consideration of the indications for Asian patients taking thienopyridine derivatives. This especially applies to patients undergoing gastric ESD without discontinuation of or with a switch to aspirin.

P0717 A SECOND-LOOK ENDOSCOPY AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION MAY NOT BE USEFUL FOR PREVENTING POSTOPERATIVE BLEEDING

N. Yoshitake[1,*], F. Takahashi[1], T. Akima[1], H. Kino[1], M. Nakano[1], C. Tsuchida[1], K. Tsuchida[1], K. Tominaga[1], T. Sasai[1], H. Masuyama[1], H. Hiraishi[1]
[1]*Gastroenterology, Dokkyo Medical University, Mibu, Shimotsuga, Japan*

INTRODUCTION: Gastric endoscopic submucosal dissection (ESD) has gradually come to be recommended as the optimal treatment for early gastric cancer; however, one of the primary issues is postoperative bleeding. Although second-look endoscopy is conventionally performed to reduce the risk of postoperative bleeding, its benefit has not yet been clearly elucidated. The objective of this study was to elucidate the benefit of second-look endoscopy.
AIMS & METHODS: From among 488 lesions in patients who underwent gastric ESD between May 2004 and April 2013 at our hospital, a total of 29 lesions in patients who had a residual lesion, perforation, or concurrent aspiration pneumonitis, or in patients in whom the treatment modality had been switched to open surgery or there was no evidence of cancer in the resected specimen were excluded, and the remaining 459 lesions were included in the analysis. The patients were divided into those who had bleeding within 24 hours after ESD (immediate bleeding) and those in whom bleeding occurred 24 hours or more after the procedure (delayed bleeding); the underlying disease, age, lesion site, diameter of the resected specimen, and lesion diameter were analyzed to identify the risk factors for postoperative bleeding after ESD.
RESULTS: Post-ESD immediate or delayed bleeding occurred in 23 of the 459 cases (5.0%). Second-look endoscopy was performed in 210 of 447 cases (47.0%) excluding 12 cases with immediate bleeding; in the remaining 237 of the 447 cases (53.0%), it was not performed. Post-ESD delayed bleeding occurred in 6 of the 210 cases (2.9%) and 5 of the 237 cases (2.1%), with no statistically significant difference between the two groups. Overall, the following factors were identified as the risk factors for postoperative bleeding: young age ($P = 0.005$), lesions in the L segment ($P = 0.042$), and large size of the resected specimen ($P = 0.005$). The risk factors identified in the immediate bleeding group were lesions in the L segment ($P = 0.032$), large size of the resected specimen ($P < 0.001$), and large tumor size ($P = 0.011$), and those in the delayed bleeding group were young age ($P = 0.013$) and concomitant renal disease ($P = 0.011$).
CONCLUSION: The results of this study suggest that second-look endoscopy after gastric ESD may not be useful for preventing postoperative bleeding.

P0718 EARLY CLINICAL EXPERIENCE OF THE EFFECTIVENESS OF HEMOSPRAY IN ACHIEVING HAEMOSTASIS IN PATIENTS WITH ACUTE NON-VARICEAL BLEEDING

N. Sagar[1,*], T. Iqbal[1]
[1]*Gastroenterology, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom*
Contact E-mail Address: *dr.nidhisagar@gmail.com*

INTRODUCTION: Despite advances in management, mortality from acute upper gastrointestinal bleeding remains high at 10%1. Current endoscopic modalities have found to be effective in achieving haemostasis in 85-95% of cases, however 5-10% of patients still experience rebleeding despite combination therapy2. Bleeding may occur from sites, which are challenging to access or lesions that are large and actively bleeding causing poor views for effective endoscopic therapy. Hemospray is a novel powder designed to be a simple endoscopic technique in applying to large surface areas even in difficult positions.
AIMS & METHODS: This was a retrospective review of patients at the Queen Elizabeth Hospital Birmingham where Hemospray was used for an acute non-variceal upper gastrointestinal bleed. Eight patients (4 male and 4 female) were identified between May 2012 and February 2013.
RESULTS: The median age was 63 years (range 37 – 84 years). Two patients had a Forrest classification of 1a, 2 were 1b, 1 was 2a and 3 were 2b. Causes of bleeding were duodenal ulcer (4), gastric ulcer (2), oesophageal cancer (1) and Diuelafoy lesion in stomach (1). Hemospray was used as the sole endoscopic modality in 1 patient and in combination with other modalities in 7 patients. Other modalities used were adrenaline (3), clips (1), adrenaline and clips (1), adrenaline and heater probe (1), adrenaline, clips and heater probe (1). Immediate haemostasis was achieved in all 8 patients. 3 patients re-bled within 7 days. All 3 patients had a duodenal ulcer (Forrest classification 1a, 1b and 2b). Two patients required further definitive therapy: radiological coiling of gastroduodenal branches (1) and endoscopic therapy with adrenaline and clips (1).
CONCLUSION: From the small number of patients in this study, we can conclude that Hemospray is an effective method in achieving immediate haemostasis when combined with other endoscopic modalities. However, there is a high rebleeding rate within 7 days in patients with duodenal ulcers, irrespective of their Forrest classification, who mostly required further definitive management. Larger studies are required to assess the efficacy of Hemospray in this particular group of patients to determine whether they are truly at higher risk.

INTRODUCTION: Identification of a precise demarcation line (DL) is indispensable for performing pathological complete en bloc endoscopic submucosal dissection (ESD) for early gastric cancer (EGC). Recently, chromoendoscopy with combination use of indigo carmine and acetic acid was reported as a novel technique for identifying the DL; however, this technique is not effective in all EGC cases.
AIMS & METHODS: The aim of this study was to evaluate the usefulness of chromoendoscopy with indigo carmine and acetic acid for marking dots around lesions during ESD for EGC. We examined 98 consecutive patients with 109 intramucosal EGCs (mean diameter, 17.8 ± 12.4 mm; location, U 21/M 34/L 54; main histologic type, 96 intestinal and 13 diffuse) resected by en bloc ESD after chromoendoscopy with indigo carmine and acetic acid at Hiroshima University Hospital between December 2012 and February 2014. We identified the DL by chromoendoscopy with indigo carmine and acetic acid just before ESD (mean chromoendoscopy observation time, 71.6 s), and then marking dots were placed around the EGC. Four physicians participated in the evaluation of improved EGC visibility. Conventional endoscopic images were presented to each of the physicians in random order for comparison with chromoendoscopy images. Physicians scored each of the chromoendoscopy images for visibility of the DL, and the four physicians' scores for each image were tallied. EGCs were classified into two groups: useful for identifying the DL or useless. The tumor diameter, histologic type (intestinal/diffuse), macroscopic type (elevated, 0-I & IIa & IIb; depressed, 0-IIa+IIc & IIc), tumor lesion (U or M/L), tumor depth (intramucosal/submucosal), tumor color (reddish/normal or pale), atrophic gastritis around tumor (present/absent), intestinal metaplasia around tumor (present/absent), and rate of histologically positive horizontal margin were evaluated in each group.
RESULTS: Forty-two of the 109 cases (38.5%) were useful for chromoendoscopy with indigo carmine and acetic acid, which were compared to the other 67 cases. Univariate analysis showed that histologic type (intestinal type), macroscopic type (elevated type), and atrophic gastritis around the tumor (present) were associated with the usefulness of chromoendoscopy using indigo carmine and acetic acid. Multivariate analysis with logistic regression showed that macroscopic type (elevated type) and atrophic gastritis around the tumor (present) were independently associated with the usefulness of chromoendoscopy using indigo carmine and acetic acid for identifying the DL of EGCs ($P < 0.05$). The histologically positive horizontal margin after ESD was 0% (0/42) in useful cases, and 7.5% (5/67) in useless cases.
CONCLUSION: To make precise markings around EGCs before ESD, chromoendoscopy with indigo carmine and acetic acid is useful for elevated-type EGC or in cases of existing atrophic gastritis around EGCs.

P0720 THE DIAGNOSIS OF INVASION DEPTH IN SUPERFICIAL ESOPHAGEAL CANCER: A COMPARISON BETWEEN A MAGNIFYING NARROW-BAND IMAGING (NBI) OBSERVATION AND EUS

N. Matsuura[1,*], N. Hanaoka[1], R. Ishihara[1], S. Yamamoto[1], T. Akasaka[1], Y. Takeuchi[1], K. Higashino[1], N. Uedo[1], H. Iishi[1]
[1]*Gastrointestinal Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka-city, Japan*
Contact E-mail Address: *matuura-no@mc.pref.osaka.jp*

INTRODUCTION: The diagnosis of cancer invasion depth is crucial for selecting the optimal treatment strategy for esophageal cancer. Endoscopic ultrasonography (EUS) is regarded as the standard modality for diagnosing invasion esophageal cancer depth in the West. In Japan, magnifying endoscopy has been used for diagnosis by observing the architecture of the esophageal microvasculature. This modality represents a rapid and simple diagnostic procedure without the need for any additional equipment. However, the accuracy of magnifying endoscopy has not been compared with that of EUS for the diagnosis of cancer invasion depth.
AIMS & METHODS: Patients with esophageal squamous cell carcinoma suspicious for muscularis mucosa or submucosal invasion in non-magnifying white light imaging were included. All patients received magnifying narrow-band imaging (NBI) observation followed by EUS. Magnifying NBI observation was performed by endoscope with magnification (GIF-Q240Z, or H260Z; Olympus, Tokyo, Japan). EUS was performed using a high-resolution probe by jelly-filled method. Before examination, several syringes (5 mL) containing sufficient amounts of jelly (K-Y lubricating jelly, Johnson and Johnson, k. k.) were prepared. After endoscope insertion (GIF-2TQ260M; Olympus) into the target area within the esophagus, a 30-MHz miniature probe was then inserted through the left channel of the endoscope and 30 to 40 mL of echo jelly was instilled through the right channel until the esophageal lumen was filled. Cancer invasion depth was diagnosed as T1a or T1b using both modalities. The diagnostic accuracy of magnifying NBI observation was compared with that of EUS while the histologic diagnosis of resected specimen served as reference standard.
RESULTS: From January 2011 to February 2014, 166 patients with esophageal squamous cell carcinoma were examined using the two modalities. Of the 166 patients, 91 treated with chemoradiotherapy or photodynamic therapy were excluded from analysis because histologic specimens were not obtained. Seventy-five patients treated either by esophagectomy ($n = 15$) or endoscopic resection ($n = 60$) were included in the final analysis. Histologic diagnosis was T1a in 43 lesions, T1b in 31 lesions, and T2 in one lesion. The overall accuracy of diagnosing invasion depth was 66.7% (50/75 lesions) by magnifying NBI and 70.7% (53/75 lesions) by EUS ($P = 0.602$). The accuracy of diagnosing invasion depth in lesions with protrusions was 58.8% (20/34 lesions) and 76.5% (26/34 lesions) by magnifying NBI and EUS, respectively ($P = 0.194$). The accuracy of diagnosing invasion depth in lesions without protrusions was 73.2% (30/41 lesions) and 65.9% (27/41 lesions) by magnifying NBI and EUS, respectively ($P = 0.632$).
CONCLUSION: EUS and magnifying NBI exhibited high diagnostic accuracy in lesions with and without protrusion. Furthermore, there was no significant difference in the overall accuracy of these two modalities. Considering its simplicity of use, magnifying NBI has the potential to be the standard modality for diagnosing invasion depth of esophageal squamous cell carcinoma.

P0721 ENDOSCOPIC DIAGNOSIS OF HIATUS HERNIAS - VARIABILITY BETWEEN ENDOSCOPISTS

O.S. Omer[1,*], J.S. Nayagam[1], J. Hayat[1]
[1]*Kingston Hospital, London, United Kingdom*
Contact E-mail Address: *oso04@ic.ac.uk*

INTRODUCTION: There is a wider discrepancy in the diagnosis of hiatus hernias (HH) at upper gastro-intestinal endoscopy (OGD) compared to other techniques, such as manometry and barium swallow, or during surgery.[1] Endoscopic diagnosis may be affected by the method used (eg during intubation or extubation[2]), and variable definition of the gastro-oesophageal junction (eg proximal margin of the gastric folds, squamo-columnar junction or distal margin of the palisade zone).
AIMS & METHODS: Our aim was to assess variability in diagnosis of hiatus hernias by different endoscopists.
A retrospective review of the endoscopy database at Kingston Hospital, was performed. Consecutive OGD were analysed over a 3 month period (2/4/13 - 28/6/13). Complete data was obtained for 451 endoscopies, from 21 different endoscopists. Mean age for patients was 60.1 years (range 20-98), female to make ration of 1:1.04. Unpaired t-test and one-way ANOVA with Tukey's Test were used for normal data, and Chi-squared for proportional differences.
RESULTS: Of the 451 OGD, HH were diagnosed in 168 (36.6%), most HH under 5cm (81.55%). Main indications were for dyspepsia (14.2%), reflux symptoms (17.7%), abdominal pain (22%), anaemia (14%). There was a wide variability in the diagnosis of HH depending on speciality and grade (range 0-100%). Age, indications and gender were similiar between groups of endoscopists. Surgical Consultants were more likely to diagnose HH than Gastroenterology Consultants ($p < 0.002$) or Registrars ($p < 0.04$), and Nurse Endoscopists more likely than Gastroenterology Consultants ($p < 0.0001$) or Registrars ($p < 0.0004$).

Speciality & Grade	Number of endoscopies	Number of HH diagnosed	% HH
Gastroenterology Consultants	142	27	19%
Gastroenterology Registrars	34	6	17.7%
Surgical Consultant	55	23	41.8%
Surgical Registrars	19	11	57.9%
Nurse Endoscopists	189	99	52.4%
GP Endoscopists	12	2	16.7%

CONCLUSION: Endoscopic diagnosis of HH is highly variable and may be affected by level of training and speciality of the endoscopist. This may lead to under or overdiagnosis. A standardised approach to landmark measurement may lead to a more consistent diagnosis of HH.

P0722 THE EFFECT AND USEFULNESS OF CHROMOENDOSCOPY WITH INDIGO CARMINE DYE ADDED TO ACETIC ACID IN DIAGNOSIS OF EARLY GASTRIC CANCER DIFFERS DEPENDING ON ITS MUCIN HISTOCHEMISTRY

O. Yoneyama[1,*], K. Furukawa[1], H. Hashidate[2], M. Ogawa[1], S. Ikarashi[1], A. Osaki[1], M. Sato[1], T. Aiba[1], N. Waguri[1], K. Igarashi[1]

[2]*Diagnostic Pathology, Niigata City General Hospital, NIigata City, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) became a very popular technique of therapeutic endoscopy for superficial gastrointestinal neoplasms, and it made possible to perform a reliable en bloc resection with higher success rate and lower recurrence rate compared with conventional endoscopic mucosal resection. For a complete en bloc resection of cancer lesions, it is indispensable to accurately delineate the margin, in other words, the lateral extent of the cancer. Chromoendoscopy with indigo carmine dye added to acetic acid is thought to be useful in the diagnosis of early gastric cancer. Usually this method helps to clarify the lateral extent of gastric cancer. But in some cases, this method can not help satisfactorily to delineate the margin between cancer and non-cancer parts. We assumed that the difference of dyeing pattern arises from quantity and character of mucus secreted from each lesion.
AIMS & METHODS: Subjects were 33 early gastric cancer lesions resected by using ESD technique in our institution, and were divided in two groups. We defined the lesions which were delineated clearly by acetic acid-indigo carmine method as group A ($n = 17$), and lesions which were not delineated clearly enough as group B ($n = 16$). We evaluated the mucin histochemistry of the specimens about stain levels of d-PAS and immunohistochemistry of MUC2, MUC5AC and CD10, and compared between the two groups.
RESULTS: Both group showed lower level of d-PAS stain in its cancer tissue than its non-cancer parts, suggesting that mucin productivity is decreased in the cancer tissue compared with non-cancer parts. Classification grouping using immunohistochemistry of MUC2, MUC5AC and CD10 showed that many cases of group A have intestinal type mucin (68.8%), and group B tends to have gastro-intestinal type mucin (64.7%).
CONCLUSION: Chromoendoscopy with indigo carmine dye added acetic to acid is generally useful and effective in case of early gastric cancer which has intestinal type mucin histochemistry. But on the other hand, cancer lesions having gastro-intestinal type mucin often show unclear margin even if using this technique.

INTRODUCTION: Colonoscopy can reduce colorectal cancer (CRC) incidence and mortality through early detection and removal of adenomas, but estimates suggest that up to 24% of adenomas are missed; various colonoscopic techniques are evolving to improve its diagnostic yield and avoid interval CRC. Recently a new colonoscopy platform (FUSE^{TM} system, EndoChoice Inc., Atlanta, GA, USA) was introduced with promising initial results. FUSE-colonoscopy (F-C) provides a 330°-field of view instead of the 170° of standard colonoscopy (S-C); this allows polyps hidden behind folds or flexures to be seen easier.

AIMS & METHODS: The aim of this study is to evaluate F-C additive contribution to detection of polyps/adenomas, compared to S-C, with and without the addition of right-colon retroflexion (R-C), in a series of patients undergoing same-day, back-to-back randomized (1:1) tandem colonoscopies in 2 tertiary endoscopy centres. ClinicalTrials.gov Identifier: NCT02117674
RESULTS: Of 150 totally planned, 84 pts have been enrolled until now; 40 (47.6%) of them were randomized to undergo F-C first. There were 7 incomplete cases for both F-C and S-C (including 1 failed case for both F-S and S-C and 1 case where F-C was not performed due to technical failure). Thus, 83 (46 screening/surveillance, 32 symptomatic and 5(6%) with polyps) were included in the per-protocol analyses. R-C was attempted in 57/83 cases; successful in 37. Insertion time did not differ between F-C and S-C (5min, IQR:4-10.25 vs. 5min, IQR: 4-8, respectively, $p = 0.4$), whereas, withdrawal was marginally longer for F-C (8min, IQR:6-10 vs. 7min, IQR:6-9, respectively, $p = 0.05$). Overall, 133 polyps were found (53 right colon); of these 61 were adenomas, 32 in the right colon (histology available for 24/28 pts with polyps).
By per-lesion anlaysis, F-C detected significantly more missed polyps compared to S-C overall (26 vs. 4, $p = 0.033$) and right-sided ones (14 vs. 2, $p = 0.038$) and detected more adenomas (9 vs. 3, $p = 0.162$) overall and right-sided ones (7 vs. 2, $p = 0.184$). R-C offered no additional gain in polyp or adenoma detection in the right colon.
CONCLUSION: Our initial results show that F-C could be an advancement in colonoscopy by detecting more polyps. However, if this improvement actually represents detection of more adenomas requires further investigation.

INTRODUCTION: We aimed in this randomized prospective controlled trial to evaluate the effect of orally administration of Otilonium bromide over the quality of the colonoscopy in the meanings of adenoma detection rate, caecal intubation time, and the tolerability.
AIMS & METHODS: Two-hundred consecutive volunteer outpatients were randomized to Otilonium Bromide group (100 patients) and the control group (100 patients). The patients in the Otilonium Bromide group received 30 mg Otilonium Bromide 3 times a day for five days with the last dose given two hours before colonoscopy. The bowel preparation quality was graded according to the Boston bowel preparation scale. For each colon area, a distension scale was awarded by using a previously validated 5-point scale. The pain experienced during colonoscopy was determined by using a 1-10 visual analog pain scale.
RESULTS: Twenty-one patients in Otilonium bromide group and 22 patients in control group were excluded from the study because of uncompleted colonoscopy. Caecum intubation time was comparable between groups ($p = 0.4$). There was no statistically difference between groups in the terms of mean bowel preparation quality scores ($p = 0.4$), while mean distension score was greater in Otilonium bromide group ($p = 0.007$). Polyp detection rate (26 polyps in 22 patients vs. 14 polyps in 12 patients) (32.9% vs. 17.9%, $p = 0.03$) was significantly higher in OB group. Also, adenoma detection rate (22 adenomas in 21 patients vs. 11 adenomas in 11 patients) (27.8% vs. 14.1%, $p = 0.03$) was significantly higher in OB group. The visual analog pain scale scores were comparable between groups ($p = 0.07$)
CONCLUSION: Otilonium bromide administration before colonoscopy increases colonic distension, polyp detection and adenoma detection rates. Further clinical investigations are required to determine the utility of relieving colonic spasm with oral antispasmodics to improve adenoma detection rates.

P0725 NEW GENERATION FLEXIBLE SPECTRAL IMAGING COLOR ENHANCEMENT IS USEFUL TO PREDICT HISTOLOGY OF SMALL COLORECTAL POLYPS

J. Weigt[1,*], A. Kandulski[1], P. Malfertheiner[1]
[1]*Gastroenterology, Hepatology & Infectious Diseases, UNIVERSTITY MAGDEBURG, Magdeburg, Germany*
Contact E-mail Address: *jochen.weigt@med.ovgu.de*

INTRODUCTION: Prediction of colon polyp histology is decisive as small non advanced adenoma may be discarded after resection and hyperplastic lesions may be left in place. The NICE classification system for NBI endoscopy and magnification has been shown to be effective in prediction of histology. There is only little data for the flexible spectral imaging color enhancement (FICE). Newest generation of endoscopes have over mega pixel CMOS sensors that allow FICE aligned with electronic zoom without loss of image quality. With this new technology, histology prediction may easily be possible during standard colonoscopy without using optical zoom endoscopes.
AIMS & METHODS: To assess the accuracy of endoscopic prediction of histology of small colorectal polyps using white light (WLE) and FICE and CMOS endoscope
Methods:
We randomly assigned patients for colonoscopy using a CMOS colonoscope (EC-600 WM, Fujifilm Europe Düsseldorf). All detected polyps were assigned to Types 1-3 according to the NICE classification system criteria using WLE and FICE (modes 1,8,9) with and without electronic zoom. Classification was assessed during the examination. Before starting the study, the endoscopist underwent endoscopic training using NBI. All detected polyps were removed for histopathology. The concordance of endoscopic classification and histology was calculated.
RESULTS: We investigated 27 polyps in 11 patients. Median polyp size was 4 mm (range 3-20 mm) Polyps location were in the rectum and sigmoid colon ($n = 15$) in the right colon ($n = 10$) and in the left colon ($n = 2$). According to the endoscopic classification 18 polyps were hyperplastic (Type 1) and 9 polyps were adenomas (Type 2). No colorectal cancer or high grade adenoma were identified. Histology proofed that 100 % of polyps were classified correctly. One polyp classified as adenoma revealed serrated adenoma in histology.
CONCLUSION: The NICE classification system criteria can successfully be applied for colorectal polyps being investigated with FICE and electronic zoom using a CMOS colonoscope.

P0726 MEASUREMENT OF COLONIC POLYPS. IS VISUAL ESTIMATION ACCURATE?

J. Woo[1,*], H. Rozati[1], K. Besherdas[1]
[1]*Gastroenterology, Barnet and Chase Farm Hospitals NHS trust, London, United Kingdom*
Contact E-mail Address: *jwoo@nhs.net*

INTRODUCTION: Colon polyp size is a critical biomarker for clinical management of colonic polyps. Larger polyps have a greater malignant potential. During colonoscopy, it is important to correctly measure the size of the polyps because of the direct correlation of size with colon cancer.[1] During polypectomy, size of the colonic polyps encountered are often gauged by visual estimation or the open forceps method.[2] However, some data exists on the questionable reliability of a visual estimate even amongst expert colonoscopists. We aim to compare the estimation of polyp size using the visual estimation of colon polyp with or without the open biopsy forceps technique against actual polyp size measurement by our histopathology department for all polyps >1cm in size.
AIMS & METHODS: A single centre, retrospective analysis using the Unisoft GI auditors software was used to identify patients who have had polypectomies done for polyps >1cm in size from October 2005 till September 2013. The size of the polyps documented in the endoscopy report was then compared to the lab measured actual polyp size.
RESULTS: A total of 39 patients were identified with polyps >1cm in size who has had polypectomy done. Results are as below:

Visual estimated size (mm)	Actual lab measured size (mm)					
	3~9	10~14	15~19	20~24	25~29	>30
3~9						
10~14	XXXXXXX	XXXX	XXXX			
15~19	XXXX	X	X		X	
20~24		XXX	X	X		
25~29	X	X	XXX	X		X
>30	X		X	XX	X	

CONCLUSION: From this study we can conclude that visual estimation with or without the open biopsy forceps technique is completely inaccurate with wide variations between the reported size and the actual size of the polyps when measured in our laboratory. Accurate measurement of colonic polyps is important as inaccuracies can lead to potentially larger polyps not being tattooed and subsequent difficulty in identification during surgery and surveillance. We advocate that the 'gold standard' practice of direct measurement of the polyp once excised and outside the body be adopted and the actual size should be documented according to direct measurement.

INTRODUCTION: Bowel wall thickening is a common and often unexpected finding on abdominal computed tomography (CT) scans, and yet its significance and further investigation is unclear from the literature. This study aims to clarify the incidence of bowel wall thickening, and its investigation and outcomes in a District General setting.
AIMS & METHODS: In this retrospective observational study, all in-patients who underwent abdominal CT imaging were included over a 4 month period regardless of indication. Radiology reports were analysed, and patients with gastrointestinal wall thickening were identified for further analysis.
RESULTS: 1227 patients underwent abdominal CT imaging over the 4 month period, of which 116 (9.5%) were found to have bowel wall thickening. 53 patients subsequently had an endoscopic examination and in 49 cases the area of interest was visualised. 33 patients had positive endoscopic findings at the site of bowel thickening, of which 16 had mucosal inflammation, 8 had malignancy, 6 had diverticulosis and 3 had polyps.
In the remaining 63 patients who did not have endoscopic examination, 42 were investigated by other means including surgery or other imagining modalities, or further investigation was not appropriate. In 21 patients, it was unclear as to why further investigation did not take place.
CONCLUSION: Endoscopic evaluation of gastrointestinal wall thickening found on CT imaging led to a positive diagnosis in 62.3% (33/53) patients of which 15% (8/53) were found to have malignancy. This highlights both the importance of further investigating GI wall thickening and the value of endoscopic visualisation.

P0728 THE COMPARATIVE STUDY OF SPLIT-DOSE OF POLYETHYLENE GLYCOL (PEG) BETWEEN LOW VOLUME PEG PLUS ASCORBIC ACID FOCUSING ON THE BOWEL CLEANSING EFFICACY, PATIENTS' AFFINITY TO PREPARATION SOLUTION AND MUCOSAL INJURY: A PROSPECTIVE RANDOMIZED TRIAL

J. Park[1,*]
[1]*Department of Internal Medicine, Haeundae Paik Hospital, Inje University School of Medicine, Busan, Korea, Republic Of*
Contact E-mail Address: *mechant79@hanmail.net*

INTRODUCTION: Adequate bowel cleansing is essential for a high-quality, effective, and safe colonoscopy. The aims of this study were to compare the efficacy and patients' affinity to preparation solution and mucosal injury of split dose of polyethylene glycol (PEG) solution with low volume PEG plus ascorbic acid for outpatients who underwent scheduled colonoscopy.
AIMS & METHODS: This study was prospective randomized investigator-blinded. Overall, 160 patients were enrolled for split-dose of PEG and 159 for the low volume PEG plus ascorbic acid, respectively. The bowel cleansing efficacy of preparation was rated according to the Ottawa bowel preparation scale and patients' affinity to preparation solution was assessed using a questionnaire. All mucosal abnormalities observed during colonoscopy were noted and biopsied. These biopsy specimens were reviewed by pathologists.
RESULTS: Of the 319 patients, 308(96%) ingested more than 75% of the bowel preparation. There was no significant difference between the two groups for the mean total score using the Ottawa bowel preparation scale ($p = 0.376$). Significantly greater residual colonic fluid was observed in the low volume PEG plus ascorbic acid group (0.81 ± 0.54) than in the split-dose PEG group (0.66 ± 0.62) ($p = 0.023$). There was significant difference in the Ottawa bowel preparation score for the middle colon (split-dose PEG vs. low volume PEG plus ascorbic acid: 1.19 ± 0.94 vs. 1.42 ± 0.73; $p = 0.014$). In patients' preference and acceptance, low volume PEG plus ascorbic acid group showed better results ($p = 0.001$). The overall incidence of adverse events was not significantly different between the two groups (69/160 [43.1%], 69/159 [43.4%], $p = 0.972$); however, the split-dose PEG group tended to had less headache and dizziness ($p = 0.056$). Endoscopically, mucosal lesions, possibly associated with two preparation regimen, were observed in total 11 patients (split-dose PEG: 5, low volume PEG plus ascorbic acid: 6, respectively). Mucosal ulceration occurred in 1 patient taking split-dose PEG compared with 2 patients receiving low volume PEG plus ascorbic acid.
CONCLUSION: Low volume PEG solution plus ascorbic acid, compared with split-dose PEG, was associated with more residual fluid, but showed equivalent colon cleansing efficacy and resulted in more patient preference, and acceptance. There was no significant difference in mucosal injury.

P0729 COLON STENTING: CAN WE PREDICT PERFORATION? CONSIDERING FACTORS BEFORE PLACING A COLON STENT

J.R. Umaña Mejia[1,*], A. Alvarez Delgado[1], A. Velasco Guardado[1], C. Piñero Perez[1], A. Fernandez Pordomingo[1], A. Mora Soler[1], V. Prieto Vicente[1]
[1]*servicio de aparato digestivo, hospital clinico universitario de salamanca, salamanca, Spain*
Contact E-mail Address: *josueum1@hotmail.com*

INTRODUCTION: In the last decade, Colon Stenting has become a well accepted technique for use as "bridge to surgery" or as palliative treatment in cases of malignant colon strictures. None the less, recent meta-analysis had suggested that there is a high rate of complication due to this procedure carrying an increase in morbidity in these patients that in some cases must be treated with emergency surgery due to Peritonitis in relation to colon perforation secondary to the procedure. In that matter we focused our study on identifying factors, before the procedure, that can predict colon perforation.
AIMS & METHODS: Data from 213 ($n = 213$) patients admitted in our hospital between January 2004 to November 2012 were analyzed. All of the items reviewed were before the procedure. Demographic factors were age and sex. Clinical factors include length of symptoms, presence of peritoneal irritation, cardiac frequency, temperature and blood pressure. Laboratory tests were CRP, LDH, WBC, pH and lactate. Radiologic features included the presence of colon dilatation, measurement in centimeters of the cecum and the most dilatated area, function of the ileo-cecal valve and the presence of metastasis in CT scan. Factors analyzed from the procedure include timing (urgent or elective) (<48 hrs or >48 hrs), length of the procedure, level of expertise of the endoscopist, location of the tumor, angulations of the tumor, length of the Stent and the visualization of feces coming through the Stent after released.
RESULTS: We review data from 213 cases, after statistical analysis, rate of colon perforation found was 12% (21 patients); factors with statistic significance related to patients demonstrated that the presence of colonic dilatation in the radiologic study was associated with a higher risk of perforation compared with patients that did not have dilatation (18.1% vs 2.3%, $p = 0.009$), being the risk of perforation increased almost eight times [$R = 7.9$ (IC 95%: 1.1-57.1)]. The mean in centimeters of colon dilatation in patients that had perforation was significantly longer (8.75 cm vs 6.79 cm, $p = 0.012$). In the other hand, factors related to the procedure with statistic significance, revealed that seeing feces coming through the stent after released was associated with a lower risk of perforation (10.3% vs 31,3%, $p = 0.004$), there was an increased risk of three times, for colon perforation, in patients that did not present the pass of feces through the stent after liberation [$R = 3.04$ (IC 95%: 1.5-6.1)].
CONCLUSION: Colon dilatation and the length of dilatation before procedure is an important factor to take in consideration when deciding to place a colon stent, in our study we saw an important increase in colon perforation when the length of the cecum was more than 8 cms. In the other side, seeing feces passing through the stent when it is released, reveals an adequate function of the stent, and demonstrated a less number of perforations. In the future, predictive models taking these factors into consideration might be developed with the objective to select better the patients for this procedure reducing the rate of complications.

P0730 THE OFFER OF ADVANCED ENDOSCOPIC IMAGING TECHNIQUES LEADS TO HIGHER ACCEPTANCE RATES FOR COLONOSCOPY – A PROSPECTIVE STUDY

J. Gallitz[1,*], M. Vieth[2], G.E. Tontini[1,3], M.F. Neurath[1], H. Neumann[1]
[1]*UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen,* [2]*Klinikum Bayreuth, Bayreuth, Germany,* [3]*IRCCS Policlinico San Donato, San Donato Milanese, Italy*

INTRODUCTION: In Germany patients over the age of 55 years should undergo colonoscopy for colorectal cancer screening. The acceptance rate of patients undergoing screening colonoscopy is still low.
AIMS & METHODS: Aim was to evaluate whether the offer of advanced endoscopic imaging techniques including chromoendoscopy, magnification endoscopy, spectroscopy, confocal laser endomicroscopy, endocytoscopy, capsule endoscopy, CT-colonography or device-assisted enteroscopy may lead to an increased awareness and improved acceptance rates of patients to undergo colonoscopy.
Prospectively, 372 patients were randomly included (168 female, 204 male). At baseline, a standardized questionnaire was developed. Afterwards, knowledge of advanced imaging techniques was inquired and if the patient was motivated by the specific offer of these imaging techniques to undergo colonoscopy. In the second phase, several media campaigns through press, internet, TV coverage, and information events were organized reporting about advanced imaging techniques, followed by repeat evaluation of the patients. This sequence (media campaign and patients' evaluation) was repeated every 3 months over a period of 12 months.
RESULTS: At baseline, 64% of the patients reported that knowledge about new endoscopic methods is completely unknown. After the evaluation period this was reported by only 34% of patients ($P < 0.05$). Despite general information about all advanced imaging techniques was given in the media campaigns, patients were most interested in chromoendoscopy (baseline: 5% - after 12 months: 22%), endomicroscopy (5% vs. 17%), CT colonography (16% vs. 37%) and capsule endoscopy (12% vs. 47%). The overall grade of information increased significantly from 14% at baseline to 35% after 12 months ($P < 0.05$). The percentage of patients who decided to undergo colonoscopy because of the offer of new imaging methods increased significantly from 12% at baseline to 42% after 12 months ($P < 0.05$).
CONCLUSION: Patients were highly interested in advanced endoscopic imaging techniques and patient's knowledge about new imaging methods increased significantly over the study period. The offer of advanced imaging techniques lead to higher acceptance rate for screening or surveillance colonoscopies.

P0731 CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR HUGE COLORECTAL NEOPLASMS: COMPARISON BETWEEN SESSILE TUMORS AND LATERALLY SPREADING TUMORS

J.H. Bae[1,*], D.-H. Yang[1], J.-S. Byeon[1], J.S. Soh[1], S. Lee[1], H.-S. Lee[1], H.J. Lee[1], S.H. Park[1], K.-J. Kim[1], B.D. Ye[1], S.-J. Myung[1], S.-K. Yang[1], J.-H. Kim[1]
[1]*Department of Gastroenterology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Although endoscopic submucosal dissection (ESD) is thought as an effective treatment for large laterally spreading tumors (LSTs) of the colorectum, the therapeutic effectiveness of ESD for large sessile colorectal tumors has not been evaluated.
AIMS & METHODS: We aimed to evaluate the outcomes of ESD for the huge colorectal tumors (30 mm or larger in diameter) and compare therapeutic outcomes between sessile tumors and LSTs. We retrospectively reviewed medical records of the patients who underwent ESD for huge sessile tumors and LSTs of the colorectum from July 2007 to November 2013. En-bloc resection rate, complete resection rate, procedure time and procedure-related complications were evaluated in the sessile tumor and LST groups. Multivariate analysis was performed to identify independent factors for incomplete resection.
RESULTS: ESD was attempted for a total of 191 patients with huge colorectal tumors (48 with sessile colorectal tumors and 143 with LSTs) by two endoscopists. The mean (± SD) time required for ESD was 82.5 ± 4.4 minutes (range, 17-392), and mean size and height of the lesions were 43.2 ± 1.1 mm (range, 30-135) and 9.6 ± 0.5 mm (range, 1-33). The rate of en bloc resection and complete resection were 85.9% and 75.9%. With regard to complications, 11.0% (21/191) cases of intra-procedural bleeding and 15.7% (30/191) cases of perforation were observed in total; none of the complications required surgical intervention. In the sessile colorectal tumors, the endoscopic en bloc resection and complete resection rate were 72.9% (35/48) and 62.5% (30/48) respectively. In the LSTs, they were 90.2% (129/143) and 80.4% (115/143) respectively. Although endoscopic findings suggesting submucosal (sm) invasion such as Vi or Vn pit pattern were not different between the two groups, higher sm invasion rate was noted in the sessile tumors than the LSTs (39.6% vs 23.1%, $p = 0.026$). Intra-procedural bleeding was more frequent in sessile tumors than LSTs (22.9% vs 7.0%, $p = 0.002$). There was no significant difference in procedure time and perforation between the two groups. The rate of operation, caused by non-curative resection, was higher in sessile tumors (14.6% vs 5.6%, $p = 0.045$). There was no mortality associated with procedure or operation. On multivariate analysis, sessile morphology (OR 2.125; 95% confidence interval (CI) 1.006-4.488; $p = 0.048$) and presence of fibrosis (OR 2.290; 95% CI 1.216-5.251; $p = 0.013$) were independent risk factors of incomplete resection in ESD of huge colorectal neoplasia.
CONCLUSION: The complete resection rate of ESD for sessile tumors was relatively lower than that of ESD for LSTs. Presence of fibrosis was another independent risk factor of incomplete resection in ESD of huge colorectal neoplasia.

P0732 THE FEASIBILITY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY COLORECTAL NEOPLASM WITH HIGHLY TECHNICAL DIFFICULTY

K. Sasajima[1,*], R. Chinzei[1], M. Takahashi[1], Y. Koushima[1]
[1]*Gastroenterology, SAITAMA RED CROSS HOSPITAL, Saitama, Japan*
Contact E-mail Address: *qqfa98m9@mist.ocn.ne.jp*

INTRODUCTION: Colorectal endoscopic submucosal dissection (ESD), has not been widely spread because of technical difficulty and high incidence of perforation. Before ESD, we need to recognize whether a lesion can be removed with or without technical difficulty. The aim of study is to assess the feasibility of colorectal ESD for lesions accompanied by highly techinical difficulty.
AIMS & METHODS: We established the indication of colorectal ESD as follows: LST-NG, LST-G (mixed nodular type), local recurrent lesion after previous endoscopic piecemeal mucosal resection (EPMR)≧20mm, and Is/Isp≧30mm. 330 colorectal consecutive lesions were enrolled in this study. Flush knife was used in all cases. From the viewpoint of morphological type and tumor size, we defined (1) LST-NG≧40mm, (2) LST-G (mixed nodular type)≧50mm, (3) Is/Isp≧40mm, and (4) local recurrent lesion after EPMR≧20mm, as highly difficult lesion. A lesion except for these four groups was defined as an ordinary lesion (5). We investigated {tumor size(mm), en bloc resection rate(%), operative time(min), perforation/delayed bleeding rate(%), moderate/severe fibrosis rate(%)}, respectively. Each highly difficult group was respectively compared to the group (5) for all factors. A P value $< .05$ was considered statistically significant.
RESULTS: The total average diameter of lesions was 33.8mm. For morphological type, 153 lesions were LST-NG, 110 LST-G, 37 protruded, 15 depressed and 15 recurrent lesions. By histological examination, 226 intramucosal cancers, 49 slightly invasive submucosal cancers, 19 massively submucosal invasive cancers, and 36 tubular adenomas. The average operative time was 85.8 minutes, and the en bloc resection rate was 97.9% (323/330). With regard to complications, postoperative bleeding was observed 0.9% (3/330). Microperforation which occurred in only 1 case was conservatively repaired with endoscopic clipping. The clinical outcome of each group is as follows: (1) LST-NG≧40mm, n = 31 {44.4mm, 93.5%, 149.8min, 0%/0%, 25.8%/6.5%} (2) LST-G(mix)≧50mm, n = 29 {62.9mm, 93.1%, 169.7min, 3.4%/6.9%, 25.8%/6.5%} (3) Is/Isp≧40mm, n = 12 {51.3mm, 100%, 121.3min, 0%/0%, 25.0%/41.7%} (4) local recurrent lesion after EPMR≧20mm, n = 15 {29.9mm, 100%, 118.3min, 0%/0%, 0%/100%} (5) ordinary lesion, n = 243 {28.7mm, 99.2%, 63.3min, 0%/0.4%, 24.7%/2.1%}. The tumor size was significantly larger for the group (1) (2) (3) than the group (5), respectively. Operative time was significantly longer for these four groups than the group (5). En bloc resection rates didn't significantly differ respectively between the two groups. Except for local recurrent lesion, moderate severe fibrosis rates were respectively similar between the two groups. Furthermore, all recurrent lesions had severe fibrosis and the severe fibrosis rate was significantly higher for the group (3) than the group (5). The perforation rates were respectively similar between the two groups. The delayed bleeding rate was significantly higher only for the group (2) than the group (5).
CONCLUSION: It is confirmed that we should regard both LST-NG and Is/Isp≧40mm as lesions with highly technical difficulty. We acquired the high curability and safety even for highly difficult lesions irrespective of longer operative time.

INTRODUCTION: Colorectal adenoma develops into cancer with the accumulation of genetic and epigenetic changes. We studied the underlying molecular and clinicopathological features to better understand the heterogeneity of colorectal neoplasms (CRNs).
AIMS & METHODS: We evaluated both genetic (mutations of *KRAS*, *BRAF*, *TP53*, and *PIK3CA*, and microsatellite instability [MSI]) and epigenetic (methylation status of nine genes or sequences, including the CpG island methylator phenotype [CIMP] markers) alterations in 158 CRNs including 56 polypoid neoplasms (PNs), 25 granular type laterally spreading tumors (LST-Gs), 48 non-granular type LSTs (LST-NGs), 19 depressed neoplasms (DNs) and 10 small flat-elevated neoplasms (S-FNs) on the basis of macroscopic appearance.
RESULTS: S-FNs showed few molecular changes except *SFRP1* methylation. Significant differences in the frequency of *KRAS* mutations were observed among subtypes (68% for LST-Gs, 36% for PNs, 16% for DNs and 6% for LST-NGs) ($P < 0.001$). By contrast, the frequency of *TP53* mutation was higher in DNs than PNs or LST-Gs (32% vs. 5% or 0%, respectively) ($P < 0.007$). We also observed significant differences in the frequency of CIMP between LST-Gs and LST-NGs or PNs (32% vs. 6% or 5%, respectively) ($P < 0.005$). Moreover, the methylation level of LINE-1 was significantly lower in DNs or LST-Gs than in PNs (58.3% or 60.5% vs. 63.2%, $P < 0.05$). *PIK3CA* mutations were detected only in LSTs. Finally, multivariate analyses showed that macroscopic morphologies were significantly associated with an increased risk of molecular changes (PN or LST-G for *KRAS* mutation, odds ratio [OR] 9.11; LST-NG or DN for *TP53* mutation, OR 5.30; LST-G for *PIK3CA* mutation, OR 26.53; LST-G or DN for LINE-1 hypomethylation, OR 3.41).
CONCLUSION: We demonstrated that CRNs could be classified into five macroscopic subtypes according to clinicopathological and molecular differences, suggesting that different mechanisms are involved in the pathogenesis of colorectal tumorigenesis.

P0734 ENDOCYTOSCOPY CAN PREDICT THE VENOUS AND LYMPHATIC VESSEL PERMEATION OF EARLY COLORECTAL ADENOCARCINOMA

K. Takeda[1,*], S.-E. Kudo[1], K. Wakamura[1], K. Ichimasa[1], M. Kutsukawa[1], M. Misawa[1], Y. Mori[1], T. Kudo[1], T. Hayashi[1], H. Miyachi[1], E. Hidaka[1], F. Ishida[1]
[1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama city, Japan*

INTRODUCTION: Endocytoscopy (EC), which enables observation of in vivo cells and nuclei at about 380-fold magnification, provides more detailed information about the lesions.
AIMS & METHODS: The aim of our study is to evaluate the possibility of EC with regard to prediction of venous and lymphatic vessel permeation.
The subjects were 117 colorectal differentiated adenocarcinomas (53 Tis, 41 T1 carcinomas, 12 T2 carcinomas, 11 T3 carcinomas) from 115 patients treated by endoscopic or surgical resection after observation with EC at Showa University Northern Yokohama Hospital from February 2009 to March 2014. In observing EC images, we defined the average scale of four vessels as ''vessel diameter'' and proportion between maximum portion and minimum portion of the vessel as ''vessel caliber variation''. We analyzed the correlationship between these parameters (''vessel diameter'' and ''vessel caliber variation'') and venous or lymphatic vessel permeation.
RESULTS: The mean vessel diameter of venous permeation positive tumors was 41.0μm, and that of negative tumors was 31.4μm. The mean vessel caliber variation of venous permeation positive tumors was 0.45, and that of negative tumors was 0.38 ($P < 0.05$). In lymphatic vessel permeation, the mean vessel diameter of lymphatic vessel permeation positive tumors was 39.1μm, and that of negative tumors was 34.4μm. The mean vessel caliber variation of venous permeation positive tumors was 0.45, and that of negative tumor was 0.40 ($P < 0.05$).

There were differences in vessel diameter and vessel caliber variation between venous permeation positive tumors and that of negative tumors especially in T1carcinomas ($p < 0.05$).
CONCLUSION: EC has the possibility to evaluate the venous and lymphatic vessel permeation by observing the vessel formation, especially in T1 carcinoma.

P0736 NATURE OF WHITE OPAQUE SUBSTANCE WITHIN COLORECTAL NEOPLASTIC EPITHELIUM AS VISUALIZED BY MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING: A NOVEL BIO-MARKER FOR COLORECTAL NEOPLASIA

K. Imamura[1,2,*], K. Yao[3], T. Hisabe[1], K. Otsu[1], H. Ishihara[1], T. Nagahama[1], T. Kanemitsu[1], T. Matsui[1], M. Nambu[2], A. Ota[2], A. Iwashita[2]

INTRODUCTION: Background: We previously reported the presence of a white opaque substance (WOS), opaque to the endoscope light, inside the epithelium when we use magnifying endoscopy (ME) to examine gastric epithelial neoplasia (adenomas and carcinomas) and chronic gastritis (intestinal metaplasia)[1)]. Through further pathohistological study we elucidated that this substance is comprised of minute lipid droplets (LDs) accumulated within the mucosal epithelium of gastric epithelial neoplasia or intestinal metaplasia.[2)] These minute LDs strongly backscatter the projected light, and are visualized as a white substance. When we examined colorectal neoplastic lesions (adenomas and carcinomas) using ME, we observed WOS as in the stomach. However, it is unclear whether WOS in colorectal epithelial tumors is in fact an accumulation of LDs as in the stomach.
AIMS & METHODS: Aims: To elucidate whether WOS observed in colorectal epithelial tumors (adenomas and carcinomas) is composed of LDs.
Methods: We analyzed a continuous series of both 40 WOS-positive and 40 WOS-negative colorectal epithelial tumors. We examined colorectal neoplastic lesions (adenomas and carcinomas), prior to planned treatment, using ME with narrow-band imaging (NBI), determining whether WOS was present in the surface layers of the most anal part of the colorectal epithelial tumor. We took targeted biopsies from this part of the tumor. Biopsy specimens were immediately frozen, slices taken, and the slides were stained for lipids using oil-red O. Slides were examined using light microscopy immediately after staining for the presence of LDs within the neoplastic epithelium. We investigated the correlation between the presence of WOS as visualized by ME with NBI and the presence of LDs in the histological specimens.
RESULTS: The prevalence of LDs in WOS-positive *vs* WOS-negative lesions was 47.5% (19/40) and 5% (2/40), respectively ($P < 0.001$, Fisher's exact test).
CONCLUSION: Conclusion: LDs do not accumulate in the normal colorectal epithelium. However, this study elucidated for the first time that endoscopically visualized WOS may be composed of LDs accumulated in colorectal epithelium. This phenomenon has the potential to be a new biomarker for the pathology and diagnosis of colorectal neoplasia.

INTRODUCTION: Maintaining remission in patients with ulcerative colitis (UC) is the most important achievement for the present treatments. Although precise evaluation of the mucosal inflammation is necessary to keep the remission status as long as possible, the procedures have been inadequate to detect this inflammation. Autofluorescence imaging (AFI) is a novel technology that can capture the fluorescence emitted from living tissues. While AFI has been demonstrated to be useful for diagnosing colorectal neoplasms, it is unclear whether AFI can assess the severity of ulcerative colitis (UC).
AIMS & METHODS: The aim of this prospective study was to evaluate the efficacy of AFI and its quantification for detecting mucosal inflammation in patients with UC. Forty-three patients diagnosed with UC who underwent AFI at Asahikawa Medical University Hospital between 2007 and 2010 were enrolled in this study. One hundred and thirty-five areas of the colon in the enrolled patients were first photographed using conventional endoscopy, followed by AFI. Eleven endoscopists separately evaluated the photographs captured with WLE and AFI, and quantified the intensities of fluorescence. Biopsy specimens were evaluated according to Matts' criteria, and active inflammation was defined when Matts' grade was 2 or higher. 1) When the WLE image corresponded to a Mayo endoscopic subscore 0 or 1, the inflammation was categorized as inactive. AFI images were visually categorized into two groups, green-dominant (G) and magenta-dominant (M) (vAFI). 2) AFI images were quantified using an image-analytical software program. The ratio of the reverse gamma value of green (fluorescence) divided by that of red (reflex) was defined as the fluorescence index (F index). These endoscopic assessments and the F index were compared with the histological findings. A cutoff value for the F index of active inflammation was determined using an ROC analysis. 3) The inter-observer consistency of WLE, vAFI and the quantified AFI for eleven endoscopists was calculated.
RESULTS: 1) The average diagnostic accuracy of WLE and vAFI for the histological activity was 78.5% and 78.6%, respectively. No significant difference was observed between these modalities. 2) The correlation coefficient between the F index and the histological findings was closely associated with the inflammatory grade ($r = -0.558$, $p < 0.0001$). The ROC analysis showed that active inflammation was defined when the F index was less than 0.906. The average diagnostic accuracy of the F index (84.7%) was higher than that of WLE and AFI ($p < 0.01$, $p < 0.05$). 3) The kappa value for inter-observer agreement of WLE, vAFI and the F index by the overall observers, residents and experts were 0.58, 0.56 and 0.95, 0.53, 0.49 and 0.97 and 0.67, 0.64 and 0.93, respectively.
CONCLUSION: The quantified AFI is therefore considered to be a useful and objective modality for assessing the activity of ulcerative colitis, particularly by residents.

P0738 EFFICACY OF COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE TREATMENT OF RESIDUAL OR LOCALLY RECURRENT TUMOR OCCURRING IN THERAPEUTIC SCAR

K. Hirasawa[1,*], R. KOBAYASHI[1], H. KANEKO[1], M. MAKAZU[1], C. SATO[1], S. MAEDA[2]

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been widespread as a treatment of superficial gastric neoplasm even for ulcerative scar cases. This technique has been recently introduced as a treatment option for colorectal tumor; however, the efficacy of ESD for residual or locally recurrent colorectal tumor occurring in therapeutic scar has not been fully evaluated.
AIMS & METHODS: To clarify the clinical outcomes of colorectal ESD for residual or locally recurrent tumor occurring in therapeutic scar.
Between April 2008 and March 2014, 285 consecutive superficial colorectal tumors in 267 patients were treated using ESD. Of these, 17 lesions in 17 patients were treated as residual or locally recurrent tumor with therapeutic scar. These contained 12 that recurred after endoscopic mucosal resection (EMR) and 5 after transanal endoscopic microsurgery (TEM) (scar group). The others were defined as non-scar group and treatment outcomes and complications were evaluated between two groups.
RESULTS: In all patients, the rates of en bloc resection, R0 resection and curative resection were 98.9% (282/285), 90.2% (257/285) and 82.5% (235/285) respectively, and mean tumor size was 33.3 mm, mean treatment time was 67.2 minutes, and perforation rate was 9.5%. All patients with perforation were managed with conservative medical treatment after endoscopic closure with clipping and did not need emergent surgery.
No significant differences were observed between the two groups with respect to the rate of en bloc resection, R0 resection and curative resection; however, univariate analysis showed that perforation rate and treatment time were significantly higher and longer in the scar group compared with the non-scar group.
In addition, we evaluated age, sex, tumor location, tumor depth, tumor size, tumor morphology and the presence of therapeutic scar by multivariate analysis, and found that large tumor size and the presence of therapeutic scar were an independent risk factor for both perforation and long treatment time.
CONCLUSION: This finding implies that colorectal ESD may be used as a treatment choice for residual or locally recurrent tumor occurring in therapeutic scar. However, we need to perform ESD in consideration of the risk for perforation, and it will require cooperation with surgery when treating those cases.

INTRODUCTION: Although adequate bowel preparation is prerequisite to colonoscopy, preparation for inpatients is often suboptimal.
AIMS & METHODS: This study aimed to evaluate the impact of education for ward nurses on the quality of inpatients' bowel preparation. A prospective, endoscopist-blinded, non-randomized, controlled study was performed. Gastroenterology experts provided the education to nurses who belonged to educated ward and this education was repeated every week for 1 month. 103 inpatients in educated ward and 102 inpatients in control ward of gastroenterology department who were scheduled for colonoscopy were enrolled. The primary outcome was the quality of the bowel preparation using the Ottawa Bowel Preparation Scale (OBPS). The secondary outcomes were polyp detection rate (PDR), patient compliance and subjective feelings.
RESULTS: Baseline data including patient characteristics, indication of procedure, and preparation quality before the study were comparable between 2

Table to abstract P0740

Indication (n)	Ileoscopy abnormal			Ileoscopy normal			P value (all / clinically relevant)
	Number	Biopsy abnormal	Clinically relevant	Number	Biopsy abnormal	Clinically relevant	
Diarrhoea (67)	15	11	9	52	7	3	<0.001 / <0.001
Abdo pain (39)	12	9	8	27	3	2	<0.001 / <0.001
IBD assessment (29)	12	10	9	17	3	3	<0.001 / 0.006
Other* (18)	2	2	1	16	3	1	0.194 / 0.284
Total≠ (129)	34	25	21	95	14	1	<0.001 / <0.001

wards. Mean scores of OBPS were 4.42±2.23 and 6.15±2.38 in educated and control ward, respectively ($p<0.001$). Rate of poor preparation (OBPS <6) in educated ward was significantly lower than that of control (31.1% vs. 58.8%, $p<0.001$). PDR of educated ward was significantly higher than that of control ward (74.8% vs. 52.0%, $p=0.001$). Compliance with preparation and diet instructions in education group was superior to that in control ($p<0.001$). Control group was more likely to be anxious before colonoscopy ($p<0.001$) while education group showed a higher level of satisfaction with better sleep quality ($p<0.001$). In multivariate analysis, no ward nurse education (OR 2.36, $p=0.025$), constipation (OR 6.52, $p<0.001$) and no additional water ingestion (OR 2.05, $p=0.042$) were factors associated with poor bowel preparation.

CONCLUSION: Ward nurse education is effective to improve the quality of inpatient bowel preparation, PDR, and compliance. Additional effort is needed to control constipation and to encourage additional water ingestion for better inpatient bowel preparation.

P0740 WHEN SHOULD I TAKE TERMINAL ILEAL BIOPSIES? EXPERIENCE FROM A SINGLE UNIT

L.J. Neilson[1,2,*], R. Bevan[1,2], C.J. Rees[1,2]
[1]*South Tyneside District Hospital, South Shields,* [2]*Northern Region Endoscopy Group, Newcastle, United Kingdom*
Contact E-mail Address: *neilson.laurajane@hotmail.co.uk*

INTRODUCTION: Terminal ileum (TI) intubation at colonoscopy may be useful in the investigation of patients with diarrhoea or possible inflammatory bowel disease.[1,2] The yield of TI biopsies has been shown to be variable and there are no standards for current practice.[2,3] Furthermore, in the UK, concerns remain regarding the potential for prion transmission.

AIMS & METHODS: We aim to establish the yield of TI biopsies in a single unit.

All TI biopsies recorded on the pathology system in a 3-year period were reviewed. Colonoscopy reports for these cases were reviewed, as well as case records to establish if biopsy results were clinically relevant (defined as leading to a change in management). Statistical analysis was performed using SPSS. P values were calculated using the Fisher's exact test to show any difference in biopsy yield between normal and abnormal looking mucosa for each indication. The values were calculated for all abnormal biopsy results, and for clinically relevant biopsy results.

RESULTS: 129 TI biopsies were taken between September 2010 and September 2013, 49 (38%) male and 80 (62%) female. Mean age 44 years (s.d. 17.2). There were 29 (22.5%) cases of known inflammatory bowel disease (IBD). 5 (3.9%) cases were completion colonoscopies after colorectal cancer surgery, where TI biopsies are taken to prove a complete examination.

CONCLUSION: We demonstrate that when investigating patients with diarrhoea, abdominal pain, or IBD, if the terminal ileum is visually normal, biopsies do not add to the clinical picture. There is a higher yield of relevant biopsy abnormalities when the TI appears abnormal. We can recommend within our practice that a visual assessment of a normal terminal biopsy is adequate, thereby reducing unnecessary biopsies. This reduces the workload for pathology laboratories, reduces risk from biopsies, and improves patient care as normal results can be communicated sooner to the patient.

P0741 PHARMACODYNAMIC AND CLINICAL EVALUATION OF LOW-VOLUME POLYETHYLENE GLYCOL (PEG)-BASED BOWEL CLEANSING SOLUTIONS (NER1006) USING SPLIT DOSING IN HEALTHY AND SCREENING COLONOSCOPY SUBJECTS

M. Halphen[1,*], B. Tayo[1], S. Flanagan[1], L. Clayton[1], R. Kornberger[2]
[1]*Norgine Ltd, Uxbridge, United Kingdom,* [2]*PAREXEL International, Berlin, Germany*
Contact E-mail Address: *MHalphen@norgine.com*

INTRODUCTION: The effectiveness of PEG3350+electrolytes based solutions for bowel cleansing prior to endoscopy is well established but require patients to drink ≥3L of fluid. Reducing this volume without compromising efficacy/safety is the next challenge.

AIMS & METHODS: This open-label, randomised, 2-part (Part A: healthy subjects; Part B: screening colonoscopy subjects), phase II study investigated the pharmacodynamics (stool weight), tolerability, and clinical efficacy of dose- and taste-optimised low-volume PEG-based formulations (NER1006) after split dosing compared with MOVIPREP®. Subjects (40–70y) were randomised to 1 of 4 treatment arms in Parts A and B (1:1:1:1): 3 formulation arms for NER1006; 1 for MOVIPREP. NER1006 consisted of different PEG3350 formulations, mineral salts (including ascorbate), electrolytes and flavouring, reconstituted with water plus additional intake of specified volumes of water (Table). Treatment was administered on Day 1 (evening dose) and Day 2 (morning dose). The primary endpoint in Parts A and B was 24h stool weight (desired target ≥2750g). Cleansing success rate (Harefield Cleansing Scale) was a co-primary endpoint in Part B. Secondary endpoints included time and volume of study drug to reach clear effluent, safety and tolerability (vomiting rate).

RESULTS: 120 subjects were included in each part (n = 30/arm). 24h stool weight was significantly >2750g for NER1006 formulations OPT002 and OPT003 in Part A, and OPT003 and OPT007 in Part B. Reversed order of administration of the split dose (i.e., TF043 morning/TF048 evening) in OPT002 was as efficacious, with a similar safety profile. Most subjects in the NER1006 arms reached clear effluent. Mean volume of study drug required and time to reach clear effluent are shown in the Table. In Part B, cleansing success rate was: 100% for OPT003 and OPT007; 90% for OPT006 and OPT004. For subjects who completed dosing, vomiting rates were <7.0% and <3.5% for all treatments in Parts A and B, respectively, with no significant differences between arms in either part.

CONCLUSION: In healthy and screening-colonoscopy subjects, the new low-volume, split-dose bowel preparation NER1006 achieved high quality bowel cleansing comparable with MOVIPREP. Stool output was consistently higher with NER1006 treatments, and safety/tolerability profiles between treatments were comparable.

P0742 OLYMPUS "NEAR FOCUS" NARROW BAND IMAGING (NBI) VS CONVENTIONAL NBI FOR IN VIVO ENDOSCOPIC HISTOLOGY OF COLONIC POLYPS: A RANDOMIZED CONTROLLED TRIAL

M. Bustamante[1,*], L. Puchades[1], M. Ponce[1], L. Argüello[1], V. Pons[1]
[1]*Gastrointestinal Endoscopy Unit, Hospital Universitari i Politècnic La Fe, Valencia, Spain*
Contact E-mail Address: *bustamante_mar@gva.es*

INTRODUCTION: A lower diagnostic accuracy of pathologic in vivo diagnosis with NBI has been described in nonacademic settings compared to expert centers. Recently, Olympus has launched the 190 series, which has a pushbutton-controlled optical magnification system (near focus).
AIMS & METHODS: Aims: to assess the reliability of the near focus system compared to conventional NBI in the histologic prediction (adenoma vs hyperplastic) of small (6-9 mm) and diminutive (1-5 mm) colonic polyps. Secondary objective was to assess the fulfillment of PIVI criteria.[1]
Patients and methods: Patients scheduled for colonoscopy were consecutively included. Patients were assigned to 190 series (group 1) or 180 series (group 2) endoscopes using a computer-generated random number sequence. A sample size calculation was performed, and a minimum of 136 lesions per group was programmed. All examinations were performed by the same endoscopist (MBB) with expertise in NBI analysis. NICE classification criteria[2] were used for *in vivo* histological diagnosis.
RESULTS: 98 patients were included (49 women, 50%), median age 63 yr. CRC screening was the most frequent indication (51%). Group 1 was comprised of 51 patients (52%). Finally 333 lesions were included, 82.6% from 1 to 5 mm of diameter, and 231 (69.4%) adenomas. Under NBI examination, the histology of 277 lesions (83.2%) was predicted with high confidence. The 51 patients from group 1 harbored 171 lesions (142 predicted with high confidence) and the 48 patients from group 2 harbored 162 lesions (135 predicted with high confidence). Sensitivity, specificity and diagnostic accuracy for lesions diagnosed with high confidence in both groups are summarized in table 1. There were no differences in diagnostic accuracy between both groups (92.2% vs 89.6%, p = 0.5).

(%) (CI 95%)	Group 1		Group 2	
	High confidence	High confidence Diminutive lesions	High confidence	High confidence Diminutive lesions
Sensitivity	91.8 (85.9-97.7)	90.0 (82.8-97.2)	91.2 (84.8-97.6)	87.7 (78.9-96.5)
Specificity	93.2 (84.6-100)	94.1 (84.7-100)	86.4 (75.1-97.6)	86.4 (75.1-97.6)
Accuracy	92.2 (87.5-97.0)	91.2 (85.6-96.9)	89.6 (84.1-95.1)	87.2 (80.4-93.9)

Six (10.3%) of the 54 diminutive lesions located in rectum and sigmoid colon and diagnosed as hyperplastic with NBI were finally categorized as adenomas. The overall NPV for the diagnosis of adenoma was 89.7%. In 61 (95.3%) out of the 64 patients in whom a colonoscopy control was scheduled, there was an agreement between NBI and the final pathological diagnosis (kappa = 0.9), without differences between groups.
CONCLUSION: The near focus technology does not increase the diagnostic accuracy of conventional NBI at least for an expert examinator. NBI achieves a good accuracy for in vivo pathological diagnosis, fulfilling PIVI criteria; therefore it may represent an alternative to pathological diagnosis in a near future.

P0743 CONFOCAL LASER ENDOMICROSCOPY FINDINGS IN PRIMARY SCLEROSING CHOLANGITIS (PSC) -IBD PATIENTS

M. Iacucci[1,*], X. Gui[2], R. Panaccione [1], S. Ghosh[3], B. Eksteen[4]
[1]*Inflammatory Bowel disease clinic,* [2]*pathology departement,* [3]*Departement of Medicine,* [4]*Division of Gastroenterology&Hepatology, University of Calgary, Calgary, Canada*
Contact E-mail Address: *miacucci@ucalgary.ca*

INTRODUCTION: Controversy exists as to whether the colitis seen in patients with primary sclerosing cholangitis (PSC) represents a different entity than that classically observed in patients with Crohn's disease (CD) or ulcerative colitis (UC). Specific differences have been described in the nature of the endoscopic and histological findings. Confocal laser endomicroscopy (CLE) is a new technology which enables real time endoscopy and histological investigation. PSC colitis has not been investigated by CLE.
AIMS & METHODS: To describe the CLE appearance in the colon in patients with PSC, with or without associated IBD. **Patients and Methods** 24 patients (16 male: median age 43y, range 20-71y) with PSC underwent colonoscopy with CLE (Pentax, Tokyo) between 02/12 and 12/13. The Mayo endoscopy sub-score was used to grade endoscopic findings in UC, and the SES-CD score was used to describe the white light findings in CD. CLE findings were classified using the 4 grade classification system of inflammation, describing crypt architecture, infiltration of the cells, microvasculature alteration and leakage of fluorescein. CLE images were collected for each segment of the colon, and targeted biopsies were taken for histologic analysis.
RESULTS: Of the 24 PSC patients, 20 had co-existent IBD (10UC, & 10CD). Absence of rectal inflammation based on CLE findings was seen in 20/24 patients. 10/24 had moderate to severe inflammation present in the right colon with irregular, decreased or necrotic crypts. Two patterns of fluorescein leakage were observed. A) In 10 patients leakage of fluorescein were observed in spaces amongst epithelial cells, or non-uniform abundant leakage in the lumen of the crypts associated with moderate to severe inflammation; B) In 12 patients we observed uniform leakage of the fluorescein into the lumen of crypts in the left side of the colon, associated with normal crypt architecture and micro-vasculature - the absence of active inflammation was confirmed by histology. The remaining 2 patients did not showed leakage of fluorescein. Four patients did not have a diagnosis of IBD but 3 of these patients had subtle inflammation on CLE characterized by cellular infiltration within the lamina propria in the sigmoid colon and rectum (by histology). One had a new diagnosis of UC after examination by CLE and colonoscopy.
CONCLUSION: CLE effectively characterizes the inflammation of PSC –IBD patients, confirming that these patients are likely have a different phenotype with inflammation in the right side of the colon and rectal sparing. The finding of uniform leakage of fluorescein into the lumen of the crypts, in the absence of active inflammation, may represent a defect in the intestinal barrier. Even patients not known to have IBD associated with PSC may demonstrate subtle infiltration of mononuclear cells into the lamina propria as demonstrated at CLE.

P0744 ANALYSIS OF THE ENDOCYTOSCOPIC IMAGE OF COLORECTAL LESION FROM THE ASPECT OF MICRO VASCULAR PATTERN

M. Misawa[1,*], S.-E. Kudo[1], H. Nakamura[1], S. Kataoka[1], S. Hayashi[1], H. Oikawa[1], N. Toyoshima[1], Y. Mori[1], T. Kudo[1], N. Ogata[1], T. Hayashi[1], K. Wakamura[1], Y. Wada[1], H. Miyachi[1], F. Ishida[1]
[1]*Digestive disease center, Showa University Northern Yokohama Hospital, Yokohama-shi, Japan*

INTRODUCTION: Endocytoscopy (EC) is an ultra-magnification technique, which can be performed to evaluate structural and cellular atypia with observation of lumens and nuclei in the surface layer of the mucosa. EC has made it possible to diagnose living tumor cells in vivo and to obtain an ultra-magnification pathological image simply by applying the scope to the target mucosa during an endoscopic examination. On the other hand, analysis of the surface microvessels of colorectal lesions using magnifying narrow-band imaging is useful for identifying the appropriate treatment method for colorectal lesions. In addition, the surface microvessels can be analyzed using EC.
AIMS & METHODS: The aim of this study was to investigate whether the observation of surface microvessels using EC was useful in predicting the histopathology of colorectal lesions.
The study included 273 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and December 2013. A total of 337 lesions (10 normal mucosae, 23 hyperplastic polyps, 210 adenomas, and 94 submucosally invasive cancers) were retrospectively evaluated. The colonic surface micro-vascular patterns observed using EC were classified into the following 3 groups: EC-V1, the surface microvessels were obscure; EC-V2, the surface microvessels were clearly observed, and their caliber and arrangement were uniform; and EC-V3, the surface microvessels were thick, and their caliber and arrangement were non-homogeneous.
RESULTS: The sensitivity, specificity and accuracy of EC-V1 for diagnosis of hyperplastic polyp were 97.0%, 99.0% and 98.8%, respectively. As regards the sensitivity, specificity and accuracy of EC-V3 for diagnosis of invasive cancer were 84.7%, 97.7% and 94.1%, respectively.
CONCLUSION: Vascular patterns of colorectal cancers observed by endocytoscopy were useful in predicting the histopathology of colorectal lesions.

INTRODUCTION: Endoscopic resection (ER) is increasingly used to treat small rectal neuroendocrine tumors (NETs). Currently, several guidelines recommend ER as a treatment of rectal NETs less than 10 mm without muscularis invasion. However, limited data are available on the long-term outcomes of rectal NETs treated by ER. In addition, the significance of known risk factors for metastasis of rectal NETs, including lymphovascular invasion, remains elusive.
AIMS & METHODS: The aim of this study was to clarify the prognosis of rectal NET patients treated by ER and to characterize the known risk factors for metastasis of these lesions. Ninety-eight patients underwent ER for rectal NETs at our institution between 1997 and 2011. Among them, 3 patients who underwent colectomy for colorectal cancers after ER of rectal NETs and 8 patients with a follow-up period shorter than 1 year were excluded. Thus, a

total of 87 patients with 91 lesions were included in this study. The patients' records were retrospectively analyzed for clinical outcomes and pathological findings including size, invasion depth, and lymphovascular invasion. Also, we additionally evaluated tumor proliferation by Ki-67 immunohistochemistry and lymphovascular invasion using elastic staining and double staining immunohistochemistry (CD31/synatophysin and D2-40/synaptophysin).
RESULTS: ER procedures included endoscopic submucosal resection with a ligation device (ESMR-L) (n = 82), EMR (n = 5), and ESD (n = 4), with an R0 resection rate of 90.1% (ESMR-L 76/82, EMR 3/5, and ESD 3/4, respectively). No major complications were observed. All cases were followed up without surgery after ER; with the median follow-up period of 68 months (range, 12–167), no metastasis or recurrence was detected and the 5-year overall survival rate was 95.9%. The median tumor size of these cases was 5 mm (range, 2–13) and no lesion showed invasion beyond the submucosal layer. Based on the results of Ki-67 immunohistochemistry, all 91 lesions were classified as NET G1 (WHO 2010 classification). The original diagnoses based on haematoxylin and eosin staining identified no case with lymphatic invasion and only one case with positive venous involvement. However, additional analysis using elastic staining and double staining immunohistochemistry revealed lymphovascular invasions in 33 lesions (36.3%) by elastic staining, 9 lesions (9.9%) by CD31/synaptophysin double staining, and 23 lesions (25.3%) by D2-40/synaptophysin double staining. Collectively, lymphovascular invasion was identified in a total of 42 lesions (46.2%) with at least one of these staining procedures. Size of NETs with lymphovascular invasion (median, 5 mm; range, 3–13) was significantly but only slightly larger than that of NETs without lymphovascular invasion (median, 4 mm; range, 2–10; $p = 0.02$, Mann–Whitney U test).
CONCLUSION: Long-term clinical outcomes of rectal NETs following ER were favorable. While lymphovascular invasion was believed to be a strong risk factor for metastasis, a detailed analysis revealed that it was frequently present even in minute rectal NETs. The present results raise a question on the clinical significance of lymphovasucalar invasion in small rectal NETs.

INTRODUCTION: Long lasting lifting is a key factor during ESD and can be obtained by water-jet injection of saline solution or by injection of viscous macromolecular solutions. In a previous animal study, we assessed the ability of the Nestis Enki II system to combine jet injection and macromolecular viscous solutions. In the present work, we used this combination in humans in the different sites of the digestive tract.
AIMS & METHODS: To assess the effectiveness and safety of Nestis® system using viscous solutions. We report retrospectively all the consecutive cases of ESD procedures made with Nestis Enki II system with injection of viscous solutions. Information was collected about: the lesion (site, histology), the procedure (time, perforations, bleedings, monobloc or piece meal resection), the piece (size, R0, Rx or R1 resection) and the outcomes for the patient (curative treatment, surgery, recurrence, delayed complications).
RESULTS: 45 resections were complete macroscopically. Procedures were performed by 6 operators: 5 experts and one beginner with only one previous experience in human ESD (11). The lesions were: 22 lateral spreading tumors of the rectum 11 gastric lesions, 10 esophageal lesions, 1 of the right colon and 1 of the second duodenum. The average maximal lesion diameter was 4.8 cm (SD 2.4, range 2-11 cm), the average surface was 19.8 cm2 (SD 17.7, range 2.2-72 cm2) and the average time of procedure was 79.9 min (SD +/- 50.3, range 19-225 min). Three adverse events occurred with two diminutive perforations (and two delayed bleedings treated conservatively. R0 resection rate was 91.1%. Obstruction of the catheter occurred in 6 cases in bloody situations.
CONCLUSION: This is the first multicenter report on a new water jet system allowing injection of viscous solutions. This system is safe and effective and allows working in retroflexed position with different viscous solutions.

P0747 OPTIMISATION OF ENDOSCOPIC FOLLOW-UP WAITING LISTS IN A NEW ZEALAND DISTRICT HEALTH BOARD

N. Bhala[1,*], H. Myint[1], J. Lewis[1], C. Virtue[1], A. Simpson[1], R. Cameron[1]
[1]*Department of Gastroenterology, Capital & Coast District Health Board, Wellington Hospital, New Zealand*
Contact E-mail Address: *neeraj.bhala@ccdhb.org.nz*

INTRODUCTION: New Zealand (NZ) has the one of the highest bowel cancer death rates in the Western world, so prompt access to lower GI endoscopy for new referrals is of importance in diagnosis, treatment and prevention. However, partly as a result of follow-up colonoscopy demands, waiting lists have increased substantially, and so the NZ Ministry of Health has funded initatives to ensure appropriate clinical investiagtions are being done for the right indication at the right time.
AIMS & METHODS: We sought to evaluate an optimisation exercise of follow-up lower GI endoscopy lists in a single District Health Board covering a population of around 300.000 people in the lower North Island of North New Zealand. Evidence-based criteria were agreed by the endoscopy user multi-disciplinary group for recall criteria for repeat colonoscopy for a number of conditions, including: colorectal cancer resections; colorectal adenoma follow-up; family history of colorectal cancer; and inflammatory bowel disease surveillance. These were then applied to those patients on the waiting list for repeat endoscopic appearances in 2014 by a single consultant gastroenterologist.
RESULTS: Of 511 patients on the waiting list, >97% were for repeat colonoscopies. 164 procedures (32.1%) did not meet the criteria for repeat procedures, and were cancelled. Within 2 months of this exercise, only four primary care practitioners (2.5%) sent queries regarding cancellation, which were dealt with. 183 (35.8%) did meet the criteria, but were not being done at the appropriate time interval, so were deferred (range 6 months - 3 years). 165 (32.3%) did meet the indication for repeat procedure in the appropriate time interval, and were approved and duly listed.
CONCLUSION: Initiatives to apply evidence-based criteria for repeat endoscopic procedures can improve quality, productivity and prevent unnecessary procedures. In this real-life application in NZ, a third of repeat endoscopy workload were removed from waiting lists, and more than an additional third were deferred to a clinically appropriate time, allowing new referrals to be seen sooner. Centrally funded initiatives to apply evidence-based guidelines to help manage waiting lists may be relevant to other populations.

P0748 PICOSALAX PROVIDES SUPERIOR BOWEL CLEANSING TO TRADITIONAL POLYETHYLENE GLYCOL IN THE ELDERLY POPULATION

R. Gingold-Belfer[1,*], A. Geller[1], A. Vilkin[1], Y. kelner[1], Y. Niv[1], Z. Levi[1]
[1]*Gastroenterology Department, Rabin Medical Center, Petah Tikva, Israel*

INTRODUCTION: Lately, life expectancy was prolonged. Therefore, endoscopic procedures are performed in an elderly population too. The level of bowel cleansing during colonoscopy is one of the quality indicators that were determined in order to improve the procedure's efficacy. An elder age is one of the factors for poor preparation.
AIMS & METHODS: Aims: We aimed to evaluate the level of bowel cleansing of the elderly population, by assessing the bowel preparation with Picosalax as compared to polyethylene glycol (PEG).
Methods: Included 6,844 patients aged ≥75y (mean 81.1y±4.6) who underwent colonoscopy at our endoscopy unit during 2003-2013. 3,659 (53.5%) patients were men. 1,258 patients had preparation with Picosalax and 5,444 with PEG. The quality of bowel cleansing was assessed according to the Aronchick scale. Multivariable logistic regression analysis for good preparation were used and included: the patients' age, gender and bowel preparation type.
RESULTS: Total, good preparation was achieved in 1,024 (79.8%) patients who used Picosalax as compared to 3,528 (63.4%) with PEG ($p < 0.001$). Fair preparation was achieved in 183 (14.5%) patients by Picosalax as compared to 1,322 (24.3%) by PEG. Bad and poor preparations were reported in 44 (3.5%) and 7 (0.6%) patients who used Picosalax as compared to 544(10%) and 50 (0.9%), respectively. By using multivariable logistic regression analysis, good preparation, was significantly associated with female gender [OR: 1.38 95% confidence interval (CI) 1.24-1.52, $p < 0.001$] and Picosalax preparation [OR: 2.15 95% CI 1.85-2.5, $p < 0.001$, PEG- ref]. An increased age, was negatively associated with good preparation [OR: 0.9595% CI 0.97-0.99, $p = 0.009$].
CONCLUSION: Female gender is significantly associated with good preparation in patients aged ≥75y. The usage of Picosalax was associated with a 2.15 odds ratio for predicting good bowel preparation. Despite lack of conventional guidelines of bowel preparations regimens for the elderly population, the usage of Picosalax is indicated as an effective preparation for this age group, too.

P0749 MULTIPURPOSE USE OF THE OVER-THE-SCOPE-CLIP SYSTEM: SWISS EXPERIENCE IN A TERTIARY CENTER

M.C. Sulz[1], R. Bertolini[1], **R. Frei**[1,*], G.-M. Semadeni[1], C. Meyenberger[1]
[1]*Gastroenterology and Hepatology, Kantonsspital St. Gallen, St. Gallen, Switzerland*
Contact E-mail Address: *michael.sulz@kssg.ch*

INTRODUCTION: The Over-the-scope-clip (OTSC) system (Ovesco Endoscopy AG, Tübingen, Germany) is a fairly new endoscopic device suitable to close gastrointestinal (GI) perforations, post-surgical fistulae or to resect submucosal tumors. It can also be used as hemostatic tool in GI bleeding and for esophageal stent fixation. To the best of our knowledge, in literature there are only case reports or small case series regarding the efficacy and safety, so far human clinical randomized controlled trials are not available. The available case series and reports are inhomogeneous concerning indication, study design, site of application and definition of success.
We present a prospective case series reflecting our all-day clinical experience with OTSC in a tertiary endoscopy center in Switzerland. This case series illustrates the primary successful closure in over 80% of GI lesions, mainly fistulae or anastomotic leakages and adds data to the increasing experience with this tool.
AIMS & METHODS: Aim: To evaluate the outcome of the over-the-scope-clip system (OTSC) regarding various indications in all-day clinical practice in Switzerland.
Methods: This is a prospective, consecutive case series conducted at a hospital with tertiary care endoscopy from September 2010 until January 2014. Indications were fistulae, anastomotic leakages, perforations, deroofed submucosal lesions for biopsy, refractory bleeding and stent fixation in the gastrointestinal (GI) tract. Primary technical success was defined as an adequate deployment of the OTSC on the target lesion. Clinical success was defined as resolution of the problem, for instance no need for surgery or further endoscopic intervention. In case of recurrence retreatment of a lesion with a second intervention was possible. Complications were classified into those related to sedation, endoscopy or deployment of the clip.
RESULTS: A total of 28 OTSC system applications were carried out in 21 patients (median age 64 years [range 42-85], 33% females). Main indications were fistulae (52%), most of them after percutaneous endoscopic gastrostomy (PEG) tube removal and anastomotic leakage after GI surgery (29%). Further indications were unroofed submucosal lesions after biopsy, upper gastrointestinal bleeding or esophageal stent fixation. 48% of the OTSC were applied in the upper and 52% in the lower GI tract. The range of lesion size was 2-20 mm (mean 8 mm). Primary technical success and clinical success were achieved in 85% and 67%, respectively. In 53% of cases the suction method was used without accessories like Twin grasper or Tissue anchor. No endoscopy-related or OTSC-related complications were described.
CONCLUSION: OTSC is a useful tool for endoscopic closure of various GI lesions like fistulae or leakages. Future randomized prospective multicenter trials are needed.

P0750 INVESTIGATING THE INVESTIGATION - INCIDENTAL COLONIC HOTSPOTS ON PET-CT SCANS

R. Sinha[1,*], W.S. Ngu[2], A. Ramadas[1], A. Reddy[2], R. Anandavelu[1], D. Aitken[2], M. Jha[2]
[1]*Gastroenterology,* [2]*Colorectal surgery, South Tees NHS Foundation Trust, Middlesbrough, United Kingdom*
Contact E-mail Address: *rohits78@gmail.com*

INTRODUCTION: Positron emission tomography (PET) measures metabolic changes at a cellular level enabling detection of early stage disease. Incidental 2-deoxy-[^{18F}F]fluoro-2-D-glucose (FDG) colonic uptake is detected in 1.3-3% of patients with up to a third resulting in false positive results [1]. Follow-up endoscopy is recommended to further distinguish these FDG avid lesions [2]. Cancer detection rates of 7.8-18.9% have been quoted in various studies [1,3]
AIMS & METHODS: Our aim was to evaluate incidental colonic FDG avid lesions on PET-CT by endoscopy.
An analysis of retrospectively collected database of all patients (n = 1564) who had PET-CT for extra-colonic malignancy between January 2011 to September 2013 was performed.
RESULTS: Fifty-nine (3.77%) patients had focal colonic FDG uptake and 44 (2.87%) patients went on to have colonoscopy.
Indications for PET CT for those undergoing endoscopy was lung carcinoma (22), oesophageal carcinoma (5), gastric carcinoma (3), head and neck carcinoma (7), lymphoma (6) and unknown primary (1).
Median age was 68 with a male preponderance (2.4:1).
Location on PET CT was categorized to sigmoid (22), rectal (9), anorectal (4), caecal (3), hepatic flexure (2), transverse (1), splenic flexure (1), ascending (1) and descending (1).
Findings on endoscopy ranged from polyps (21), normal (9), diverticulosis (8), sigmoid cancer (4), caecal cancer (1) and colitis (1).
In total, out of the all patients who had endoscopy, 19 (43.2%) were found to have low-grade tubullovillous adenomas, 5 (11.1%) had cancer, whilst 2 (4.4%) had hyperplastic polyps on histology.
CONCLUSION: These findings are in keeping with other series and suggests to carry on with current practice of following up these "hot-spots" with endoscopic investigations.

Contact E-mail Address: *roisinbevan@hotmail.com*

INTRODUCTION: The English Bowel Cancer Screening Programme has been expanded to include a one-off flexible sigmoidoscopy offered to all 55 year olds, called BowelScope Screening. Screening commenced in May 2013, with 6 pilot sites performing flexible sigmoidoscopies in the first 8 months of screening.
AIMS & METHODS: We aim to describe ADR in BowelScope Screening. The NHS Bowel Cancer Screening System database was interrogated and ADRs reviewed for each screening centre and screening endoscopist. ADR was reviewed graphically, with a funnel plot, constructed using the log odds method.
RESULTS: 49 endoscopists have performed 4444 sigmoidoscopies at 6 screening centres. Endoscopists had performed 2-330 procedures (median 66, mean 91). 29 endoscopists had performed ≥50 procedures; of these, 17 had performed ≥100 procedures.
Centre 2 has a higher ADR than the other centres. When considering all procedures, this difference reaches statistical significance when compared to centres 3, 5, and 6 ($p < 0.05$), and approaches significance when compared to centre 1 ($p = 0.0687$) and centre 4 ($p = 0.0548$). When considering only the procedures done by endoscopists who have performed ≥50 or ≥100 sigmoidoscopies, there remains a significant difference ($p < 0.05$) between centre 2 compared to centres 5 and 6, but not to the other centres. A funnel plot of individual endoscopist ADRs demonstrates one endoscopist below the 99.8% control limit.
Overall BowelScope ADR is 8.6%. ADR by centre is shown in Table 1.
Table 1 - ADR by centre and endoscopist volume

	Centre 1	Centre 2	Centre 3	Centre 4	Centre 5	Centre 6	**All Centres**	
Endoscopist procedure counts	ADR %	ADR %	ADR %	ADR %	ADR %	ADR %	**ADR %**	**ADR range %**
All	8.8	11.7	8.9	7.6	6.5	7.3	**8.6**	**0.0-60.0**
≥50	8.9	11.3	8.1	8.6	6.4	6.4	**8.6**	**3.1-14.0**
≥100	9.0	11.3	8.9	8.6	3.1	5.2	**8.7**	**3.1-13.0**

CONCLUSION: Adenoma detection rates within BowelScope screening show variation between centres. There is also variation between endoscopists in terms of individual ADRs, although all but 1 endoscopist are above the 99.8% lower control level on funnel plot. These variations require further exploration at both centre and individual level, and feedback and education methods will be used to improve ADRs.

INTRODUCTION: UK population colorectal cancer (CRC) screening has been successfully implemented with Bowel Cancer Screening Programme (BCSP) faecal occult blood testing biannually from age 60-75.
A large UK study of once-only flexible sigmoidoscopy (FSIG) demonstrated a reductions in CRC incidence of 33% & death rates of 43%1. This, with the screening centre infrastructure developed for the FOB programme, allowed provision of a new arm of BCSP, offering FSIG to 55 year olds in England, known as BowelScope screening.
BowelScope screening began May 2013, with 6 pilot sites performing FSIGs in the first 7 months.
AIMS & METHODS: We aim to describe procedural data from the early months of BowelScope screening. Data were obtained from The Bowel Cancer Screening System (BCSS) database for all participants invited and participating in BowelScope FSIGs May-Dec 2013. Procedural data were recorded, including

insertion depth, adenoma detection rates (ADR), cancer detection, discomfort levels, entonox usage & colonoscopy conversion rates.
RESULTS: 13927 people have been invited to or opted into BowelScope screening at 6 screening centres. Overall uptake is 43.5% (range 37.0-51.9%). 4 cancers have been detected. Polyps were detected in 16.4-23.8% of procedures (mean 20.7%). Mean ADR was 8.4%. One centre has a significantly higher ADR than the other 5 sites ($p < 0.05$). (see Table 1).
Table 1 – BowelScope outcomes by anonymised centre

Screening Centre	Invitees	Attended (%)	B/S with adenoma(s)	ADR %	Cancer	Colonoscopy required (%)	Entonox used
1	3125	1128 (51.9)	100	8.9%	1	39 (3.5)	121
2	1866	524 (37.0)	64	12.1%	0	23 (4.4)	94
3	3779	1070 (40.9)	90	8.4%	0	50 (4.7)	60
4	986	311 (46.6)	25	8.0%	0	12 (3.9)	15
5	1970	625 (47.4)	38	6.1%	2	21 (3.4)	28
6	2181	479 (37.2)	30	6.2%	1	18 (3.8)	25
TOTAL	**13927**	**4135**	**347**	**8.4%**	**4**	**163 (3.9)**	**343**

Most (52.7%) procedures were completed in 6-10 minutes. 78.6% of procedures were reported as causing no or minimal pain only, with only 34 procedures (0.8%) reporting severe pain.
CONCLUSION: Uptake has varied between centres, but is lower than for the FOB arm of the BCSP. The average ADR is 8.4% (range 6.1-12.1%), lower than in the UK flexible sigmoidoscopy screening trial (12.1%, range 8.6-15.9%[1]) although the age range studied in the trial differs from this cohort.
Further work will be required to investigate the variation in uptake rates and to improve these rates. ADR variations may also need to be addressed in future work.

P0753 PATIENT-REPORTED EXPERIENCE OF COMFORT AND DIGNITY IN FLEXIBLE SIGMOIDOSCOPY: DATA FROM THE NHS BOWEL SCOPE SCREENING PILOT

C.Von Wagner[1], H. Bowyer[1], **R. Bevan**[2,3,*], C. Rees[3,4], W. Atkin[5], J. Wardle[1]
[1]Epidemiology and Public Health, UCL, London, [2]Northern Region Endoscopy Group, Newcastle, [3]South of Tyne Bowel Cancer Screening Centre, Gateshead, [4]School of Pharmacy and Health, Durham University, Stockton on Tees, [5]Department of Surgery and Cancer, Imperial College, London, United Kingdom

INTRODUCTION: The NHS Bowel Cancer Screening Programme started flexible sigmoidoscopy (FS) screening (also known as Bowel Scope Screening, BSS) at six centres across England (Gateshead, Guildford, London, Medway, Norwich, Wolverhampton) in March 2013. The aim of this analysis was to investigate the extent to which high levels of patient satisfaction recorded in previous UK trials can be replicated in the early stages of a routine screening programme.
AIMS & METHODS: We used data from an ongoing study monitoring patient-reported experience in the pilot phase of the BSS Programme. We report data from the 'post-AM questionnaire' which is given to patients at the end of their FS appointment and supposed to be completed on the following day.
RESULTS: As of January 2014, we had received 2,324 questionnaires. Satisfaction with the test was high with 98.8% of patients being either satisfied (21.1%) or very satisfied (77.7%). Nonetheless, 43% of patients reported moderate (34%) or severe pain (9%) which was high compared with the St Marks' demonstration programme[1] and the UK Flexible Sigmoidoscopy Trial[2]. Women were three times as likely to report severe pain during the test than men (14.3% vs 4.6%), and twice as likely to find the test as more painful than they had expected (39.9% vs 20.1% respectively). Only about 1 in 10 patients reported being moderately (9.8%) or severely (1.4%) embarrassed during the test, with women being slightly more likely than men to fall into these categories (13.4 vs. 8.9%). Women also had a much stronger preference for the test to be carried out by a female practitioner than men (41.2% vs 7.1% respectively).
CONCLUSION: The vast majority of patients were satisfied with their experience of FS screening. However, levels of pain appear high when compared with previous trials. Emphasis should be placed on ensuring that patients have as comfortable a procedure as possible. Additional consideration should be given to women being able to choose the sex of the practitioner performing the test.

P0754 PATIENTS' EXPERIENCE OF COLONOSCOPY IN THE ENGLISH BOWEL CANCER SCREENING PROGRAMME

A. Ghanouni[1], A. Plumb[2], C. Rees[3,4], P. Hewitson[5], H. Miller[3], **R. Bevan**[3,6,*], C.Von Wagner[1]
[1]Epidemiology and Public Health, [2]Centre for Medical Imaging, UCL, London, [3]South of Tyne Bowel Cancer Screening Centre, Gateshead, [4]School of Medicine, Pharmacy and Health, Durham University, Stockton on Tees, [5]Nuffield Department of Population Health, University of Oxford, Oxford, [6]Northern Region Endoscopy Group, Newcastle, United Kingdom

INTRODUCTION: In the English Bowel Cancer Screening Programme, colonoscopy is the standard investigation to exclude cancer in participants who receive a positive faecal occult blood test result. A questionnaire is sent to all patients 30 days post-test. These data were used to assess patients' experience of colonoscopy.
AIMS & METHODS: Anonymised data were extracted from the Bowel Cancer Screening System. These included all patients who had colonoscopy between 01/01/11 and 31/12/12. Questionnaire items on the pre-test experience (whether patients understood the risks/benefits), the hospital experience (the test itself, issues of dignity/privacy) and post-test complications (bleeding/pain) were analysed. Pearson chi-square tests were used to compare experiences by gender, high vs. low levels of socioeconomic deprivation (using Index of Multiple Deprivation scores), and whether patients reported receiving sedation or not.
RESULTS: After excluding patients outside the target date range and those who did not have colonoscopy, 76,717 patients were eligible for analysis, of whom 60,581 (79.0%) responded to the questionnaire. Nearly all patients felt they understood the risks (95.7%) and benefits (98.2%) of the test, and 97.8% felt the preparation instructions were clear. Comparison by gender and deprivation did not yield clinically meaningful (≥3%) differences. In terms of the hospital experience, virtually all patients felt they were treated with respect (98.5%) and had privacy (98.0%), but 20.8% experienced more discomfort than expected (although only 5.2% asked for the test to be stopped/paused). Procedural discomfort was moderated by gender, with more women than men reporting higher-than-expected discomfort (25.4% vs. 17.9%; $p < .0005$), and requesting that the test be stopped/paused (7.1% vs. 3.9%; $p < .0005$). Use of sedation showed only a weak association with patient experience: 22.2% of sedated vs. 20.2% of non-sedated patients reported unexpected discomfort; 6.4% vs. 4.8% asked for the test to be stopped/paused; both p-values $< .0005$). Post-test, 14.3% of patients reported pain and 6.9% reported rectal bleeding. Pain was more common in women (18.0% vs. 11.9%; $p < .0005$) but there were no other clinically meaningful differences post-test related to gender or deprivation level.
CONCLUSION: Most patients referred for colonoscopy as part of the Bowel Cancer Screening Programme have a positive colonoscopy experience. The most negative aspect of the experience was the test being unexpectedly uncomfortable. Patients are extensively counselled pre-procedure but more emphasis on managing expectations, along with continued measures to reduce discomfort and pain are required, particularly for women.

P0755 ENDOSCOPIC RESECTION OF GIANT COLONIC POLYPS – SIZE MATTERS!

R. Bhattacharyya[1,*], G. Longcroft-Wheaton[1], P. Bhandari[1] on behalf of Portsmouth, UK
[1]Gastroenterology, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom

INTRODUCTION: Colonic polyps sized 50mm and above are traditionally treated by surgical resection. Endoscopic resection has now become increasingly common as the expertise of western endoscopists improves. There is very little published literature on endoscopic resection of these giant polyps.
AIMS & METHODS: The aim of the study was to evaluate the feasibility, safety and efficacy of endoscopic resection of giant polyps ≥50mm in size.
This was a prospective cohort study. All patients who underwent endoscopic resection of colonic polyps ≥50mm from 2007-2013 were prospectively entered into a database. We excluded all polyps with fibrosis related to previous intervention. All patients were tertiary referrals from experienced gastroenterologists. All procedures were performed by a single experienced endoscopist.
RESULTS: N = 124 polyps in 122 patients. Mean polyp size = 71mm. Range 50-170mm. 27(22%) in right colon and 97 (78%) in left colon. M:F ratio 1.1:1. All polyps were resected in a piecemeal fashion. The mean procedure time was 120 minutes (range 90 to 240).
The complication rate was 11/124(8.9%). All these patients required inpatient stay. There were 9 bleeds (3 immediate and 6 delayed), 1 post polypectomy syndrome and 1 case of split muscle fibres (clipped endoscopically). 1 case of immediate bleeding required surgery to control the bleeding. All the others were managed conservatively. 4 of the 9 bleeds required blood transfusion. The complication rate was independent of polyp size, resection technique or site of the lesion.
Follow up data was available for 90 polyps. The recurrence rate was 21/90(23.3%). Of the 21 recurrences, 16/21(76%) patients achieved complete clearance with a further 1 to 2 endoscopic procedures. The recurrence rate was significantly dependent on polyp size and was not dependent on the resection technique or the site of the lesion. Recurrence gradually increased with an increase in polyp size up to 70mm. Recurrence was seen in 3/34(8.8%) polyps ≤55mm, in 7/54(12.9%) polyps ≤60mm and in 9/63(14.2%) polyps ≤70mm. However, in polyps >70mm, the recurrence rate greatly increased to 12/27(44%) **(p = 0.002)**.

	Size			
Recurrence 21/90 (23.3%)	**≤55mm** 3/34 (8.8%)	**≤60mm** 7/54 (12.9%)	**≤70mm** 9/63 (14.2%) **p = 0.002**	**>70mm** 12/27 (44.4%)

CONCLUSION: 1) It is safe and feasible to endoscopically resect polyps 50-170mm in size.
2) Recurrence is significantly dependent on polyp size.
3) Giant polyps resected endoscopically have a significant recurrence rate. The majority of these can be cleared by further endoscopic procedures. However, we believe that the recurrence rate in polyps above 70mm is very high and surgery should be considered in these cases.
4) Complication rates are independent of size.

P0756 ADVISABILITY OF COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION IN ELDERLY: TREATMENT AND LONG-TERM OUTCOMES

R. Kobayashi[1,*], K. HIRASAWA[1], H. KANEKO[1], M. MAKAZU[1], C. SATO[1], A. KOKAWA[1], S. MAEDA[2]
[1]*Division of Endoscopy, Yokohama City University Medical Center,* [2]*Department of gastroenterology, Yokohama City University Graduate School of Medicine, Yokohama city, Japan*
Contact E-mail Address: *ryo_1001@yokohama-cu.ac.jp*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is becoming widespread as a treatment of superficial colorectal neoplasm; however, the efficacy and safety of colorectal ESD in elderly patients has not been fully evaluated.
AIMS & METHODS: In the present study, we assessed the treatment and long-term outcomes of colorectal ESD in elderly patients.
Between April 2008 and March 2014, 285 consecutive superficial colorectal tumors in 267 patients were treated using ESD. Patients were divided into two groups; elderly (75 years of age or older) and non-elderly (less than 75 years of age), then were retrospectively compared to patient and tumor characteristics and treatment outcome.
Long-term outcomes in elderly patients were also evaluated.
RESULTS: The elderly group comprised 93 lesions in 83 patients and non-elderly group comprised 192 lesions in 184 patients.
No significant differences were observed between the two groups with respect to patient and tumor characteristics as the following factors: sex, tumor location, tumor depth, tumor size, tumor morphology.
In all patients, the rates of en bloc resection, R0 resection and curative resection were 98.9% (282/285), 90.2% (257/285) and 82.5% (235/285) respectively. Mean procedure time was 67.2 minutes (range 10-273 minutes), the rate of delayed bleeding was 3.9% (11/285) and the rate of perforation was 9.5% (27/285). There were no significant differences between the two groups in the rates of en bloc resection, R0 resection, curative resection, delayed bleeding, perforation, and procedure time.
In 83 elderly patients, during a median follow-up period of 20.2 months (range 1.4-63 months), 6 patients were excluded from the long-term prognosis analysis because of missing follow-up. Four of 16 patients who judged as non-curative resection underwent additional surgery, and the others requested only observation. Two of 77 patients (2.6%) died of infection of unknown cause (n = 1) and heart failure (n = 1). The 3- and 5-year overall survival rates were 96.4% and 87.7%, respectively. However, we did not observe local or distant recurrences in any of the patients were followed up. Therefore, the 3- and 5-year disease-specific survival rates were 100%.
CONCLUSION: Because there was no significant difference in treatment outcome between in elderly and non-elderly group, colorectal ESD could be used as a treatment choice for superficial colorectal tumors in elderly patients. However, many of the elderly non-curative cases were observed without additional surgical treatment, implying that such patients are necessary for careful follow-up by computed tomography (CT) or measuring tumor markers.

P0757 A COMPARATIVE STUDY OF TWO DIFFERENT SNARES FOR THE COMPLETENESS OF POLYP EXCISION

S. Din[1,*], A. Ball[1], S. Riley[1], P. Kitsanta[2], S. Johal[1]
[1]*Gastroenterology,* [2]*Histopathology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*

INTRODUCTION: Polypectomy with cold snare is a frequently used technique for the removal of small colorectal polyps. The influence of snare type on completeness of excision is unknown. We have therefore compared the effectiveness of two different snares.
AIMS & METHODS: Patients attending for colonoscopy at Sheffield Teaching Hospitals, England were prospectively included in the study. We assessed the endoscopic and histological completeness of excision following cold snare of 3-7mm polyps using the Exacto mini-snare (diameter 0.30mm) and Olympus mini-snare (diameter 0.47mm). Prior to the study, consensus regarding the endoscopic completeness of excision was standardised to complete, incomplete or uncertain using the Delphi method. Completeness of excision was aided by chromoendoscopy (indigo carmine 0.1%). The primary outcome was endoscopic completeness of excision. Secondary outcome measures included: completeness of histologic excision, polyp 'fly away', retrieval rate, early bleeding (48 hours), delayed bleeding (2 weeks) and perforation.
RESULTS: A total of 157 polyps were removed. Median (range) polyp size was 4.0mm (3-7mm). There was no significant difference in the patients' demographic details or polyp characteristics between the two groups. Endoscopic completeness of excision was significantly higher with the Exacto snare compared to the Olympus snare (90.2% vs. 73.3%, $p < 0.05$). There was also a trend towards a higher complete histological excision rate with the Exacto snare (71.9% vs. 64.4%), but this did not reach statistical significance ($p = 0.4$). Polyp 'fly away' occurred less often with the Exacto snare (14.6% vs. 35.3%, $p < 0.05$), but there was no significant difference in the polyp retrieval rate (84.3% vs. 83.8%, $p = 0.9$). There were no significant complications with either snare. Where the completeness of excision was assessable (complete or incomplete), there was a fair level of agreement (kappa = 0.36) between endoscopic and histological assessment.
CONCLUSION: This is the first study we are aware of that compares completeness of excision with different snares. Our findings suggest that snare type may be an important factor determining completeness of excision when removing small polyps by the cold snare techniques.

INTRODUCTION: Recent studies have highlighted the role of Confocal Laser Endomicroscopy (CLE) for the characterization of colorectal lesions *in vivo*, specifically for the real time characterization of polyps and endoscopic mucosal resection (EMR) sites.
AIMS & METHODS: We sought to develop consensus recommendations for the role of CLE in the management of patients with colorectal lesions. To this end, a single CLE expert developed a series of preliminary statements on the use of CLE for the characterization of colorectal lesions based on the available clinical evidence. Twenty statements were submitted for external review by a group of 16 gastrointestinal CLE experts using a modified Delphi approach. After two rounds of votes to assess the quality of evidence and strength of recommendations based on relevant studies, statements were adopted if the threshold of agreement exceeded 75%.
RESULTS: 15 of 20 statements achieved consensus and were adopted: CLE has been shown to be highly accurate for real-time histopathological classification of colonic neoplasia *in situ*. CLE criteria can be used to accurately and reliably identify normal, hyperplastic, adenomatous (dysplastic), and cancerous mucosa; criteria for serrated neoplasia require further validation. CLE criteria characterize colonic tissue accurately both in real time during endoscopy as well as off-line. CLE can be used to define the extent of flat lesions. The combination of CLE and virtual chromoendoscopy (VCE) is highly accurate for classifying colonic polyps < 5 mm both in real time and offline and should undergo further study toward enabling a resect-and-discard approach. A diagnosis of intramucosal carcinoma and/or high-grade dysplasia by CLE alone is sufficient to trigger an appropriate therapeutic resection. CLE can be used to classify lesions and define margins for EMR/ESD. CLE has a role in resurveillance 3-12 months following EMR/ESD of advanced colonic neoplasia. Absence of residual neoplasia by CLE and VCE at 3-12 months obviates the need for re-EMR/ablation. The extent of therapy for residual neoplasia post-EMR can be guided in real time by the combination of CLE and VCE.
CONCLUSION: According to a panel of 16 gastrointestinal endoscopy experts in Confocal Laser Endomicroscopy, CLE is an important adjunct to current endoscopic practice for the management of colorectal lesions. Standardized guidelines are in development to serve as an educational resource for physicians to provide increasingly personalized, state-of-the-art care for their patients.

P0759 IMMEDIATE AND DELAYED BLEEDING AFTER ERCP: RESULTS FROM SINGLE CENTRE EXPERIENCE AT A DISTRICT GENERAL HOSPITAL IN JAPAN

H. Hisai[1,*], T. Hirako[1], Y. Ikeda[1], S. Miura[1], Y. Koshiba[1], E. Miyazaki[1]
[1]*Department of Gastroenterology, Japanese Red Cross Date General Hospital, Date, Japan*

INTRODUCTION: Bleeding following endoscopic retrograde cholangiopancreatography (ERCP) including endoscopic sphincterotomy (ES) is one of the most frequent complications, and has been reported in 1-10% of patients. Haemorrhage that cannot be controlled by conservative management needs to be controlled endoscopically, radiologically, or surgically. However, there are few reports about the incidence and the outcomes at a district hospital.

AIMS & METHODS: The aim of this study was to assess the incidence of ERCP-related haemorrhage and the clinical outcomes in the district general hospital setting. A review of all patients undergoing ERCP at our institution from April 1996 and March 2014 was performed to assess the ERCP-related haemorrhage. ERCP-related haemorrhage was classified according to the timing of bleeding. Immediate bleeding was defined as any haemorrhage during ERCP and warranting endoscopic haemostasis within the procedure following epinephrine spray. A diagnosis and severity of delayed bleeding was made according to Cotton's classification (GIE 1991).
RESULTS: Out of 6002 ERCPs, we performed ES in 975 patients, needle knife sphincterotomy (NKS) in 195 patients, NKS followed by ES in 22 patients, endoscopic papillectomy in 12 patients and endoscopic large balloon dilatation in 47 patients. No patients were taking anticoagulants at the time of ERCP. During ERCP, 48 patients (0.80%) experienced immediate bleeding. All patients underwent endoscopic haemostatic method including balloon tanponade, dilute epinephrine (1:10000), heater probe, clipping, covered metallic stent and combined hemostatic procedures. Initial haemostasis was achieved in all patients. However, delayed bleeding occurred in 3 patients (6%). By definition, delayed bleeding occurred in 26 patients (0.43%). There were 14, 5 and 7 cases of mild, moderate and severe bleeding, respectively. The time period between ERCP and haemorrhage ranged from 1 d to 14 d (median 4 d). The time to onset of delayed bleeding was not significantly different between patients with or without immediate bleeding. Seventeen out of 26 (65%) were managed endoscopically with various haemostatic methods including dilute epinephrine, heater probe, argon plasma coagulation, clipping, fibrin glue, covered metallic stent and combined procedures. Initial haemostasis was successfully attained in all patients. The re-bleeding rate was 15% (4 of 26). The treatment for the 4 patients with re-bleeding was as follows: 1 underwent 1 session, 1 underwent 2 sessions and 2 underwent 3 sessions of endoscopic combined procedures (2 patients required fibrin glue) and the bleeding was finally controlled. No patients required angiographic embolisation and surgery. No complications of the hemostatic procedure occurred in any patients. There was no bleeding-related death.
CONCLUSION: Early recognition and appropriate management of ERCP-related haemorrhage is crucial for optimal results.

INTRODUCTION: Successful biliary cannulation is an essential for therapeutic retrograde cholangiopancreatography (ERCP). In special cases of difficult cannulation due to anatomy, diverticulum, lack of space or bulky papilla other methods are needed. Various methods depending on the practices of the endoscopist have been developed to overcome difficult cannulation.
AIMS & METHODS: We report a retrospective case series of patients with difficult cannulation due to periampullary diverticulum and assess the utility and safety of cap-assisted ERCP for biliary cannulation.
From November 2013 to March 2014, inclusion criteria were: (a) documented periampullary diverticulum; and (b) use of cap-assisted ERCP as a rescue method on the first endoscopic encounter after failed attempts to perform ERCP with a standard side-viewing endoscope. Among 73 patients with periampullary diverticulum, 5 consecutive patients (6.8%) underwent therapeutic ERCP using a cap-fitted forward-viewing endoscope as a rescue method due to difficult biliary cannulation.
RESULTS: There were three men and two women, with median age of 69 years (range 53–90 years). The indications for ERCP were bile duct stones (n = 4) and common bile duct stricture (n = 1). All of the ampulla is located at 6 o'clock. The causes of difficult biliary cannulation were tangential approach in two patients and hidden papilla in three patients. A selective biliary cannulation was achieved with needle knife fistulotomy in four patients. The mean number of ERCP sessions was 1.8 per patient and the mean procedure time was thirty eight minutes. Therapeutic ERCP was successfully performed in all patients. In four patients, the therapeutic ERCP was completed with a cap-fitted forward-viewing endoscope. But in the only one patient who had a pyloric stenosis with bulbar deformity due to duodenal ulcer scar, CBD stones were successfully removed by percutaneous procedure combined with rendezvous method although we performed endoscopic balloon dilation of the stenosis. The one patient undergoing biopsy was pathologically confirmed to carcinoma of ampulla of Vater. This patient was managed previously with biliary stent insertion due to biliary stricture.
Two patients experienced complications; post-ERCP pancreatitis and hyperamylasemia. But their complications were not clinically significant and self limitied.
CONCLUSION: As a rescue method, cap-assisted ERCP is effective and safe technique in patients with difficult cannulation due to periampullary diverticulum.

P0761 SEQUENTIAL PERFORMANCE OF DOUBLE GUIDEWIRE TECHNIQUE AND TRANSPANCREATIC PRECUT SPHINCTEROTOMY IN DIFFICULT BILIARY CANNULATION

J. Park [1,*], J.H. Chang[1,2], C.W. Kim[1], S.W. Han[1]
[1]*The Catholic University of Korea, Seoul,* [2]*Internal Medicine, The Catholic University of Korea, Bucheon, Korea, Republic Of*

INTRODUCTION: Double guidewire technique (DTG) and transpancreatic precut sphincterotomy (TPS) are alternative techniques in failed standard biliary cannulation during endoscopic retrograde cholangiopancreatography (ERCP) when a guidewire proceeds into the pancreatic duct. However, the sequential performance of TPS after DTG has not been evaluated.
AIMS & METHODS: We aimed to investigate the usefulness and complications of seqeuntial DTG-TPS in comparison with needle knife precut (NK). We consecutively enrolled 612 patients with naïve papilla undergoing ERCP for biliary cannulation between March 2010 and April 2014. In cases of unsuccessful standard technique, DTG or NK was performed according to the guidewire passage through the pancreatic duct. TPS was sequentially performed when DTG had failed. Patients' demographics, laboratory, and procedure-related data were analyzed retrospectively.
RESULTS: During 612 ERCPs, DTG and NK was attempted in 67 and 58 patients, respectively. Sequential DTG-TPS were performed in 38 patients. Successful biliary cannulation was performed in 42%, 74%, and 66% of the DTG, TPS, and NK group, respectively ($P = 0.002$). The cannulation rate was higher in the sequential DTG-TPS group (85%) than in the NK group ($P = 0.014$). Post-ERCP pancreatitis (PEP) occurred in 37% of the sequential DTG-TPS group and in 10% of the NK group ($P = 0.002$). In the sequential DTG-TPS group, PEP developed in 24% patients with pancreatic duct (PD) stent, but in 62% patients without PD stent ($P = 0.023$). Among them, one patient without PD stent expired due to severe pancreatitis.
CONCLUSION: The sequential DTG-TPS is a useful alternative technique for biliary cannulation compared with NK in patients who have failed standard technique. Their rate of PEP was higher than that in the NK group, but PD stent had a protective role over PEP.

INTRODUCTION: Patients suspected of having choledocholithiasis are diagnosed with a combination of laboratory tests and/or imaging studies. The American Society for Gastrointestinal Endoscopy (ASGE) proposes a stratification of patients according to the risk for choledocholithiasis, influencing subsequent management.
AIMS & METHODS: The aim of this study was to assess the practical applicability and to validate the current ASGE guidelines in our population. This was a retrospective single center study, covering a 4-year period, from January 2010 to December 2013. All patients who underwent endoscopic retrograde cholangiopancreatography (ERCP) for suspected choledocholithiasis were included. Based on the presence or absence of predictors of choledocholithiasis (clinical ascending cholangitis, common bile duct (CBD) stones on ultrasonography (US), total bilirubin >4mg/dL, dilated CBD on US, total bilirubin 1,8-4mg/dL, abnormal liver function test, age >55 years and gallstone pancreatitis), patients were stratified in low, intermediate or high risk for choledocholithiasis. For each predictor and risk group we used the Chi-square to evaluate the statistical associations with the presence of choledocolithiasis at ERCP. Statistical analysis was performed using SPSS version 21.0. A p value of less than 0.05 was considered statistically significant.
RESULTS: A total of 268 ERCPs were performed for suspected choledocholithiasis. Except for gallstone pancreatitis ($p = 0.063$), all other predictors of choledocholitiasis (clinical ascending cholangitis, $p = 0.001$; CBD stones on US, $p < 0.001$; total bilirubin >4mg/dL, $p = 0.035$; total bilirubin 1,8-4mg/dL, $p = 0.001$; dilated CBD on US, $p < 0.001$; abnormal liver function test, $p = 0.012$; age >55 years, $p = 0.002$) showed a statistically significant association with the presence of choledocholithiasis at ERCP. Approximately four fifths of patients in the high risk group (79.8%, 154/193) had confirmed choledocholithiasis on ERCP, versus 34.2% (25/73) and 0 (0/2) in the intermediate and low risk groups, respectively. The definition of "high risk group" had a sensitivity of 86%, positive predictive value 79,8% and specificity 56.2% for the presence of choledocholithiasis at ERCP.
CONCLUSION: The use of clinical, analytical and imaging predictors, as well as risk stratification according to ASGE guidelines, may improve risk estimation of choledocholithiasis and should be considered to optimize patients' selection for ERCP. However, even in the "high risk group" the specificity was low (56.2%), meaning that a significant proportion of patients (20%) will still perform ERCP unnecessarily. Thus, at this point, it seems advisable that also "high risk" patients undergo further testing before being submitted to ERCP, similarly to those patients with "intermediate risk", while for patients with "low-risk" of choledocholithiasis a watchful waiting strategy seems adequate.

INTRODUCTION: Acute pancreatitis is the most common and the most fearful complication of endoscopic retrograde cholangiopancreatography (ERCP). A recently published meta-analysis reported that a single dose of indomethacin or diclofenac (100 mg) administred rectally before or immediately after ERCP decreases the incidence of post ERCP pancreatitis (PEP).
AIMS & METHODS: A retrospective single-center non randomized study was conducted with 304 patients who underwent a primary ERCP. Patients were divided into 2 groups. The patients in the first group had a single dose of ketoprofen 100mg administred rectally immediately after ERCP. The 2nd group was a control group.
The aim of this study was to determine whether prophylactic rectal ketoprofen will reduce the incidence of PEP and to determine the risk factors of this complication.
RESULTS: Three hundred and four patients (M/F = 197/107, Mean age = 62.4 y.o) were included. 107 patients (35.2%) were in the first group. The groups were similar with regard to patient demographics and to patient and procedure risk factors for PEP. The overall incidence of PEP was 6.9%: 4.6% (5/107) in the group 1 versus 8.1% (16/197) in the placebo group (p = 0.34, IC = 95%). The pancreatitis was graded as severe in 33% of the patients. There was no significant difference between the groups in the frequency or severity of PEP. Two risk factors were associated with a higher incidence of PEP:a difficult cannulation of the common bile duct (52.4 vs 16%, p = 0.0004. IC = 95%) and contrast injection into the pancreatic duct (47.62 vs 24.38 %, p = 0.008, IC = 95%).
CONCLUSION: Prophylactic rectally administered ketoprofen (100mg) did not affect the frequency or severity of PEP. Prospective randomized studies with a higher number of patients are needed.

INTRODUCTION: Pancreatic ductal fusion occurs in the early weeks of gestation. It has been suggested the possible association between pancreatic ductal morphology and the incidence of post-ERCP pancreatitis.
AIMS & METHODS: Our aim was to evaluate the possible association between abnormal fusion of the pancreatic duct and the development of post- ERCP pancreatitis. We reviewed the pancreatic ERCPs (PERCP) performed in our center from June 2009 to June 2013. The wirsungrafies were blindly reviewed by one ERCPist who classified the pancreatic ductal fusion unaware of the identity and evolution of patients after PERCP. The ductal fusion was classified into four groups: Normal (Group I), when the dorsal duct joined the upper branch of the ventral duct and Santorini duct; Ansa Pancreatica (Group II), when the dorsal duct was fused to the upper branch of the ventral duct but the Santorini duct was fused to the lower branch of the ventral duct; Pancreatic Loop (Group III), when the dorsal duct was fused to the lower branch of the ventral duct; and Pancreas Divisum (Group IV), when there was no fusion between dorsal and ventral duct. Incomplete wirsungrafies which could not be classified in either group were considered indeterminate and not analyzed. Groups II, III and IV were considered together as Fusion Anomalies Group (FA). We compared the incidence of post-ERCP pancreatitis in each of the groups with respect to the rest and the AF group with Group I.
RESULTS: We performed 134 PERCPs in 68 patients during the inclusion period. We were able to determine with certainty the type of ductal fusion in 56 patients (40 men). Twenty-seven patients suffered a previous acute pancreatitis bout and 28 had chronic pancreatitis. Women had significantly more FA (69 % vs 37 %, p = 0.04). Thirty patients were included in Group I; 10 in Group II; 3 in Group III and 13 in Group IV. Thus, 26 patients were included in FA Group. Complications occurred in 8 patients (14 %), pancreatitis in 5 of them (8.9%). Only Group III was significantly associated with a higher rate of post-ERCP pancreatitis (67%vs11.3%,p = 0.019). The incidence of post-ERCP pancreatitis in Group II and IV was 10 % and 15.4 % respectively. FA Group showed a significantly higher incidence of post-ERCP pancreatitis compared with Group I (19.2%vs0%,p = 0.017) and this comparison remained significant after adjusting for sex (p = 0.017). Variables such previous acute or chronic pancreatitis, sex and placement of pancreatic stent did not influenced post-ERCP pancreatitis incidence (p > 0.05).
CONCLUSION: Pancreatic ductal fusion anomalies are a risk factor for development of post-ERCP pancreatitis. This association should be confirmed by means of prospective comparative studies.

INTRODUCTION: Duodenal perforation in the periampullary region due to sphincterotomy (Type II) is a rare post - ERCP complication with significant mortality. The aim of this study was to determine the incidence of retroperitoneal duodenal perforations after periampullary interventions, management options, and clinical outcome.
AIMS & METHODS: All cases of retroperitoneal duodenal perforation (Type II) after ERCP during a ten year period (1/2004 - 12/2013) in our Department were retrospectively reviewed. All patients were initially treated with broad-spectrum antibiotics, nasogastric aspiration and parental nutrition and/or CT-guided drainage when needed.
RESULTS: A total of 19 patients with retroperitoneal duodenal perforation (Type II) after 3428 ERCPs (0.55%) were managed. Indications for performing a periampullary procedure were known or suspected choledocholithiasis in 15 (79%) and biliary stricture in 4 patients. Diagnosis was made during the first 12h, (during the procedure in 3 cases). Radiological drainage was performed in 7 patients (36%) and were successful in all patients except one who eventually required surgery. Surgical intervention was required in 4 patients (21%). Total parental nutrition was given to 4 patients (21%). Three patients died (two post - postoperatively) giving an overall mortality of 15.8%.
CONCLUSION: Retroperitoneal duodenal perforation (Type II) is a rare complication after ERCP with high morbidity and mortality but aggressive conservative management seems effective for the majority of cases.

INTRODUCTION: Endoscopic sphincterotomy (EST) is currently recognized as the main treatment for choledocholithiasis. However, the treatment of large common bile duct stones (≥15 mm in diameter) or multiple common bile duct stones (3 or more stones) by EST alone is difficult, and a new therapeutic procedure to supplant EST is needed. Sporadic reports have shown the usefulness of endoscopic papillary large balloon dilation (EPLBD) in the treatment of common bile duct stones, and this technique is anticipated to replace use of EST alone. This study aimed to comparatively assess the therapeutic outcomes and short-term complications of EST versus EPLBD in cases of biliary tract stones ≥15 mm in diameter or multiple (3 or more) stones presumed to be rather refractory to EST alone.
AIMS & METHODS: Data from 70 cases of choledocholithiasis (≥15 mm in diameter or ≥3 stones) that were treated (EPLBD, n = 34; EST, n = 36) in our department between April 2010 and March 2013 were comparatively reviewed and analysed with respect to stone removal success rate, success rate of complete stone removal in 1st session, procedure time, concomitant mechanical lithotripsy (ML) application status, and short-term complications. Stone size and number were checked by endoscopic cholangiography, and the patients treated using EPLBD underwent EST before balloon dilation. EPLBD was performed using 12–18-mm-diameter balloons, and stone collection was performed using a Dormia basket or retrieval balloon. ML was added to the procedure in case of difficulty in expelling the stones.
RESULTS: The stone removal success rate was comparable between groups (EPLBD 100% vs. EST 89%, $p = 0.115$). The EPLBD group exhibited a significantly higher success rate of a complete stone removal in 1st session (EPLBD 88% vs. EST 56%, $p = 0.03$). Further, the procedure time was significantly shorter for the EPLBD group (EPLBD 42 min vs. EST 67 min, $p = 0.011$), and the concomitant ML application rate was significantly lower for the EPLBD group (EPLBD 50% vs. EST 94%, $p < 0.001$). Short-term complication included pancreatitis in 2 patients and haemorrhage in 1 patient of the EPLBD group and pancreatitis in 8 patients and haemorrhage in 2 patients of the EST group (EPLBD 9% vs. EST 25%, $p = 0.112$), but there was no statistically significant intergroup difference.

CONCLUSION: We successfully treated large moulded (≥15-mm diameter) stone or multiple stone choledocholithiasis by EPLBD with fewer sessions and a shorter procedure time compared to EST alone. Our findings suggest the usefulness of EPLBD for difficult cases. However, it is necessary to accumulate further experience of cases and examine long-term complications.

INTRODUCTION: Cholestasis and cholangitis are among the most common and life-threatening complications of Alveolar Echinococcosis (AE) of the liver, because of the liver invasion by the metacestode associated with extensive fibro-inflammatory host reaction. Biliary complications of AE are usually treated by surgery or radiological percutaneous biliary drainage. During the last decade the indication of per-endoscopic biliary drainage following endoscopic retrograde cholangio-pancreatography (ERCP) has markedly increased in various benign or malignant biliary tree obstructions, because of its less invasive nature and better outcome. AE is an emerging indication in this field; only little is known about its efficacy and safety.
AIMS & METHODS: Our aim was to collect and analyse the European experience in per-endoscopic management of AE biliary complications. All European physicians practicing ERCP and/or in charge of AE patients were recruited directly or through various professional/scientific associations to participate in the retrospective survey. Data were collected from May, 2013 to January, 2014. Physicians were asked to report any AE case with ERCP. Data on patients' and disease characteristics, endoscopic techniques and follow-up filled-out through an online questionnaire were analysed. Ethical Committee of Franche-Comté Hospitals approved this study.
RESULTS: Between 1986 and 2014, 12 centres performed ERCP for AE in Europe. Detailed data available for 23 patients (18 men and 5 women) in 8 centres were analysed. Sixty-one ERCP were performed (median: 2 {1-9} ERCP per patient). Patients were 55-years-old at the time of AE diagnosis and 60-years-old at the time of the first ERCP. Indications for ERCP were: biliary pain, 14 (23%), cholangitis, 24 (39%), jaundice or chronic cholestasis, 22 (36%). Seventy-four plastic stents and 7 fully (5) or partially (2) covered self expandable metallic stents (SEMS) were placed in the biliary tree. The average time between two stenting procedures was 19.5 weeks (1-98). Two patients needed surgical intervention or radiological drainage because of endoscopic treatment failure. There were 11 adverse events (18%): 1 perforation, 1 hepatic collection, 4 acute pancreatitis, and 5 cholangitis. Resolution of cholestasis was obtained in 42/44 therapeutic ERCP (95.4 %). Biliary duct calibration was obtained by stent placement in 8 patients after an average of 2 procedures; definitive stent removal was possible after a median time of 45 weeks of treatment. Among them, recurrence of stenosis led to a new stent placement 4 years later in 1 patient and gallstones extraction in 2 patients.
CONCLUSION: Endoscopic retrograde drainage is efficient in AE with biliary obstruction. ERCP and stenting, which are less invasive than surgery and avoid long-term external drainage, may be proposed as a valid alternative to radiological and surgical drainage. Several procedures with stenting are usually needed to ensure long-term efficacy and using of antibiotics are necessary during and after the ERCP.

INTRODUCTION: Aspiration pneumonia is the one of complications of various Endoscopic procedures. But there have been few reports of that complication after Endoscopic retrograde cholangiopancreatography (ERCP).
AIMS & METHODS: The aim of this study is to identify the rate and risk factors for aspiration pneumonia after ERCP.
978 consecutive patients who underwent ERCP between January 2011 and December 2013 were included. The cumulative rate and potential risk factors for aspiration pneumonia, such as patient attributes (Age, sex, underlying conditions, and medication) and ERCP procedures were retrospectively investigated.
RESULTS: Of the 978 patients 673 patients were male (68.8%). The median age was 71.4 years (29-99y.o). 55 patients (5.62%) were diagnosed with aspiration pneumonia after ERCP. Age over 75years (OR:5.11 P < 0.0001), a procedure time of >30min (OR2.31 P < 0.0059), the infusion of naloxone (OR :3.68 p = 0.0151), history of heart disease (OR: 2.24 p = 0.0083), eGFR < 30 (OR :5.45 P < 0.001), hemodialysis (OR :5.95 P < 0.0001), cancer-bearing (OR :1.96 p = 0.03), diabetes (OR :2.08 p = 0.0213), history of cerebral infarction (OR:3.68 P < 0.0001) and serum Alb < 3.5mg/dl (OR:5.76 P < 0.0001)were identified as the risk factors for the pneumonia by the univariate analysis. Multivariate analysis showed age over 75years (OR:3.26 p = 0.0018), a procedure time of >30min (OR:2.55 p = 0.0062), history of cerebral infarction (OR:3.06 p = 0.0063), serum Alb < 3.5mg/dl (OR:3.11 p = 0.00016)and hemodialysis (OR:2.59 p = 0.048)were revealed to be the significant risk factors for aspiration pneumonia after ERCP.
CONCLUSION: Age over 75years, a procedure time of >30min, history of cerebral infarction, serum Alb < 3.5mg/dl and hemodialysis are the independent risk factor for the aspiration pneumonia after ERCP. Careful attention should be taken when managing patients with these attributes.

P0769 EVALUATION FOR ERCP USING A BALLOON ASSISTED ENDOSCOPY IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY: COMPARISON OF A SHORT TYPE DOUBLE BALLOON ENDOSCOPE AND A NEWLY DEVELOPED SHORT TYPE SINGLE BALLOON ENDOSCOPE

M. Shimatani[1,*], M. Takaoka[1], T. Mitsuyama[1], H. Miyoshi[1], T. Ikeura[1], K. Okazaki[1]
[1]*The Third Department of Internal Medicine, Kansai Medical University, Hirakata, Japan*

INTRODUCTION: The advent of the short type double balloon endoscope (s-DBE) and the short type single balloon endoscope (s-SBE) radically made the endoscopic approaches feasible for pancreatobiliary diseases in patients with altered gastrointestinal anatomy, which had been considered unpractical. Recently many papers are published to report the efficacy of using these techniques, however, there are so far few studies regarding the comparison of s-DBE and s-SBE.
AIMS & METHODS: This present study aimed to evaluate the usefulness of a newly developed s-SBE for therapeutic ERCP in patients with gastrointestinal anatomy, and also to make a comparative assessment of the respective features and the distinctions of s-DBE and s-SBE. From March 2013 to November 2013, ERCP using a s-SBE (s-SB-ERCP) was performed in 26 postoperative patients who had a reconstructed intestine in our hospital. We retrospectively evaluated the success rate of reaching the blind end, the mean time required to reach the blind end, the diagnostic success rate, the therapeutic success rate, the mean procedure time, and complications. Among 26 patients, the s-SB- ERCP was applied to those 18 patients who previously had undergone s-DB-ERCP and required the recurrent procedure. It allowed us the unique comparison of the s-DBE and the s-SBE in the same patients analyzing the data of the mean time required to reach the blind end and the mean procedure time.
RESULTS: The success rate of reaching the blind end was 92.3% (24/26 patients). As for 2 patients in whom s-SBE failed to reach the blind end, the procedure was successfully accomplished after switching the scope to s-DBE. The mean time required to reach the blind end was 28.6 min. (range, 5–58 min). The diagnostic success rate was 91.7% (22/24 patients). Regarding 2 patients in whom cholangiography failed using s-SBE, they were the cases with Roux-en-Y gastrectomy and with naïve papilla. Switching the scope to s-DBE, the procedure was successfully accomplished subsequently in both cases. Therapeutic success rate was 100% (24/24 patients). Complication occurred in 1 patient (3.8%; 1/26 patients). Regarding the 18 patients who had previously undergone s-DB-ERCP, s-SB-ERCP was successfully completed in 17 patients. The mean required time of s-SBE to reach the blind end was 24.7 min. (range, 7-50 min.), whereas that of s-DBE was 13.5 min. (range, 3-31 min.). The mean procedure time of s-SB-ERCP was 52.3 min. (range, 16-107min.), whereas that of s-DB-ERCP was 70.4min. (range, 21-168min.).
CONCLUSION: ERCP using a newly developed s-SBE for patients with gastrointestinal anatomy is safe and effective. In comparison with s-DBE, for the present, we conclude that a newly developed s-SBE is advantageous in the point of efficiency of performing ERCP-related interventions.

P0770 IMPACT OF PREOPERATIVE ENDOSCOPIC BILIARY DRAINAGE ON POSTOPERATIVE COMPLICATIONS AFTER PANCREATICODUODENOSTOMY FOR PERIAMPULLARY CANCER

M. Chiba[1,*], H. Imazu[1], K. Kanazawa[1], N. Mori[1], H. Toyoizumi[1], N. Shimamoto[1], H. Tajiri[2]

INTRODUCTION: The clinical impact of preoperative endoscopic biliary drainage (P-EBD) on the outcome after pancreaticoduodenostomy (PD) for periampullary cancer with obstructive jaundice is not well known.
AIMS & METHODS: The present study was aimed to investigate whether P-EBD was associated with increased morbidity after PD in patients with periampullary cancer. Patients with periampullary cancer, including pancreatic carcinoma, cholangiocarcinoma, and ampullary cancer, who underwent PD from October 2003 to September 2013 were analyzed retrospectively. At our institution, P-EBD was routinely performed with a 7 Fr or 8.5 Fr plastic stent. In addition, endoscopic nasobiliary drainage (ENBD) or switching to a larger caliber stent was done if biliary drainage was insufficient after P-EBD.
RESULTS: One hundred and sixty-seven patients who underwent PD (85 with pancreatic carcinoma, 47 with cholangiocarcinoma, and 35 with ampullary carcinoma) were analyzed. 98 patients received P-EBD before PD and their mean bilirubin level before P-EBD was 7.78 mg/dl. The other 69 patients underwent

PD without preoperative biliary drainage and their mean bilirubin level before PD was 1.59 mg/dl. Complications of P-EBD occurred in 34 patients (mild post-ERCP pancreatitis in 10, minor bile duct perforation by the guidewire in 1, stent occlusion in 7, and insufficient biliary drainage in 16). There was no significant difference in the time from the diagnosis of periampullary cancer until PD between the patients with and without complications of P-EBD. Multivariate regression analysis was performed to clarify the influence of P-EBD on post-operative complications, including pancreatic fistula. This analysis showed that cholangiocarcinoma and ampullary carcinoma, but not pancreatic carcinoma, were independent risk factors for postoperative complications ($p = 0.002$, $OR = 4.9$), while P-EBD had no influence on postoperative complications. Insufficient biliary drainage was also associated with postoperative complications, but not significantly ($p = 0.06$, $OR = 4.1$).
CONCLUSION: P-EBD was not associated with a higher incidence of post-operative complications. However, insufficient biliary drainage after P-EBD was associated with postoperative complications, so the development of more effective P-EBD might be useful to prevent such complications. The present findings showed that P-EBD is a safe and effective procedure for distal malignant biliary stricture due to periampullary cancer.

P0771 TECHNICAL SUCCESS WITH WIRE-GUIDED CANNULATION FOR CHOLANGIOGRAPHY USING EARLY PANCREATIC GUIDE WIRE PLACEMENT WITHOUT PRECUT SPHINCTEROTOMY

M. Murata[1,*], O. Inatomi[1], H. Hasegawa[1], H. Ban[1], M. Shioya[1], S. Bamba[1], A. Andoh[1]
[1]*Division of Gastroenterology, SHIGA UNIVERSITY OF MEDICAL SCIENCE, Otsu, Japan*

INTRODUCTION: Wire-guided cannulation (WGC) and pancreatic guidewire (P-GW) placement may increase the success rate of deep cannulation of the common bile duct (CBD) and reduce the risk of complications compared with contrast-assisted cannulation (CC); however, the data is still unclear. Previous studies have suggested that repeated and unintentional injections or P-GW insertions may cause post-ERCP pancreatitis due to mechanical trauma or an increase in the hydrostatic pressure of the main pancreatic duct. Therefore, we compared the effect of early P-GW placement on the success of deep cannulations and the risk of post-ERCP pancreatitis with the outcomes of WGC or CC procedures.
AIMS & METHODS: We retrospectively assessed 143 patients who required ERCP because of known or suspected biliary duct disease; we excluded patients who had previously undergone endoscopic manipulations. Early P-GW placement was defined as placing a guidewire after one or two attempts into the main pancreatic duct without accomplishing cannulation of CBD. We performed ERCP with CC as the initial option for CBD cannulation in the early period and utilized WGC during the late period. The success rate of bile duct cannulation, the frequency and risk of post-ERCP pancreatitis and the frequency of requiring a pre-cut sphincterotomy were evaluated.
RESULTS: Conventional cannulation was attempted in 47 patients and WGC in 80 patients. The success rate of CBD cannulation was 96.0% in all cases, with 91.4% in the CC group and 97.5% in the WGC group. The frequency of early P-GW placement was 20.4% in all cases, with 10.9% in the CC group and 27.5% in the WGC group. Pre-cut sphincterotomy was performed in only one patient in the CC group. The frequency of post-ERCP pancreatitis was 7.6% in all cases and was 9.2% in the CC group and 7.9% in the WGC group. There were no significant differences among the groups with regard to each cannulation, the surgeon, actual pancreatic guide wire placement and IDUS.
CONCLUSION: Early P-GW placement can lead to a high success rate for CBD cannulation without the use of pre-cut sphincterotomy, and it does not increase the incidence of post-ERCP pancreatitis. In addition, WGC may be more suitable for early P-GW placement when compared with CC. WGC with early P-GW placement may be an ideal option for CBD cannulation in difficult cases and may involve a low rate of pre-cut sphincterotomy.

P0772 DOWNSTREAM REVENUE GENERATED BY PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY (PCLE) IN UNDETERMINED PANCREATICO-BILIARY LESIONS

S. Bharmal[1], R. Sharaiha[1], P. Kedia[1], N. Kumta[1], H. Umrania[1], M. Gaidhane[1], **M. Kahaleh**[1,*]
[1]*Gastroenterology & Hepatology, Weill Cornell Medical College, New York, United States*
Contact E-mail Address: *mkahaleh@gmail.com*

INTRODUCTION: Probe-based Confocal Laser Endomicroscopy (pCLE) increases diagnostic accuracy via targeted biopsies and greatly impacts management decisions, with accuracy rates above 80%. The improved diagnostic capability of pCLE may result in high post-procedure health resource utilization with increases in subsequent surgical and interventional procedures. Our aim was to examine downstream revenue and profit generated from surgical and interventional radiology procedures after pCLE.
AIMS & METHODS: A retrospective chart review was performed in a tertiary care institution. We identified patients who underwent diagnostic pCLE between August 2011 and December 2012 for indeterminate pancreaticobiliary lesions. Revenue data was generated using AllScripts EPSi and billing information to generate financial estimates.
RESULTS: 67 patients underwent diagnostic pCLE for indeterminate pancreaticobiliary lesions during the study period. Of these, 12 (18%) patients had subsequent procedures related to their diagnosis. Diagnoses included adenocarcinoma ($n = 8$), intraductal papillary mucinous neoplasm ($n = 1$) and benign disease ($n = 3$). Major post pCLE procedures included pancreaticoduodenectomy ($n = 4$), exploratory laparotomy ($n = 2$) and orthotopic liver transplant ($n = 1$). Average revenue generated from procedures was 100,512 dollars while the average net profit was 25,592 dollars per person.
CONCLUSION: For indeterminate pancreaticobiliary lesions, PCLE has major economic implications. Profit generated from surgical and interventional radiology procedures after pCLE is significant and negates the cost of the procedure itself. A large scale study examining the downstream financial impact of pCLE in otherpathologic settings may be useful for further analysis.

INTRODUCTION: To analyze the safety and clinical effectiveness of EUS guided drainage of peri-pancreatic collections (PPCs) using a fully covered self-expanding stent incorporated in an electrocautery enhanced delivery system, the Hot-AXIOS system (Xlumena Inc. Mountain View, Ca, USA).
AIMS & METHODS: Retrospective analysis of consecutive patients with PPCs who underwent EUS guided drainage using the Hot-AXIOS system in 12 European Endoscopy Centers.
RESULTS: From March 2013 to April 2014, 72 patients (median age 60 yrs; 55 male) with PPCs underwent drainage using the Hot AXIOS system. Median diameter of PPCs was 100 mm (range 38-246). 18 were pseudocysts, 35 WOPN, 15 abscesses, and 4 were acute PPCs. 41/72 PPCs were infected. In 57/72 cases (79%) the Hot-AXIOS system was used to enter the PPCs, while in the remaining 15 cases (21%) a 19G needle was utilized. The main approach was transgastric (68/72), and all were technically successful with all but one procedure described as easy to be performed. Early complications were mild fever in 2 cases and self-limiting bleeding in 2 other cases. Late complications were: Infection (1); self-limiting pneumoperitoneum (1); perforation (1); massive bleeding (1). Both last two complications were related to the naso-cystic drainage placement. 3 out of these 4 patients required surgery. Direct necrosectomy was performed in 29 cases. Overall, resolution of PPCs was achieved in 69/72 cases (95.8%). Stent removal was done after a median of 61 days. Recurrence was seen in only two of 69 cases (2.9%), one of which was treated with repeat EUS-guided drainage while the other did not require treatment. At the end of follow up 69 patients are alive and asymptomatic. Complications of the PPCs was the cause of the death in two out of the three patients who died.
CONCLUSION: EUS guided drainage with the Hot AXIOS system is a safe, easy to use, and highly effective minimally invasive treatment modality for peri-pancreatic collections.

INTRODUCTION: Endoanal ultrasonography shows good accuracy in definition of the anatomy of perianal fistulae, including those associated with Crohn's disease (CD). Several studies have been proposed ultrasonographic features to discriminate anal fistulae associated with CD in relation to cryptoglandular fistulae.
AIMS & METHODS: Our aim was to evaluate several ultrasonographic features that may distinguish these two types of fistulae.
Retrospective study including fifty-eight patients who underwent endoanal ultrasonography 2D between 2008 and 2013. The perianal fistulae variables studied were the complexity, transversal diameter, presence of secondary tracks and fistulous debris. For patients with CD was also calculated the adapted perianal disease activity index (PDAI excluding the influence in sexual activity).
Statistical analysis was performed using the SPSS program vs20.0 and a p value of less than 0.05 was considered statistically significant.
RESULTS: Fifty-eight patients were included, 48% with CD with a mean PDAI of 7.6 ± 3.2. In CD patients a higher PDAI was statistically associated to more

complex fistulae (8.5 vs 5.5, p = 0.028). 38% of all patients had been previously submitted to a surgery intervention for fistula resolution. The ultrasonographic features that correlated with the presence of fistulae associated with CD were the complexity (OR:5; IC95% 1.6-15.3; p = 0.004), the presence of secondary tracks (OR:3.2; IC95% 1.1-9.5; p = 0.036) and the presence of fistulous debris (OR:5.9; IC95% 1.6-15.3; p = 0.002). There was no statistical difference between cryptoglandular fistulae and fistulae associated with CD with respect to dimensions (4.1mm vs 4.9mm, p = 0.24).
CONCLUSION: In our study, the complexity of the perianal fistulae and also the presence of secondary tracks and debris revealed to be strong predictors of Crohńs related perianal fistulae.

P0776 NOVEL COMPUTER-AIDED QUANTITATIVE ANALYSIS OF THE DISTRIBUTION OF CONTRAST IN CONTRAST-ENHANCED EUS FOR DIFFERENTIAL DIAGNOSIS OF PANCREATIC TUMORS

H. Imazu[1,*], T. Kato[1], M. Chiba[1], S. Koyama[1], T.L. Ang[2], H. Tajiri[3]
[1]*Department of Endoscopy, THE JIKEI UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan,* [2]*Department of Gastroenterology and Hepatology, Changi General Hospital, Singapore, Singapore,* [3]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, THE JIKEI UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan*
Contact E-mail Address: *himazu21@aol.com*

INTRODUCTION: Differentiating between pancreatic carcinoma (PC) and chronic pancreatitis (CP) with pseudotumor is still challenging, even with contrast-enhanced EUS (CE-EUS) or EUS-FNA. We developed the novel computer-aided diagnostic software (Madara, Inspeedia Inc., Kariya, Japan) to quantify the pattern of contrast distribution in CE-EUS.
AIMS & METHODS: The aim of this study was to evaluate the utility of CE-EUS with Madara for differential diagnosis of PC and CP with pseudotumor. Consecutive patients who had PC or CP with pseudotumor and underwent CE-EUS from January 2011 to December 2013 were retrospectively analyzed. A curvilinear echoendoscope (GF-UCT260), Aloka Prosound α10 processor and intravenous administration of 0.015ml/kg of Sonazoid were used for CE-EUS. Using our software, a region of interest (ROI) which divided into 100 cells was placed to cover an area within pancreatic mass. Differences of grade of gray scale levels between the adjoining cells within the ROI were detected, and the number of adjoining cells which showed a difference of the gray scale level was automatically calculated in each frame rate of CE-EUS (heterogeneity index). A heterogeneity index curve was also automatically generated to depict the changes of the heterogeneity index over time, and the mean heterogeneity index from start to one minute after injection of Sonazoid was calculated. Moreover, using a conventional software to quantify the degree of enhancement, in which ''time intensity curve (TIC: Hitachi/Aloka Co., Ltd., Tokyo, Japan)'' was generated to depict the changes in the signal intensity, maximum intensity gain (MIG: peak intensity – base intensity) was also calculated. The final diagnosis of PC was based on the results of surgery or EUS-FNA, while CP was diagnosed from EUS-FNA, the clinical course and other imaging tests.
RESULTS: Fifty-nine patients (39 with PC and 20 with CP) were analyzed. The heterogeneity index curve showed ''bell and flat curve type'' in 9 patients with CP, ''irregular curve type'' in 11 patients with CP and 37 with PC, and ''flat curve type'' in 2 with PC. Thus, ''bell and flat curve type'' was specific to CP, while ''flat curve type'' were specific to PC. The mean heterogeneity index in PC patients was significantly higher than CP patients (15.6 vs. 6.1, p < 0.0001). Flat curve type of heterogeneity index curve and the mean value of heterogeneity index showed sensitivity of 92.3% and specificity of 90% for differentiating between PC and CP with pseudotumor. On the other hand, MIG in CP patients was significantly higher than PC patients (21.1 vs. 15.7, p = 0.01), and showed sensitivity of 71.8% and specificity of 65%. Combined assessment of heterogeneity index curve and MIG with time intensity curve, using the cut-off value of heterogeneity index of 10.3 and MIG of 14.3, yielded sensitivity of 94.3% and specificity of 95% to differentiate between PC and CP with pseudotumor.
CONCLUSION: CE-EUS with ''Madara'' diagnostic software to quantify the pattern of contrast distribution might be useful for making a differential diagnosis between PC and CP with pseudotumor.

P0777 TRANSMURAL STENT PLACEMENT AS THE DOMINANT STRATEGY FOR ENDOSCOPIC ULTRASOUND-GUIDED BILIARY DRAINAGE

I. Peñas Herrero[1,*], N. Alcaide[1], R. Sanchez-Ocaña[1], P. Gil-Simon[1], C. De la Serna-Higuera[1], M. Perez-Miranda[1]
[1]*Gastroenterology, Hospital Universitario Río Hortega, Valladolid, Spain*
Contact E-mail Address: *mpmiranda5@hotmail.com*

INTRODUCTION: There are several ways to perform endoscopic ultrasound-guided biliary drainage (EUSBD): transductal (rendezvous [RV] and direct antegrade [DAG] options) or transmural (intrahepatic [hepaticogastrostomy, HGS] and extrahepatic [choledochoduodenostomy, CDS] options). Best approach remains contentious, while patient selection and case-volume confound evidence from limited available comparative data.
AIMS & METHODS: To identify current dominant strategy for EUSBD at high-volume Unit. Data from 44 patients (male 25, mean age [SD] 75 [13], malignant/benign 77% / 33%) undergoing EUSBD from Jan-Dec 2012 at single Unit were prospectively captured. Standardized techniques (single-puncture following comprehensive target choice, minimal needle-guidewire interplay, graded-dilation with salvage-only 6.5F cystotome use) and algorithms for access (intrahepatic for hilar strictures and/or altered GI anatomy; extrahepatic for the opposite when stable scope) and drainage (transductal if early guidewire passage or if failed cannulation of native papilla in benign obstruction, transmural if otherwise) were used. Caliber of access duct was 9.1 mm (IQR 6.3-15.6) for extrahepatic (27%) and 5.5 mm (IQR 4.0-7.9) for intrahepatic access (73%). Number of ERCP/PTBD over study period was 1048/5 (EUSBD = 4.2% of ERCP; PTBD = 11% of EUSBD). Clinical success was defined as bilirubin < 80% baseline values, symptom disappearance and hospital discharge. Adverse events as per consensus. Follow-up through chart review and phone contact.
RESULTS: Technical success was achieved in 43 patients (97.7%) and clinical success in 70%. There were adverse events in 6 patients (13.6%): 5 mild (3 mild bleedings, 1 acute pancreatitis, 1 hypoxemia) and 1 fatal case of cholecystitis. Transductal EUSBD was performed in 11 patients (7 DAG and 4 RV techniques), and transmural EUSBD in 36 (26 HGS/hepaticojejunostomy and 10 CDS/choledocogastrostomy, including dual DAG-HGS in 4). Fully covered metal stents were used in 90.6% for transmural EUS-guided biliary drainage (22 Hanaro stent, 7 Wallflex stents). A variety of stent-anchorage techniques were employed in 65% of these patients (hemoclips, flaps, double pig-tails, balloon expansion or more than one anchorage technique). Accurate follow-up was obtained in 35 patients. After a mean of 146 days (SD 141), 5 dysfunctions occurred (2 patients with plastic stents [1 migration, 1 occlusion], 3 with metal stents [2 angulation, 1 late migration]).
CONCLUSION: After a decade-long usage, the dominant strategy for EUSBD was transmural fully covered metal stents with ancillary anchorage. No short-term migration, minimal late dysfunction and comparable adverse event rate to purported less invasive RV were found. Intriguing higher rate of intrahepatic Vs extrahepatic possibly explained by patient selection/PTBD use patterns warrants clarification.

P0779 FACTORS ASSOCIATED WITH THE ACCURACY OF EUS-GUIDED FINE NEEDLE ASPIRATION FOR THE DIAGNOSIS OF SOLID PANCREATIC MASSES

J. Iglesias-García[1,*], D.de la Iglesia-García[1], N. Vallejo-Senra[1], J. Lariño-Noia[1], I. Abdulkader[2], L. Uribarri-González[1], J.E. Dominguez-Muñoz[1]
[1]*Gastroenterology, University Hospital of Santiago de Compostela. Foundation for Research in Digestive Diseases,* [2]*Pathology, University Hospital of Santiago de Compostela, Santiago de Compostela, Spain*

INTRODUCTION: Endoscopic ultrasound (EUS)-guided fine needle aspiration (FNA) and biopsy (FNB) are accurate techniques for sampling pancreatic solid lesions. Diagnostic yield of FNA/FNB may be influenced by different factors, but information on this regard is lacking.
AIMS & METHODS: Aim of our study was to evaluate potential factors associated with the diagnostic accuracy of EUS-FNA/FNB for the differential diagnosis of solid pancreatic masses.
447 consecutive patients (mean age 66.4 years, range 17-92, 262 male), who underwent EUS-FNA/FNB for the evaluation of solid pancreatic lesions over the last 4 years were identified from a prospectively collected endoscopy database, and included in the study. EUS was performed using a convex array echoendoscope (Pentax EG-3870UTK and EG-3270UK). FNA/FNB was performed with standard cytology and Procore™ histology needles (Cook Medical Inc, Limerick Ireland). The impact of the type of scope, location and size of the lesion, on-site cytopathological evaluation, number of needle passes and type of needle on the diagnostic accuracy of FNA/FNB was evaluated. Overall diagnostic accuracy was calculated by using surgical histopathology in operated cases and global clinical and radiological assessment and follow-up in non-operated cases as gold standard. Data were analyzed by multivariate stepwise logistic regression.
RESULTS: Mean size of solid pancreatic masses was 36.1±16.4 mm. 283 tumors were located in the head of the pancreas, 124 in the body, and 40 in the tail. Final diagnosis was pancreatic adenocarcinoma in 294 cases, inflammatory lesions in 74 cases, neuroendocrine tumor in 23 cases, pancreatic metastasis in 17 cases, cystic lesions with solid components in 36 cases and pancreatic lymphoma in 3 cases. Overall diagnostic accuracy was 87.5% (95%CI 84.1-90.2). Size of the lesion (OR 1.03; 95%CI 1.00-1.06; p = 0.014), onsite evaluation of the FNA/FNB sample (OR 4.36; 95%CI 1.3-14.9; p = 0.019), and the use of Procore™ needles (OR 3.02; 95%CI 1.4-6.5; p = 0.005) were independently associated with a correct diagnosis after FNA/FNB.
CONCLUSION: EUS-guided FNA/FNB is an accurate technique. Factors associated with a higher diagnostic yield are large lesions, onsite cytopathological evaluation and the use of the Procore™ needles.

P0780 DOES EUS-BASED CHRONIC PANCREATITIS PROGRESS TO OBVIOUS CHRONIC PANCREATITIS? - THE FOLLOW-UP STUDY USING EUS

K. Imbe[1,*], A. Irisawa[1], G. Shibukawa[1], Y. Abe[1], A. Saito[1], K. Hoshi[1], A. Yamabe[1], R. Igarashi[1]
[1]*Department of Gastroenterology, Fukushima Medical University Aizu Medical Center, Fukushima, Japan*
Contact E-mail Address: *kohimbe@hotmail.com*

INTRODUCTION: Endoscopic ultrasonography (EUS) has been commonly used for diagnosis of chronic pancreatitis (CP) and assessment of its severity. In 2009, ''Rosemont criteria'' was proposed as EUS-based criteria for CP. EUS

can detect minimal changes in the pancreatic duct and parenchyma, and may reveal early pancreatic abnormalities. However, it is not clear whether the pathological condition revealed by EUS will progress to obvious CP or not.
AIMS & METHODS: The aim of this study is to clarify a clinical significance of EUS-based CP.
We retrospectively reviewed all the medical records and EUS images of the patients who had underwent EUS for pancreas from April 2010 to March 2012 in our center. The study patients were picked-up fulfilling criteria as follows; 1) the patients who had pancreatic abnormalities (Hyperechoic foci with/without shadowing, Lobularity with/without honeycombing, Cysts, Strands, MPD calculi, Irregular MPD contour, Dilated side branches, MPD dilation, Hyperechoic MPD margin) on the initial EUS, 2) the patients who were followed by EUS more than twice until April 2014. These patients were classified into 4 categories by Rosemont criteria; Consistent with CP (C-CP), Suggestive of CP (S-CP), Indeterminate for CP (I-CP), and Normal (N). We assessed the progression of pancreatic condition in each patient.
RESULTS: 10 of 22 patients who had pancreatic abnormalities on initial EUS had undergone EUS more than twice (M/F:8/2, mean age: 73.5 (58-82)). Initial diagnosis was C-CP in 1, S-CP in 2, I-CP in 3 and N in 4, respectively. In 10 patients, 5 were aggressively intervened (abstinence, taking orally protease inhibitor), and the other 5 were not taken medical intervention. In intervention group, the number of EUS criteria increased in 2 patients. However, there was no patient who changed the category of Rosemont classification between initial and follow-up EUS. On the other hand, in no intervention group, the number of EUS criteria increased in 4 patients. Moreover, 3 patients got worse the category of Rosemont classification from N to I-CP.
CONCLUSION: It was considered that early medical intervention might be necessary in patient with pancreatic abnormalities on EUS, even if Rosemont classification indicated ''Normal''.

INTRODUCTION: EUS-FNA is widely used to diagnose pancreatic malignancies. Few studies have compared different sites of aspiration when performing EUS-FNA of pancreatic lesions.
AIMS & METHODS: to evaluate the diagnostic accuracy between center and margin of pancreatic adenocarcinoma. 69 consecutive patients with a solid pancreatic lesion, with long axis ≥2cm, were included in this study between January 2012 and December 2013 in 3 hospitals. All FNA procedures were performed using a 22G needle with 5ml suction, 7-8 uniform to-and-fro movements with 2cm depth of insertion were made within the lesion. The first puncture was performed within the central part of the lesion and the second was along the edge of lesion closed to unaffected tissue. A liquid-based cytologic (LBC) preparation was used to rinse the aspiration needle and fix the cytologic specimen after every puncture and specimens were evaluated by expert cytotechnologists. An expert cytopathologist, blinded for the sites of aspiration, reviewed the slides for diagnosis and assessed sampling quality. The final diagnosis was based on pathological examination of tissues obtained either surgically or by EUS-FNA, pathological negative cases need at least 6 months' follow-up to rule out benign diseases. Data were analyzed with Student's t-test and chi squared test, assuming a significant p-value of 0.05.
RESULTS: 64 patients were confirmed with pancreatic adenocarcinoma. The sensitivity of central site is 71.9%(46/64) and 48.4%(31/64) in marginal site ($p = 0.039$).
CONCLUSION: Our study shows EUS-FNA in center of tumor is more sensitive for the diagnosis of pancreatic adenocarcinoma.

INTRODUCTION: Pancreatic NeuroEndocrine Tumors (P-NETs) are a heterogeneous group of neoplasms with highly variable clinical behavior. In the attempt to assess a better prognostic description, The European Neuroendocrine Tumors Society (ENETS) proposed a new grading and TNM-based staging system.
AIMS & METHODS: To compare pre-operative and post-operative Staging and Grading in P-NETs and their prognostic significance; secondary to determine if a new cut-off value of Ki-67 proliferative index for P-NETs Grading can improve the accuracy of prognostic stratification.
Our retrospective long-term survival case study is composed of 285 patients with P-NETs observed at San Raffaele Scientific Institute from 1988 to 2012. 274 neoplasms were classified according to ENETS classification models; out of these, 90 and 42, respectively, were classified according to a new pre-surgical classification, composed of pre-operative Staging (CT, MRI, EUS) and Grading (EUS-guided fine needle aspiration and cytological Ki-67 evaluation). Comparison between pre- and post-operative models (Pre-Stage vs. Stage e Pre-Grade vs. Grade) was possible for 88 and 33 neoplasms, respectively. Ki-67 proliferative index was evaluated through immunocytochemical (Pre-Grade) and immunohistochemical (Grade) analyses. Agreement between pre-operative and post-operative models was performed through k-statistics (Cohen). A p-value < 0.05 was considered significant.
RESULTS: Among all pre-operative and post-operative models, Pre-Grade shows the highest Harrell's C (0.97), resulting the best tool for a proper prognostic stratification. When comparing pre-operative and post-operative models, percent agreement between Pre-Stage and Stage was good (83%, $k = 0.74$), otherwise agreement between Pre-Grade and Grade was moderate (70%, $k = 0.42$), when used a 2% cut-off for Grade 1 tumor definition; contrarily, when used a 5% cut-off, Pre-Grade and Grade showed a good agreement (88%, $k = 0.66$). The definition of a new 5% cut-off for cytological and histological Ki-67 index improved the accuracy of patients' prognostic stratification, being not significant the difference between patients' 10-year survival for Ki-67 levels within 5% (93.75% vs. 90%).
CONCLUSION: The new proposed pre-surgical classification, based on Pre-Stage and Pre-Grade, is comparable to post-surgical models. This system shows a good agreement with post-surgical one, being efficient in pre-surgical disease's biology evaluation.

P0783 DUPLICATION CYSTS: THE ROLE OF ENDOSCOPIC ULTRASONOGRAPHY

M.J. Magalhães[1,*], F. Castro-Poças[1], T. Araújo[1], P. Lago[1], T. Moreira[1], I. Pedroto[1]
[1]*Gastroenterology, Centro Hospitalar do Porto - Hospital de Santo António, Porto, Portugal*
Contact E-mail Address: *mj.magalhaes@gmail.com*

INTRODUCTION: The duplication cysts are uncommon congenital anomalies and rarely diagnosed in adults. They can be found in any part of the digestive tract. The cysts are typically discovered incidentally on endoscopy or radiologic imaging since they are usually asymptomatic. However complications such as infection, bleeding, perforation, ulceration, obstruction and malignant transformation can occur. Their management can be challenging and increased availability of new diagnostic modalities such as endoscopic ultrasonography (EUS) may change their approach.
AIMS & METHODS: To describe the experience of a center in the diagnosis of duplication cysts by EUS.
We performed a retrospective analysis to the upper EUS performed between 2000 and 2013, with the diagnosis of duplication cyst. The patient characteristics and the endoscopic/imaging findings were analyzed. The contribution to the diagnosis of fine needle aspiration (FNA) was also evaluated.
RESULTS: Between 2000 and 2013, 23 patients (16 men (69.6 %)) with a mean age of 51.9 ± 15.9 years underwent EUS, whose final diagnosis was duplication cyst. Prior to EUS: 19 underwent gastrointestinal endoscopy (EGD), 13 of them by symptoms such as dyspepsia ($n = 9$) and dysphagia ($n = 4$). Of the 19 EGD performed, 3 had no endoscopic abnormalities and 16 had suspection of subepithelial lesions (10 esophageal); Four patients had previous imaging study by computed tomography (CT), 2 with suspected esophageal duplication cysts. EUS detected 16 anechoic lesions with endosonographic criteria of duplication cyst in the esophagus (average size 24.2 x14, 2 mm; 7 with echogenic material inside) and 7 in the stomach (average size 23.6 x14, 1 mm, 2 with fluid levels and septae). There were 8 cases where EUS FNA was performed (5 esophagus); in 75% of cases one pass FNA was done using a 22 Gauge needle. There was cytological confirmation in 3 cases, and in 3 other cases other entities besides cysts were excluded. A CT scan was performed in four patients after EUS, with diagnostic agreement in one case. Annual EUS follow up was performed in 9 patients, with no changes in the lesions characteristics.
CONCLUSION: EUS plays a central role in the diagnosis and monitoring of an entity which, although rare, has potential serious risks and complications associated.

INTRODUCTION: In recent years, due to the spread of endoscopic submucosal dissection (ESD) for early gastric cancer (EGC), preoperative determination of ESD indication has become increasingly important.
AIMS & METHODS: In determining the ESD indication for EGC, we diagnose the depth of invasion by endoscopic ultrasonography (EUS) in all cases as much as possible in our hospital. We investigated its efficacy by decision tree analysis. We performed EUS in 179 cases from January 2011 to March 2014. We performed EUS using 20MHz small-diameter probe. The average age was 69 years

old. Male-to-female ratio was 142:37. We classified the invasion depth into M, M-SM and SM. We evaluated the accuracy of the invasion depth by area, morphological type, histological grading and UL according to the pathology specimen after resection.
RESULTS: The accuracy of all 179 cases was 89 %. It was 91 % in the 150 cases that ESD was performed, and 75% in the 29 cases that surgery was performed. Total cases and accuracy according to area was 83% in 42 U area cases, 93% in 80 M area cases, and 88% in 57 L area cases. According to the macroscopic type, accuracy was 91% in 89 0-IIc type cases, 88% in 60 0-IIa type cases, 92% in 13 0-IIb type cases, 60% in 10 0-IIa+IIc type cases, and 100% in 7 0-I type cases. Accuracy was 68% in 32 UL (+) cases. According to histological type, accuracy was 92% in 155 differentiated type cases, 75% in 24 undifferentiated type cases. 164 cases were diagnosed as M or M-SM, which are indications for ESD, and correct diagnostic rate was 91%. 15 cases were diagnosed as SM, in which surgical treatment is indicated, and accuracy was 67%. In decision tree analysis, accuracy was 69% in UL(+) cases, and as low as 84% in undifferentiated UL (-) cases, and 97% in other cases.
CONCLUSION: In ESD cases, decision tree analysis enabled differentiation between high and low accuracy groups in diagnosis of the depth of invasion.

INTRODUCTION: Preoperative pathological diagnosis in patients with biliary strictures suspected for malignancy is often difficult. The diagnostic yield of endoscopic retrograde cholangio-pancreatography (ERCP) guided brushing is low and endoscopic ultrasound fine needle aspiration (EUS-FNA) may be difficult to perform in non-mass forming lesions. We report a case series of patients affected with suspected cholangiocarcinoma in which a cytological diagnosis was attempted by EUS-FNA.
AIMS & METHODS: All the cases of EUS-FNA performed in patients with biliary strictures suspected for malignancy from June 2012 to October 2013 were reviewed. Patients were excluded if the EUS examination showed a mass lesion. Only patients in whom an EUS-FNA was attempted were included in the analysis.
RESULTS: During the study period 12 patients (8 males, mean age of 75, range 60 to 85) diagnosed with a non mass forming biliary stricture underwent EUS-FNA. The stenosis was distal from the cystic duct insertion in 8 cases. Aspirates were carried out using a 25 G core needle with the capillary suction technique. The material was put on smears and processed in the standard fashion. The results were definite for malignancy in 9 patients and suspected in 2 patients. In one patient the cytological results were inconclusive. All the patients were resected. The surgical pathology results showed a cholangiocarcinoma in all these patients. The sensitivity of EUS-FNA was 75% considering only the positive cytology and 91% considering also the suspected ones. No complications were reported.
CONCLUSION: Our results suggest that EUS-FNA is a safe and useful procedure for investigating biliary strictures suspected of malignancy even without a mass. Although false-negative diagnosis can still occur, core biopsy needle seems to improve the diagnostic yield of cytology.

INTRODUCTION: Over the past years, capsule endoscopy (CE) has been established as an imaging technique in the diagnosis of small bowel diseases. The aim of this study was to examine the limitations of this method by analysing a large number of consecutive CEs.
AIMS & METHODS: This was a retrospective study, including 1193 consecutive examinations performed at our centre in 1091 patients (male/female = 517/574, mean age ± SD: 61.83 ± 17.46a, range: 9-93a) between 2002 and 2012. In 1061 examinations the system of Given® (Yoqneam, Israel) was used. In 132 examinations the capsule endoscope MiroCam® (IntroMedic, Seoul, South Korea) was used.
RESULTS: *Complications* requiring an endoscopic or surgical intervention occurred in 0.34% (4/1193) of examinations: In two patients the capsule was retained in a duodenal diverticulum or a hiatal hernia, respectively. In both cases the capsule could be removed endoscopically. In one patient with Crohn's disease (CD) the capsule was retained in a stenosis of the terminal ileum and was removed during colonoscopy after dilation of the stricture. One patient underwent surgery after the capsule was retained in a stenosis caused by CD.
Technical defects of the capsule or the data recorder occurred in 16 (1.34%) CEs: Hence the passage through the small intestine was not completely recorded (n = 12) or the pictures could not be used for further evaluation (n = 4).
Transit abnormalities: In 1017 examinations (85.25%) the cecum was reached within the recording period.
Visibility conditions were classified as very good 54.41%, as partly limited in 32.05% and as severely limited during the most part of recording in 13.54% of examinations.
CONCLUSION: Complications of CE requiring endoscopic or surgical intervention are very rare (0.34%). However, technical defects as well as transit abnormalities and limited visibility may decrease the diagnostic yield of CE in some cases.

INTRODUCTION: Oesophageal capsule endoscopy (OCE) is a non-invasive technology that allows the investigation of the oesophagus. Our aim was to evaluate prospectively the diagnostic yield of OCE in patients with cirrhosis and suspected portal hypertension (PHT).
AIMS & METHODS: 330 patients with cirrhosis and without known oesophageal variz (OV) were enrolled. Patients first underwent OCE, then OGD; endoscopists who performed OGD were blind to OCE result. In case of discrepancy for the presence of VO, a second exploration by OGD was immediately performed. Patient's satisfaction was assessed by an VAS (visual analogic scale, maximal score = 100).
RESULTS: Thirty patients were not included in the analysis because neither OCE nor OGD were performed. Patients (216 male, mean age 56 years) had mainly alcoholic (45%) or viral (22%) cirrhosis. The diagnostic yields of OCE to detect, and to adequately classify, OV were as follows: sensitivity 76% [95% CI, 69% - 83%] and 64% [95% CI, 50% - 78%], specificity 91% [95% CI, 86% - 95%] and 93% [95% CI, 87% - 100%], positive predictive value 88% [95% CI, 82% - 93%] and 88% [95% CI, 77% - 99%] and negative predictive value 81% [95% CI, 75% - 87%] and 78% [95% CI, 68% - 87%] respectively. OCE patient satisfaction scored significantly higher than OGD (87±22 vs. 58±35; $p < 0.0001$).
CONCLUSION: OCE was well tolerated and safe in patients with liver cirrhosis and suspicion of PHT. The sensitivity of OCE is not currently sufficient to replace OGD as a first exploration in these patients. However, due to its excellent specificity and PPV, OCE may have a role in cases of refusal or contra-indication to OGD. OCE might also improve compliance to endoscopic follow-up and help in making important therapeutic decisions in the prophylaxis of bleeding.

INTRODUCTION: Small bowel capsule endoscopy (SBCE) represents the gold standard diagnostic technique in case of obscure gastrointestinal bleeding. Moreover, its use is gaining acceptance also as diagnostic procedure when an organic disease of the small bowel (i.e. duodenum/jejunum/ileum) is suspected. On the other hand, SBCE is an expensive, invasive tool and data about its cost/effectiveness are lacking. Thus, non-invasive markers of small bowel disease are desirable in order to increase the rate of positive SBCE examinations.
AIMS & METHODS: We aimed to evaluate the role fecal markers of inflammation (i.e. fecal calprotectin and lactoferrin) and intestinal permeability test (i.e. lactulose-mannitol ratio, L/M) in predicting the presence of enteropathy at SBCE. We included consecutive patients who underwent SBCE because of symptoms suggestive of small bowel disease (i.e. chronic diarrhea, chronic anemia, signs of malabsorption) and with negative upper and lower endoscopy. Patients dosed levels either of fecal calprotectin (normal values, n.v., 0-50 ug/g) or lactoferrin (n.v. 0-7 ug/ml) and performed L/M test (n.v. < 0.030) at the time of SBCE. Erosions, aftous lesions, ulcers and vascular abnormalities at SBCE were considered positive for small bowel disease presence.
RESULTS: In this retrospective analysis of prospective collected data, 101 consecutive patients (66F/35M; mean age 40 years) with dosed levels either of fecal calprotectin or lactoferrin were included. In 51 (50%) patients, SBCE detected the presence of small bowel disease. Sixty-three (62%) patients had increased levels of fecal markers, whereas in 38 (38%) patients these markers were normal. The diagnostic accuracy of fecal markers for the detection of small bowel disease was 62.4%, with 75% sensitivity and 46% specificity, a positive

likelihood ratio (PLR) of 1.49 and a negative likelihood ratio (NLR) of 0.51. Sixty-seven out of 101 patients performed also L/M test. This was abnormal in 46 (69%) patients and normal in 21 (31%). In 36/67 (54%) patients, SBCE was positive for small bowel disease. The diagnostic accuracy of L/M test for the detection of small intestine disease was 76%, with 75% sensitivity and 56% specificity, a PLR of 1.7 and a NLR of 0.45. The alteration of at least one between fecal markers and L/M test has a diagnostic accuracy of 56.7%, whereas having both fecal markers and L/M test abnormal had a diagnostic accuracy of 64.6%.

	N° patients	Sensitivity % (95%CI)	Specificity % (95%CI)	PLR (95%CI)	NLR (95%CI)
Fecal markers	101	75 (60-86)	50 (34-64)	1.36 (1.08-2.05)	0.57 (0.30-0.88)
L/M test	67	75 (58-88)	56 (40-71)	1.70 (1.15-2.50)	0.45 (0.24-0.84)
At least 1 abnormal	67	83 (67-94)	26 (12-45)	1.12 (0.87-1.45)	0.65 (0.25-1.66)
Both abnormal	48	79 (60-92)	42 (20-66)	1.37 (0.89-2.10)	0.49 (0.20-1.19)

CONCLUSION: Although fecal calprotectin and lactoferrin are established markers of colonic inflammation, their diagnostic yield in detecting small intestinal disease through SBCE seems suboptimal. Their combination with L/M test minimally improves this diagnostic accuracy, whereas that of L/M test alone appears the most satisfactory. It remains to establish whether performing either fecal markers or L/M test (or both) might be cost-effective in the selection of patients to address for SBCE when a small bowel disease is suspected.

INTRODUCTION: A few researchers have tried to make the paradigm shift "from diagnosis to treatment with the capsule endoscopy (CE) application". Though technical innovation is rapidly spreading throughout the CE field, there are still several crucial problems with both the hardware and software which were highlighted by the system we presented at the last UEGW in Berlin. This report presents a wirelessly controlled robotic endoscope equipped with some newly developed tools; a syringe for injecting or spraying drugs or contrast medium, a scalpel for cutting and a rubber band for suturing.
AIMS & METHODS: Our goal is to realize a patient-friendly, swallowable, therapeutic and wirelessly controlled robotic endoscope. We tested three newly developed therapeutic tools in a phantom, which had part of its inner wall covered with a patch of porcine stomach. 1) A 0.3ml syringe for injecting or spraying was driven by a spring and switched on electrically. The amount used was dependent on the drug, dye or contrast medium. 2) The rubber band (similar to a variceal ligater) was held between two cylinders and released by a spring. When the spring was released the outer cylinder pushed the band over the mucosa. 3) The scalpel blade was vibrated by a motor similar to a harmonic scalpel. All the tools were triggered by signals originating from a controller in the hospital via a smartphone next to the phantom. In addition, similar to the previous version the tools were controlled via the Internet.
RESULTS: It was possible to control all the new tools in the phantom both locally (Bluetooth) and via the Internet. However, the cuts made by the scalpel in the mucosa were a little bit jagged. In retrospect, it would have been better to move the robotic endoscope slowly backwards during cutting to improve the operator's view of the lesion, so that they could have made a cleaner cut. The tools occupied a large volume and therefore it was difficult to fit all the tools in a single robotic endoscope. To enable the robotic endoscope to be swallowed, it will be necessary to equip it with only one or two tools. The best approach might be to build several specialized robotic endoscopes and the number of endoscopes that a patient would swallow would be determined by their circumstances.
CONCLUSION: This study has built on the previous study by increasing the number of therapeutic tools from two to five and hopefully, it has brought treatment by a robotic endoscope, a little bit closer. However, the current prototype has a number of limitations (e.g. too large to be swallowed and the tools could only be used once) and these will need to be addressed if treatment by robotic endoscope is to become a reality.

P0790 KINETICS OF COLON CAPSULE ENDOSCOPY: A NEW MODEL OF PREPARATION

I. GUTIERREZ-DOMINGO[1,*], C. GUTIERREZ-GONZALEZ[1] on behalf of Instituto de Patología Digestiva de Sevilla, **A. GUTIERREZ-DOMINGO**[1], I. MORENO-GARCIA[1]
[1]*Digestive Diseases, Instituto de Patología Digestiva de Sevilla, Sevilla, Spain*
Contact E-mail Address: *ignaciogutierrezdomingo@hotmail.com*

INTRODUCTION: Up until now, the use of colon capsule endoscopy (CCE) has been limited by the inabilities to achieve a complete examination. A pilot study was conducted to determine the efficacy of a new preparation based on associating Prucalopride (Resolor) and polyethylene glycol plus ascorbic acid (Moviprep). Prucalopride is a highly selective serotonin 5HT4 receptor agonist which stimulate the release of acetylcholine necessary for smooth bowel muscle contraction and therefore peristalsis. After observing its benefits on the treatment for constipation, we believe that Prucalopride could be useful in the preparation of colon capsule endoscopy, speeding up intestinal transit and therefore making the examination shorter, increasing the excretion rate. This article presents the results obtained in terms of transit times, total examination time and expulsion rates.
AIMS & METHODS: Pilot study with 50 patients (cases) with the new preparation compared with 50 control patients with the standard preparation (PEG/ Fosfosoda/). Each video is read by two researchers.
Preparation protocol: - Two days of residue-free diet - Day before the test, liquid diet - Resolor 2 mg, 1 on each day of the diet and 2 on the examination day - Moviprep, 1 liter in the evening prior to the examination and 1 liter in the morning of the examination – Then 2 boosters of half a liter each in alarms 1 and 2.
RESULTS: A cohort with 41 men and 59 women, mean age of 54.6 years old (10-90). Expulsion rate over time of 87% in the cases with respect to 55.5% in the controls ($p = 0.188$). The mean gastric transit time (75 vs. 49.5 minutes; $p = 0.12$), intestinal transit time (81.4 vs. 44 minutes; $p = 0.001$) and colon transit time (252 vs. 232 minutes; $p = 0.79$) were shorten.
CONCLUSION: The higher excretion rate as well as the shortened gastric and intestinal transits, without modifying the colon transit, with the new preparation (Prucalopride+Polyethylene glycol plus ascorbic acid), allow conducting a higher quality study of the colon over time and with less adverse effects and better tolerance as a result of excluding sodium phosphate.
This procedure may be considered as an alternative, particularly for patients in whom sodium phosphate-based preparations are contraindicated.

INTRODUCTION: Some studies[1] suggest that the MiroCam ® endoscopy capsule (CE) has a small bowel transit time (SBTT) greater than Given® CE, which may result in greater detection of positive lesions.
AIMS & METHODS: Aims: To compare the SBTT, the detection of positive lesions and percentage of complete studies between Mirocam ® and Given ®.
Methods: retrospective study of 429 patients who underwent CE between 2005-2013. Lesions were considered positive according to the indication of CE: obscure gastrointestinal bleeding (OGIB) - multiple erosions/ ulcers, typical angiodysplasias, tumor and blood; suspected Crohn's disease (CD)/ evaluation of the extension of CD - multiple erosions/ ulcers and blood; abdominal pain - tumor, multiple erosions / ulcers and blood. Statistical tests: t-student; X^2
RESULTS: The mean age was 54.2 years. MiroCam® CE was performed in 48.7% of patients and Given® CE in 51.3% patients. Indications for performing CE: OGIB – 62.5%, suspected CD/ evaluation of the extension of CD - 21.2%, polyposis – 5%, abdominal pain – 4.4% and others – 6.8%.
The mean gastric transit time (GTT) in MiroCam ® and Given ® CE was identical – (38min vs 41min, $p = 0.52$). The mean SBTT of MiroCam ® CE was superior to Given® CE - 5h17min vs 4h45min, $p = 0.004$. We did not find any differences between the two CE with respect to mean age (MiroCam® - 54.9 years; Given® - 53.6 years, $p = 0.46$), sex (Mirocam ®- female sex 57%; Given® - female sex - 61.3%, $p = 0.35$), percentage of diabetic patients (10.1% MiroCam® - 10.1%; Given® - 14.5%, $p = 0.2$), percentage of complete exams (MiroCam® - 90%; Given® - 89%, $p = 0.63$) and positive lesions (MiroCam ® - 38.2%, - Given® - 39.5%, $p = 0.78$). There were also no differences regarding the indications for CE ($p = 0.051$).
CONCLUSION: Our study suggests that the SBTT of MiroCam ® CE was superior to Given ® CE, but it does not influence the positive findings or complete examination rate. However, a longer SBTT is associated with a longer reading time, an important aspect in daily clinical practice.

P0792 THE USE OF SMALL BOWEL CAPSULE ENDOSCOPY IN OCTOGENARIANS; THE EDINBURGH EXPERIENCE

L. Bartzis[1], **A. Koulaouzidis**[1,*]
[1]*Centre for Liver & Digestive Disorders, The Royal Infirmary OF Edinburgh, Edinburgh, United Kingdom*

INTRODUCTION: Over the last 13 years, the clinical use of capsule endoscopy (CE) has revolutionised the investigation pathways for the small-bowel. Although (as procedure) non-invasive, there are reports of capsule aspiration in certain patient-groups.[1] Moreover, CE video sequence review is a time-consuming process and – on occasions – with limited diagnostic yield (DY). There is scarcity of data on the use of CE in octogenarians.[2-4]
AIMS & METHODS: Aim: We aim to report our centre's experience in using CE in octogenarians. **Setting:** University hospital & tertiary referral centre for CE for the South East of Scotland. Retrospective study; the small-bowel CE database of our unit was interrogated for patients > 80 years of age who underwent CE. Categorical data are reported as mean ±SD (range). The *Fischer's* exact, the *chi-square* and the *t* (unpaired) tests were used to compare datasets. A two-tailed *P* value of <0.05 was considered statistically significant.
RESULTS: 1,477 patients underwent small-bowel CE between 2005 and 2013. 93 CE were performed in 84 (35M/59F) octogenarians; mean age 84 ±2.9 years. PillCam®SB1/SB2 & MiroCam® were used in 61 & 32 CE examinations, respectively. Ten (11.9%) patients had more than 1 CE. One patient was unable to swallow the capsule, and in another the capsule was retained in the stomach. The CE report was unavailable in one case. Indications for small-bowel CE were iron deficiency anaemia (IDA): 44, obscure gastrointestinal bleeding (OGIB): 29, OBIG+IDA: 6, diarrhoea: 4,?small-bowel varices:1. Forty-five (53.6%) patients subsequently died. The mean time from small-bowel CE to death was 23 ±20.9 months, (range: 0.13-83 months). The DY (all findings) of CE in our octogenarian cohort was 56.8%. Vascular lesions (any P class)/active bleeding were found in 33, inflammatory pathology in 9, and other findings in 4 CE. No neoplastic pathology was identified. The DY was independent to the indications for the procedure ($P=0.166$), the small-bowel CE system used ($P=0.068$), the patient final outcome i.e. deceased/alive ($P=0.051$) and/or the time from CE to death ($P=0.053$).
CONCLUSION: CE in patients >80 years of age has high DY, but sinister pathology in this cohort is rare. Furthermore, small-bowel CE has limited impact on the final patient outcome in this patient-group.

P0793 USEFULNESS OF FLEXIBLE SPECTRAL IMAGING COLOR ENHANCEMENT (FICE) IN DIFFICULT TO INTERPRET MUCOSAL ULCERATIVE LESIONS OF THE SMALL BOWEL

M. Rimbas[1,2,*], L. Negreanu[2,3], L. Ciobanu[4], C. Spada[5], A. Bengus[2], C.R. Baicus[2,6], G. Costamagna[5]

INTRODUCTION: Identification of subtle small bowel mucosal lesions can sometimes be challenging, as small differences in mucosal hue or pattern are difficult to detect. To overcome this problem, chromoendoscopy virtual techniques based on narrowing the bandwidth of the conventional white light endoscopy (WLE) image were imagined, possibly allowing for contrast-enhanced assessment of the nature of small-bowel mucosal lesions. However, data on the already implemented FICE (Flexible spectral Imaging Color Enhancement) software application in videocapsule endoscopy (VCE) are limited.[1-3]
AIMS & METHODS: This is a multicenter study involving a selection of mixed de-identified images of 250 difficult to interpret small bowel ulcerative lesions (selected as the least representative visualization of an unequivocally confirmed erosion from a succession of images, comprising small or shallow mucosal defects, erosions lacking a clear rim of erythema or located marginally in the field of view, or lesions with a poor image quality due to luminal content), and 50 artifacts mimicking ulcerative lesions, all selected from the 64 VCE recordings in a prospective study (*ClinicalTrials.gov ID NCT00768950*). The evaluation was performed by three blinded experienced VCE readers in two steps, initially as white light images, then with the addition of all available FICE settings (1,2,3 and Blue), labeling them as real or faked lesions and rating each FICE setting as useful or not. The comparison of accuracies in correctly categorizing the images was performed between the two readings (McNemar's test).
RESULTS: Between the first (WLE only) and the second (FICE aided) reading, in terms of accuracy, there was a 19.5% [95% CI:15.7% to 23%] improvement (from 52% to 71.5%) in the global evaluation of all images ($p<0.001$), coming from a 26% [95% CI: 22% to 30%] improvement (from 47% to 73%) in the evaluation of true ulcerative images ($p<0.001$), and a 12% [95% CI: 3.5% to 22%] decrease (from 75% to 63%) in the evaluation of faked ulcerative images ($p<0.01$), results reproduced for all three readers. FICE 1 and 2 settings were rated as most useful.
CONCLUSION: This study demonstrates that FICE virtual chromoendoscopy (mostly settings 1 and 2) applied for VCE is useful to enhance surface patterns and color differences and to better categorize difficult to interpret small bowel mucosal ulcerative lesions. However, care must be taken, and individual images should only be evaluated as part of a succession in a recording, as the technology could also misguide the interpretation of artifacts as ulcerative lesions.

P0794 THE CORRELATION OF WIRELESS VIDEO CAPSULE ENDOSCOPY AND OTHER RADIOLOGICAL IMAGING IN THE INVESTIGATION OF SUSPECTED AND ESTABLISHED SMALL BOWEL CROHN'S DISEASE

P. Moore[1,*], G. Holleran[1], B. Hall[1], D. McNamara[1]
[1]*Tallaght Hospital, Tallaght, Ireland*
Contact E-mail Address: *moorepe@tcd.ie*

INTRODUCTION: Background: In recent times there have been significant advances in both the radiological, CT and MRI Enterocolysis (CTE / MRE) and the endoscopic, video capsule endoscopy (CE) investigation of small bowel disease. The optimal complimentary and appropriate use of various new evolving and standard diagnostic modalities remains to be established. In particular, their role in identifying small bowel Crohn's disease remains unclear. Early identification of ileal Crohn's disease is desirable to guide treatment and impact on long-term outcome.
AIMS & METHODS: Aim: To compare the diagnostic performance of CE and radiological imaging in detecting small bowel Crohn's disease in the local population and to correlate the findings of CE with other various imaging modalities. Method: A retrospective analysis was undertaken of a database of patients who underwent capsule endoscopy from 2009 to 2013 at Tallaght Hospital. Those patients who underwent CE for known histologically-confirmed or suspected Crohn's disease were identified. This cohort was cross-referenced with the Hospital Radiology Report system "Keogh" for the same period. Patient demographics, radiological procedures, CE and radiology findings were recorded. The diagnostic yield and correlation coefficient was calculated for radiological tests compared to CE.
RESULTS: Results: In all, 263 patients, 155 female (59%), mean age 41 years, had a CE for known (n = 29, 11%) or suspected (n = 234, 89%) Crohn's disease. In all 110 (42%) had active disease on CE. In only 96 (37%) patients additional radiological tests were available for comparison, 73 (76%) and 23 (24%) in positive and negative CE cases. Of 28 CTEs, 28 SBFTs and 17 Abdominal CTs performed in positive CE subjects only 37 (51%) also reported evidence of active Crohn's disease, overall correlation coefficient k = 0.49, 95% CI 0.37-0.61. SBFT was the least sensitive test, 32% (9/28), while CTE and Abdominal CTs had similar diagnostic yields of 64% (11/17) and 61% (17/28). Correlation was better among patients without active Crohn's disease, with 20 of 23 radiological tests, 7 CTEs, 7 SBFTs and 9 Abdominal CTs also being reported as normal, correlation coefficient k = 0.87, 95% CI 0.72-1.0. The incremental diagnostic yield for CE in patients with suspected or known Crohn's disease in our cohort compared to radiological investigations was 34%, CE 76% and all Radiology 42%. Table 1: Diagnostic yield according to test.

Number (%)	CE	CTE	CT-Abd	SBFT
Positive	73 (76%)	18 (51%)	11 (42%)	11 (31%)
Negative	23 (24%)	17 (49%)	15 (58%)	24 (69%)
Total	96	35 (36%)	26 (27%)	35 (36%)

CONCLUSION: Despite its poor diagnostic yield and the advent of new diagnostic modalities SBFT remains a frequently employed test in CD. Notwithstanding the inherent bias in our study, the findings suggest the correlation between CE and standard and targeted small bowel radiology is at best moderate, with CE having a higher diagnostic yield. CE should be considered in all subjects with suspected Crohn's disease.

INTRODUCTION: Mesenteric panniculitis (MP) is a rare, non-specific inflammatory process affecting the adipose tissue of the mesentery. Symptoms may be absent or there may be fever, abdominal pain, vomiting or diarrhea. MP is characterised on computed tomography (CT) scan by an increased mesenteric fat density called "misty mesentery" and the presence of lymph nodes within the fatty mass; and sometimes the presence of a hypodense halo surrounding blood vessels and nodes called "fat ring sign", and/or a hyperdense pseudocapsule surrounding the mesenteric fat. Prior studies suggested an association of MP with malignancy and also with acute abdominal disorders, infectious or inflammatory diseases. However data are heterogeneous and mainly retrospective and patients' care and follow-up remain unclear.
AIMS & METHODS: We aimed to evaluate the prevalence of cancer in patients with MP on abdominopelvic CT scans, and to study clinical and radiological course of patients. A prospective and descriptive study was performed in a French University hospital. All CT scans performed in the Radiology department between January 2012 and February 2013 with a diagnosis of MP were recorded. The diagnosis of MP was defined as the presence of "misty mesentery", infracentimetric nodes, and the absence of invasion of the adjacent small-bowel loops and vascular structures. Clinical and radiological characteristics of patients with MP were recorded, and patients with isolated MP were followed-up in the Gastroenterology department. An initial search for associated disease, especially for cancer, was performed and prospective 1-year follow-up was proposed.
RESULTS: MP was diagnosed based on CT findings in 100 consecutive patients among 9027 abdominopelvic CT scans (1.1%) over the study period; 54 patients (54%) had cancer, of which 12 (22 %) were melanomas and 11 (20 %) were lymphomas. MP was present at the time of diagnosis (35/54), or appeared within the subsequent months (7/54). Twenty-two patients had MP associated with acute abdominal disorders, and 24 patients had isolated MP. Among those patients and during the prospective follow-up only one cancer was diagnosed, and it was a basal cell carcinoma. Regarding radiological aspects of MP: a pseudocapsule was found in 58 % of cases, a fat ring sign in 63 % of cases and a left-sided location in 88 % of cases. There were no significant difference between the radiological characteristics of MP according to the associated diseases, especially cancer.
CONCLUSION: This study is one of the largest to describe MP diagnosed at CT scan and the first to propose prospective evaluation of patients. MP is frequently associated with cancer, mainly melanoma and lymphoma, already documented at the time of MP diagnosis. However data from follow-up suggest that when PM is isolated, or associated with other disease there does not appear to be underlying or incidental cancer.

P0796 CT RADIOLOGICAL MODELLING OF THE UPPER GI TRACT ANATOMY; ESSENTIAL CLUES TO PERFORMING MAGNETIC ASSISTED CAPSULE ENDOSCOPY (MACE)

I. Rahman[1,*], M. Kay[1], T. Bryant[1], S. Pelitari[1], P. Patel[1]
[1]*University Hospital Southampton, Southampton, United Kingdom*
Contact E-mail Address: *imdi81@hotmail.com*

INTRODUCTION: Capsule endoscopy, employed to investigate the small bowel, is now being further developed to visualise the upper GI tract. In a pig model, using a hand held magnet, we have demonstrated that magnetic assisted capsule endoscopy (MACE) in the stomach is feasible. However, it is unclear what the best methodology is to achieve complete gastric luminal views in humans. Our aim was to utilise CT modelling of the abdomen to determine the optimal placements of a capsule endoscope in the stomach to allow complete mucosal visualisation and to determine the optimal placement of the hand held magnet to aid pyloric traversing.
AIMS & METHODS: Using multiplanar reformatting, 100 good quality contrast abdominal CT scans were analysed to assess luminal visualisation by a magnetic capsule endoscope from 5 fixed stations throughout the stomach. From each station, we assessed the ability of a capsule endoscope to visualise 6 anatomical landmarks (cardia, fundus, body, incisura, antrum and pylorus). Success of visualisation of an anatomical area was only accepted when >90% mucosal visualisation was achieved from a particular station. The pyloric canal angles were calculated to create a vector. We mapped the position of this vector on the patient's skin (pyloric canal vector surface point) to determine the optimal placement of the magnet that would allow traversing of the capsule endoscope through the pylorus.
RESULTS: There were 65 female and 35 male patients. Mean age of patients was 53 years (s.d+/-18 years). Best mucosal visualisation of the stomach landmarks was achieved from 3 stations; fundal dependant, antral dependent and opposite the antral dependent points. Maximal visualisation of the whole of the stomach, required combining 2 stations as shown in Table 1

Station	Cardia (%)	Fundus (%)	Body (%)	Incisura (%)	Antrum (%)	Pylorus (%)
Station 1 + Station 3	87	99	99	100	100	45
Station 1 + Station 4	92	99	99	100	100	86

The optimal positioning of the magnet to aid pyloric traversing was posteriorly between vertebrae T5 to L2, in an area 10cm to the left and 18cm to the right (83% cases). Age > 55yrs ($p = 0.03$) and the ability to view the pylorus from station 3 ($p = 0.04$) was associated with an extreme pyloric canal vector.
CONCLUSION: CT modelling has provided important data regarding the optimal stations in the stomach to position a magnetic capsule endoscope to allow maximal luminal mucosal visualisation and traversing the pylorus. Although there is some extreme variation in the upper GI anatomy, the majority of cases will allow the use of a single standard method in performing MACE which may be very useful for screening purposes.

P0797 INVESTIGATION OF URGENT REFERRALS WITH UNEXPLAINED IRON DEFICIENCY ANAEMIA: IS A CT SCAN RELEVANT?

J. Iqbal[1,*], G. Kaur[1]
[1]*Surgery, SCUNTHORPE GENERAL HOSPITAL, Scunthorpe, United Kingdom*
Contact E-mail Address: *gkaur@email.com*

INTRODUCTION: Anaemia is a common medical problem and can be due to deficiency of one or more nutrients, blood loss or a variety of medical problems. Generally, anaemia of almost any degree requires medical assessment so that the correct cause can be ascertained and appropriate treatment given. The patient's symptoms and initial FBC findings will influence both the urgency and direction of initial clinical investigation. Upper and lower GI investigations should be considered in all males and post-menopausal females with iron deficiency anaemia unless there is an obvious alternative cause. NICE guidelines for referral for suspected colorectal/ Upper GI cancer includes referral of patients with unexplained iron deficiency anaemia who are men of any age with a haemoglobin of 11 g/100 ml or below and who are non-menstruating women with a haemoglobin of 10 g/100 ml or below. Unexplained iron deficiency anaemia does not usually prompt a referral to chest physicians, gynaecologists nor the urologists.
AIMS & METHODS: All our urgent referral patients with iron deficiency anaemia are investigated with upper and lower GI endoscopy where possible and a CT scan of the chest abdomen and pelvis. We aimed to evaluate our management of these patients with respect to investigations performed, especially the cost effectiveness of a adding on a CT scan to the upper and lower GI scopes that are always part of this investigation.
All Urgent referrals to the Colorectal unit over a 3 month period were retrospectively analysed. CT scan, Colonoscopy and Flexible sigmoidoscopy data was collected as well as any histology obtained from biopsies taken.
Of 73 urgent referrals, 54 were referred with Iron deficiency anaemia. Of these, 46 (85%) underwent a Lower GI scope (37 Colonoscopy and 9 Flexible sigmoidoscopy); 8 did not undergo any scope - 1 failure, 1 refusal (both underwent CT pneumocolon) and 6 patients who were considered too frail, poor mobility etc. 43% patients undergoing colonoscopy were reported normal; of the 57% with findings, 28% were found to have bowel cancer. 98% patients referred urgently with unexplained iron deficiency anaemia underwent a CT scan; of these, 15 (28%) were normal. Of the remaining 38 patients, 47% had significant findings with respect to malignancy (half of which were bowel related) and the remaining 53% had other relevant non-cancer pathology (40% of which was bowel related). Hence, CT scans picked up non bowel related pathology that would not have been found on colonoscopy alone in 39% patients referred urgently with iron deficiency anaemia, 17% of which was significant with respect to malignancy.
CONCLUSION: Patients with iron deficiency anaemia are generally referred to gastroenterology / colorectal surgery for further investigations, with appropriate urgency. These patients are usually investigated with a gastroscopy and colonoscopy. We found our routine use of an addition of a CT scan chest, abdomen and pelvis yielded useful results, both related to malignant and non malignant non-bowel related pathology. This helped us guide further management appropriately, with an urgency dependent on the causative pathology. We would therefore recommend the routine use of a CT scan in the investigation of a patient referred urgently with iron deficiency anaemia, unless contraindicated for any reason.

Contact E-mail Address: *Nagata7@aol.com*

INTRODUCTION: Although CT colonography (CTC) is minimal invasive procedure, the actual patient acceptance for CTC varies between patients.
AIMS & METHODS: The aim of this prospective study was to assess patient tolerance and to identify the patient-related factors affecting the patient

acceptance of reduced-laxative CTC in screening purpose. A total of 1242 outpatients at average risk for colorectal cancer were consecutively enrolled in this study. All patients underwent reduced-laxative fecal-tagging CTC with 64-detector row CT using carbon dioxide insufflation. Patient's age, gender, height, weight, and the bowel habits were recorded before the procedure. After the procedure, acceptance and preference were evaluated using self-assessed questionnaires regarding tolerance assessment for overall procedure and preference for future testing.
RESULTS: Percentages of patients in good tolerance category for CTC were 83.9% (897/1069). Sixty percent (641/1062) of patients were willing to accept CTC as a future method of examination. Discomfort factors during CTC were abdominal distention (64.8%) and abdominal pain (4.9%). Among the patient factors, only the older age affected the degree of discomfort during CTC (over 60 vs. under 60, odds ratio = 1.59, p = 0.006). Patient factors of gender, BMI, constipation/laxative use, history of abdominal surgery, and previous colonoscopy or barium enema experiences were not related to patient tolerance during CTC.
CONCLUSION: An uncomfortable CTC procedure may be expected in elder patients. Overall, reduced-laxative CTC has excellent patient tolerance.

INTRODUCTION: Barium-contrast radiography originally constituted the first development in diagnosing hiatal hernia (HH) and reflux disease however, conventional radiology is no more a gold standard investigation for their assessment. We observed in clinical practice a worrisome rate of HH type I reported as extracolonic finding during CT with water enema (CT-WE) and CT colonography (CTC), likely induced by increased intra-abdominal pressure due to colon distension. HH has been positively related with the incidence and severity of reflux disease and with the risk of its complications. Although HH is not a life-threatening condition it is our opinion that erroneous reporting of HH may trigger consecutive diagnostic unnecessary processes that induce unmotivated anxiety and expensive and time-consuming for the patient and the socio-sanitary system.
AIMS & METHODS: To determine whether colonic distension at CT-WE and CTC can induce a small incidental physiologic sliding hiatal hernia and whether exist differences between water and gas distension achieved with the two different techniques. We retrospectively evaluated 400 consecutive patients, 200 undergoing CT with water enema and 200 undergoing CT colonography, including 59 subjects who also underwent a routine abdominal CT evaluation at a different time, used as internal control, while a separate group of 200 consecutive patients who underwent abdominal CT evaluation was used as external control. Two abdominal radiologists assessed the CT exams for the presence of a sliding HH, grading the size as small, moderate, or large; the internal control groups were directly compared with the corresponding CT-WE or CTC study looking for a change in hernia size. We used the Fisher exact test applying a size-specific correction factor, in order to account for the effect of colonic distention: these "corrected" values were then individually compared with the external control group.
RESULTS: Sliding HH was present in 51% (102/200) of the CT-WE patients and in 48.5% (97/200) of the CTC patients. Internal control CT of the 31 patients with a hernia at CT-WE showed resolution of the hernia in 58.1% (18/31) of patients, including 76.5% (13/17) and 45.5% (5/11) of small and moderate HH. Comparison CT of the 28 patients with HH at CTC showed absence of the it in 57.1% (16/28) patients, including 68.8% (11/16) and 50% (5/10) of small and moderate HH. Its prevalence in the external control group was 22% (44/200), lower than the CT-WE and CTC cohorts' prevalence of 51% ($p < 0.0001$) and 48.5% ($p < 0.0001$). After applying the correction factors for the CT-WE and the CTC groups, the estimated residual prevalences (16% and 18.5%, respectively) were much closer to that of the external control patients ($p = 0.160$ for CT-WE and $p = 0.455$ for CTC).
CONCLUSION: Incidental findings at CT-WE and CTC should be considered according to the clinical background. Small sliding HH should not be reported in patients with unrelated symptoms undergoing CT-WE or CTC: when encountering these findings, accurate anamnesis and review of medical history looking for GERD-related symptoms are essential, in order to address these patients to a correct diagnostic iter, taking advantage from appropriate techniques such as GI endoscopy or esophageal manometry.

P0800 THE POTENTIAL OF MR COLONOGRAPHY AS A SCREENING TOOL FOR COLORECTAL CANCER: A COST-EFFECTIVENESS ANALYSIS

M. Greuter[1,*], E. Demirel[1], J. Berkhof[1], R. Fijneman[1], J. Stoker[2], G. Meijer[1], V. Coupé[1]
[1]*VU University Medical Center,* [2]*Academic Medical Center, Amsterdam, Netherlands*
Contact E-mail Address: *mj.greuter@vumc.nl*

INTRODUCTION: For colorectal cancer (CRC), a range of screening modalities is available. Based on diagnostic accuracy, colonoscopy is the preferred test but there is a low risk on serious complications and, due to the burdensome procedure, the population uptake is low. MR colonography may have potential as a CRC screening tool since it has comparable test characteristics as colonoscopy but is less invasive. Furthermore, innovators in the field of MR technology are striving to develop a targeted contrast agent that specifically detects adenomas at high risk of progressing to CRC. This might even further increase the potential of MR colonography for CRC screening.
AIMS & METHODS: To explore the potential of conventional and targeted MR colonography in terms of (cost-)effectiveness using the Adenoma and Serrated pathway to Colorectal CAncer (ASCCA) model.
Thirteen screening strategies were evaluated, differing in primary screening instrument and number of screening rounds. The strategies under consideration were conventional MR colonography, targeted MR colonography, colonoscopy and CT colonography with two, three and four screening rounds at a ten year screening interval. In addition, eleven rounds of biennial faecal immunochemical test (FIT) screening were evaluated because this is the current Dutch screening programme. For each strategy, both realistic and perfect participation rates were taken into account. Incremental costs and effects were estimated from a societal perspective with an ICER less than the Dutch GDP per capita in 2012, i.e. €35,823/LYG, considered as cost-effective.
RESULTS: All screening strategies were cost-effective compared to no screening. For conventional MR colonography, the ICER ranged between €1,271/LYG to €3,003/LYG for two to four screening rounds at a participation rate of 34%. For participation rates of 62% and 100%, this range was respectively €1,576/LYG to €3,777/LYG and €1,971/LYG to €4,577/LYG. However, conventional MR colonography screening was more expensive than other screening strategies at comparable LYG, for all participation rates. For example, colonoscopy at two to four screening rounds at realistic participation (22%) led to cost-savings of €71 to €87 at 0.025 to 0.035 LYG per person. The effectiveness of targeted MR colonography was only slightly higher than of conventional MR colonography but it was considerably more costly, even under the most favourable assumptions regarding test characteristics and costs per test.
CONCLUSION: This is the first study to evaluate the cost-effectiveness of MR colonography screening for CRC. Although conventional and targeted MR colonography are cost-effective compared to no screening, at the moment they cannot compete with more established screening tests because of the high costs per test.

P0801 PRELIMINARY STUDY OF PHOTODYNAMIC DIAGNOSIS USING 5-AMINOLEVULINIC ACID IN GASTRIC AND COLORECTAL TUMORS

M. Nakamura[1,*], J. Nishikawa[1], K. Hamabe[1], A. Goto[1], J. Nishimura[1], H. Shibata[1], M. Nagao[1], S. Hashimoto[1], T. Okamoto[1], I. Sakaida[1]
[1]*Department of Gastroenterology and Hepatology, Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan*

INTRODUCTION: Photodynamic diagnosis (PDD) using 5-aminolevulinic acid (5-ALA), has been performed to detect the accumulation of fluorescent protoporphyrin IX (PpIX) in tumors. 5-ALA is a precursor of the fluorescence-emitting PpIX, and PpIX accumulates specifically in tumor cells and emits fluorescence when the excitation light irradiated on them. This property of 5-ALA may improve the endoscopic diagnosis of gastric and colorectal tumors.
AIMS & METHODS: In this preliminary study, we investigated the utility of 5-ALA using PDD in the detection of gastric and colorectal tumors. This prospective single-center study investigated inter-subject variability in patients with early stage gastric or colorectal tumor indicated for endoscopic resection. Patient selection criteria were age 20–80 years, either sex, and provision of informed consent. After oral administration of 5-ALA, endoscopic resection of gastric or colorectal tumors was performed, then the resected specimens were subjected to fluorescence endoscopy to examine for red fluorescence. Endoscopic, macroscopic, and histopathologic findings of the tumors were assessed.
RESULTS: Ten patients (7 men and 3 women) with a total of 13 lesions (10 gastric and 3 colorectal tumors) were enrolled in this study. Fluorescence was detected in 7 (53.8%) of the 13 lesions. No significant differences were observed in sex, age, color of the tumor, tumor diameter, macroscopic type, histological type, invasion depth, lymph node metastasis, or procedure time between the cases with and without fluorescence. The detection rate of fluorescence tended to be high for elevated lesions. Liver dysfunction developed in 4 (40.0%) of the 10 patients.
CONCLUSION: The results of this preliminary study suggest the utility of PDD using 5-ALA for screening gastric and colorectal cancers.

P0802 INCREASED VISCERAL TO SUBCUTANEOUS FAT RATIO IS ASSOCIATED WITH LOWER RISK OF IBD RELATED SURGERY IN PATIENTS WITH CROHN'S DISEASE ON INFLIXIMAB

P. Brown[1,*], D. Tolan[2], L. Warren[3], T. Clark[3], G. Dowson[3], J. Hamlin[3], V. Subramanian[1]

Contact E-mail Address: *v.subramanian@leeds.ac.uk*

INTRODUCTION: Fat wrapping and mesenteric hypertrophy are characteristics of Crohn's disease (CD). In patients with CD, mesenteric adipose tissue releases higher levels of adiponectin, which could up-regulate production of tumor necrosis factor-α and increase the risk for aggressive disease. We have

previously shown that a higher visceral to subcutaneous fat ratio was associated with complicated (stricturing or fistuling) CD (reference).
AIMS & METHODS: The aim of this study was to investigate the effect of visceral fat accumulation on clinical outcomes in patients with CD on Infliximab. We identified patients with a confirmed diagnosis of CD on Infiximab who had computed tomography or magnetic resonance imaging scans of their abdomens within 12 weeks of starting infliximab, from the biologics database of Leeds Teaching Hospital NHS Trust. Areas of subcutaneous and visceral fat were measured in 1 cross-sectional scan, taken at the level of the umbilicus using a previously validated method. All measurements were made using Adode™ CS3 with magic wand function. The outcomes of interest were 1) IBD related flare (defined as increase in dose or steroid use or need for IBD related hospitalization or surgery), 2. Any IBD related surgery and 3) IBD related resectional surgery.
RESULTS: 150 patients with CD on Infliximab met our predefined inclusion criteria. The mean age of the patients was 37.2 ± 13.9 years. On multivariate analysis a higher visceral to subcutaneous fat ratio was associated with a lower risk of all IBD related surgery (HR 0.125 and 95% CI 0.02 0 0.81) and a lower risk of an IBD related flare that almost reached significance (HR 0.39, 95% CI 0.13-1.14). Females were less likely to need IBD related surgery ($p = 0.03$) and ileal and ileo-colonic disease was associated with a higher risk of surgery compared to colonic disease ($p = 0.03$). Only structuring and fistulating disease phenotype was significantly associated with a higher risk of resectional surgery ($p = 0.0.2$).
CONCLUSION: Higher visceral to subcutaneous fat on cross sectional imaging at baseline is associated with better clinical outcomes in patients with CD on Infliximab. This could imply that mesenteric fat hypertrophy has a protective role in CD.

P0803 "DOUBLE-DUCT" SIGN - WHAT IS THE CLINICAL SIGNIFICANCE?

K. Padala[1,*], T. Gardner[1], R. Sinha[2], O. Elneima[1], S. Niaz[1], J.R. Greenaway[2], D. Joy[2]

Contact E-mail Address: *rohits78@gmail.com*

INTRODUCTION: "Double-duct" sign on endoscopic retrograde cholangiopancreatography (ERCP) is considered suggestive of pancreatic or biliary malignancy [1]. This sign is frequently encountered in radiological imaging. We wish to investigate the prognostic value of the "double-duct" sign in patients who undergo magnetic resonance cholangio-pancreatogram (MRCP), attempting to define the associated features, which would predict underlying malignant disease [1,2].
AIMS & METHODS: An analysis of retrospectively collected database of all patients (n = 2,741) who had MRCP over a four-year period; January 2010 to December 2013 was performed. All the radiological reports showing both a dilated common bile duct (CBD) and pancreatic duct (PD) or the "double-duct" sign were included. These were all interpreted and reported by specialist gastrointestinal radiologist. The demographics, liver biochemistry, final diagnosis and outcome for all patients with the "double duct" sign were accessed using the radiology PACS® system, biochemical results WebICE®, hospital letters and case notes. Follow up information was available for a mean of 36 months (range 12-48 months).
RESULTS: 81 patients (annual incidence 2.2% - 3.3% incidence) had "double-duct" sign with a mean age of 71 years. The ratio of male to female patients was (F: M) 1.2:1. The commonest cause of double duct sign was choledo-cholithiasis (27.2%) followed by malignancy (20%). Patients with jaundice in the context of "double-duct" sign had a higher incidence of malignancy (48%). More than half of the patients, (48/81; 59%) with "double-duct" sign were anicteric. None of the anicteric patients were found to have malignancy ($p = 0.002$). Of the anicteric patients, 25% (12/48) had completely normal liver test and the remaining 75% (36/48) had some abnormality of the liver enzymes (raised GGT and/or Alkaline phosphatase). Four patients in the anicteric group had benign tumours (1 case of benign IPMN [Intra-ductal papillary mucinous neoplasm] and 3 cases of benign ampullary tumour, histology confirming low grade and high grade dysplasia without evidence of invasive malignancy on resection specimens). The benign nature was confirmed on clinical, pathological and radiological follow-up. All four patients remained anicteric over the period of follow-up (mean 24 months; and one unrelated death at 18 months). Our results show that "double duct" sign in the absence of jaundice makes a malignant aetiology unlikely.
CONCLUSION: In patients with cross-sectional imaging evidence of "double-duct" sign, the absence of jaundice makes a malignant aetiology unlikely. Conversely, in jaundiced patient a malignant cause is much more likely.

P0804 QUANTITATIVE ASSESSMENT OF GLOBAL SMALL BOWEL MOTILITY IN CHRONIC INTESTINAL PSEUDO-OBSTRUCTION AND CONTROLS: A PRELIMINARY STUDY

S.K. Butt[1,*], A. Menys[2], D. Atkinson[2], A. Plumb[2], S.A. Taylor[2], N. Zarate-Lopez[1], A. Emmanuel[1]
[1]*Gastroenterology,* [2]*Centre for medical imaging, UCLH, London, United Kingdom*
Contact E-mail Address: *s.butt@ucl.ac.uk*

INTRODUCTION: In this preliminary report, we present the initial results of a prospective investigation comparing MRI quantified global small bowel motility in healthy controls and patients with proven clinical and radiological Chronic Intestinal pseudo-obstruction (CIPO). Diagnosis is initially difficult and often delayed, many patients undergoing unnecessary surgical intervention prior to final diagnosis. MRI offers a potential non-invasive modality of diagnosis and monitoring, employing post-processing quantitation of global metrics describing small bowel motility[1].
AIMS & METHODS: Subject selection: 11 healthy non-smoking volunteers (7 Male, mean age 33[22 to 48]) and 5 CIPO patients (3 Male, mean age 53[32 to 82]) were recruited. CIPO patients stopped any medications that influenced small bowel motility for one week prior to scan including opioids, anti-emetics & anti-diarrhoeals.
Study overview: Participants underwent a single MRI motility scan before and immediately after an injection of 0.5mg IV neostigmine, a cholinomimetic with potent prokinetic action.
MR Protocol: The motility scan protocol used a 3D Balanced Turbo Field Echo (BTFE) motility sequence capturing one coronal volume through the abdomen and pelvis per second over a 20 second breath hold (2.5x2.5x10 in mm resolution, FA 20, TE = 1.7ms, TR = 3.5ms, 15cm thickness in 15 reconstructed slices)
Motility Analysis: Dynamic time-series data was registered using a modified 2D optic-flow technique for each slice through the abdominal volume[2]. The deformation fields generated by the registration process were used to provide a motility metric (arbitrary unit, AU) expressed as the standard deviation of pixel's Jacobian (a measure of local area change) and averaged across a user defined ROI.
ROI Placement: A radiologist, with 5 years experience reading MRE, placed regions of interest (ROIs) around the small bowel in each coronal slice over the 15-slice volume. The radiologist was blinded both to subject group and whether the scan was pre-
RESULTS: 1) Mean baseline small bowel motility scores in CIPO patients was 0.19AU (range 0.1 to 0.25) and in controls 0.35AU (range 0.275 to 0.37) with a statistically significant difference of 0.17AU, ***p = 0.0026*** (CI 0.09 to 0.23).
2) The mean percent increase in small bowel motility scores in CIPO patients following noestigmine was 29% (95% CI from 19 to 50%) and in controls 10% (range 0 to 34) with a statistically significant difference in groups response to neostigmine of 19%, ***p = 0.029*** (95% CI from 4 to 40%).
CONCLUSION: This study demonstrated significant differences in both resting and cholinomimetic-induced global motility between CIPO patients and healthy controls. Despite marked bowel distension in the CIPO patients, motility appeared present but reduced compared to controls, and responded to provocation with neostigmine suggesting the bowel still exhibits the expected pro-kinetic effects following pharmacological stimulation. With just five patients this is a preliminary study, nevertheless initial results appear promising and support our ongoing investigation program.

P0805 MALIGNANT GASTRODUODENAL OBSTRUCTION – TREATMENT WITH SELF-EXPANDABLE METALLIC STENTS IN A SINGLE REFERRAL CENTRE

L.C. R. Freitas[1,*], L. Meireles[1], P. Sousa[1], J. Lopes[1], L.C. Ribeiro[1], J. Velosa[1]
[1]*Gastrenterology and Hepatology Department, Hospital de Santa Maria, Lisbon, Portugal*
Contact E-mail Address: *luisfreitas29@gmail.com*

INTRODUCTION: Endoscopic treatment is a valid choice in treating malignant gastroduodenal obstruction, when patients are not candidates to surgery. Self-expandable metallic stents (SEMS) have been increasingly used in this context.
AIMS & METHODS: To retrospectively analyze the use of SEMS in malignant gastroduodenal obstructions, in one referral centre, over a period of 8 consecutive years.
RESULTS: SEMS were successfully inserted in 43 patients in this period (male sex 21 (48.8%); mean age 70.67+/-13.46 years), all of them complaining with stasis symptoms. Primary tumor was gastric adenocarcinoma in 26 patients (60.5%), pancreatic adenocarcinoma in 12 patients (27.9%), and cholangiocarcinoma, gallbladder and colon cancer in 5 patients (11.6%). The median time between tumor diagnosis and stent placement was 27.5 days (range 0-980). Complications to the procedure occurred in 3 patients (7%): hypovolemic shock, perforation and aspiration pneumonia. Clear clinical improvement (tolerance to oral intake) was seen in 26 patients (60.5%). In 10 patients (23.3%), reintervention due to stent occlusion was necessary, including stent-in-stent placement in 6 patients, balloon dilation in 2 and argon plasma coagulation in 2. Median survival after sent insertion was 42 days (range 1-420), with 15 patients (34.9%) dying within less than 30 days after the procedure, with no statistical significant differences between different ages and different types of primary tumor.
CONCLUSION: When feasible, SEMS placement is a safe and efficient therapy for malignant gastroduodenal obstruction. The relatively high percentage of patients that were dead one month after stent placement, in our series, may reflect an over-selection of patients that had too advanced a disease to benefit from this technique.

P0806 SELF EXPANDIBLE METAL STENTS IN VARICEAL BLEEDING AS THE BLAKEMORE-SENGSTAKEN TUBE OF NOWADAYS? – A SINGLE INSTITUTION EXPERIENCE

M. Müller[1,*], T. Seufferlein[1], M. Wagner[1], A. Kleger[1]
[1]*Department of Gastroenterology, Universitätsklinikum Ulm, Ulm, Germany*
Contact E-mail Address: *martin.mueller@uniklinik-ulm.de*

INTRODUCTION: Despite a dramatic reduction of lethality rates due to upper gastrointestinal bleeding, esophageal variceal bleeding remains a challenge and still accounts for a mortality rate of up to 50 % within the first 6 weeks. Rapid and efficient varical ligations in combination with vasoactive terlipressin are key requirements for the initial patients stabilization. However, a relevant proportion of esophageal varical bleeding remains refractory, thus, making a call for additional tools to achieve hemostasis. Self expandible metal stents (SEMS) incorporate such a tool.
AIMS & METHODS: We report 12 cases of stent application in patients with variceal bleeding between 2011 and 2014. A retrospective analysis reporting a series of clinically relevant parameters in combination with bleeding control rates and adverse events was performed.
RESULTS: The initial bleeding control rate was 100 %. Despite this success, we observed a 30% mortality within the first 42 days due to non-hemorrhage associated reasons in the cirrhotic patients. Interestingly, we found in 7 out of 12 patients stent dislocation even after a proven correct position 24 h after hemostasis. The stent removal procedure appeared to be safe with slight reactivation of bleeding in only one of our patients. Of note, our study cohort required an extensive amount of hospital care.
CONCLUSION: Self expandible metal stents seem to be safe and efficient in patients with therapy refractory variceal bleeding. Despite high rates of stent migration no serious adverse events were observed in short term observation. This contrasts strongly with the formerly used Blakemore-Sengstaken tubes. Thus, SEMS should be considered as the new Gold standard in case of refractory esophageal bleeding.

P0807 SAFETY AND EFFICACY OF COLONIC STENTING: 7 YEAR EXPERIENCE FROM A DISTRICT GENERAL HOSPITAL IN THE UK

M. Hu[1,*], V. Mitra[1], V. Krishnan[1], D. Majumdar[1], B. Chaudhury[1], J. Hancock[1], D. Dwarakanath[1]
[1]*Department of Gastroenterology, University Hospital of North Tees, Stockton-on-Tees, United Kingdom*
Contact E-mail Address: *deepak.dwarakanath@nth.nhs.uk*

INTRODUCTION: A significant proportion of patients with colon cancer present with partial or complete bowel obstruction. Emergency decompression surgery may be associated with up to 25% mortality[1]. Self expandable metal stents (SEMS) provide an alternative low-risk option for managing these patients[2] and have been routinely used as the first line of treatment of these patients in our hospital. The aim of this study was to assess the safety and efficacy of SEMS in malignant colonic obstruction (MCO) in a district general hospital (DGH) setting.
AIMS & METHODS: A retrospective study of patients presenting with MCO and treated with uncovered SEMS between 2007 and 2013 was carried out. All stents were deployed by experienced gastroenterologists. Data including patient demographics, indication and treatment intent, site of lesion, stent type, procedure outcome, adverse events, and outcome at six months were obtained using the endoscopy reporting software and hospital patient record.
RESULTS: 78 patients were included. 53 (68%) had elective and 25 (32%) had emergency stenting. Median age was 77 years (range 47-96 years). 53 (68%) patients were male. 4 (16%) out of 25 patients who underwent emergency stenting subsequently had curative surgery. 6 (11.3%) patients in the elective stenting group (n = 53) had curative surgery. Overall, SEMS was used as a bridge to surgery in 10 (12.8%) patients while 68 (87.2%) underwent palliative stenting. The sites of malignancy were as follows: sigmoid colon 40 (51.3%), descending colon 15 (19.2%), rectum 14 (17.9%), transverse colon 7 (9.0%) and anastomotic recurrence post left hemicolectomy 2 (2.6%). Procedure related serious complications included one case of stent related perforation (proceeded to palliative rescue Hartmann's procedure) and one of contrast extravasation (successfully managed conservatively). 3 patients presented with early stent failure from blocked stent – patency was restored in one with endoscopy, one underwent Hartmann's procedure and the third patient chose to be palliated. The stents did not adequately restore luminal patency in 2 patients despite optimal positioning. Stent migration was discovered in 2 patients who represented with partial obstruction. 2 patients with rectal stents complained of discomfort and were managed conservatively. The technical success rate was 98.7% (n = 77) and the clinical success rate (functional stent without complication) was 88.5%. The 30-day all-cause mortality was 10.3% (n = 8) with none being attributable to the procedure.
CONCLUSION: Our study shows that a safe and effective colonic stenting service can be delivered in a DGH setting. There was no procedure related mortality compared to emergency decompression surgery which has a higher mortality rate[1]. This relates to service delivery by experienced operators. We suggest that all DGH with acute surgical admissions should provide this service to reduce the morbidity and mortality related to emergency decompression surgery.

P0808 ENDOSCOPIC STENT PLACEMENT OR SURGICAL GASTROJEJUNOSTOMY FOR THE PALLIATION OF MALIGNANT GASTRIC OUTLET OBSTRUCTION CAUSED BY UNRESECTABLE OR METASTATIC GASTRIC CANCER

M. Murakami[1,*], R. Takenaka[1], C. Sakaguchi[1], S. Oka[1], Y. Baba[1], N. Okazaki[1], D. Kawai[1], H. Tsugeno[1], K. Takemoto[1], S. Fujiki[1]
[1]*Gastroenterology, Tsuyama, Japan*

INTRODUCTION: Malignant gastric outlet obstruction (GOO) is traditionally treated with gastrojejunostomy (GJJ). Recently, endoscopic placement of a self-expanding metal stent (SEMS) to the GOO was covered by insurance and spread widely in Japan because it was a minimally invasive and effective method. The aim of this study was to verify the usefulness of SEMS compared with GJJ.
AIMS & METHODS: We conducted a retrospective study comparing the patients treated with endoscopic SEMS placement from April in 2010 to December 2013 with those treated with GJJ from April in 2000 to December 2013 in the management of malignant GOO caused by gastric cancer. Endoscopic SEMS placement was performed by using WallFlex duodenal stent (Boston Scientific, Tokyo, Japan). Following variables were evaluated between the SEMS group and the GJJ group; age, gender, clinical stage of gastric cancer, procedure time, Gastric Outlet Obstruction Scoring System (GOOSS) score, fasting period after placement, period of hospitalization after placement, survival period after placement, and complications.
RESULTS: The study subjects consisted of 16 patients in the SEMS group and 28 patients in the GJJ group. Between the 2 groups, there were no significant differences in median age (70 years vs. 72 years), percentage of women (31% vs. 18%), percentage of clinical stage at IV (81% vs. 89%), median GOOSS score (1 vs. 1). The technical success rates were 100% both in the SEMS group and the GJJ group. Median procedure time for SEMS stent placement was shorter than that for GJJ (25 minutes vs. 128 minutes; $P < 0.0001$). The clinical success rates were 88% in the SEMS group and 71% in the GJJ group ($p = 0.28$). The median GOOSS score after SEMS placement was similar to that after GJJ (3 vs. 3). However, the time to oral intake was significantly less in the SEMS group than in the GJJ group (2 days vs. 7 days; $p < 0.0001$). Early adverse event (occurring < 1 week) rates did not differ significantly between the 2 groups: (6% in the SEMS vs. 7% in the GJJ group). The median postprocedure length of hospital stay was shorter in the SEMS group than in the GJJ group, but not significant (17 days vs. 26 days; $p = 0.13$). Median postprocedure survival periods was similar in 2 treatment groups (68 days vs. 109 days; $p = 0.85$). Late adverse event (occurring ≥ 1 week) occurred in 2 patient in the SEMS group and 3 patients in GJJ group.
CONCLUSION: Endoscopic stent placement is preferable to GJJ in terms of shorter treatment time and more rapid improvement of food intake. Endoscopic stent placement seems to contribute to improve quality of life for the palliation of malignant GOO cause by gastric cancer.

INTRODUCTION: Endoscopic prosthesis migration from the originally stented area occurs in up to 40% of cases and may lead to serious life-threatening complications. Endoscopic suture fixation of the stent using the OverStitch™ Suturing System (Apollo Endosurgery, Inc.) significantly reduces migration. However, suturing with the OverStitch™ has a steep learning curve and is time-consuming. A novel memory shape over-the-scope endoscopic clip, the Padlock™ clip, has been developed recently by Aponos Medical. The device is a preloaded "point & shoot" single-use instrument.
AIMS & METHODS: The aim of this study was to demonstrate that the anchoring of a covered Self-Expandable Metallic Stent using the Padlock™ clip is as effective as endoscopic suturing by means of the OverStitch™ and that Padlock™ fixation can be faster and user-friendly. Eleven pigs were involved in this experimental study. A fully covered esophageal stent (Wall-Flex, Boston Scientific) of 12.3cm in length, 18mm in diameter, was placed under endoscopic guidance at the esophagogastric junction. Five pigs underwent stent fixation with 1 figure-of-eight suture using the OverStitch™. In 4 pigs, the stent was fixed by firing the Aponos Clip over a loop of Vicryl 0, which was attached to the upper edge of the stent. In two pigs, the stent was placed but not fixed and was used as a control. A laparotomy was performed and a specifically designed pulling device made of 4 fishing hooks attached to a plastic ring was anchored to the distal part of the stent at 4 cardinal points after performing a gastrotomy. A suture attached to the plastic ring was passed over the holding hook of a Digital Dynamometer (Chatillon II, Ametek, Inc.). Constant traction was applied on the sutures until full stent mobilization was achieved. The force required to remove the stent was recorded.
RESULTS: Mean force to mobilize the stent was higher in the OverStitch™ group when compared to the Padlock™ group (23.99N; SD 14.91 vs. 19.97N;

SD 7.62), but the difference was not statistically significant. In the 2 control pigs, the force required was 7 and 11 Newtons respectively. Mean suturing time was statistically significantly higher when compared to the time required to apply the Padlock™ clip (455.4sec; SD 144.83 vs. 155sec; SD 12.9; p = 0.002).
CONCLUSION: Full-thickness Padlock™ clip application is faster and may achieve a comparable stent fixation when compared to endoscopic suturing with the OverStitch™.

P0810 ENDOSCOPIC DILATATION OF BENIGN PYLORIC STENOSIS: IS IT A GOOD ALTERNATIVE TO SURGERY?

M. Acharki[1,*], M. Bakkar[2], N. Kabbaj[2]
[1]*EFD hepato gastro enterology,* [2]*EFD hepato gastro enterology, Ibn Sina Hospital, Rabat, Morocco*

INTRODUCTION: Pyloric stenosis is a common complication of ulcerative disease which requires surgery. The endoscopic dilatation is now a good alternative.
AIMS & METHODS: Aim: evaluate the efficiency of the endoscopic dilatation in the managment of benign pyloric stenosis due to ulcer diseases.
It is a prospective study from January 2009 to January 2014 including 21 patients. The dilatation was performed using a hydrostatic balloon.
RESULTS: There were 13 men and 8 women. Mean age was 48 years (35-70 years). 58 dilations were performed. In 11 cases (52 %), patients had ulcer disease and in 6 cases (29 %) non steroidal anti -inflammatory medication. The duration of symptoms was 13 months (3 months - 3 years). Vomiting and epigastric pain were the predominant clinical signs (90%). All patients underwent an upper endoscopy and had pyloric stenosis and / or pyloro - bulbar stenosis. 12 cases (57%) had impassable strictures. The average number of dilatations was three per patient (1-5). 17 patients (81%) had favorable response. The average follow-up time was 30 months (3-60 months).
CONCLUSION: Through this prospective study, we identified factors of success and failure of endoscopic dilation in benign pyloro-bulbar stenosis: the passable nature of the stenosis, the extent of the stenosis, the distance between the pylorus and the dental arches reflecting gastric distension and food stasis.

INTRODUCTION: Gastroduodenal uncovered Self Expandable Metal Stent (SEMS) placement is the first line treatment in advanced malignant gastroduodenal obstruction. The main disadvantage of uncovered stents is recurrent obstruction, mainly due to tumor ingrowth. Covered SEMS (cSEMS) reduce the re-obstruction rate. As cSEMS are removable they could represent an alternative to surgery or endoscopic dilation in benign stricture. However, cSEMS placement covering the major papilla has been suspected to be responsible of mechanical occlusion the ampullary of Vater, which could lead to cholangitis or pancreatitis. Despite the lack of data, some authors recommend concomitant biliary stenting to guarantee the adequate bile outflow before duodenal cSEMS placement. Nevertheless, the need for biliary stenting in patient without concomitant biliary stricture before cSEMS placement remains unknown.
AIMS & METHODS: The aim of our study is to compare the occurrence of jaundice or pancreatitis after duodenal cSEMS placement in patients with biliary stenting *vs* patients with no biliary stenting.
All consecutive patients who underwent endoscopic duodenal cSEMS placement in the second duodenum area between June 2005 and March 2014, because of obstructive symptoms were assessed. Biliary stenting was performed when patients presented with associated biliary stricture. Patients with previous or concomitant biliary stenting (cSEMS+BS group) were compared to patients with no biliary stent (cSEMS group). The primary end point was the occurrence of jaundice during an observation period of 90 days. Secondary end points were bilirubinemia at baseline compared to day 10, technical success, clinical effectivenes and complications rates, during a follow-up period of 90 days.
RESULTS: 106 patients were included: 53 patients in the cSEMS group (58% male, mean 66.4+/-13.3 y/o) and 53 patients in cSEMS+BS group (60% male, mean 70.4+/-11.6y/o). The obstruction was due to cancer in 45% in cSEMS group and 87% in cSEMS+BS group. **No case of jaundice was reported in the cSEMS group or in the cSEMS+BS group.** We report one case (2%) of edematous pancreatitis after stent removal 90 days after stent placement in the cSEMS group (p = 1). In cSEMS group the mean bilirubin level (µmol/L ± SD) was 9.3± 5.8 at baseline and 8.4± 4.5 at day 10, while in the cSEMS-BS group it was 90.3±106.9 at baseline and 34.7 ±39 at day 10. No significant difference was observed between the two groups in term of technical success, clinical effectiveness, migration and other complications. In all patients, endoscopic duodenal stenting was successful. The global clinical effectiveness was 90%. The overall migration rate was 25% and the symptomatic migration rate, defined as obstructive symptoms recurrence, was 16%. Other reported complications were gastrointestinal bleeding (2% in cSEMS group vs 4 % in cSEMS-BS group), Duodenal perforation (0% in cSEMS group vs 4% in cSEMS-BS group), death from all causes (13% in cSEms group vs 28% in cSEMS-BS group, p = 0.06). We report 3% of stent obstruction due tumor ingrowth.
CONCLUSION: Concomitant biliary stenting is not recommended before covered duodenal SEMS placement in patients with no concomitant biliary obstruction.

P0812 ENDOSCOPIC THERAPY OF ESOPHAGEAL LEAKS WITH STENTS: EXPERIENCE IN A REFERRAL CENTER

P. Sousa[1,1,*], L. Meireles[1], L.C. Freitas[1], J. Lopes[1], C. Noronha Ferreira[1], R. Palma[1], L. Carrilho Ribeiro[1], J. Velosa[1]
[1]*Gastrenterologia, Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Lisboa, Portugal*
Contact E-mail Address: *patlizbms@gmail.com*

INTRODUCTION: Esophageal leaks have an important morbi-mortality. The best approach is still unclear; some studies show a potential benefit of stents. Randomized controlled trials are difficult in this area.
AIMS & METHODS: The aim of this study was to evaluate the efficacy of esophageal stents for the treatment of esophageal leaks.
Retrospective analysis of stent use for esophageal leaks. In a period of 60 months demographic data, leak etiology, endoscopic procedures, time until closure and fistula's relapse were analyzed.
RESULTS: 45 consecutive patients were included (29 males; mean age 63 years). 42% had post-operative leaks (10 after gastric sleeve, 6 after Y-Roux and 3 after subtotal esophagectomy), 42% had malignant esophagopulmonary fistulas (16 esophageal and 3 bronchogenic), 7% had boerhaave syndrome and 9% had iatrogenic perforation (2 foreign body and 2 after esophageal dilation). The median time for post-operative fistula detection was 16 days (4-145).
In 36 of the 45 patients the initial approach was using a stent. Of these, in 16 patients this was the only endoscopic therapy done. Metallic stents were inserted in 40 (13 partially covered, 27 fully covered) and plastic in 5. The rest of patients had another therapeutic endoscopic procedure - another stent (n = 10), through-the-scope (TTS) clip (n = 3), nasoenteric tube (n = 10), over-the-scope clip (n = 2) and argon-plasma coagulation (n = 6).
The median time for leak closure was 48.5 days (13-308). In 6 cases the fistula's closure wasn't documented.
In 4 patients there was relapse of the leak in a median of 125 days after the initial closure. All cases were managed endoscopically - metallic stent (n = 3), argon-plasma coagulation (n = 6), nasoenteric tube (n = 3) and TTS clip (n = 1). In 3 cases there was closure in a median of 27 days after the diagnosis.
In 12 patients the overall endoscopic approach failed and surgery was needed in 8 patients and percutaneous drainage in 4.
The observed complications were: stent migration (n = 10), upper GI bleeding (n = 2). There was no need for surgery in any case or death for a procedure related complication.
CONCLUSION: The use of esophageal stents seems to be a safe and effective therapy for esophageal leaks.
Disclosure of Interest: None declared

P0813 TREATMENT OF POSTOPERATIVE LEAKS OF THE UPPER GASTROINTESTINAL TRACT WITH COLONIC SELF-EXPANDABLE METAL STENTS: SINGLE CENTRE EXPERIENCE

P.R. Sousa[1,*], A. Castanheira[1], P. Ministro[1], R. Araújo[1], E. Cancela[1], L.F. Pinheiro[2], R. Simão[2], J. Castro[3], A. Silva[1]

INTRODUCTION: The use of self-expandable metal stents (SEMS) for the treatment of postoperative leaks of the upper gastrointestinal tract is already established. However, there are discrepancies between the relatively small caliber of the esophageal stents available in our center and the post-surgical luminal size, which may determine an inadequate juxtaposition. As colonic stents have a bigger diameter, they might be more adequate. Additionally, stents with a larger diameter might have a lower risk of migration.
AIMS & METHODS: The aim of this study was to evaluate the efficacy and complications associated with the use of colonic SEMS in the treatment of postoperative leaks in critical patients. All patients with postoperative leaks of the upper gastrointestinal tract treated with colonic stents (Hanarostent® CCI) between 2010 and 2013 were retrospectively included.
RESULTS: Four patients with postoperative leaks treated with colonic SEMS were identified (3 men, 1 woman) with a mean age of 63. The underlying surgeries were a gastric bypass, an esophagogastrectomy for Boerhaave syndrome, a primary repair of esophagopleural fistula due to Boerhaave syndrome and an esophagectomy due to squamous cell cancer of esophagus. The leaks were detected on average 17 days after the initial surgery, and surgical resolution wasn't possible. In this way, the four cases were of difficult management, and in need of urgent care. They were all admitted to the intensive care unit.
Stent placement was technically feasible in all patients. There were no cases of stent dislocation. The median residence time of the stent was 7 weeks, and no complications were verified when they were removed. The treatment was successful in all patients, with complete healing of the leaks. On follow-up, one of the patients needs periodic endoscopic dilation due to esophagogastric stenosis. Another patient died 15 days after stent removal, due to septic shock not related to the procedure.
CONCLUSION: The placement of colonic SEMS seems to be successful and safe in the treatment of postoperative leaks of the upper gastrointestinal tract.

P0814 TIPS BEYOND THE CLASSICALLY RECOMMENDED: IN SEVERE HYPERTENSIVE GASTROPATHY

S. Campos[1,*], A. Oliveira[1], A. Agostinho[2], V. Carvalheira[2], D. Gomes[1], C. Sofia[1]
[1]*Gastroenterology,* [2]*Imagiology, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal*
Contact E-mail Address: *saratcampos@gmail.com*

INTRODUCTION: In addition to variceal hemorrhage, upper gastrointestinal bleeding due to hypertensive gastropathy may also occur in liver cirrhosis with portal hypertension, contributing to the poor prognosis of these patients. The portal decompression achieved by transjugular intrahepatic portosystemic shunts (TIPS) has shown positive results in the treatment/secondary prophylaxis of variceal hemorrhage, and in that sense, the analysis of their value in other complications of portal hypertension becomes relevant.
AIMS & METHODS: The aim of this study was to evaluate the efficacy and safety of TIPS in patients with severe hypertensive gastropathy.
Retrospective study including patients undergoing TIPS for severe hypertensive gastropathy in a hospital in the period between 2000 and 2013, evaluating: demographic characteristics (age, gender), liver disease (cirrhosis etiology, prior therapy, Child-Pugh, MELD), episode of decompensation (clinical and analytical parameters) and outcome (effectiveness, complications after TIPS, liver transplantation, death at 30 days and at 1 year).
RESULTS: Of the 8 patients with severe hypertensive gastropathy with recurrent medical therapy undergoing TIPS, 62.5% were male with a mean age of 53 ± 15 years. In terms of the underlying liver disease: 37.5 % had alcoholic cirrhosis, average MELD of 17 and Child-Pugh stage C in 50%. TIPS has proved effective in only 28.6% of the patients. Portosystemic encephalopathy was recorded in 57.4% of the cases. Mortality: 1 case at 30 days and 28.6% at year, both Child-Pugh C. No other feature was implicated in the prognosis of patients after TIPS placement. Two patients underwent liver transplantation. The mean follow-up was 773 days (0-3534 days).
CONCLUSION: Given the low rates of efficacy and high morbidity and mortality rates, TIPS should be carefully weighed in patients with severe hypertensive gastropathy, especially in those with more advanced liver disease.

P0815 TIPS IN REFRACTORY HYDROTHORAX – A CONTRIBUTION TO AN INCREASED RELEVANCE

S. Campos[1,*], A. Oliveira[1], A. Agostinho[2], V. Carvalheira[2], D. Gomes[1], C. Sofia[1]
[1]*Gastroenterology,* [2]*Imagiology, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal*
Contact E-mail Address: *saratcampos@gmail.com*

INTRODUCTION: Hepatic hydrothorax (HHT) is a relatively rare complication of portal hypertension, but potentially severe. Although conservative therapy may be effective, it is not without risk and refractory cases are not rare. The portal decompression achieved by transjugular intrahepatic portosystemic shunts (TIPS) have shown positive results in the treatment of refractory ascites, and in that sense, the analysis of their value in other complications of portal hypertension becomes relevant.
AIMS & METHODS: The aim of this study was to evaluate the efficacy and safety of TIPS in patients with HHT.
Retrospective study including patients with HHT undergoing TIPS in a hospital in the period between 2000 and 2013, evaluating: demographic characteristics (age, gender), liver disease (cirrhosis etiology, prior therapy, Child-Pugh, MELD) episode of decompensation (clinical and analytical parameters) and outcome (effectiveness, complications after TIPS, liver transplantation, death at 30 days and 1 year).
RESULTS: 15 patients with HHT underwent TIPS, most previously underwent multiple thoracenteses and all with hypoalbuminemia, 60% > male, mean age 63 ± 9years, 73% with cirrhosis of alcoholic etiology, mean MELD-16 and 53% with Child-Pugh B. TIPS was effective in 50% of cases. Portosystemic encephalopathy was recorded in 66.6% of the cases. Mortality: 20% at 30 days and 40% at year with septic complications or progression of liver disease. Two cases underwent liver transplantation. In the univariate analysis, only the hematocrit value had prognostic value ($p = 0.016$). The mean follow-up was 443 days (1-2250 days).
CONCLUSION: TIPS appears to be a relatively efficient method of control HHT, making it a valid option in refractory cases despite the high risk of portosystemic encephalopathy and mortality. Low hematocrit levels seem to imply a worse prognosis of patients to be considered for TIPS for refractory HHT.

P0816 DIFFERENCES IN MORTALITY BETWEEN ARTERIAL, VENOUS AND NON-OCCLUSIVE MESENTERIC INFARCTION. A SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL STUDIES

F. Adaba[1,*], A. Askari[2], S. Gabe[2], C. Vaizey[2], J. Nightingale[2], J. Warusavitarne[2]
[1]*Intestinal Failure,* [2]*St Marks Hospital, Harrow, United Kingdom, London, United Kingdom*
Contact E-mail Address: *f.adaba@nhs.net*

INTRODUCTION: Acute mesenteric infarction is a rare but often lethal event. Primary vascular aetiology can be of arterial, venous or a Non-occlusive mechanism. Mortality from acute mesenteric infarction may vary with aetiology. The aim of this study is to determine whether there are differences in mortality between arterial, venous and non-occlusive mesenteric infarction.
AIMS & METHODS: A literature search was performed via PubMed, Ovid and Google Scholar. Studies that had reported comparative mortality between arterial, venous and Non-occlusive mesenteric infarction (NOMI) were included. Odds ratios of mortality were calculated using a Mantel-Haenszel, random effect model. Meta-regression was attempted, however due to lack of adequate information in studies, it was not possible.
RESULTS: A total of 1,207 articles were screened. Of which, 20 were suitable for data synthesis for arterial vs. venous infarction, 16 for NOMI vs. venous infarction and 15 for Arterial vs. NOMI. When compared with venous infarction, patients who had arterial infarction were significantly more likely to die during primary hospital admission (OR 3.47, CI 2.43-4.96, $p = < 0.001$). Similarly, patients with NOMI were over three times more likely to die during hospital admission compared with those with venous infarction (OR 3.2, CI 1.83-5.6, $p = < 0.001$). There was no difference in mortality rates between arterial infarction and NOMI (OR 1.08, CI 0.57-2.03, $p = 0.82$)
CONCLUSION: Patients with arterial infarction or NOMI are over three times more likely to die from mesenteric infarction during primary hospital admission.

INTRODUCTION: During the last decade, conservative management is suggested to be a safe and effective alternative to appendectomy for selected patients with non-perforated (simple) appendicitis. However, preoperative selection of patients with uncomplicated appendicitis is proven to be a challenge. Computed tomography (CT) is generally accepted as the most accurate test for the diagnosis of acute appendicitis, but the performance of CT in distinguishing simple from perforated appendicitis is by far not accurate enough.
AIMS & METHODS: The aim of this study was to analyse clinical and CT features associated with perforation and to develop a scoring system for the selection of patients with simple appendicitis.
All patients with a final diagnosis of acute appendicitis were selected from a prospective database including adult patients with acute abdominal pain. The final diagnosis was assigned by an expert panel based on perioperative data, histopathology and at least 3-months of follow-up. Predefined clinical and imaging features were recorded in a structured online case record form. Only patients in whom CT was performed were included in the present analysis. Medical literature was searched and several clinical and imaging features suggested to be associated with perforated appendicitis were selected. Stepwise backward elimination ($p < 0.05$) was used to construct a multivariable regression model with independent predictors of perforation. The discriminatory capacity of the model was expressed as the area under the curve (AUC). The model was transformed into a clinically applicable scoring system and a cut-off analysis was performed to illustrate the consequences in our cohort.
RESULTS: A total of 333 patients with a final diagnosis of acute appendicitis were identified. A CT was performed in 281 patients of whom 65 (23%) had perforated appendicitis. The final model for clinical and CT features included; age > 45 years (OR 2.726; 95%CI 1.363-5.452), temperature >37.2 (OR 6.066; 95%CI 2.632-13.978), white blood cell count > 10 x 10^9/L (OR 4.786; 95%CI 1.532-14.952), c-reactive protein 45 > mg/L (OR 4.761; 95%CI 2.263-10.016), appendicolith on CT (OR 2.309; 95%CI 1.142-4.661), destruction of appendiceal wall on CT (OR 2.370; 95%CI 1.028-5.467) and free extraluminal air on CT (OR 4.026; 95%CI 1.172-13.829). The model had a discriminative value of 0.850 (95%CI 0.801-0.898). A scoring system was constructed and points were assigned for every variable, with a maximum score of 27 points. Using this score in the study cohort, 134 (48%) patients were identified with a score of 12 or less of whom 7 (5%) had perforated appendicitis, resulting in a negative predictive value of 95%.
CONCLUSION: Using this simple scoring system, a subgroup of patients with simple appendicitis can be identified based on clinical and CT features with a low percentage (5%) of false negatives (i.e. patients with perforated appendicitis). These patients can be considered for treatment options other than appendectomy.

INTRODUCTION: The aim of this study was to compare the methodological quality and input paper characteristics of systematic reviews and meta-analyses done in the medical and surgical literature by performing a systematic "overview of reviews". Ulcerative colitis (UC) and Crohn's disease (CD) were used as the framework for this comparison as they are relatively common, serious conditions with medical and surgical therapy options.
AIMS & METHODS: MEDLINE, Embase, CINHAL and the Cochrane Database were searched to November 2013. Eligible papers were systematic reviews or meta-analyses that considered a question of therapy in either CD or UC. Two independent reviewers selected the papers, extracted the data and scored their methodology using the AMSTAR scoring system. The papers were categorized into medical therapy (M), surgical therapy (S), or surgical and medical therapy (MS) groups.
Following retrieval of the sample of meta-evidence papers, the original input studies used in their creation were identified and a search of MEDLINE, Embase, CINHAL and the Cochrane Database was performed. A team of researchers then examined this collection of papers for bibliographic and financial information.
RESULTS: 500 papers were identified in the meta-evidence search. 114 were deemed eligible. There was a significant difference in the AMSTAR-rated average quality of the papers (S 7.36, M 8.87, MS 8.11, ANOVA $p=0.016$). On average S papers were published in journals with a lower impact factor (S 3.26, M 5.13, MS 5.32, $p<0.001$). S papers also showed more heterogeneity (I^2: S 37%, M 24%, MS 10%, $p<0.001$). Some 25% of S meta-analyses used data-sets with significant heterogeneity ($I^2 > 75\%$), compared to 8% of M meta-analyses and 3% of the MS group. Some 5% of S papers were done on data sets that had I^2 values $> 90\%$.
There was no significant difference in the average number of papers assessed in each group (S 15.5, M 12.33, MS 15.2, p 0.38), the average number of patients per meta-paper (S 1,304, M 1,757, MS 2,576, $p=0.2$), the average time over which the reviews covered (S 16.1yrs, M 15.2yrs, MS 14.8yrs, $p=0.93$), the average number of papers considered within each meta-analysis (S 5.7, M 5, MS 3.8, $p=0.45$), or the average number of patients considered within each meta-analysis (S 632, M 689, MS 473, $p=0.12$). Considering the conclusions of each meta-analysis, S meta-evidence was 50% more likely than M meta-evidence to be unable to make recommendations for practice.
1,443 original input papers were identified, of which 469 were duplicates. Within the non-duplicate papers ($n=974$) the average impact factor within the S group was lower than that of the M and the MS groups (3.805 vs 10.241 & 7.062, ANOVA $p<0.001$). When compared with S papers, M papers had higher rates of pharmaceutical sponsorship (M 51% vs S 1%) and twice the level of government support (M 14% vs S 7%). Of note, 21% of M papers had corporate sponsorship but did not list any conflict of interest.
CONCLUSION: Compared to medical meta-analyses, surgical meta-analyses, in the UC and CD domain, are more likely to be of poorer methodological quality, are of a greater degree of heterogeneity, and less often offer a positive conclusion. The input papers used to generate meta-evidence in medical papers have a greater degree of corporate and government sponsorship, and are more likely to come from journals with higher impact factors.

INTRODUCTION: The role of intact sensory function of both the rectum and the anal canal has been recognized to be essential for fecal continence. We hypothesized that a cause of idiopathic fecal incontinence is related to changes in the afferent sensory pathways and that this would be reflected in cortical potentials evoked by mechanical stimulation of the rectum.
AIMS & METHODS: Nineteen healthy women (mean age 54±12, mean Wexner score 1.5) and 20 women suffering from ideopathic fecal incontinence (mean 61±13, mean Wexner score 14.5) underwent repeated rapid balloon distensions of the rectum at the level of discomfort/ urge to defecate under simultaneous recording of cortical evoked potentials. Single sweep spectral band analysis was conducted to obtain the relative EEG amplitude within each frequency band.
RESULTS: The latency of the cortical evoked potentials generated in the vertex electrode of idiopathic fecal incontinence patients was longer than in healthy subjects ($p<0.001$), but there were no differences in location or strength of electrical sources in areas involved in the cerebral processing (insula, secondary somatosensory cortex and mid-cingulate gyrus bilaterally).
Analysing spectral contents of single sweeps, we found a significant increase in the alpha (8 - 12 Hz) and beta (12-32 Hz) bands ($p<0.001$) and a significant decrease in the gamma (32-70 Hz) band ($p<0.0001$) whereas low frequency bands did not differ. The changes in the gamma band were negatively correlated to the anal resting- and squeeze pressure as well as the first urge to defecate.
CONCLUSION: Our study indicates that idiopathic fecal incontinence is associated with abnormal rectal sensory perception and cortical processing of the afferent activity.

INTRODUCTION: The most common complications of sleeve gastrectomy (SG) are gastric line leaks (GLL). Standard management protocol for GLL is not yet established. We report our experience about endoscopic internal drainage (EID) using double plastic pigtails stent changed between 4 and 6 weeks until healing.
AIMS & METHODS: 34 pts (26 F), 43.6 y (23 – 70) presented GLL 12.8 days (1 – 97) from surgery. 8 patients underwent single port and 26 laparoscopic SG. 25 patients underwent a second surgery at 10.6 (0 – 97) days from SG. 9 out 34 patients presented peri-gastric collections and fever. One, two or three plastic pigtail stents (AdvanixÒ, Boston Scientific®), according to orifice's size and collection, were delivered with the one end in the collection and the other one in the stomach. In 26 patients a naso-jejunal feeding tube was inserted and kept NPO. 2 presented jejunostomy, and 4 kept to eat normal. Endoscopic control was performed systematically between 4 - 6 weeks, with either re-stenting (if the leak was still present), or removal (if no extravasation of contrast medium in the peritoneal cavity was detected), or closure with an OTSC® (if contrast material passed through the crossing stent without concomitant detection in the peritoneal cavity).
RESULTS: EID was possible in 97% (33/34) of patient. 1 (3%) was perforated during stenting deliver. 13 patients were healed at first control, 32.3 days (26 – 54) from stenting, 2 needed OTSC®. At a second control, 61.6 days (48 – 87) by first EID, 10 patients respected criteria of good outcome, 4 presented a sealed fistula, 6 needed OTSC®. Three patients healed as follows: three changes at 84 days, fourth change at 135 days, and at 180 days follows 7 changes respectively. 1 patient died, 24h later EID for pulmonary embolism. Overall, 6 out 32 patients (18.8 %) are still under treatment, and 26/32 (81.2 %) were healed with an average time of EID treatment of 57.4 days (26 – 180), they are now symptom-free, on a normal diet at a median follow up of 129 days (2 – 276).
CONCLUSION: EID is a promising therapeutic mini invasive approach for the treatment of leaks following SG, well tolerated by patients, despite the need of multiple endoscopic sessions. It allows draining peri-gastric collections and promotes tissue regrow, permitting to avoid re-surgery.

Contact E-mail Address: *G. D. Musters@amc.nl*

INTRODUCTION: Intensified treatment for distal rectal cancer has improved oncological outcome but at the cost of more perineal wound problems in patients undergoing an abdominoperineal resection (APR). The aim of this study was to analyse perineal wound healing after APR with primary perineal wound closure over time.
AIMS & METHODS: All patients undergoing APR for primary rectal cancer with primary wound closure between 2000 and 2013 were included and analysed in three consecutive time periods. Both early (<30 days postoperatively) and late perineal wound complications were determined. Independent risk factors of perineal wound complications were identified using multivariable analysis.
RESULTS: In total 136 patients were identified, of whom 129 patients underwent primary perineal wound closure. The use of neo-adjuvant (chemo)radiotherapy increased from 58% to 91% and the use of an extralevator approach increased from 9% to 19%. The rate of complicated perineal wound healing increased from 18% to 31%. An extralevator approach (OR 3.17; 95% CI 1.16-8.66) and intra-operative perforation (OR 3.35; 95% CI 1.06-10.57) were independent predictors for perineal wound complications. No differences in oncological outcome were found in patients with and without perineal wound complications. During a median follow-up of 28 months (IQR 14-56), 3% developed a perineal fistula, in 8% a persistent presacral sinus was diagnosed, and in 8% of the patients a perineal hernia occurred.
CONCLUSION: The increased use of an extralevator approach significantly increased the perineal wound complication rate over time. Intra-operative perforation was also an independent predictor of perineal wound problems.

P0822 SEALING BOWEL DEFECTS WITH TISSUE ADHESIVES: A COMPARATIVE ANALYSIS OF THE CLINICAL, MECHANICAL AND HISTOPATHOLOGICAL EFFECTS OF 7 SURGICAL ADHESIVES

K. Vakalopoulos[1,*], Z. Wu[1], L. Kroese[1], K. Lam[2], G.-J. Kleinrensink[3], H. Jeekel[1], J. Lange[1]
[1]*Surgery,* [2]*Pathology,* [3]*Neurosciences, Erasmus MC, Rotterdam, Netherlands*
Contact E-mail Address: *k.a.vakalopoulos@gmail.com*

INTRODUCTION: The use of tissue adhesives (TA) in bowel surgery is gaining popularity. Sealing bowel defects with TA may be a quick and safe alternative to suture closure. This study provides information on the sealing capability of several TA, as well as their histopathological effects on colonic tissue, providing a tool for the selection of the optimal TA.
AIMS & METHODS: 160 rats received a 0.5 cm incision in the proximal and distal colon which was then sealed with 1 of the following TA: Histoacryl Flex, Bioglue, Dermabond, Evicel, Duraseal Xact, Gelatin-Resorcinol-Formaldehyde and Glubran 2. A control group without TA was also included. Follow-up was 3 or 10 days. Leakage related complications were noted, bursting pressure (BP) and histopathological analysis were performed.
RESULTS: At 3 days leakage rates were highest in the control group and for Bioglue, Duraseal Xact and Tissucol. Glubran 2 and Tissucol showed the lowest Leakage rates. BP was highest in Duraseal Xact, Tissucol and Omnex. Histopathologically Tissucol, Omnex and the control group showed highest inflammation scores. At day 10 Controls, Bioglue and Duraseal showed the highest leakage rates and Tissucol and Omnex the lowest. BP was highest in Tissucol, Glubran 2 and Histoacryl Flex. Histopathological analysis showed highest inflammation for Bioglue, Omnex and Tissucol.
CONCLUSION: Sealing of colonic defects with TA is a safe and effective way to prevent leakage-related complications while maintaining high mechanical strength. However, large differences exist between the safety and effectiveness of the available TA. In this study, the cyanoacrylates Histoacryl Flex, Omnex and Glubran 2 as well as the fibrin glue Tissucol showed lowest leakage rates and the most inert histopathological profile while maintaining sufficient mechanical strength.

P0823 CASE CONTROL STUDY OF USEFULNESS OF INTRA-GASTRIC BALLOON BEFORE BARIATRIC SURGERY IN MORBID OBESITY

A. Ortega[1], **L.R. Rabago**[1,*], C. Vicente[2], A. Olivares[1], M.L. Arias[1], A. Castillo[1], A. Alonso[1], J. Vazquez Echarri[3], N. Herrera[3]
[1]*gastroenterology,* [2]*internal Medicine,* [3]*Surgical Department, HOSPITAL SEVERO OCHOA, Leganés, Spain*
Contact E-mail Address: *lrabagot@gmail.com*

INTRODUCTION: Bariatric surgery has an important morbidity with a scarce number of reports using intragastric- balloons (IGB-BIB®) before surgery trying to lose weight and subsequently to reduce postoperative complications.
AIMS & METHODS: In the setting of an on-going randomized study of (IGB-BIB® for 6 months before Bariatric surgery [sleeve resection (SR) or gastric bypass (GB)]) to reduce postoperative complications. We present an interim case-control study comparing with patients came from our historic surgical group "gr2" and operated by the same surgical team. We matched cases, by gender, age (± 5 years) and type of surgery (1:1). The study protocol was approved by the H. Ethical Committee. All patients provided their informed consent OBJECTIVE: to evaluate if morbidity (medical and surgical) and hospital stay will decrease after IGB-BIB treatment, and to check if there was any relationship between patient (pt) weight before surgery and morbidity
RESULTS: The historic group included 47 pts, 21.7% were male, with a mean age of 45.9 y-o (SD 10.33), a weight before surgery of 125.05 kg (SD 21.25) and BMI of 47.42 (SD 6.77). 50% of pts were ASA III. 61% of these pts were operated with GB. All in all the surgical complications rate was 32.6% (57.1% of them severe,15pts). The hospital stay was 8 days (P25-75: 6-9). ***The case-control study*** included 48 pts, 24 in each group matched by sex (58.3% women), type of surgery (66.7% GB and 33.3% SR) and age (***gr1***, 41.5 y-o, SD 10.04, ***gr2***, 44.4 y-o,SD 10.04, p 0.261). When we compared the age, sex, weight before surgery, surgical morbidity, hospital stay and ASA score between ***gr2*** and the pts left in the historic group, we did not find statistical differences. The rate of IGB-BIB failure was 20,9% in ***gr1.*** The ***gr1*** had a lower ASA score than the ***gr2*** (ASA III, 25% vs. 54.2%, p 0.04). The mean weight loss before surgery was greater in ***gr1*** than ***gr2***: 16.7 kg (SD 9.7) vs. 1.6 (SD 6.1), p 0.0001. the morbidity related to the balloon was 8,3% in ***gr1.*** Surgical complications rate was 29.2% in ***gr1*** (38,5% of them severe) vs 33.3% in ***gr2***(58.8% severe). The reoperation rate was 8,3% in both groups. The hospital stay was 7 days (p25-75: 5.2-8) in ***gr1*** and 8 d (p25-75: 7-9.2) in ***gr2***, p 0.061. One patient died in ***gr2*** representing a 2.1% rate of mortality in the historic group. We did not find any significative differences either in surgical morbidity (p 0.781) or in total morbidity [surgical plus balloon morbidity (p 1)] in the case-control analysis. There was also not difference in morbidity classified as severe (p 1) in this case control-study. **Multivariable** logistic **Regression Analysis** in all the cohort patients of the study (***gr1+historic group***) did not find that weight before surgery,type of surgical procedure, age of sex were predictors of morbidity.
CONCLUSION: 20.9% of pt with IGB-BIB failed to lose weight. It has not been found yet a decrease in morbidity or hospital stay in the IGB-BIB® group compared with their matched control group in spite of the fact that that the case group had a lower ASA score. Case control and Multivariate analysis have not proven any relationship between patient weight before surgery and morbidity.

P0824 ROUTINELY CRP QUANTIFICATION AFTER APPENDECTOMY DUE TO ACUTE APPENDICITIS – A WASTE OF MONEY?

M. Tachezy[1,*], I. Anusic[1], F. Gebauer[1], J.R. Izbicki[1], M. Bockhorn[1]
[1]*General, Visceral and Thoracic Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
Contact E-mail Address: *m.tachezy@uke.de*

INTRODUCTION: Appendectomy is the most frequent non elective surgical procedure in general surgery. Until now, indication is generally based on clinical findings. However, laboratory results such as leukocyte count and C-related Protein (CrP) are usually determined before and after the surgical procedure, and clinicians are not infrequently confronted with the question, if a patient can be discharged with an increasing inflammatory laboratory parameter. A clear evidence for a prospective value of the parameters and their trend regarding complications is missing.
AIMS & METHODS: Between November 2004 and April 2010, nine hundred sixty-nine patients underwent a surgical procedure due to clinically suspected acute appendicitis. All clinical, laboratory and histopathological data were obtained from the clinical and pathological records and a quality control data base containing information 0 ($n = 243$). Laboratory results were correlated with clinical and histopathological data (t-test, Chi-square test, regression analysis, ROC curve, respectively).
RESULTS: Eight hundred ninety-two (92%) patients had a histological confirmed acute appendicitis; median hospitalisation was 3 days (range 1-38 days). Overall morbidity was 6.2%; 60 (5.7%) patients suffered from infectious complications. Strongest predictive parameter for complications was a CrP value of more than 108 mg/l on the first postoperative day with an odds ratio of 16.6 (96% CI 6.4/42.8, $p < 0.001$). ROC analysis revealed an AUC of 0.821 with a Specificity of 88% and Sensitivity of 69%. Patients with below the threshold suffered from complications in 1.1% in contrast to the patients above with 16.8% ($p < 0.001$). In patients without acute appendicitis Operative trauma causes a CrP increase from less than 5 mg/l up to a median of 30 mg/l (25^{th} percentile: 8mg/l and 75^{th} percentile 100mg/l) on POD 1 to 47 mg/dl (25^{th} percentile: 23mg/l and 75^{th} percentile 125mg/l) on POD 2.
CONCLUSION: Operative trauma due to a non-acute inflamed appendectomy causes a significant increase of serum CrP, which must be taken into account for clinical assessment after appendectomy. Therefore, a moderate elevation of CrP values postoperatively is no general contraindication for discharge. However, postoperative determination of CrP serum values after appendectomy seems to be an effective predictor for complications and should therefore be measured in the clinical routine.

Contact E-mail Address: *baegmk@catholic.ac.kr*

INTRODUCTION: Patients with implantable cardiac devices who undergo endoscopic electrosurgery are at risk of potentially harmful electromagnetic interference (EMI). However, few reports on the association between the two exist.
AIMS & METHODS: We aimed to analyze the effects of endoscopic electrosurgery in patients with implantable cardiac devices. The medical records of patients who underwent endoscopic procedures requiring the use of electrosurgery, such as snare polypectomy, endoscopic submucosal dissection (ESD), and endoscopic retrograde cholangiopancreatography (ERCP) with endoscopic sphincterotomy (EST), were analyzed retrospectively. Patients with implantable cardiac devices had their medical records reviewed, which included postprocedural patient symptoms, demographic data, and outpatient follow-up data. Electrical data, including preprocedural and postprocedural arrhythmia records, such as pacemaker interrogation, 24 h Holter monitoring, and electrocardiogram, were also reviewed.
RESULTS: Forty-nine patients who underwent 59 procedures were analyzed. Fifty procedures were performed in 43 patients with pacemakers, and nine procedures were performed in six patients with implantable cardioverter-defibrillators. There were 44 colon snare polypectomies, one colon ESD, one gastric snare polypectomy, five gastric ESDs, and eight ERCPs with EST. Fifty-five cases of electrical follow-up were observed, with two postprocedure changes noted that were not caused by electrosurgical EMI. Thirty-one pacemaker interrogations

had recordings of the procedure, with two cases of asymptomatic tachycardia events. All patients were asymptomatic, and no adverse events after the procedure were reported.
CONCLUSION: Our study reported no adverse events from endoscopic electrosurgery in patients with implantable cardiac devices, which suggests that this procedure is safe. However, because of the possibility of EMI, recommendations regarding endoscopic electrosurgery should be followed.

P0826 RISE IN TROPONIN T AFTER MAJOR GASTROINTESTINAL SURGERY IS ASSOCIATED WITH OCCURRENCE OF NEW MAJOR CARDIOVASCULAR EVENTS

P.W. Chiu[1,*], M.T. Chan[2], S.S. Ng[1], A.Y. Teoh[1], S.K. Wong[1], E.K. Ng[1]
[1]*Department of Surgery,* [2]*Department of Anesthesia and Intensive Care, THE CHINESE UNIVERSITY OF HONG KONG, Hong Kong, China*

INTRODUCTION: A risk in Troponin T is associated with myocardial infarction, cardiovascular death and heart failure. Recently, an international prospective cohort study recently suggested a significant association between peak postoperative Troponin T (TnT) within three days after surgery and 30-day mortality. However, there is no study to investigate the long term risk of cardiovascular events among those with elevated troponin T level after surgery. This study aimed to investigate elevated Troponin after gastrointestinal surgery and 3 year outcomes.
AIMS & METHODS: This is a prospective cohort study including patients age above 45 years who underwent either elective or emergency upper or lower GI surgery under general anesthesia. Those recruited had measurement of peak troponin T (TnT) levels by fourth generation TnT assay. The data for assessing perioperative mortality and cardiovascular diseases were collected, including baseline demographics, smoking status, history of cardiovascular disease, type of surgery performed as well as clinical outcomes. The primary outcome was 3 year mortality after surgery. Secondary outcomes included new major cardiovascular events (which were defined as myocardial infarction, stroke, deep vein thrombosis and pulmonary embolism), new use of anti-platelet medication (e.g. aspirin, clopidogrel) and new use of anti-coagulation drugs (e.g. warfarin) within 3 years after surgery.
RESULTS: A total of 213 patients were recruited including 128 male and 85 female. 53 patients underwent upper gastrointestinal surgery and 152 underwent lower gastrointestinal surgery. 28 patients (13.1%) had elevated peak troponin T level (>0.01ng/mL) in at least one measurement within 3 days after surgery. 5 out of 213 patients drop out of the study with 97.7% of patients completed 3-year follow-up. There was no difference in 3 year mortality between those with and without elevation of TnT after surgery. Those in the elevated TnT group sustained significantly higher rate of cardiovascular events (57.1% vs 10.4%; $p < 0.001$) and also higher use of anti-platelets agents (30% vs8.2%; $p = 0.009$) within 3 years after surgery when compared to the normal TnT group. There was no difference in 3 year cancer recurrence between the two groups.

	Elevated Troponin T group (TnT) (n = 28)	Non-elevated Troponin T group (non-TnT) (n = 185)	P value
Age	75 (51-99)	68 (45-90)	0.002†
BMI	22.70 (15.36-30.03)	22.10 (14.91-29.29)	0.426
Gender M:F	15/13	113/72	0.450

P0827 DEFUNCTIONING ILEOSTOMY DOES NOT PREVENT ANASTOMOTIC LEAKS AFTER RESTORATIVE PROCTOCOLECTOMY; A MULTICENTER EVALUATION OF CLINICAL AND SURGICAL RISK FACTORS

S. Sahami[1,*], C. Buskens[1], P. Tanis[1], T. Young Fadok[2], A. De Buck van Overstraeten[3], A. D'Hoore[3], W. Bemelman[1]

INTRODUCTION: Anastomotic leakage (AL) is a serious complication after restorative proctocolectomy with ileal pouch-anal anastomosis (IPAA) that could lead to pelvic sepsis and ultimately to pouch failure. Previous studies have shown significantly decreased leak rates in diverted patients with less severe clinical consequences. The last decade, a trend has been seen towards more extensive medical treatment in IBD patients, leaving refractory patients in a worse condition when it comes to surgery. Since timely identification of high-risk patients could influence surgical decision-making and diminish the risk for complications, the aim of our study is to identify clinical and surgical parameters associated with AL and to analyse whether a defunctioning ileostomy should be considered as standard care in patients undergoing IPAA.
AIMS & METHODS: In a retrospective study, 691 patients undergoing IPAA for IBD, dysplasia, or FAP were identified from prospectively maintained databases of three large IBD centres. The creation of an ileostomy was left at the discretion of the surgeon. AL was defined as any leak confirmed by either contrast extravasation on imaging or by re-laparotomy. Multivariable regression models were developed to identify risk factors for AL.
RESULTS: In 305 IBD patients (49.1%), an ileostomy was created during IPAA. A comparable overall leak rate was found in the stoma group when compared to non-diverted patients (16.7% vs 17.1%, $p = 0.92$). This unexpected finding of high leak rates despite stoma formation could probably be explained by the increased use of anti-TNF (12.6% versus 4.6%, $p < 0.001$), steroids (33.0% vs 12.1%, $p < 0.001$), and weightloss (>5% of bodyweight) (14.6% vs 8.5%, $p = 0.02$) when compared to non-diverted patients. Despite having a stoma, a high leak rate (40.0% vs 15.1%, $p = 0.02$) was found in patients treated with a combination of anti-TNF and steroids. This was also emphasized by the fact that patients undergoing subtotal colectomy with IPAA at a later stage (weaned of medication) had a significantly decreased leak rate when compared to patients undergoing primary IPAA (11.6% vs 20.7%, $p = 0.003$). Multivariable regression models demonstrated, long-term disease course (OR 2.01, 95%CI 1.27–3.19), high ASA score (OR 1.94, 95%CI 1.09–3.47) and a combination of anti-TNF and steroid treatment (OR 5.61, 95%CI 1.71–18.48) as independent risk factors for AL.
CONCLUSION: These results imply that in daily practice surgeons perform ileostomy in more fragile and disease affected patients. This strategy seems ineffective in the prevention of AL in these series implicating that a staged procedure, that is subtotal colectomy followed by completion proctectomy and IPAA after weaning of the medication, is more appropriate when preoperative risk factors are identified. Long-term disease course, high ASA score, and a combination of anti-TNF and steroid treatment within 3 months before IPAA were all independent risk factors for AL.

INTRODUCTION: IBD patients display a variety of nutritional deficiencies because of decreased nutrient intake or absorption and/or increased losses. Magnesium (Mg) is a critical cofactor for numerous enzyme systems and its deficiency may result in several clinical manifestations. Recent evidence showed that Mg participates in immune system regulation. Intestinal mucosa and kidneys, are the natural access routes for magnesium into the blood stream which involves cation channels and transporters, like TRPM-6 and -7. Few information exist on Mg in IBD pathogenesis.
AIMS & METHODS: The aim of the study is to assess whether Mg receptors TRPM-6 and -7 are involved in an experimental model of colitis. DSS colitis was induced in C57BL/6 mice. 5 Mice received 2.5% DSS in tap water for 5 days and then sacrificed, while controls received only water. 5 further mice received 2.5% DSS for 5 days and then exposed to water for further 7 days to observe recovery. At the sacrifice plasma was collected from each animal, stored at -80°C and then assessed for Mg content by atomic absorption spectroscopy; a first section of liver, kidney and bowel were snap frozen and then analized by Real Time (RT)-PCR for TRPM-6 and -7; a second section of each was fixed in 4% formalin and embedded in paraffin for immunohistochemistry (IHC).
RESULTS: As expected mice exposed to DSS for 5 days developed a mild colitis, which was associated to lower Mg plasma concentration (mean value 0.64mM) compared to healthy controls (mean value 0.77 mM). At IHC and RT-PCR analysis TRPM-6 and -7 expression did not differ in liver and kidney among healthy and colitic mice. On the contrary, their expression in bowel decreased drastically in colitic mice. By IHC, we observed a decrease of TRPM6 expression and a change of localization of TRPM7 within enterocytes from apical to basolateral position. In recovered mice, the intestinal expression of
TRPM-6 and -7 was restored.
CONCLUSION: Mg plasma concentration decrease during active colitis. This observation paralleled the decrease of intestinal TRPM-6 and -7 expression. Further experiments are required to show the immunological consequences of this observation.

INTRODUCTION: Oxidative stress-induced disruption of epithelial tight junctions (TJ) plays a critical role in the pathogenesis of intestinal disorders, including inflammatory bowel disease (IBD).
AIMS & METHODS: The current study investigated the protective effect of diarylheptanoid hirsutenone against disruption of the intestinal barrier *in vitro* and in a mouse model of colitis. Caco-2 cells were stimulated with *tert*-butyl hydroperoxide (*t*-BH). Monolayer permeability was assessed by measuring the transepithelial electrical resistance and inulin flux. Colitis was induced in mice by intrarectal administration of trinitrobenzene sulfonic acid (TNBS). The mRNA and protein levels were analyzed by real-time polymerase chain reaction (PCR) and immunoblotting, respectively.
RESULTS: Hirsutenone prevented the *t*-BH-induced increase in permeability by inhibiting the reduction in zonula occludens-1 (ZO-1) expression, and rapidly stimulated tyrosine phosphorylation of the epidermal growth factor receptor (EGFR). Hirsutenone-mediated protection against the loss of ZO-1 depends on the activation of both ERK1/2 and Akt signaling pathways. Interestingly, hirsutenone-mediated activation of Akt, but not ERK1/2, signaling was EGFR-dependent. Hirsutenone increased heme oxygenase-1 (HO-1) expression through both EGFR/Akt- and ERK1/2-dependent pathways, contributing to the protective effects against TJ dysfunction. Hirsutenone administration improved the clinical parameters and tissue histological appearance, stimulated HO-1 expression, attenuated reduction of ZO-1 and occludin mRNA, and promoted BrdU incorporation in the colonic epithelium of TNBS-treated mice.
CONCLUSION: Hirsutenone reversed disordered intestinal permeability by activating EGFR/Akt and ERK1/2 pathways, which are involved in HO-1 expression regulation. These findings highlight the potential of hirsutenone for clinical applications in the treatment of IBD.

INTRODUCTION: It is well accepted that in animal models of intestinal inflammation nicotine activates a cholinergic counter-inflammatory mechanism through the alpha7 nicotinic acetylcholine receptors (α7nAChR). However in inflammatory bowel diseases (IBD) nicotine shows opposing effects on intestinal inflammation: it's beneficial in ulcerative colitis (UC) while it increases risk of surgery and relapse in Crohn's disease (CD).
AIMS & METHODS: In this study we measured α7nACh expression on peripheral and intestinal mucosa-derived macrophages from patients with UC, CD and healthy controls (HV) and evaluated the effect of nicotine on LPS-induced cytokines production in macrophages. Peripheral blood derived macrophages (MΦc) were obtained by supplementing blood monocytes from UC and CD patients (in clinical remission) and HV with M-CSF (7 days). α7nAChR mRNA and protein levels were evaluated by qRT-PCR and FACS analysis using α-bungarotoxin (αBgt)-FITC. MΦc were pre-incubated with nicotine (1mg/ml 30min) and then stimulated with LPS (1μg/ml 24 hrs). TNFα levels were measured on supernatant using ELISA. Colonic mucosa macrophages (MΦi) were isolated from biopsies of UC (n = 12), CD (n = 11) and HV (n = 17) and α7nAchR expression was evaluated by FACS analysis using αBgt-FITC. Macrophages were incubated for 24 hrs with LPS (1μg/ml) in presence or absence of nicotine (1mg/ml) and TNFα and IFNγ assessed by staining with specific antibodies and cytofluorimetric analysis.
RESULTS: MΦc from UC showed greater α7nAchR mRNA levels then cells from CD ($p = 0.006$), while no differences were found with HV. FACS analysis confirmed greater α7AChR expression in UC patients than in CD (90.75 Gmean in UC Vs 15.62 Gmean in CD, p 0.031) but not in HV. Although nicotine significantly decreased LPS-stimulated TNFα release in MΦc from HV, CD and UC, no differences were observed among groups. Indeed, in UC derived MΦi α7nAChR levels were significantly higher than in CD and HV cells ($p < 0.01$ vs both). Furthermore, nicotine significantly specifically reduced LPS-induced TNFα upregulation in MΦi from UC patients (from 18.91±2.57 to 10.81±1.99 %fluorescence, $p = 0.013$) but not in CD and HV whereas nicotine had no effect on LPS-induced IFNγ upregulation in MΦi in the different experimental groups.
CONCLUSION: The selective α7nAchR upregulation in MΦi from UC patients and their responsiveness to the anti-inflammatory effects of nicotine may explain nicotine's protective effects in UC but not in CD patients.

INTRODUCTION: The intestinal epithelium is maintained by the stem cell residing at the bottom of the crypt. Olfactomedin-4 (OLFM4) is one of the specific marker genes of the human intestinal stem cell. The gene encodes secretory-type, as well as intracellular-type, OLFM4 proteins. Reports have shown that secretory-type OLFM4 facilitates cell adhesion and may take part in mucosal defense, whereas intracellular-type OLFM4 can exhibit anti-apoptotic property. Also, it has been shown that the expression and secretion of OLFM4 is upregulated in the inflamed mucosa of ulcerative colitis (UC), where Notch signaling is highly activated. However, the expression of the intracellular-type OLFM4 protein in the inflamed mucosa, or the mechanism regulating its expression, remains unclear.
AIMS & METHODS: We aimed to identify the expression of intracellular-type OLFM4 in the normal and inflamed mucosa of the human colonic tissue, and also to clarify the molecular mechanism regulating its expression in the inflamed mucosa. Expression of intracellular-type OLFM4 in colonic tissues of normal and UC patients was analyzed by immunohistochemistry (IHC). Human colonic epithelial cell lines, Ls174T and DLD1, were employed to analyze the expression of OLFM4 in response to various inflammatory stimuli. Involvement of Notch signaling in OLFM4 protein expression was examined by using a sub-line of Ls174T cells (Ls174T-NICD cells) in which Doxycycline-dependent activation of Notch signaling can be induced. Using those cell-lines, the expression of secretory-type OLFM4 protein was quantified by ELISA, whereas that of intracellular-type OLFM4 protein was examined either by immunoblot analysis or by immunocytochemistry.
RESULTS: IHC analysis of the normal human colon tissues showed that OLFM4 is expressed mostly at the apical surface of epithelial cells residing at the lower crypt, indicating dominant expression of secretory-type OLFM4. However, in the inflamed mucosa of UC patients, an increased number of colonic epithelial cells clearly expressed OLFM4 in their cytoplasm, indicating high-level expression of intracellular-type OLFM4. In vitro analysis using human colonic epithelial cell-lines showed that, among various pro-inflammatory cytokines, TNF-α significantly upregulates secretion of OLFM4, but do not promote accumulation of the intracellular-type OLFM4. In contrast, forced activation of Notch signaling never induced secretion of OLFM4, but induced accumulation of intracellular-type OLFM4. Upon addition of TNF-α under forced activation of Notch signaling, those stimuli synergistically up-regulated the accumulation of intracellular-type OLFM4 protein to a remarkably high-level, but did not give any additional change to secretion of the OLFM4 protein. Immunocytochemistry clearly confirmed the cytoplasmic accumulation of OLFM4 protein by the synergistic effect of TNF-α and Notch activation.
CONCLUSION: Notch signaling and TNF-α synergistically promotes accumulation of intracellular-type OLFM4 protein in human colonic epithelial cells. As it has been suggested that those type of OLFM4 protein can exhibit anti-apoptotic function, such an accumulation may contribute to protect human colonic epithelial cells in the inflammatory environment.

INTRODUCTION: The peroxisome proliferator-activated receptor-γ (PPARγ) is a key factor of mucosal homeostasis and the pharmaceutical target of 5-aminosalycilates. Thus, understanding of the primarily decrease expression of PPARγ during UC remains challenging and of therapeutic interest. Mucosal hypoxemia has been well described during UC. The aim of the study was to assess and to study the link between hypoxia and PPARγ expression in intesintal epithelial cell during UC.
AIMS & METHODS: *In Vitro*, PPARγ mRNA and protein were quantified in various epithelial cell lines 1) during exposure to hypoxia (1%O2) at several time points 2) after chemical induction of HIF-1α 3) after transfection of miR-27a or knockout of miR-27a (a microRNA induced by hypoxia and with high affinity to PPARγ *in silico*) and 4) after stimulation by sildenafil (a phosphodiesterase type 5 inhibitor used for blood vessel dysfunction). *Ex vivo*, PPARγ and miR27a expressions were quantified from mucosal biopsies of surgical specimens from controls or patients with UC.
RESULTS: *In vitro*, exposure of Caco-2 and HT29 cells to hypoxia (1% O2) decreased significantly mRNA and protein expression of PPARγ (at least 50%) as compared to normoxic condition (21% O2) at days 2. To assess the link between hypoxia and the decreased expression of PPARγ, we first induced HIF-1α expression, a key factor of cells response under hypoxic condition, by chemical treatment of cultured cells lineages (deferoxamine, cobalt chloride and dimethyloxaloylglycine). No effect was observed either on PPARγ expression neither on miR27a expression. Regarding this result suggesting an independent HIF-1α way that controls PPARγ expression during hypoxia, we focused on

miR-27a. MiR-27a was induced by hypoxia in epithelial cells. When miR-27a was overexpressed by transfection in caco-2 cells during normoxic condition, PPARγ expression was decreased. Conversely, PPARγ was not affected by hypoxia after knockout for miR27a of caco-2 cells by transfection of miR-27a inhibitors. *Ex vivo*, we confirmed a decreased of PPARγ expression in colonic mucosa of patients with UC and higher miR-27a expression as compared to controls. In order to affect the variation of PPARγ expression during hypoxia we used the sildenafil. The sildenafil raised PPARγ expression in caco-2 cells exposed to hypoxia. Furthermore the use of sildenafil resulted in the absence of overeexpression of miR-27a expression during hypoxia.
CONCLUSION: A direct relationship was observed between hypoxia and PPARγ expression. Mir-27a which is overexpressed during hypoxia and in patients with UC might be the key factor involved during hypoxia to control PPARγ expression. These results open new insight into the pathophysiology of UC and the role of hypoxia as well as new therapeutic strategy such as the use of sildenafil.

P0833 MECHANISMS UNDERLYING THE EFFECTS OF CALCITONIN GENE-RELATED PEPTIDE IN A RAT COLITIS MODEL

H. Yamasaki[1,*], R. Yamauchi[1], K. Kuwaki[1], S. Yoshioka[1], H. Takedatsu[1], K. Mitsuyma[1,2], T. Torimura[1]
[1]*Department of Medicine,* [2]*Infllamatory Bowel Disease Center, KURUME UNIVERSITY SCHOOL OF MEDICINE, Kurume, Japan*

INTRODUCTION: Calcitonin gene-related peptide (CGRP), a vasodilative neuropeptide, is involved in potent tissue repair and anti-inflammatory actions. Previous studies have shown that the administration of CGRP prevents colonic injury. However, the mechanism of action responsible for the effect of CGRP on colitis remains unknown.
AIMS & METHODS: Colitis was induced by the oral feeding of 3% dextran sulfate sodium to rats for up to 7 days. After the induction of colitis, CGRP (200 μg/μL/day) was administered via the tail vein twice a day for 7 consecutive days. Disease severity was assessed by clinical and endoscopic evaluation, and histologic scoring. The tissue levels of pro-inflammatory cytokines (interleukin [IL]-1α, IL-6, and tumor necrosis factor [TNF]-α) and CGRP receptors (receptor activity-modifying protein-1 [RAMP1] and calcitonin receptor-like receptor) were determined using real time-PCR. Bone marrow cell induction and colonic blood flow were also investigated. Additionally, the cytokine response in peripheral blood mononuclear cells stimulated by lipopolysaccharide with or without CGRP was examined in vitro.
RESULTS: The administration of CGRP, but not a control vehicle, improved the clinical disease activity ($P=0.009$) and the endoscopic disease activity ($P=0.009$). CGRP decreased the mRNA levels of IL-1α ($P=0.032$), IL-6 ($P=0.032$) and TNF-α ($P=0.016$) and increased the mRNA level of RAMP1 ($P=0.001$). CGRP increased the colonies of CFU-GM in the bone marrow ($P=0.016$) and the number of endothelial progenitor cells in the peripheral blood ($P=0.040$) and enhanced the colonic blood flow ($P=0.032$). The mRNA and protein levels of the inflammatory cytokines in lipopolysaccharide-stimulated peripheral blood mononuclear cells were significantly reduced after the addition of CGRP in vitro.
CONCLUSION: The administration of CGRP effectively suppresses colonic injury through the down-regulation of pro-inflammatory cytokines and the up-regulation of protective events, including bone marrow-derived cell induction, in addition to promoting colonic blood flow. Consequently, CGRP is an attractive and novel therapeutic target for the treatment of inflammatory bowel disease.

P0834 SERUM IL-23 DIFFERENTLY CORRELATES WITH COLONIC MMP-9/TIMP-1 AND MMP-9/TIMP-2 IN CROHN'S DISEASE, BUT NOT ULCERATIVE COLITIS PATIENTS

A. Piechota-Polańczyk[1], M. Jonakowski[1], A. Pilarczyk[1], M. Włodarczyk[2], A. Sobolewska[2], M. Wiśniewska-Jarosińska[2], **J. Fichna**[1,*]

INTRODUCTION: Intestinal alterations in IBD are triggered and sustained by over-expression of pro-inflammatory cytokines. Cytokine quantification may become a non-invasive tool to monitor the disease progression and effectiveness of therapy, or assist in understanding disease etiology. Currently, there are limited non-invasive biomarkers for monitoring IBD progression; however, the role of selected cytokines like IL-23 and IL-17, or proteolytic proteins like matrix metaloproteinases (MMP) or their tissue inhibitors (TIMP), is under consideration.
AIMS & METHODS: The aim of this study was to evaluate if IL-17 and IL-23 correlate with MMP-9/TIMP complexes in IBD and if those parameters differ in affected and unaffected colon mucosa.
Serum and biopsy specimens from affected and unaffected colonic mucosa of 19 patients with IBD (9 with ulcerative colitis, UC and 10 with Crohn's disease, CD) and 8 controls were included in our study. Serum and tissue cytokines, and tissue MMP-9/TIMP-1 and MMP-9/TIMP-2 were quantified at the protein level by ELISA.
RESULTS: The UC subjects had significantly lower serum IL-23 ($p=0.002$) and slightly higher serum IL-17 level ($p=0.09$) compared with control. In unaffected tissues, there was a significant decrease in IL-23 content ($p=0.002$ vs. control). In CD patients no difference in serum IL-23 or IL-17 content was measured; however, both IL-23 and IL-17 were significantly decreased in unaffected colon tissues ($p=0.00003$ and $p=000002$ vs. control). The levels of IL-23 or IL-17 in affected tissues from UC and CD groups were comparable.
As IL-17/IL-23 axis directly influences MMP-9 activity, we measured the concentration of MMP-9 in complex with TIMP-1 or TIMP-2. The UC group had significantly higher MMP-9/TIMP-1 level in unaffected tissue compared with control ($p=0.001$), while in CD an opposite tendency was observed. Regarding MMP-9/TIMP-2, there was a decrease in unaffected tissue in both UC and CD groups compared with control ($p=0.07$ and $p=0.08$, respectively). Further analysis revealed that IL-23 correlates with MMP-9/TIMP-1 in UC and with MMP-9/TIMP-2 in CD. In the UC group serum IL-23 negatively correlated with MMP-9/TIMP-1 in unaffected tissue ($r=-0.903$), but positively in affected colon sections ($r=0.72$). In CD subjects, there was a strong negative correlation between serum IL-23 and MMP-9/TIMP-2 in unaffected tissue ($r=-0.94$); and positive correlations between tissue IL-23 and MMP-9/TIMP-2 in both unaffected and affected areas ($r=0.66$ and $r=0.62$, respectively).
CONCLUSION: It is believed that higher IL-23 levels decrease the content of MMP-9/TIMP complexes, which in turn may lead to elevated MMP-9 levels and MMP-9-induced tissue damage. The correlations between serum and tissue IL-23 and MMP-9/TIMP-1 in UC or MMP-9/TIMP-2 in CD, in particular in unaffected mucosa, may therefore be an indicator of an ongoing inflammatory process. However, further studies are necessary to explain the interaction between cytokines, especially IL-23 and pro- and anti-proteolytic proteins in inflamed and non-inflamed areas in IBD subjects.

P0835 CROHN'S DISEASE-ASSOCIATED ADHERENT-INVASIVE E. COLI INDUCE SECRETION OF EXOSOMES WITH PRO-INFLAMMATORY ACTIVITY BY INTESTINAL EPITHELIAL CELLS

J. Carriere[1,*], H. Nguyen[1], A. Darfeuille-Michaud[1]
[1]*UMR 1071 Inserm, University of Auvergne, Clermont-Ferrand, France*

INTRODUCTION: Crohn's disease (CD) is a chronic inflammatory bowel disease of which the etiology involves environmental, genetic and microbial factors. Our group and others have shown a high prevalence of the invasive E. coli strains, designated adherent-invasive E. coli (AIEC), in the intestinal mucosa of CD patients. Exosomes are small endosomal-derived vesicles involved in cell to cell communication and have been implicated in various diseases including cancer and infectious disorders. It has been reported that mammalian cells infected with pathogens can release exosomes containing microbial compounds.
AIMS & METHODS: Here, we investigated the capacity of CD-associated AIEC bacteria to induce secretion of exosomes by intestinal epithelial cells and to determine the inflammatory characteristics of the released exosomes. Human intestinal epithelial T84 cells cultured on transwell filters were infected with an AIEC reference strain LF82. Exosomes were purified using the ExoQuick exosome precipitation reagent. Exosomes released into the apical or basolateral compartments of LF82-infected T84 cells were tested for their ability to promote a pro-inflammatory response in naïve macrophagic cells.
RESULTS: Electron microscopy and immunogold-labeling for an exosomal marker, CD63, analyses showed that differentiated T84 cells infected with AIEC LF82 secreted an increased amount of exosome compared to uninfected cells. This was confirmed by increased levels of four exosomal markers (CD63, CD81, CD9 and Hsp70) as assessed by Western blot. Exosomes apically secreted by infected T84 cells but not from uninfected cells significantly induced production of the pro-inflammatory cytokines TNF-α and IL-6 in human macrophages, and this was not due to the presence of lipopolysaccharide, known to induce a pro-inflammatory response.
CONCLUSION: In conclusion, our study shows that upon infection with CD-associated AIEC bacteria, differentiated intestinal epithelial cells release exosomes that can trigger pro-inflammatory responses in naïve macrophagic recipient cells.

P0836 DIAGNOSIS AND PERSISTENCE OF HISTOLOGICAL CHANGES IN LYMPHOCYTIC COLITIS

J. Rasmussen[1,*], P. Engel[2], L.K. Munck[3,4]
[1]*Department of medicin, Køge Sygehus, Køge,* [2]*Department of pathology, Roskilde Hospital, Roskilde,* [3]*Department of medicin, Køge Hospital, Køge,* [4]*Faculty of Health and medical sciences, University of copenhagen, copenhagen, Denmark*
Contact E-mail Address: *jul.rasmussen@gmail.com*

INTRODUCTION: The topographic distribution of histological changes in microscopic colitis (MC) remains controversial. The main conception has been that in order to detect or rule out MC, biopsies from the right colon is necessary. However this has to some extent been proposed on the basis of a selected population of patients included in randomised trials with collagenous colitis (CC). A sigmoideoscopy is more gentle with the patient, cheaper and often more accessible and thus would be preferred if sufficient in detecting MC.
AIMS & METHODS: Aims: To access the topography of histological changes in the colon diagnostic of lymphocytic colitis (LC) in a complete series of consecutive, non-selected patients and to provide the sensitivity of left- and right-side biopsies respectively. Furthermore to analyse the persistence of changes in repeated endoscopies.
Methods: Retrospective review of the pathologic descriptions in the Danish National Pathology Database in patients diagnosed with lymphocytic colitis in the coverage area of Køge Hospital from 2000 through March 2014. Biopsies from the rectum were excluded.
RESULTS: LC was diagnosed in 238 patients; in 81 (34%) by sigmoideosopy and in 136 (57%) by colonoscopy. A medical history of watery diarrhoea could be retrieved in 196, 1 did not have diarrhoea. The median number of biopsies

taken was 6 (mean 7.6). Biopsies were taken from both right and left colon in 122 (51%) and showed LC in both left and right colon of 119 (98%). At the diagnostic endoscopy 3 patients (2%) had changes in the left colon only and no one had changes in the right colon only. The histological diagnosis in the right colon were: normal (1), chronic inflammation (1) and incomplete LC (1). The sensitivity of left sided biopsies for the primary diagnosis of LC were 100% (95% CI: 97-100%) and right sided 98% (94-100%). A second endoscopy following the diagnostic one was performed in 50 (21%) of the 238 patients after a median of 13.5 months (mean 27.2) with a median of 6.5 biopsies (mean 7.1). LC was reconfirmed in 28 (56%). Other histological changes found were: normal (4), chronic inflammation (2), incomplete LC (2), CC (2) and non specific changes (10). In 3 patients histological changes diagnostic of collagenous colitis were found in one or more of the endoscopies following the diagnostic one. Looking at the total number (161) of colonoscopies diagnostic of LC (with biopsies from both right and left colon) done in the population, 1 patient (1%) had changes in the right colon only and 3 patients (2%) had changes in the left colon only. Prior non-diagnostic endoscopies were performed in 22 patients (9%) with a median of 4 (mean 5) biopsies. In these histological changes were: normal (4), chronic inflammation (10), incomplete LC (4) and non specific changes (4).
CONCLUSION: While a full colonoscopy can be necessary in order to exclude other diagnoses, biopsies from the left colon are suffice for diagnosing or excluding LC in patients with chronic watery diarrhoea. The histological findings are not permanent and can change from one type of microscopic colitis to another suggesting that the different types of microscopic colitis are closely related.

INTRODUCTION: Ulcerative colitis (UC) is an inflammatory bowel disease characterized by chronic inflammation of the colonic epithelium. The exact etiology of the disease is not fully understood, but the microbiota is implicated in the initiation and the propagation of the disease. Through bacterial fermentation of carbohydrates and proteins a plethora of luminal compounds is produced in the colon, which might interact with the host's physiology. In the present study, the metabolic activity of the microbiota was compared between healthy controls and UC patients with both active and quiescent disease.
AIMS & METHODS: Fecal samples were collected from healthy control subjects (HC; n = 19, 11 female/8 male, age range 20-61 years) and UC patients with active disease (UC-A; n = 45, 14 female/31 male, age range 20-84 years) and during remission (UC-R; n = 40, 15 female/25 male, age range 19-78 years). Active disease was defined as a partial Mayo score $\geq$3. Fecal water (FW) was derived from these samples by ultracentrifugation at 50.000 x g at 4°C for 2h and was sterile filtered. Profiles of volatile organic compounds (VOCs) were determined in the FW samples using GC-MS (single quadrupole), coupled on line to a purge-and-trap sample preparation system. All VOCs were relatively quantified versus an internal standard and classified according to chemical class. Partial least squares (PLS) analysis was applied to cluster samples with similar metabolite profiles and to identify VOCs accounting for discrimination between HC and UC patients.
RESULTS: A total of 201 different VOCs were identified in the FW samples, with an average of 61$\pm$8 VOCs per sample. Cluster analysis of the metabolite profiles revealed complete separate clustering between HC and UC patients. Samples from UC-A and UC-R patients were not completely separated. FW samples from UC patients were associated with a higher prevalence of alcohols, phenols and benzene-like VOCs. The two latter groups are suggested to arise from protein fermentation. UC-A patient samples were associated with the presence of primary alcohols (ethanol, 1-propanol and 1-butanol) and low levels of short and medium chain fatty acids (SCFA and MCFA) and other acids. SCFA (acetate, propionate and butyrate) are generally recognized to be beneficial for the host's health and mainly originate from carbohydrate fermentation. Similar reductions of SCFA in UC patients were previously observed by the use of proton NMR [1]. These carboxylic acids are the oxidized counterparts of the primary alcohols, which suggests an imbalance in reduction-oxidation (redox) reactions in the colonic lumen.
CONCLUSION: The metabolite profiles of fecal samples allowed to differentiate HC from UC patients, partly due to the increased presence of alcohols, phenols and benzene-derivatives in UC patient samples. We identified primary alcohols, SCFA and MCFA as the most discriminatory metabolites in UC-A patients compared to HC and UC-R patients. The role of the observed shift in intestinal redox balance in UC-A patients (more primary alcohols, less SCFA) needs to be further investigated.

P0838 THE ASM MUCINASE IS INVOLVED IN ILEAL COLONIZATION BY CROHN'S DISEASE-ASSOCIATED ADHERENT-INVASIVE ESCHERICHIA COLI

L. GIBOLD[1,2,*], C. GALLUCCI[1], G. DALMASSO[2], D. CIA[3], N. BARNICH[2], R. BONNET[1,2], J. DELMAS[1,2]

INTRODUCTION: Mucins are secreted by the intestinal epithelium and constitute an efficient component of innate immune defenses to promote homeostasis and protect against bacteria. Enteric pathogens, such as *Shigella* and *Vibrio cholerae,* can produce proteases designated mucinases that are capable of cleaving mucins. Ileal lesions of patients with Crohn's disease (CD) are abnormally colonized by adherent-invasive *Escherichia coli* (AIEC).
AIMS & METHODS: Genome analysis of the AIEC strain LF82 revealed the presence of a chromosomal gene, designated *asm,* similar to the *Hbp* gene of the avian pathogenic *E. coli* strains (79% of homology). Hbp has a mucinolytic activity. To determine whether the Asm protein cleaves mucins, we generated the LF82Δ*asm* isogenic mutant and transcomplemented this mutant with the cloned *asm* gene.
RESULTS: Concentrated supernatants from LF82 strain and transcomplemented LF82D*asm*/*asm* yielded zones of clearing on mucin gels, whereas LFD*asm* did not exhibit mucinolytic activity. We showed, by using a simple column penetration assay, that Asm promoted mucus penetration of LF82. No difference in adhesion and invasion between LF82 and LF82Δ*asm* was found in the colonic epithelial HT29 cells, which are not mucin hyperproducing. However, a significant difference between these strains was observed in the mucin hyperproducing cell line HT29-16E, suggesting a role for Asm in mucus penetration. These results were also obtained by confocal and electronic microscopy. To evaluate the involvement of Asm in LF82 colonization *in vivo*, CEABAC10 transgenic mice were orally challenged with LF82 or LF82D*asm* strains. The numbers of bacteria counted in the feces and of intestinal mucosal-associated bacteria were increased in mice infected with LF82 compared to those infected with LF82D*asm*. Quantification of *asm* mRNA levels showed that bile salts act as an activator of Asm transcription as well as ileal pH.
CONCLUSION: In conclusion, Asm has a mucinolytic activity that promotes mucus penetration of AIEC strains and enhances adhesion and invasion to epithelial cells. Asm contributes to gut colonization of AIEC in murine model. Thus, mucinases could be one of the key factors of AIEC implantation in CD patients.

INTRODUCTION: This study investigated the therapeutic effects of hyperbaric oxygen (HBO) in experimental acute distal colitis focusing on its effect on cytokines and HIF-1α.
AIMS & METHODS: Twenty-eight *Wistar* rats were divided into four groups (each group had 7 rats): I (Saline); II (Saline/HBO); III (TNBS); and IV (TNBS+HBO). Colitis was induced with a rectal infusion of 150 mg/kg of trinitrobenzenesulfonic acid–ethanol (TNBS) under anesthesia with Ketamine (50 mg/kg) and Xylazine (10 mg/kg). Control animals received only rectal saline. After induction, the colitis animals were subjected to two sessions of HBO and were then euthanized. The distal intestine was resected for macroscopic analysis, myeloperoxidase activity (MPO) measurements, Western-blot analyses of nitric oxide synthase activity (iNOS) and Cicloxygenase-2 (COX-2) and immunohistochemical analysis of HIF-1α and COX-2. Cytokines levels (IL-1β, CINC-1, IL-10 and TNF-α) in the distal intestine were measured using an enzyme-linked immunosorbent assay (ELISA).
RESULTS: HBO therapy attenuated the severity of acute distal colitis, with reduced macroscopic damage score and reduced cytokine expression. HBO therapy inhibited the acute distal colitis-induced up-regulation of HIF-1α and its downstream iNOS and myeloperoxidase activity, as well as producing diminished COX-2 levels
CONCLUSION: The results indicate that HBO therapy attenuates the severity of acute distal colitis through the down-regulation of the expression of HIF-1α and pro-inflammatory cytokines

P0840 DIFFERENCES IN EXPRESSION OF G PROTEIN-COUPLED RECEPTOR 55 IN PATIENTS WITH CROHN'S DISEASE AND ULCERATIVE COLITIS

M. Włodarczyk[1,*], A. Sobolewska[1], A. I. Cygankiewicz[2], P.K. Zakrzewski[2], W.M. Krajewska[2], K. Stec-Michalska[1], A. Piechota-Polańczyk[3], J. Fichna[3], M. Wiśniewska-Jarosińska[1]

INTRODUCTION: G protein-coupled receptor 55 (GPR55) is a newly discovered cannabinoid (CB) receptor, which has been qualified as a part of the endogenous CB system along with "classical" receptors CB1 and CB2. There is a growing interest in the possible use of CB receptor agonists in the treatment of inflammation and abdominal pain. Here we attempted at establishing the levels

of GPR55 expression in inflammatory bowel disease (IBD) patients and healthy controls and potential implication in IBD treatment.
AIMS & METHODS: The study aimed at identifying whether GPR55 is expressed in colonic tissue of IBD patients and if so, whether the GPR55 levels differ between Crohn's disease (CD) and ulcerative colitis (UC) patients and between IBD patients and controls. Twenty five adult patients with IBD (UC: n = 11; CD: n = 14) were enrolled in the study. The control group consisted of 6 healthy subjects. The GPR55 mRNA and protein expression were measured using RT-PCR and immunoenzymatic (Western blot) assay, respectively. Each assay was performed in triplicate.
RESULTS: GPR55 mRNA was detected in all samples tested. The level of GPR55 mRNA was strongly (2.7 fold) increased in CD, but only moderately in UC patients vs. controls. In CD, GPR55 mRNA expression was 3.5 fold higher in biopsies from inflamed compared to non-inflamed tissues. In contrast, GPR55 mRNA level in inflamed and non-inflamed tissues in UC was comparable. Similar results were observed for GPR55 expression at protein level. The changes in GPR55 expression were unrelated to patient age or gender.
CONCLUSION: Different patterns of expression of GPR55 at mRNA and protein levels were observed in IBD patients. We speculate that GPR55 is crucial for the inflammatory processes in IBD, in particular in CD and may affect disease severity, as well as response to treatment depending on disease type. The GPR55 receptors may become an attractive target for novel therapeutic strategies in the treatment of IBD.

P0841 HYPERACTIVITY OF THE ENDOGENOUS OPIOID SYSTEM PROTECTS AGAINST ACUTE, BUT NOT CHRONIC STRESS-INDUCED EXACERBATION OF COLITIS IN MICE

M. Sobczak[1,*], M. Salaga[1], A. Wasilewski[1], H. Zatorski[1], M. Sacharczuk[2,3], J. Fichna[1,3]
[1]*Department of Biochemistry, Medical Univesity of Lodz, Lodz,* [2]*Department of Molecular Cytogenetics, Institute of Genetics and Animal Breeding, Polish Academy of Sciences, Jastrzebiec,* [3]*Mossakowski Medical Research Center, Polish Academy of Sciences, Warsaw, Poland*

INTRODUCTION: The endogenous opioid system plays an important role in the maintenance of homeostasis in the gastrointestinal tract. Recent studies suggest that the impairment of EOS function may be crucial in the pathogenesis and progression of inflammatory bowel diseases (IBD). However, this has not been confirmed due to the lack of relevant models.
Recently, two mouse lines - with high (HA) and low (LA) opioid system activity – were developed based on the expression of swim stress-induced analgesia. The aim of our study was to characterize the role of the endogenous opioid system and stress in the development of IBD symptoms in HA and LA mouse lines.
AIMS & METHODS: Mice were bred using bidirectional selection and classified as HA or LA line based on the measurement of analgesia with the hotplate and tail-flick tests. Colitis was induced by instillation of trinitrobenzenesulfonic acid (TNBS) in 30% EtOH/saline. After 3 days, the macroscopic score was assessed and the samples for biochemical, molecular and histological studies were collected. To evaluate the influence of stress on development of colitis, we used chronic mild stress (exposure to stress stimuli for 2 and 5 weeks) and acute stress (short restraint over 3 days) models.
RESULTS: We observed a significant difference in the development of colitis between non-stressed HA and LA mice, as indicated by the macroscopic score (3.08±0.06 vs. 6.50±0.79 for HA and LA, respectively) and ulcer score (0.30±0.31 vs. 2.10±0.31 for HA and LA, respectively). Chronic mild stress had no influence on colitis in both mouse lines. Colitis was improved in HA mice exposed to acute stress in comparison with non-stressed animals (1.77±0.12 vs. 4.60±1.60), but did not change the inflammation score in LA line.
CONCLUSION: Our studies strongly support the hypothesis that the activity of the endogenous opioid system may be crucial in IBD development and affect the success rate in IBD treatment. We also evidence that acute, but not chronic stress influence significantly the exacerbation of IBD symptoms depending on the endogenous opioid system activity.

P0842 ENTERIC GLIAL CELLS FROM CROHN'S DISEASE PATIENTS MISPRODUCE 15-DEOXY-Δ12,14-PROSTAGLANDIN J2: DEFECT IN INTESTINAL EPITHELIAL BARRIER RESISTANCE

S. Coquenlorge[1], N. Cenac[2], M. Biraud[1], J. Jaulin[1], N. Vergnolle[2], **M. neunlist**[1,*], M. Rolli-Derkinderen[1]
[1]*Inserm UMR913, Nantes,* [2]*INSERM UMR-1043 CNRS UMR-5282, Toulouse, France*

INTRODUCTION: Enteric glia, the major constituent of the enteric nervous system, plays a key role in the control of intestinal epithelial barrier (IEB) functions. Under physiological conditions, enteric glial cells (EGC) inhibit intestinal epithelial cells (IEC) proliferation, enhance IEB repair and increase its resistance to pathogens. All these mechanisms are altered during inflammatory bowel disease (IBD), such as Crohn's Disease (CD). EGC lesions have also been observed in this pathological context, and we investigated here the possible link between CD EGC and IEB dysfunctions.
AIMS & METHODS: First, we have characterised EGC isolated from CD and cancer patients (considered as control EGC) by real time Q-PCR and immunostaining. Next, we studied EGC functional impact on IEB using an indirect co-culture model with human intestinal epithelial cell (IEC; Caco-2) cell line seeded on Transwell filters, measuring transepithelial resistance (EVOM), IEC spreading (ZO1 immunostaining) and IEC proliferation (DAPI cell counting). EGC-derived soluble factors (IL6, TGFβ, proEGF, GSH) and thirty polyunsaturated fatty acid (PUFA) metabolites were quantified in EGC supernatants. 15dPGJ2, PPARγ agonist (Rosiglitazone) and PPARγ antagonist (GW9662) functional impacts were then measured on IEC spreading and IEB resistance.
RESULTS: EGC isolated from CD and cancer patients (considered as control EGC) expressed the same level of glial markers (GFAP, S100beta, Sox10). Whereas control EGC increased significantly IEC transepithelial resistance, IEC spreading and decreased IEC proliferation, CD EGC had no significant effect. EGC supernatants showed a severe decrease in 15dPGJ2 and 11betaPGF1alpha production but no change in others EGC-derived soluble factor expression. 15dPGJ2 also induced a decrease in IEC proliferation but also an increase in IEC spreading and IEB resistance. In addition, PPARγ agonist reproduced these effects and PPARγ antagonist abrogated them.
CONCLUSION: All together, these results show that human EGC from Crohn's disease patients have lost their protective properties on IEB integrity among the regulation of IEB resistance, IEC spreading and proliferation. This could be due to a defect in the 15dPGJ2 pathway in CD EGC.

P0843 HOMOCYSTEINE EXACERBATED DSS-INDUCED COLITIS BY ACTIVATION OF TH17 CELLS VIA P38 SIGNALING PATHWAY

S. Zhu[1], J. Li[1], W. Yan[1], **M. Chen**[1,*], B. Xia[1]
[1]*Department of gastroenterology, Zhongnan hospital, Wuhan, China*
Contact E-mail Address: *chenmin8106@aliyun.com*

INTRODUCTION: It is well knownz that homosysteine is a pro-inflammatory molecule and contributes to the chronic inflammation of cardiovascular and cerebral disorders. Hyperhomocysteinemia (HHcy) is a common phenomenon observed in patients with inflammatory bowel disease (IBD). The influence of HHcy on the colonic inflammation of IBD has never been explored.
AIMS & METHODS: The aim of this study is to investigate the effect of HHcy on Dextran sulfate sodium (DSS) induced-colitis. Rats were randomly divided into 5 groups (n = 6 per group): control, HHcy, DSS, HHcy+DSS and HHcy+DSS+p38 inhibitor. HHcy was induced by giving rats rodent food containing 1.7% methionine for three weeks. Colitis was induced by giving water containing 5% DSS. The p38 inhibitor (5μmol SB203508/kg) was given twice daily beginning 60h after DSS treatment. The plasmatic concentration of IL-17 was measured by ELISA. The mRNA and protein expressions of inflammatory mediators were detected by RT-PCR and Western-blot, respectively.
RESULTS: The rats of HHcy+DSS group had scientifically higher body weight loss, MPO activity, DAI score, and histological score compared to the rats of DSS group. HHcy significantly increased the plasmatic concentration, the colonic mRNA and protein levels of IL-17, as well as the protein levels of phosphorylated-p38 MAP kinase, phosphorylated cytosolic phospolipaseA2, cyclooxygenases 2 and RORγt. The increased protein expressions of these inflammatory mediators were suppressed by p38 inhibitor.
CONCLUSION: HHcy aggravated DSS-induced colitis by the activation of Th17 cells via p38 signaling pathway. The p38 inhibitor may represent a novel approach to treatment the chronic intestinal inflammation exacerbated by HHcy in patients with IBD.

P0844 MICRORNA-612 REGULATES AQUAPORIN 8 EXPRESSION AND IS UP-REGULATED IN PATIENTS WITH ULCERATIVE COLITIS

M. Min[1,*], Y. Yang[2], Y. Liu[1]
[1]*Dept. of Gastroenterology and Hepatology, Affiliated Hospital of Academy of Military Medical Sciences,* [2]*Dept. of Gastroenterology and Hepatology, Chinese PLA general hospital, Beijing, China*

INTRODUCTION: MicroRNA (miRNA) plays an important role in the pathogenesis of many diseases by regulating the gene expression at the post-transcriptional level and control crucial physiological processes. Altered levels and functions of miRNAs have been associated with ulcerative colitis (UC), although little is known about their roles in UC.
AIMS & METHODS: We screened different genes from UC tissues and healthy subjects by using genome-wide and miRNA microarray in colon samples from 20 patients with UC and 16 healthy subjects undergoing diagnostic colonoscopy. AQP8 expression and miR-612 were measured by real-time polymerase chain reaction analysis. Regulation of gene expression by miRNAs was assessed by luciferase reporter construct assays and transfection of specific miRNA mimics and inhibitor.
RESULTS: We identified that 1596 genes and 33 miRNAs were increased, 1301 genes and 35 miRNAs were decreased in UC patients compared to healthy subjects. Among them, aquaporin 8 (AQP8) was decreased in patients with UC compared with control tissues ($P < 0.01$). We searched candidate target miRNAs of AQP8 through bioformatics and the luciferase report assay analysis

indicated that miR-612 which has complementary site in the 3-untranslated region (UTR) of AQP8 could decrease the relative luciferase activities by 45% and transfection of HT29 cells with the miR-612 mimic resulted in inhibition of the basal AQP8 protein.
CONCLUSION: miR-612 appears to regulate the expression of AQP8. Increased levels of miR-612 in colon tissues of active UC appear to decrease expression of AQP8, which could involved in the pathogenesis of UC.

INTRODUCTION: Inflammatory bowel disease (IBD) patients often exhibit common manifestations, which are not characterized as ''classic'' extra-intestinal manifestations, posing clinical dilemmas.
AIMS & METHODS: The aim of our study was to investigate the prevalence and characteristics of certain common manifestations from the liver, biliary tree, pancreas and kidneys in IBD patients followed-up in tertiary centers. Data from 1741 IBD patients (females: 43.5%, Crohn's disease: 53.9%, median [IQR] age at IBD diagnosis: 32.9 [23.0-48.4] and IBD duration until 1st EIM diagnosis: 3.0 [0.2-8.0] years) have been retrospectively retrieved and registered according to a pre-defined protocol. Positive results were based on imaging findings and/or pre-existing compatible clinical diagnosis. The impact of certain demographic and IBD characteristics on results was studied.
RESULTS: Cholelithiasis was present in 113/1489 (7.6%) patients mainly in females ($p<0.0001$) with Crohn's disease ileitis or extensive ulcerative colitis ($p=0.042$), concomitant nephrolithiasis ($p<0.0001$) and those having undergone a major IBD surgery ($p=0.031$), appendectomy or tonsillectomy ($p<0.0001$). Non-alcoholic fatty liver disease was detected in 159/1489 (10.7%) patients mainly in females ($p<0.0001$) with ulcerative colitis ($p=0.014$) and concomitant nephrolithiasis ($p<0.0001$). Pancreatitis was diagnosed in 46/1656 (2.8%) patients. In particular, autoimmune IgG4-related pancreatitis was observed in 5/46 (10.9%), drug-induced in 34/46 (73.9%) and lithiasic in 6/46 (13%) patients. Pancreatitis was more frequent in smokers ($p=0.004$) with concomitant nephrolithiasis ($p=0.002$) and in patients with an ileal-anal pouch anastomosis ($p=0.049$). Nephrolithiasis was present in 140/1592 (8.8%) patients less frequently in those with perianal Crohn's disease ($p=0.019$).
CONCLUSION: One tenth or less of our IBD patients exhibited at least one hepatobiliary, pancreatic or renal manifestation. A different pattern of appearance was observed between Crohn's disease and ulcerative colitis patients. Nephrolithiasis often accompanies the other manifestations.

INTRODUCTION: Patients with inflammatory bowel disease (IBD) frequently undergo abdominal imaging. This may result in an increased number of incidentalomas including renal cell carcinoma (RCC). A high percentage of incidentally found RCCs might improve cancer outcome; however, immunomodulators and biological agents, as used in the treatment of IBD, may also impact cancer outcome. In this study we aimed to compare the outcome of RCC between IBD patients and the general population. Next we evaluated the impact of IBD therapy on RCC outcome.
AIMS & METHODS: Using the Dutch National Pathology Registry (PALGA) we identified all IBD patients diagnosed with RCC in The Netherlands from January 1991 until May 2013. Cases were confirmed using anonymized medical records and clinical and demographic variables were collected. The control group was derived from the Eindhoven Cancer Registry (1991-2010) which provided the cancer registration for approximately 2.3 million people in The Netherlands. RCC characteristics like TNM stage, age at RCC diagnosis and treatment were compared univariately between cases and controls. Survival analyses were made with Kaplan Meier curves and confounder correction was performed with Cox regression.
RESULTS: We included 160 patients from 69 academic and non-academic hospitals with a confirmed IBD diagnosis who developed RCC. 64/160 (45.1%) IBD patients used thiopurines or biologicals during their disease course of IBD. 73/160 (51.8%) RCC cases in IBD patients concerned incidentalomas. The control group consisted of 4388 patients with RCC. Upon comparison, IBD patients had a statistically significant lower age at RCC diagnosis (median 62.0 versus 66.0; $p<0.005$), lower N-stage (5.8% N+ versus 11.4% N+; $p=0.030$) and lower M-stage (10.7% M1 versus 20.0% M1; $p<0.005$). Furthermore IBD patients underwent more frequently surgical treatment for RCC (96.2% versus 75.6%; $p<0.005$). A Kaplan Meier curve showed better overall survival in IBD patients (log rank $p<0.005$). Age at RCC diagnosis, T, and M-stage, and surgical treatment emerged as confounders. Adjusted for these confounders, a protective effect of IBD on overall survival was still present ($p=0.015$; hazard ratio 0.690; 95% CI 0.512-0.932). Comparing IBD patients with and without thiopurines and/or biologicals, overall survival was significantly better in the group who did use immunosuppression (log rank $p=0.012$). However, a Cox model adjusted for TNM stage and age at RCC diagnosis completely abolished the protective effect of immunosuppression ($p=0.949$).
CONCLUSION: Patients with IBD who develop RCC have a significantly better overall survival compared to the general population with RCC, which may partially be explained by an earlier diagnosis of RCC with a subsequent lower disease stage. Immunosuppression does not adversely affect overall survival.

P0847 INFLUENCE OF COPING ON THE CLINICAL COURSE OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE COHORT STUDY

M. Barreiro-de Acosta[1,*], R. Ferreiro-Iglesias[2], A. Lorenzo-González[3], J.E. Dominguez-Muñoz[2]
[1]University Hospital of Santiago de Compostela. Foundation for Research in Digestive Diseases, Santiago de Compostela, Spain, [2]Gastroenterology, University Hospital of Santiago de Compostela. Foundation for Research in Digestive Diseases, [3]Gastroenterology, University Hospital of Santiago de Compostela, Santiago de Compostela, Spain

INTRODUCTION: Coping strategies are used to manage conflicts and illnesses, and may have both adaptative or maladaptative effects on health status. Coping strategies have not been well studied in patients with Inflammatory Bowel Disease (IBD), and their influence on the clinical course of the disease and the use of health resources is unknown
AIMS & METHODS: The aim of the study was to evaluate the influence of the use of different coping strategies on the number of emergency or unscheduled visits and hospitalisations in IBD patients.
Methods: A prospective observational cohort study was designed. The cohort consisted of consecutive out-patients with IBD (Crohńs disease (CD) and ulcerative colitis (UC)) who attended our monographic IBD Unit. A basal demographic and clinical questionnaire was completed by all patients. Coping strategies were assessed with the Spanish version of the COPE scale. It consists of 60 items that participants rated themselves using the dispositional response format, and indicating how frequently they engaged in each coping behaviour on a 4-point Likert scale. The scale had 3 different global strategies: Problem-focused coping, avoidance coping and emotion-focused coping. All emergency and unscheduled visits and hospitalisations related to IBD over a follow-up period of 18 months were recorded. The influence of coping on clinical course was analysed by Multiple Regression analysis.
RESULTS: 776 patients were included (364 male (46.9%), mean age 45 years, age ranging from 18 to 86 years). 317 (40.9%) patients had CD and 459 (59.1%) UC. At the baseline evaluation, the most frequently used coping strategies by IBD patients were problem-focused coping (mean: 2.72 standard deviation, SD: 0.45) and avoidance coping (mean: 2.60, SD: 0.37), and the least frequently used was emotion-focused coping (mean: 2.36, SD: 0.57). The mean number of unscheduled or emergency visits was 1.05 (SD: 1.68, range 0-14) and the mean number of hospitalizations was 0.35 (SD: 0.94, range 0-9). After a follow up of 18 months, the use of avoidance coping strategies was a risk factor for a higher number of emergency or unscheduled visits in the multivariate analysis ($B=0.027$, CI95%: 0.009-0.045; $p<0.005$). However, coping strategies did not influence the need of hospitalisations.
CONCLUSION: The coping strategies mostly used by IBD patients are the problem-focused coping and avoidance coping. A frequent use of avoidance coping strategies appears to be a risk factor for requiring a higher number of emergency visits in the following months. Therefore, these patients would probably benefit from psychological support.

P0848 SEXUAL DYSFUNCTION IN INFLAMMATORY BOWEL DISEASE: DO GASTROENTEROLOGISTS OVERLOOK THIS ISSUE?

M.J. Argüero[1,*], M.J. Etchevers[1], M.J. Sobrero[1], N.S. Causada Calo[1], M. Mahler[1], P.R. Daffra[1], R.C. Gonzalez Sueyro[1], D.C. Madrid[1], D. Manazzoni[1], J.A. De Paula[1]

Contact E-mail Address: *maria.arguero@hiba.org.ar*

INTRODUCTION: Inflammatory bowel disease (IBD) is a condition associated with high morbidity and poor quality of life (QoL). This population is usually young and sexually active. Studies addressing sexual dysfunction (SD) in IBD patients are scarce and their results are controversial. Moreover, little is known about how often gastroenterologists discuss this matter with IBD patients.
AIMS & METHODS: Our primary objective was to estimate SD frequency among IBD patients in the ambulatory setting. Secondary objective was to estimate how often SD is addressed by gastroenterologists. A self-administered anonymous questionnaire was delivered to adult ($\geq$ 18 years) IBD patients

who assisted the IBD ambulatory clinic between August and September 2013. The survey had two parts. The first one assessed QoL by the EuroQol scale and SD by the Female Sexual Function Index (FSFI) and the International Index of Erectile Function (IIEF-15) in women and men, respectively. Patients were asked about whether gastroenterologists inquiry about their sexual function and if they considered this to be relevant. The second part was filled out by the gastroenterologist who was blinded to the first one. It included the Mayo and Harvey-Bradshaw Scores, IBD treatment in the previous month and IBD phenotype according to the Montreal Classification.
RESULTS: Response rate was 74.5%. Seventy five patients were recruited, 61% (n = 46) had ulcerative colitis, 37% (n = 28) had Crohn's disease and one had undetermined colitis. Median age was 37 years (IQR = 30-55) and 56% (n = 42) were women. SD prevalence in women was 69.7% (n = 30). In men, the most affected domains were overall satisfaction 64.5% (n = 20), sexual desire 38% (n = 12) and intercourse satisfaction 35% (n = 11). SD was not addressed in 84% (n = 63) of IBD patients. In this subgroup, 57% (n = 36) answered that the main reason was that the gastroenterologist did not ask them and 41% (n = 26) answered that it would had been important to be asked about it. QoL was good or very good in 97% (n = 73) of the subjects. None of the patients was consuming antidepressants.
CONCLUSION: SD was very frequent in both genders. Above 50% of our IBD patients had impaired sexuality, whereas in the general population SD is considered to be lower, around 35%. Notably, men had lower overall satisfaction and sexual desire rather than orgasmic and erectile dysfunction. Gastroenterologists did not assess SD in the majority of IBD patients, while a considerable proportion of them found discussing this topic with their physician to be relevant. Therefore, this issue should be addressed. Even though QoL was satisfactory in the vast majority, SD was prevalent and it should be included in the assessment of QoL in this population. The small sample size did not allow us to estimate associations. This is the first study in Latin America that addresses SD in IBD patients.

INTRODUCTION: Inflammatory bowel disease (IBD) often affects younger persons and may have considerable impact on the ability to maintain connected to the labour market.
AIMS & METHODS: We aimed to evaluate the occurrence and risk of sick leave (SL) and work disability (WD) in incident patients with IBD after 7 years of follow-up compared to a population-based control group and look for associations of social, phenotypic and clinical characteristics.
A subgroup of 379 IBD patients aged 18-67 years from an IBD-inception cohort (513 patients) registered Jan 1 2003 to Dec 31 2004 in a well-defined Copenhagen area were our IBD study population. Clinical data were collected from the medical records. Data on eucational level, sick leave and work disability was retrieved from national registers. A random subset of the general population (n = 1435) were matched on sex, age and residency to IBD cases. Survival curves displaying the cumulative probabilities of work disability and sick leave were derived with the Kaplan-Meier method. Cox proportional hazard regression analyses were performed to identify possible independently associated predictive factors.
RESULTS: After 7 years of follow-up the cumulative risk of SL and WD was 47.8% and 5.8% in UC respectively and 55.8% and 6.3% in CD respectively. The overall hazard of SL was 2.01 (95% CI 1.66-2.43) and 2.03 (95% CI 1.18-3.49) of WD in IBD patients. Male IBD patients (HR 2.38 (95% CI 1.10-5.14)) and patients aged 55-67 years at diagnosis (HR 4.36 (1.65-11.53)) were at increased risk of receiving WD compared to the general population. Both women (HR 1.83 (1.43-2.35)) and men (HR 2.29 (1.71-3.08)) were at increased risk of SL as well as patients aged 18 to 55 had a significantly higher risk of SL compared to the background population. Age above 55 years increased the risk of WD in patients with CD (HR 17.49 (95% CI 1.92-159.01) but WD in CD was not explained by sex, educational level, behaviour and localisation of disease, smoking or surgery after mutually adjustment. Educational level ($HR_{>\ 13\ years\ of\ schooling}$ 1.79 (95% CI 1.02-3.15)), stricturing disease behaviour (HR_{B2} 0.33 (95% CI 0.14-0.83) and surgery ($HR_{1\ resection}$ 4.09 (95% CI 2.17-7.71), $HR_{2+\ resections}$ 8.96 (95% CI 2.86-28.03)) were predictors of SL in CD. Smoking ((former (HR 0.22 (95% CI 0.02-2.16) or current (HR 6.02 (95% CI 0.95-37.99)) compared to never (p = .04)) was a predictor of WD in UC and female gender (HR 1.73 (95% CI 1.10-2.72)) and surgery (HR 4.19 (95% CI 2.09-8.38)) were predictors of SL in UC.
CONCLUSION: In this population-based study of incident Danish IBD patients we found that after 7 years of follow-up IBD patients are at increased risk of WD and SL compared to the background population and that educational level, disease behaviour and surgery were predictors of SL in CD, while high age was a predictor of WD in CD. Female gender and surgery were predictors of SL in UC, while smoking status was a predictor of WD in UC. Continuous attention early after diagnosis should be made on reducing the risk of WD in IBD patients.

INTRODUCTION: It has been reported that IBD onset occurs at old age in up to 10% of cases. Elderly patients have more comorbidities and, therefore, a potential increased risk of drug adverse effects, increased likelihood of hospital admissions and postoperative complications.
AIMS & METHODS: To evaluate the phenotypic characteristics and use of therapeutic resources in patients with elderly–onset IBD.
Methods: Retrospective, case-control, multicentre study. All those patients diagnosed with IBD over the age of 60 years (*cases*) since 2000 and with a follow-up > 12 months were identified from the IBD databases of each centre. Cases were compared with *controls,* who were diagnosed with IBD between 18 and 40 years of age, and matched by year of diagnosis, gender, and type of IBD.
RESULTS: A total of 1,374 cases and 1,374 matched controls were included, of whom 43% women, 62% ulcerative colitis (UC), 36% Crohn's disease (CD) and 2% unclassified IBD. The mean age at diagnosis was 68 years (range, 60-87) within cases and 28 years (range, 18-45) within controls. 59% of the cases (but only 3% of controls) had at least one cardiovascular risk factor (arterial hypertension, dyslipidemia or diabetes). The proportion of active smokers at the time of IBD diagnosis was 25% among controls and 13% among cases. Phenotypically, elderly-onset patients had a lower proportion of extensive UC ($p < 0.0001$), and a higher proportion of stenosing and a lower proportion of penetrating pattern ($p < 0.0001$) and exclusive colonic location ($p < 0.0001$). Elderly-onset patients had a lower rate of IBD-related complications ($p = 0.009$) but a higher prevalence of thrombotic events ($p < 0.0001$). Regarding the use of therapeutic resources, there was a significantly lower use of corticosteroids ($p < 0.0001$), immunomodulators ($p < 0.0001$) and biological agents ($p < 0.0001$) in elderly-onset patients as compared to controls, but a similar rate of surgeries. Finally, elderly-onset patients had a higher rate of hospitalizations ($p < 0.0001$), neoplasms ($p < 0.0001$) and deaths ($p < 0.0001$). In the multivariate analysis, elderly-onset of IBD was independently associated to a decreased need of immunomodulators and biological agents, and an increased need of hospital admissions.
CONCLUSION: Elderly-onset IBD is associated to a less severe/complicated phenotype and the lesser use of immunosuppressive therapies, which probably accounts for a non-increased IBD-related morbidity. Age at diagnosis might explain the increase in the rate of hospitalizations among elderly patients.

P0851 C. DIFFICILE COLONISATION AND INFECTION RATES ARE NO LONGER RAISED IN INFLAMMATORY BOWEL DISEASE

N.M. Joshi[1,*], M. Adelson[1], D. Ball[2], D.S. Rampton[1]

INTRODUCTION: While several studies in the last 10 years have reported higher rates of C. difficile colonisation (CDC) and C. difficile infection (CDI) in IBD than in non-IBD patients, the overall incidence of CDI in the UK is now falling. We have therefore reassessed the incidence of CDC and CDI in diarrhoeal patients with and without IBD.
AIMS & METHODS: All stool samples tested for C. difficile by our laboratory in the 3-month period ending October 2012 were identified using the microbiology database (Barts Health NHS Trust). A 2-step, ELISA algorithm for C. difficile testing was applied to liquid stools only: the first was a test for CDC (presence of glutamate dehydrogenase[GDH] – a C. difficile-specific enzyme); if GDH was positive, a second step was performed to look for CDI (presence of toxin in stool). Electronic patient records (EPR) were then reviewed to see if patients whose stool was tested had a known diagnosis of IBD (Crohn's or ulcerative colitis) when the sample was sent.
RESULTS: 927 stool samples were tested, EPR data was not available for 22 (2%) cases (excluded from analysis). 88 (10%) patients had IBD. Mean age (SEM) in years was 42.1 (2.1) for IBD and 58.2 (0.8) for non-IBD patients, respectively ($p < 0.0001$). With the groups combined: 109 (11%) patients had CDC and 27 (3%) had CDI. CDC was found in 4 (5%) IBD and 105 (12%) non-IBD patients ($p = 0.02$). There were no CDI cases in IBD patients and 27 (3%) in non-IBD samples ($p = 0.1$). None of the non-IBD CDC patients went on to develop IBD (EPR review to March 2014) after their samples were analysed.

CONCLUSION: In our diarrhoeal patients, CDC is now less common in IBD than in non-IBD patients. We also found no CDI in our 88 IBD samples. Although the period studied was short and the numbers of samples limited, our results suggest that the recent 'epidemic' of CDI in IBD patients may now be on the wane.

INTRODUCTION: The general psychopathology and coping processes of Crohn's disease (CD) patients are incompletely understood. Since these elements are expected to impact on quality of life, it is necessary to define their relationships precisely. The social constructionist perspective has become a useful framework for understanding coping strategies of men and women. This study examines emotional distress and coping strategies between the genders.
AIMS & METHODS: 158 consecutive CD patients undergoing clinical assessment at the IBD Clinic completed a series of questionnaires: Brief Symptom Inventory (BSI) which measures psychological distress (range: 0 = "not at all" to 4 = "extremely distressed"), Ways of Coping (WAYS) that measures thoughts and actions that people use to handle stressful encounters (range: 1-8, greater value = higher use), and IBDQ (disease-specific quality of life). Appropriate univariate analysis was performed. Data given as mean ± SD.
RESULTS: 135 patients (85%) completed the questionnaires, 62 men (age 39.1 ± 14.9 years, Harvey-Bradshaw Index (HBI) 7.1 ± 3.7, disease duration 2.2 ± 0.3 years) and 73 women (age 43.5 ± 17.2, HBI 7.9 ± 4.4, disease duration 2.4 ± 0.8). BSI scores for somatization (1.15), obsessive-compulsive behavior (1.10), interpersonal sensitivity (0.83), depression (0.81), anxiety (1.08), hostility (0.79), phobic anxiety (0.65), paranoid ideation (0.81) and psychoticism (0.59) revealed low levels of psychological distress and did not differ significantly between men and women. WAYS scores without gender differences were: range >6: acceptance, self-blame, active coping; range 5-6: self-distraction, planning, positive reframing; range 2-4.9: humor, religion, denial, behavioral disengagement, substance use. WAYS scores with gender differences were: use of emotional support (men 4.03, women 4.80, $p<0.02$), use of instrumental support (3.92, 4.64, $p<0.03$), venting (3.48, 4.32, $p<0.005$). BSI depression correlated with WAYS instrumental support ($p=0.01$), behavioral disengagement ($p<0.03$), and self-blame ($p<0.02$). IBDQ scores were men 49.2 ± 14.9; women 48.6 ± 12.6. Significant correlations were found between IBDQ and the WAYS scores of self-distraction, denial, behavioral disengagement, venting, self-blame and religion; and HBI with the BSI scores of somatization, positive symptom total and positive symptom distress index. IBDQ correlated with HBI ($p<0.001$).
CONCLUSION: In this recently-diagnosed CD cohort, men and women had similar levels of disease activity and psychological distress. The most prominent positive coping mechanisms were acceptance and active coping, and negative trends of self-blame and self-distraction. Women practiced more emotional support, instrumental support and venting. These findings need attention in clinical practice. [Supported by a generous grant from the Leona M. and Harry B. Helmsley Charitable Trust].

P0853 PREVALENCE OF ALCOHOL CONSUMPTION AND ITS INFLUENCE ON DISEASE COURSE IN SWISS IBD PATIENTS

F. Brunner[1], R.von Känel[2], S. Begré[3], C. Clair[4], A. Macpherson[1], **P. Juillerat**[1,*]
[1]*Visceral Surgery and Medicine, Gastroenterology,* [2]*Department of General Internal Medicine, Division Psychosomatic Medicine, Inselspital Bern, Bern,* [3]*Psychiatric Service, Spital Burgdorf, Burgdorf,* [4]*Policlinique médicale universitaire, University Hospital Lausanne, Lausanne, Switzerland*

INTRODUCTION: Little is known about the prevalence and influence of alcohol consumption on the disease course in patients with IBD. Pathophysiologically alcohol might have an impact on disease course by increasing intestinal permeability, disrupting gut barrier function, inhibiting intestinal immune system and favouring bacterial overgrowth. Otherwise, low to moderate alcohol consumption might have an anti-inflammatory effect by lowering IL-6 and TNF-α levels.
AIMS & METHODS: We aimed to estimate the prevalence of alcohol consumption and its influence on disease course within the Swiss IBD cohort. Frequency of alcohol consumption was assessed in a screening question provided in the enrolment questionnaire of the Swiss IBD cohort. According to the given answers patients were distributed in 3 categories: non-drinkers (abstainers or rarely), light-to-moderate drinkers (1-2x per week to daily alcohol consumption), heavy drinkers (> = 2x daily). At enrolment socio-demographic variables and disease characteristics were compared cross-sectionally to identify risk factors for increased alcohol consumption and to evaluate a possible influence of alcohol consumption on disease course. During follow-up need for surgeries and occurrence of abscesses and fistulas were compared prospectively between the 3 groups.
RESULTS: 2019 patients, who had answered the question about alcohol consumption at enrolment in the Swiss IBD cohort between July 2006 and May 2013, were included in the analysis. 870 patients (43%) drank regularly alcohol: 818 low-to-moderately, 52 heavily. Drinkers were older, by the majority male, had a higher body mass index and smoked more often. The proportion of Crohn's disease patients was lower in non-drinkers (59%) compared to low-to-moderate drinkers (52%). Drinkers reported less extraintestinal manifestations than non-drinkers (32% vs. 39%, $P<0.01$). Low-to moderate drinkers (31%) with ulcerative colitis have a lower ($p=0.03$) proportion of pancolitis than non-drinkers (41%). However heavy drinkers with ulcerative colitis had to be hospitalized less often before enrolment,which, after stratification, seems to be due to the known protective effect of smoking. Generally heavy drinkers received significantly less immunomodulators (AZA, MTX) and anti-TNF-inhibitors. During follow-up (6925 patient-years) the need for surgery was similar among non-drinkers and low-to-moderate drinkers. However heavy drinkers with Crohn's disease had to undergo less surgeries and developed fewer abscesses and fistulas.
CONCLUSION: The prevalence of regular alcohol consumption within the Swiss IBD cohort was 43%, whereof 94% drank low-to-moderately. Patients with higher alcohol consumption were older, preferably males with a higher body mass index and more often smokers. Heavy drinkers received less treatment with immunosupressants. In ulcerative colitis low-to-moderate drinking seemed to favour a shorter extent and heavy drinkers were less hospitalized. In Crohn's disease heavy drinking seemed to reduce the development of abscesses and fistulas and the need for surgeries during follow-up. A prospective project nested within the Swiss IBD cohort for a better understanding of alcohol on disease course is ongoing.

INTRODUCTION: Limited data are available on the hospitalization rates in population-based studies. This is a very important outcome measure.
AIMS & METHODS: The aim of this study was to analyze prospectively if early hospitalization is associated with the later disease course as well as to determine the prevalence and predictors of hospitalization and re-hospitalization in the population-based UC inception cohort in the Veszprem province database between 2000 and 2012. Data of 347 incident UC patients diagnosed between January 1, 2000 and December 31, 2010 were analyzed (m/f: 200/147, median age at diagnosis: 36, IQR: 26-50 years, duration: 7, IQR 4-10 years). Both in- and outpatient records were collected and comprehensively reviewed.
RESULTS: Probabilities of first UC-related hospitalization and first re-hospitalization were 28.6%, 53.7%, 66.2% and 23.7%, 55.8% and 74.6% after 1, 5 and 10 years of follow-up in Kaplan-Meier analysis. Main reasons for first hospitalization were diagnostic procedures (26.7%), disease activity (22.4%) or UC related surgery (4.8%), but the majority of the hospitalizations were unrelated to UC (44.8%). In Kaplan-Meier and Cox-regression analysis disease extent at diagnosis (HR: 1.35, $p=0.018$, $HR_{extensive}$: 1.79, $p=0.02$ vs. proctitis) or at last follow-up (HR: 1.56, $p=0.001$), need for steroids (HR: 1.98, $p<0.001$), azathioprine (HR: 1.55, $p=0.038$) and anti-TNF (HR: 2.28, $p<0.001$) were associated with the risk of UC-related hospitalization. Early hospitalization was not associated with a specific disease phenotype, however 46.2% of all colectomies were performed in the year of diagnosis.
CONCLUSION: Hospitalization and re-hospitalization rates are relatively high in this population-based UC cohort. Early hospitalization was not predictive for the later disease course.

P0855 FAECAL CALPROTECTIN IS AN ACCURATE PREDICTOR OF ENDOSCOPIC AND HISTOLOGICAL DISEASE ACTIVITY IN IBD

G. Chung-Faye[1,*], A. Rahman[2], J. Tumova[2], B. Hayee[2], R. Sherwood[2]
[1]*Gastroenterology, King's College Hospital,* [2]*King's College Hospital, London, United Kingdom*

INTRODUCTION: Assessment of disease activity in Inflammatory Bowel Disease (IBD) is challenging as the gold standards of endoscopy and histology are invasive, expensive and impractical for regular use. Faecal calprotectin (FC) is increasingly being used as a biomarker of intestinal inflammation but its role in predicting endoscopic and histological changes in IBD is limited. We explore the role of FC to assess histological disease in IBD patients, in comparison to C-reactive protein (CRP), in the largest series of IBD patients to date.
AIMS & METHODS: Retrospective analyses of 407 IBD patients who had a colonoscopy with FC (mg/g) and CRP (mg/L) measurements. The most severe histological inflammation found was graded according to the simplified histology score (0-normal, 1-mild, 2-moderate, 3-severe). Spearman's correlation coefficient (r) was used to measure correlation between the groups. Receiver operating

characteristic (ROC) curves were used to differentiate patients with normal/mild disease (histology scores 0-1) from patients with moderate/severe disease (histology scores 2-3).
RESULTS: In 203 Crohn's disease (CD) patients, the median FC values for the histology scores; 0, 1, 2, 3 were; 113, 238, 645 and 3075, respectively (graph). The corresponding medians for CRP were; 2.5, 9.8, 14.6 and 54.6. Both FC (ρ 0.59, $p<0.0001$) and CRP (ρ 0.30, $p<0.0001$) showed very strong correlations to histology scores. Using a cut-off value of 250μg/g, FC showed an 88% sensitivity and 62% specificity for predicting moderate / severe disease (AUC 0.82). CRP >6 mg/L was less sensitive and specific (70%, 44%, respectively, AUC 0.64).
In 204 ulcerative colitis (UC) patients, the median FC values for the histology scores; 0, 1, 2, 3 were; 38, 296, 520 and 1468, respectively (graph). The corresponding values for CRP were; 2.5, 5.4, 8.2 and 9.7. There was a very strong correlation between the FC values to histology scores (ρ 0.37, $p<0.0001$), compared to CRP (ρ 0.21, $p=0.003$). Using a cut off value of 222 μg/g, FC had a 71% sensitivity and 51% specificity (AUC 0.66) for predicting moderate / severe histological disease. The corresponding figures for CRP>6 mg/L were 54% and 59%, respectively (AUC 0.59).

Histology score	n (CD)	CD - Calpro (Median)	95% CI		n (UC)	UC - Calpro (Median)	95% CI	
0	42	113.0	53.0	to 161.0	25	38.0	25.0	to 66.0
1	87	238.0	175.0	to 330.0	94	295.5	205.0	to 481.0
2	65	645.0	517.0	to 955.0	73	520.0	280.0	to 770.0
3	9	3075.0	452.0	to 5575.0	12	1468.0	122.0	to 4655.0

CONCLUSION: In the largest IBD series to date, FC was strongly predictive of histological disease activity in both CD and UC patients, and with a cut off level of 220-250μg/g gave high sensitivity and moderate specificity for predicting moderate to severe disease activity. FC showed greater accuracy in CD than in UC and also performed better than CRP. This study highlights the importance of FC as a valuable, non-invasive biomarker of disease activity in IBD, which can help direct treatment and reduce the need for invasive endoscopic procedures.

P0856 THE ROLE OF CONFOCAL LASER ENDOMICROSCOPY IN THE MANAGEMENT OF PATIENTS WITH INFLAMMATORY BOWEL DISEASES: A CONSENSUS REPORT BASED ON LITERATURE

H. Neumann[1,*], R. Arsenescu[2], H. Bertani[3], E. Coron[4], A. Dlugosz[5], J. Galmiche[4], K. Ho[6], S. Singh[7]
[1]*Universitätsklinikum Erlangen, Erlangen, Germany,* [2]*Ohio State University Medical Center, Columbus, United States,* [3]*Nuovo Ospedale Civile Sant'Agostino Estense, Modena, Italy,* [4]*CHU Nantes, Nantes, France,* [5]*Karolinska University Hospital Huddinge, Stockholm, Sweden,* [6]*National University Hospital, Singapore, Singapore,* [7]*VA Boston Healthcare System- West Roxbury, Jamaica Plain, United States*
Contact E-mail Address: *helmut.neumann@uk-erlangen.de*

INTRODUCTION: Confocal Laser Endomicroscopy (CLE) allows microscopic imaging of the colonic mucosal layer during endoscopy. Clinical studies published during the past years have enhanced the potential of this technique to accurately assess the mucosa at the microscopic level and to provide accurate information either for the assessment of inflammation or for the detection of neoplasia. Those findings have the potential to improve patient management by tailoring both diagnostic and treatment approaches.
AIMS & METHODS: The aim of this study is to develop evidence-based consensus statements for the assessment of the role of CLE in the management of patients with IBD.
Initial statements on the use of CLE in the assessment of IBD were developed by a single CLE expert based on the available clinical literature. Those preliminary statements were edited and submitted by an external group of 8 GI physicians experts in CLE, using a modified Delphi approach. After two rounds of votes based on current literature and strength of recommendation, statements were adopted if the threshold of agreement was higher than 75%.
RESULTS: Out of 17 proposed statements, 11 were adopted and 6 rejected. CLE can identify Crohn's disease (CD) and ulcerative colitis (UC) associated histological changes in vivo. CLE can be used to acquire targeted biopsies for surveillance of IBD patients. Targeted biopsies should be preferably used instead of random four quadrant biopsies for surveillance in IBD. CLE can identify IBD associated histological changes in macroscopically non-inflamed mucosa. CLE provides dynamic in vivo live information about intestinal barrier function and vascular permeability. CLE provides dynamic in vivo live information about intestinal barrier function and vascular permeability. Surveillance in IBD by using CLE should be performed in macroscopically non-inflamed mucosa. CLE can redefine the term "mucosal healing" in vivo. The ultimate goal of CLE for IBD patients is to predict response to anti-tumour Necrosis Factor (anti-TNF) antibody therapy and may help to initiate an individualised therapy of IBD patients to reduce drug associated side effects, morbidity and costs for the health care system. Step-down and step-up approaches should be replaced by an individualized, adapted approach, including microscopic evaluation of the mucosa.
CONCLUSION: 11 consensus statements on the use of Confocal Laser Endomicroscopy for the management of IBD were adopted by a panel of 8 clinical experts. These statements were established based on published literature and consensus opinions, suggesting that Confocal Laser Endomicroscopy has the potential to play an important role in the management of IBD patients by assessing mucosal healing and individualizing approach with biologics. Further clinical studies are necessary to support these ideas.

P0857 NEGATIVE PREDICTIVE VALUE OF TRANSABDOMINAL ULTRASOUND FOR SHORT-TERM OUTCOMES OF INFLAMMATORY BOWEL DISEASE

I. Sturdik[1,*], J. Toth[1], T. Hlavaty[1], T. Koller[1], M. Huorka[1], Z. Zelinkova[1]
[1]*5th internal medicine department, University hospital Bratislava, Bratislava, Slovakia*
Contact E-mail Address: *igor.sturdik@gmail.com*

INTRODUCTION: Transabdominal ultrasound is considered a useful tool for the assessment of inflammatory bowel disease (IBD) activity but its negative predictive value for gold standards diagnostic methods, such as endoscopy, is limited. Therefore, usefulness of transabdominal ultrasound in monitoring of disease activity has been questioned. However, the diagnostic value of ultrasound has not been tested with regards to short or long-term outcomes of IBD.
AIMS & METHODS: The aim of our study was to assess the negative predictive value of transabdominal ultrasound in IBD for short –term disease complications. We retrospectively evaluated all IBD patients with clinical suspicion of disease flare who underwent an intestinal ultrasound performed by one sonographist at a single tertiary IBD Center. Disease activity and the presence of disease complications were evaluated according to standard parameters for intestinal ultrasound. Findings of colonoscopy performed within 2 months of the ultrasound were compared to the ultrasound findings for each respective bowel segment. For correlation of categorical findings at ultrasound and colonoscopy a chi-square test was used. The changes in therapy were noted as well as clinical remission and surgical intervention at respective month 3 and 6 following the ultrasound and negative predictive value of ultrasound was calculated for each of the outcomes.
RESULTS: In total, sixty five ultrasounds were performed in 61 IBD patients (mean age 39, range 18 to 94 years; 41% of males; 45/16 Crohn's disease/ ulcerative colitis) were evaluated. Overall, there were 45 cases (70%) of disease activity detected by ultrasound, in 18 cases (28%) no abnormalities were found and 2 cases (3%) were inconclusive. Complications of IBD, such as abscess and fistulas were found in 10 cases (15%). Colonoscopy was performed in 39 cases. Ultrasound correlated well with endoscopy in assessment of disease activity in terminal ileum ($p=0.049$) as well as in colonic disease ($p<0.0001$). The positive and negative predictive values (NPV) of ultrasound for disease activity as assessed by endoscopy were 90% and 78%, respectively, for terminal ileum disease localisation; and 100% and 75%, respectively, for colonic disease. None out of 18 cases with no abnormalities found on ultrasound needed a therapy adjustement nor surgery during the six months following the ultrasound; all these patients were in remission at respective months 3 and 6 (NPV of relapse 100%).
CONCLUSION: Transabdominal intestinal ultrasound has a high negative predictive value for short-term complications of inflammatory bowel disease.

P0858 HERPES FAMILY VIRUSES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE AND IMMUNOSUPPRESSION

P. Tsibouris[1,1], I. Koumoutsos[1], P. Apostolopoulos[1], C. Kalantzis[1], E. Chounta[1], **E. Vlachou**[1,*], **G. Alexandrakis**[1]
[1]*GASTROENTEROLOGY, NIMTS GENERAL HOSPITAL, Athens, Greece*
Contact E-mail Address: *tsibofam@yahoo.com*

INTRODUCTION: Herpes family viruses (herpes simplex virus 1 and 2 (HSV1 and HSV 2), Epstein Barr Virus (EBV), cytomegalovirus (CMV)) are prevalent in the adult population.
AIMS & METHODS: Aim: Study the primary infection in an adult population with inflammatory bowel disease and infection reactivation under immunesuppression.
Patients-Methods: 56 patients (40 with Crohn's disease, 13 with ulcerative colitis, 3 with indetermined inflammatory bowel disease) were evaluated before immunosuppression initiation (infliximab 36 patients, immunosuppressant 9, infliximab+immunosuppressant: 11). Serology was evaluated before treatment (anti-HSV IgG/IgM antibodies, anti-CMV IgG/IgM antibodies, IgG/IgM antibodies against EBV viral capsid antigens and nuclear antigen). Patients were follow-up for 3 years with serologic evaluation every 3 months and tissue sampling in case of disease flare ups for PCR.
RESULTS: In patients aged 17-20 years 3/3 (100%) were HSV 1,2 (+), 3/3 (100%) EBV (+), 2/3 (66%) CMV (+); in those aged 21-25: 6/8 (75%) were HSV 1 (+), 5/8 (63%) HSV2 (+), 8/8 (100%) EBV (+), 7/8 (88%) CMV (+); in patients aged 26-30 years: 6/7 (86%) were HSV1 (+), 5/7 (71%) HSV2 (+), 4/7 (58%) EBV (+), 6/7 (84%) CMV (+); in patients aged 31-40: 9/11 (81%) were HSV 1,2 (+), 9/11 (81%) EBV (+), 9/11 (81%) CMV (+); in patients aged 41-50: 11/11 (100%) were HSV 1 (+), 10/11 (91%) 10/11 (91%) EBV (+), 7/11 (64%) CMV (+); in patients aged over 60: 10/12 (84%) were HSV 1,2 (+), 12/12 (100%) EBV (+), 9/12 CMV (+). During follow-up 3 patients presented HSV2 seroconversion, while HSV1 was positive, 3 EBV seroconversion and 3 CMV seroconversion. All of them were reported to be asymptomatic. 3 patients presented HSV flare-ups treated with topical and systematic treatment, while immunosuppression was temporally withheld. No flare-ups reported for EBV and CMV.

CONCLUSION: Herpes family viruses are prevalent in patients with inflammatory bowel disease. Flare-ups under immunosuppression are rare while seroconversions are rather asymptomatic.

P0859 ACIDITY OF INTESTINAL CONTENTS IN THE DISTAL PARTS OF THE COLON IN PATIENTS WITH ULCERATIVE COLITIS

I. Gubonina[1,*], V. Grinevich[1], V. Ekimov[1], N. Sherstneva[2]
[1]*2nd Therapy Department,* [2]*Military Medical Academy, Saint-Petersburg, Russian Federation*
Contact E-mail Address: *giv70@bk.ru*

INTRODUCTION: It is nececcary to determine the possibility of using mesalazine-delivering drugs with different release mechanisms depending on the pH value in patients with UC relapse.
AIMS & METHODS: To evaluate the acidity of intestinal contents in the distal parts of the colon in patients with ulcerative colitis (UC) relapse. 43 patients with left-sided UC and 24 patients with extensive UC having mild or moderate relapse were evaluated. The evaluation of the pH of the chymus with use of a universal indicator test strip, as well as analysis of changes in the pH of intestinal contents depending on clinical, laboratory and endoscopic indicators of ulcerative colitis activity, were carried out in all these patients. The control group consisted of 16 healthy volunteers.
RESULTS: On the whole, there was a trend towards acidification of chymus in patients with left-sided UC as compared to healthy volunteers ($pH = 6.76 \pm 0.21$ *vs.* $pH = 6.94 \pm 0.2$, respectively); however, this difference was not statistically significant. In the group of patients with extensive UC, a decrease in pH to below 6.0 (20.8%) was noted significantly more often as compared to the patients with left-sided UC (4.7%, $p < 0.05$) or control group subjects (0%, $p < 0.05$). Statistically significant correlation between the pH of the intestinal contents with ulcerative colitis activity index (correlation coefficient (CC) = -0.23), fecal calprotectin value (CC = -0.25), UC duration (CC = -0.21) or duration of UC treatment (CC = 0.35) was not revealed.
CONCLUSION: In patients with left-sided UC, acidity of the intestinal contents in the distal parts of the colon did not differ from that in the healthy volunteers and did not depend on disease activity or duration of ulcerative colitis. Decrease in the pH of the intestinal contents to below 6.0 was noted significantly more often in patients with extensive UC as compared to patients with left-sided UC or healthy volunteers. In the treatment of patients with decreased intraluminal pH levels, preference should be given to drugs with pH-independent release of active ingredient.

P0860 IT'S ALL IN THE STOOL. FAECAL CALPROTECTIN TO HELP GUIDE ANTI-TNF THERAPY; A RETROSPECTIVE STUDY

J. Gulliver[1,*], G. Baker[1], K. Millington [1], K. Zacchariah[1], R. Makins[1]
[1]*Gastroenterology, Cheltenham General Hospital, Gloucestershire Hospitals NHS Foundation Trust, Cheltenham, United Kingdom*
Contact E-mail Address: *james.gulliver@glos.nhs.uk*

INTRODUCTION: Faecal calprotectin (FC), a protein derived mainly from neutrophils and monocytes, is detected in increased quantities in the stool of patients with inflammatory bowel disease (IBD). Recently, the National Institute of Clinical Excellence (NICE) in the United Kingdom (UK) has recommended its use as a biochemical test to differentiate between IBD and functional bowel disease; furthermore, it can also be used to evaluate disease activity or response to treatment. We routinely assess patients' symptoms and biological markers including FC at least annually once established on anti-TNF therapy. This assessment is brought forward if there is a suspicion of ongoing disease activity.
AIMS & METHODS: We sought to assess the impact of FC testing on our clinical management, specifically for our patients with Crohn's disease receiving anti-TNF therapy. We interrogated our pathology database to collect FC results from all patients at Gloucestershire Hospitals NHS Foundation Trust who were established on anti-TNF therapy for Crohn's disease. FC samples had been obtained either as part of annual assessment or earlier due to ongoing symptoms. We then reviewed the patient's notes to determine what actions, if any, had been taken as a consequence of the FC results.
RESULTS: FC results were available from 28 of 31 patients collected during 2011 and 2012. Results were subdivided based on the FC level into four groups. 1) < 50ug/g (n = 9, 32.1%); 2) 50-100ug/g (n = 7, 25%); 3) 100-200ug/g (n = 5, 17.9%) and 4) >200ug/g (n = 7, 25%).
Across all four groups anti-TNF therapy was unaltered in 14 patients (50%) and stopped in 3 (11%). The dose was increased but frequency of treatment maintained in 2 (7%), and frequency increased in a further 2 (7%). Frequency was reduced in one patient from 8 weekly to 10 weekly (3.5%). Two patients were lost to local follow up.
More specifically, in group 1, 34% had their anti-TNF therapy unaltered and 22% had their therapy stopped with consequent significant cost savings. In contrast; 43% of patients in group 4 had their anti-TNF therapy altered, either by increasing dose or frequency of administration. Regarding further investigations no patient with a FC result >100ug/g went on to have a colonoscopy compared with 33% of patients with an FC <50ug/g.
CONCLUSION: FC is a useful tool when judging clinical response to anti-TNF therapy in patients with Crohn's disease. Once treatment is established it allows identification of patients for whom anti-TNF therapy can be further optimised or stopped. It also helps guide the need for further investigation, if either to re-stage disease extent and severity or if considering alternative diagnoses.

INTRODUCTION: Assessing inflammatory activity is essential in therapeutic decision making in Ulcerative Colitis (UC). Novel scintigraphy techniques including SPECT-CT are promising to measure inflammatory load in chronic inflammatory conditions such as UC. Leukocyte scintigraphy therefore needs to be validated using other established markers of inflammation.
AIMS & METHODS: We aimed to prospectively validate leukocyte SPECT-CT as a tool to measure and quantify inflammatory load in patients with different extent and severity of UC.
UC patients with an indication for full colonoscopy were included. Within 1 week and without any changes in therapy both colonoscopy (Mayo score, UCEIS) with biopsies (Geboes score) and leukocyte scintigraphy were performed. In addition, serum CRP and fecal calprotectin (Bühlmann ELISA) were measured and clinical questionnaires (CCAI, Mayo) were collected. Patients' peripheral blood leukocytes were isolated and labelled with 200 MBq technetium-99m HMPAO. SPECT combined with a low-dose CT was performed 60 min after reinjection of labelled cells. To quantify inflammation in each colon segment the uptake of leukocytes was calculated as a ratio to the mean uptake in bone marrow of 4 lumbar vertebrae and expressed as SPECT inflammation score in each colon segment and a Summed Activity Score (SAS) for the inflammatory activity in all 5 colonic segments together.
RESULTS: Twenty-six UC patients were studied. 3/26 were using anti-TNF, 4/26 thiopurines, 3/26 prednisone and 20/26 5-ASA at inclusion. At endoscopy 6/26 (23%) of patients had proctitis, 8/26 (31%) left-sided and 12/26 (46%) pancolitis. According to endoscopic Mayo score, 1/26 (4%) of patients had inactive, 5/26 (19%) mild, 8/26 (31%) moderate and 12/26 (46%) severe disease. The median (IQR) full Mayo score was 7 (5-10), CCAI: 6 (2-9), serum CRP 4.1 mg/L (1.7-12.5) and fecal calprotectin 449 ug/g (245-1142). According to SPECT-CT patients were classified as having 9/26 mild, 12/26 moderate and 5/26 severe disease in their most affected segment. At the level of individual segments, significant correlations (Spearman) were observed between the SPECT inflammation score and endoscopic Mayo: r 0.54 ($P < 0.01$), UCEIS r 0.56 ($P < 0.01$) and histologic Geboes score r 0.59 ($P < 0.01$). The Summed Activity Score correlated much better with fecal calprotectin r 0.55 ($P < 0.01$) than with CRP: r 0.24 ($p = 0.24$), CCAI: r 0.43 ($P < 0.05$) or clinical Mayo: r 0.54 ($P < 0.01$).
CONCLUSION: SPECT-CT assessment of UC disease severity in the most inflamed colon segment is correlated with both endoscopic and histologic scores. The total inflammatory load in UC at SPECT-CT is better reflected by fecal calprotectin than by serum CRP.

P0862 A "COCOON" IMMUNISATION STRATEGY AMONG HOUSEHOLD CHILDREN OF ADULTS PATIENTS WITH INFLAMMATORY BOWEL DISEASE

K. Waszczuk[1,*], **E. Waszczuk**[2], A. Mulak[2], L. Szenborn[1], L. Paradowski[2]
[1]*Department of Pediatric Infectious Diseases,* [2]*Department of Gastroenterology and Hepatology, Wroclaw Medical University, Wroclaw, Poland*
Contact E-mail Address: *karolkap@gmail.com*

INTRODUCTION: In order to protect patients with inflammatory bowel disease (IBD) against serious infections, vaccination of their household children is recommended.
AIMS & METHODS: The aim of our study was to assess the not mandatory and not reimbursed vaccination coverage including pneumococcal, rotavirus, influenza, and varicella vaccines among household children of adult patients with IBD as the "Cocoon Strategy". A self-designed survey was conducted in 138 IBD patients hospitalised in the Department of Gastroenterology and Hepatology at Wroclaw Medical University from November 2013 to March 2014. The survey comprised questions about household children vaccination coverage and the reasons of its refusal as well as the history of infectious diseases in the patients. Randomly, patients completed the survey with a physician present to determine questions comprehension. In order to provide test-retest reliability a group of ten patients completed it twice. Fisher exact test was used for cross-classification tables.

RESULTS: The survey data from 52 IBD patients having household children (25 women, 27 men, mean age: 36 years) were analysed. Two patients declared refusing one obligatory vaccination of their children, while 40% of the patients reported at least one not reimbursed vaccine administration. Most frequently, children obtained pneumococcal (31%), rotavirus (23%), varicella (14%), and influenza (10%) vaccines. The most common reasons for non-immunisation was unawareness of the existing recommendations (46%), fear of adverse effects of the vaccines (18%) and not believing in vaccines efficacy (10%). In one case a medical health care worker discouraged from immunisation. There was statistically significant association between not reimbursed vaccines coverage and educational level of the patients ($p<0.001$). Despite the fact that 28% of IBD patients could not definitively recall varicella infection, none of their household children nor they were vaccinated against chickenpox.
CONCLUSION: The use of not mandatory vaccines recommended in Poland in IBD patients' family members is insufficient. Frequently, patients have serious doubts concerning safety and efficacy of vaccinations. Therefore, further vaccines promotion and education of patients as well as their health care providers are needed. A particular concern is associated with not vaccinating against influenza and varicella, which pose a high risk of infection. Non-immunised and VZV seronegative IBD patients should be vaccinated, and in case of their immunosupression, vaccination of household children is required.

P0863 THE ROLE OF PET-CT IN THE CHARACTERIZATION OF THE ACTIVITY OF CROHN'S DISEASE

K. Palatka[1,*], L. Szilvia[1], L. Dávida[1], I. Altorjay[1], L. Galuska[2]
[1]*Gastroenterology,* [2]*Department Of Nuclear Medicine, University Of Debrecen, Debrecen, Hungary*
Contact E-mail Address: *palatka@med.unideb.hu*

INTRODUCTION: Crohn's disease is an immune-mediated disorder with unknown etiology, characterized by segmental, transmural inflammation of the gastrointestinal tract and extraintestinal inflammatory symptoms. The diagnosis is based on endoscopy, imaging examinations, the disease activity is characterized by Crohn's disease activity index (CDAI), which includes subjective, objective sympthoms and laboratory parameters. PET-CT is a global, non-invasive, highly sensitive method to determine the location and activity of some malignant and inflammatory lesions. Former studies showed 85% sensitivity and 87% specifity of 18F-FDG-PET-CT in IBD.
AIMS & METHODS: The aim of the study was to evaluate the role of PET-CT in patients with active Crohn's disease (CDAI >300) before and after biological therapy and comparing with endoscopic index (SES-CD), CDAI and biochemical parameters. Twelve patient were examined: 5M/6F, age between 18 and 39, average age: 25 years. The evaluation of the PET-CT activity was determined considering the activity of the small intestine and the four colon segments. The SUVmax (Standardized Uptake Value) of the intestinal segment was correlated to the SUVmax of the liver, which was chosen as a reference for normal tissue activity. To get the global PET-score, the activity scores of the five intestinal segments were summed.
RESULTS: The PET-score showed correlation with CDAI ($R^2=0.1441$) and CRP ($R^2=0.0512$), but not with SES-CD ($R^2=0.0041$). After one year biologic therapy CDAI ($R^2=0.1622$), CRP ($R^2=0.0815$) and SES-CD ($R^2=0.1699$) correlated well with the PET-score. In active disease, the PET-CT was more sensitive than the endoscopy to indicate the extent of the inflammation. Examining new patients, PET-CT was the most informative on the activity and extent of the disease (small intestine involvement). In one case, the terminal ileum stenosis with high CDAI score associated with negative PET-CT score, which was a fibrotic stenosis as it turned out after the surgery. Patients with negative PET-CT score after biological treatment remained in remission during a two year follow-up period.
CONCLUSION: The PET-CT results correlated well with the activity of the Crohn's disease. In the future, this should be a promising, non-invasive method in the diagnosis of Crohn's disease and in the planning the treatment and follow-up. Negative PET-CT proved to be a good indicator of deep remission.

Contact E-mail Address: *k5mitsui@gmail.com*

INTRODUCTION: Deep enteroscopy has been widely used for various small bowel diseases. One of the most common diseases that affected the small bowel is Crohn's disease. The idea is being accepted that the mucosal healing is important parameter for the better outcome of Crohn's disease. However the efficacy and safety of the DBE is not fully understood.
AIMS & METHODS: We conducted a retrospective case series study to elucidate the efficacy of DBE in Crohn's disease. We enrolled the consecutive 40 patient who underwent the 95 DBE examinations since 2003. Patients' characteristics, indications of the deep enteroscopy, duration of procedures, therapeutic interventions and complications were assessed.
RESULTS: Subjects were 7 females and 33 males, mean age was 38±13 years old. The indications of DBE were mucosal evaluation for known Crohn's disease, obscure gastrointestinal bleeding, small bowel obstruction, removal of the retained small bowel capsule endoscopy (SBCE), suspicious of Crohn's disease and further evaluation of protein-losing enteropathy in 17, 10, 7, 3, 2, 1 case, respectively. The mean number of DBE examination per patient was 2.4±1.4. Types of scope were type T, type P (thin type), and type B (short type) in 49, 41 and 5 cases. The choice of the scope had depended on the therapeutic capability or the facility of deeper insertion. The insertion roots were antegrade (from mouth) in 31 patients and retrograde (from anus) in 64 patients. The mean insertion time was 65±31 minute. The antegrade vs. retrograde was 45±25 vs. 34±40 minutes ($p=0.005$). The mean total examination time was 83±34 min. The antegrade vs. retrograde was 83±34 vs. 56±26 min. ($p<0.0001$). The mean insertion depth was 95±93 cm. The antegrade vs. retrograde was 178±75 vs. 55±70 minutes ($p<0.0001$). Balloon dilation therapies were performed in 18 procedures in 8 patients. In 10 patients, the prior SBCE had been done and 6 patients were retained. All the retained SBCE were removed by double balloon endoscopy. In only one out of 10 patients, DBE had not shown any severe stricture and SBCE was used for the mucosal evaluation repeatedly. No complication was encountered in diagnostic and therapeutic DBE.
CONCLUSION: DBE showed that ileal lesions were more common and oral DBE was time-consuming in Crohn's disease. The evaluation with DBE also can pick out the patient who can undergo the SBCE. The dilation therapy may delay the timing of the surgical interventions. DBE, especially the retrograde DBE, have a potential to improve the outcome of Crohn's disease.

INTRODUCTION: Accurate, non-invasive methods of evaluating treatment response in patients with Crohn's disease (CD) are important in a treat to target paradigm. The aim of this study is to prospectively evaluate the ability of sonography to monitor patients on adalimumab (ADA), correlated with endoscopy as a gold standard.
AIMS & METHODS: This is an IRB-approved, single-center, prospective study, evaluating patients with CD treated with adalimumab for at least 6 months. Baseline clinical score (Harvey Bradshaw/HBI), C-reactive protein (CRP), ileocolonoscopy and transabdominal ultrasound were completed within 2 weeks at time zero and 12 months (if clinically indicated), with intervening scans at 4 and 8 months. Standard sonographic assessment included bowel wall thickness, color Doppler signal, presence of inflammatory fat and lymph nodes. Endoscopy was scored using validated simple endoscopic score (SES) and/or Rutgeert's score (Ri) in post-operative patients. Endoscopic responsiveness was defined as mucosal healing (SES-CD$\leq$5 and/or Ri$\leq$1) and sonographic responsiveness as bowel wall thickness ($\leq$6mm) with minimal inflammatory fat and Doppler signal. The aim of this study is to prospectively evaluate sonographic and endoscopic maintenance of remission in patients on adalimumab.
RESULTS: 50 patients have been recruited to date with $n=34$ included in this analysis ($n=16$ excluded given drop out, missing data or in progress). At time zero, 34 patients had endoscopy and 19/34 (56%) patients underwent follow-up endoscopy at 1 year, those who did not were deemed in clinical and serologic remission without indication for endoscopy. There were (3/34) strictures limiting endoscopic visualization of disease at time zero, and one had proximal disease. The agreement between the remaining US and endoscopy ($n=30$) at time zero was excellent (complete agreement in 26/30), as was the correlation at twelve months. Table 1 shows endoscopy and US findings for 17/19 at 12 months. Final endoscopies were limited given proximal disease in 2/19 and thus were not included. Patients with endoscopically active disease at 12 months showed active sonographic disease as early as 4 months.

	Mucosal Healing (SES-CD$\leq$3 and/or Ri$\leq$1)	Endoscopically Active (SES-CD$>$3 and/or RI$>$1)
Absence of US disease	11	0
Presence of US Disease	1	4 (+1 pouch case)

CONCLUSION: US is an accurate, non-invasive modality useful in evaluating maintenance of response to therapy, which correlates with mucosal healing on endoscopy. Thus, US may be a surrogate for endoscopy and a repeatable, objective target for treatment.

P0866 QUALITY OF LIFE IN ULCERATIVE COLITIS – ASSOCIATION BETWEEN THE SHORT INFLAMMATORY BOWEL DISEASE QUESTIONNAIRE (SIBDQ) AND THE SHORT HEALTH SCALE (SHS) AND THEIR RELATIONSHIPS WITH CLINICAL AND ENDOSCOPIC DISEASE ACTIVITY

K. Theede[1,*], M. Kiszka-Kanowitz[1], I. Nordgaard-Lassen[1], A.M. Nielsen[1]
[1]*Gastrounit, Medical Division, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark*

INTRODUCTION: Health Related Quality of Life (HRQoL) is an important part of Inflammatory Bowel Disease (IBD) assessment, and is affected by both disease activity, psychological, and social factors. Several HRQoL questionnaires

have been developed, but are primarily used in the setting of clinical trials. Little is known about the relationship between HRQoL and disease activity and between the different HRQoL questionnaires. We aimed to assess the association between the SIBDQ and the SHS and their associations with clinical and endoscopic disease activity.
AIMS & METHODS: Prospectively, 110 patients with ulcerative colitis underwent sigmoidoscopy and completed the SIBDQ and the SHS. The SIBDQ is a validated 10-question tool measuring physical, social, and emotional status (score 10-70, poor-good). The SHS is a four-part visual analogue scale questionnaire measuring bowel symptoms, activities of daily life, worry, and general well-being (score 0-40, good-poor). Clinical disease activity was assessed using the Mayo score (0-12) and was divided into remission (≤2), mild (3-5), moderate (6-9), and severe (10-12) activities. The endoscopic grade of inflammation was assessed using Mayo Endoscopic Score (MES, 0-3).
RESULTS: The median age was 37 years (19-80), and 56 % were female. The median disease duration was 4.5 years. 29 % had mucosal healing, 20 % active proctitis, 16 % active proctosigmoiditis, 18 % active left-sided colitis and 18 % pancolitis. According to the MES, 29 % had mucosal healing, 26 % had mild, 31 % moderate and 14 % severe inflammation. According to the Mayo score, 37 % were in clinical remission, 21 % had mild, 31 % moderate and 11 % severe disease activity.
HRQoL significantly decreased with increasing clinical disease activity (Mayo score) when assessed with both SIBDQ ($\chi^2 = 51.9$, $p < 0.0001$) and SHS ($\chi^2 = 56.2$, $p < 0.0001$). HRQoL also significantly decreased with increasing endoscopic disease severity (MES) when assessed by both SIBDQ ($\chi^2 = 33.1$, $p < 0.0001$) and SHS ($\chi^2 = 40.3$, $p < 0.0001$). Overall, we found a significant difference in HRQoL between patients with mucosal healing (MES = 0) and active inflammation (SIBDQ, inactive/active, 59.1/45.6, $p < 0.0001$ and SHS, inactive/active, 6.8/19.7, $p < 0.0001$). Moreover, we found a strong association between SIBDQ and SHS using linear regression (SHS = -0.73×SIBDQ+52.1, $p < 0.0001$).
CONCLUSION: In this study we demonstrate that HRQoL is not only strongly associated with clinical disease activity, but also with the endoscopic disease severity. We also demonstrate that SIBDQ and SHS are strongly associated with each other.
Both SIBDQ and SHS show significantly decreasing HRQoL with increasing clinical disease activity as well as with increasing endoscopic disease severity. The study also shows significant difference in HRQoL between patients with mucosal healing and endoscopic active disease. Both questionnaires seem equally adequate in determining the disease impact on HRQoL.
HRQoL is from the patients' perspective one of the most important parts of IBD management. SIBDQ and especially SHS can be completed quickly during regular visits, and can be used as an easy tool for HRQoL monitoring. Significant changes must be followed by exploration of the possible causes including assessment of disease activity.

INTRODUCTION: There are few data available on effect of immunomodulator/biological therapy on the accuracy of tuberculin skin test (TST, Mantoux skin test) and interferon-gamma release assay (IGRA) in BCG vaccinated immunosuppressed IBD patients.
AIMS & METHODS: Our aim was to define the accuracy of the TST and IGRA tests in a BCG vaccinated referral IBD cohort treated with immunosuppressives and/or biologicals. Data of 135 consecutive moderate-to-severe IBD (98 CD, 37 UC) patients were analyzed (male/female: 64/71, median age at diagnosis: 24.0; IQR: 18-31 years, duration: 7.0; IQR: 4-13 years). Patients were treated with immunosuppressives (azathioprine, steroids) and/or anti-TNF therapy. Blood samples for IGRA were collected during routine laboratory testing parallel with TST. The result of TST was determined according to international guidelines. Both in- and outpatient records were collected and comprehensively reviewed.
RESULTS: TST positivity rate was 21.6%, 20.1%, 13.4% or 12.7% with cut-off values of 5, 10, 15 and 20mm. IGRA positivity rate was 7.7% with indeterminate result in 1.2%. The correlation between TST and IGRA was significant, with moderate-to-good kappa values if TST results were >15mm (kappa: 0.32-0.34, $p < 0.001$). In addition, a TST of 14 and 17mm was also identified as best cut-off value in a ROC analysis (AUC: 0.70, $p = 0.04$). There was no association between the type and number of immunomodulators used or any disease phenotype characteristics and the TST or IGRA results. Importantly, smoking was identified as a risk factors for TST but not IGRA positivity (OR: 3.80, 4.88, 9.87 and 8.98, $p < 0.002$, for $TST_{cut\text{-}off}$ 5, 10, 15 and 20mm).
CONCLUSION: The TST and IGRA are partly complimentary methods and accuracy is acceptable also in BCG vaccinated and immunosuppressed IBD patients. A TST of >15mm should be used as a cut-off to identify patients at risk for latent TB in these patients. Smoking is a risk factor for TST positivity.

INTRODUCTION: Ongoing inflammation in Crohn's disease (CD) may lead to development of intestinal fibrosis and patients may present with stenosis. Inflammation is a dynamic process with a permanent remodeling of the extracellular matrix (ECM). Small fragments of the ECM generated during this process, so called neoepitopes, are released into the circulation and could be used as biochemical markers of disease activity or markers of fibrosis.
AIMS & METHODS: This study investigates a panel of these novel developed markers in patients with suspected or known CD.
106 patients referred for evaluation of CD had serum samples drawn. Patients were evaluated with colonoscopy, small-bowel imaging (capsule endoscopy, MR enterography, and CT enterography), fecal calprotectin, and C-reactive protein. 35 patients had newly diagnosed CD, 26 had CD with active inflammation or stenosis, 11 had known CD without inflammation or complication, and 34 had no evidence of Crohn's disease. The following neoepitopes were measured by competitive ELISAs; MMP-mediated of type I, III, IV collagen (C1M, C3M, C4M), N-terminus pro-collagen type I (P1NP), and MMP-degraded, citrullinated vimentin (VICM).
Data were not normally distributed and Kruskal-Wallis one-way analysis of variance was used for comparison. ROC-curve analysis were used to test the biomarkers ability to discriminate CD from non-CD.
RESULTS: Serum levels of C3M were significantly elevated in patients with CD compared to patients without CD (median 24.4 and 19.1, respectively; $P = 0.01$). C3M discriminated CD from non-CD with an AUC of 0.66. Concentrations of C1M and C4M were also elevated but statistical significance was not reached (C1M: median 68.9 and 62.9; $P = 0.12$. C4M: median 70.5 and 67.2; $P = 0.15$). In patients with CD, C1M and C3M concentrations were higher in clinically active disease (CDAI > 150) compared to quiescent disease (C1M: median 75.0 and 63.2; $P = 0.02$. C3M: median 24.5 and 22.7; $P = 0.10$), and C3M concentrations were higher in CD involving the colon compared to small bowel CD (median 26.2 and 22.1; $P = 0.05$). C1M, C3M and C4M correlated with CRP (Spearman's rho 0.76, 0.40, and 0.45, respectively; $P < 0.001$) but not with fecal calprotectin. Concentrations of ECM degradation markers were not significantly increased in patients with stricturing CD compared to patients without CD. In subgroup analysis of patients with diagnosed CD and elevated CRP compared to non-CD and normal CRP C1M, C3M and C4M discriminated CD from non-CD (AUC of 0.95, 0.88 and 0.90).
CONCLUSION: Turnover of ECM proteins is increased in patients with CD. These neoepitopes may distinguish between patients with CD and patients without CD and between active CD and disease in remission. Further studies of these promising markers of the ECM are warranted.

INTRODUCTION: Thiopurine therapy increases the risk of (Epstein- Barr virus associated) lymphomas for Inflammatory Bowel Disease (IBD) patients up to four times. Epstein- Barr virus (EBV) can cause a wide spectrum of lymphoproliferative reactions, ranging from morphologically benign with normal B lymphocytes (BL) and lymphoplasmacytic infiltrate in the lamina propria (LI) to aggressive lymphomas with atypical BL and LI.
EBV can be detected in colonic mucosa in up to 60 % of the IBD patients, but there is no consensus on when to perform EBV testing on intestinal mucosa. We hypothesized that EBV testing can be guided by histological features including morphology of BL and LI.
AIMS & METHODS: The aim of this study was to determine the value of the histology of the inflammation in predicting EBV presence in intestinal mucosa and to correlate EBV positivity with clinical endpoints such as intestinal surgery and development of lymphoma.
All IBD patients who underwent EBV testing by EBV-encoded RNA – in situ hybridization (EBER) in intestinal biopsies between January 2005 and October 2013 in our centre were identified. All biopsies were revised by a blinded, expert gastro-intestinal pathologist and scored on three histological features: number of EBV positive cells per high power field (HPF); normal or atypical LI and normal or atypical BL. Demographic and clinical data were collected from patient charts. Adverse events that were registered included intestinal surgery and lymphoma.

We used the Chi square test or Fisher's exact test to identify an association with EBV positivity.
RESULTS: 58 IBD patients were included, 28 were EBV positive and 30 were EBV negative. Ulcerative colitis was more frequent in the EBV positive group (82,1 % versus 56,7 %; p = 0.052)
EBV positive patients had significantly more frequent atypical LI (57.1 % versus 3.3 %; p = <0.001). The specificity for predicting EBV presence of the atypical LI is high (96.7 %), just as its positive predictive value (94.1 %). At time of biopsy, EBV positive patients used more often combinations of two or more anti-inflammatory drugs (5-aminosalicytes excluded; 50 % versus 16.7 %; p = 0.007) Eighteen EBV positive patients (64.29 %) had 20 pre-defined complications (18 colectomies, 2 lymphomas). Within the group of EBV positive patients, those who developed complications had a significantly higher EBV load (50 % versus 10 %; p = 0.048), expressed as the frequency of ≥ 10 EBV positive cells per HPF. 11 patients had atypical LI and BL, including 2 lymphomas: those were treated with chemotherapy. In the other 9 patients at least one immunosuppressive drug was stopped. In all patients the atypical LI showed resolution. 8 of the 9 patients became EBV negative and 1 patient had reduction of EBV positive cells.
CONCLUSION: In the present study, atypical LI was associated with mucosal EBV in IBD patients. A high EBV load is correlated with adverse events. Reduction of immunosuppression may decrease intestinal EBV associated lymphoproliferation.

INTRODUCTION: New biomarkers are required to monitor patients with Ulcerative Colitis (UC) and predict complications such as dysplasia and colitis associated cancer (CAC). Accurate plasma based biomarkers would allow physicians to make clinical decisions, thereby avoiding unnecessary invasive tests.
AIMS & METHODS: This feasibility study aimed to identify novel microRNAs (miRNAs) in the plasma of patients with Ulcerative Colitis related to disease progression.
RESULTS: Primary analysis of the array data identified the differential expression of several miRNAs from which the following miRNAs 122,125b, 139-3p, 331-5p, 375, 383-3p, 409-3p, 720, 1274B were chosen for validation. Analysis of variance was used to assess differences between groups. MiR-375 was shown to be significantly up-regulated in the CAC cohort (p = 0.002) when compared to UC and PSC. MiR-375 was found to be an effective biomarker of disease progression over disease duration, with Cox-regression analysis showing a Cox hazard ratio of 1.91 (p = 0.01).
CONCLUSION: Peripheral plasma miRNAs have the potential to act as biomarkers of disease progression in Ulcerative colitis. This study provides the first evidence that miRNA-375 is up regulated in cases of CAC. This finding needs to be extended to a larger validation cohort.

INTRODUCTION: Endoscopy is the gold standard for activity assessment in luminal Crohn's disease (CD) but, due to the full thickness involvement of the bowel wall, or presence of complications, CD activity is the result of an integration of endoscopic, clinical, laboratory, and imaging data. Recently, a radiological score which integrates both mural and extramural involvement has been validated for a global disease evaluation (1).
AIMS & METHODS: to examine the relationships among MRI, laboratory inflammatory markers, clinical activity scores and endoscopy in a series of CD patients.
45 consecutive patients with endoscopically proven CD underwent at the time of enrollment MRI enterography, performed utilizing a 1.5 T system, for the staging of disease at diagnosis and activity assessment. Endoscopic activity was measured by a quantitative score (Simple Endoscopic Score for Crohn's Disease, SES-CD (2), range 0-40) with active disease being present for a >3 score and mild, moderate ad severe disease for ranges of respectively 4-10, 11-19 and >20. MRI activity was measured by a previously validated quantitative score (Magnetic Resonance Enterography global score, MEGS, range 0-296), with active disease being present for a >0 score. For all participants the *Crohn's Disease Activity Index* (CDAI) was completed and CRP and fecal calprotectin (FC) were measured (positivity cut-off respectively > 0.50 mg/dl and >150 μg/gr).
RESULTS: We enrolled 19 males and 26 females, mean age 37±14 years, mean disease duration 5 years. According to Montreal disease classification the phenotype was L1 in 47%, L2 in 6% and L3 in 47%; the behavior was B1 in 24%, B2 in 56%, B3 in 20% and perianal disease in 2%; resectional surgery related to CD was observed in 20%. According to SES-CD, 91% of patient had active disease and 9% had inactive disease (64% mild, 20% moderate and 7% severe disease). Mean MEGS was 20±18, with 82% having active disease and 18% inactive disease (p < 0.01 in comparison to endoscopy, sensibility 88%, specificity 75%, VPP 97%, VPN 38%). MEGS, was significantly higher in penetrating than in non-penetrating and non-stricturing disease (respectively 35±9 vs 7±11, p < 0.001). MEGS was significantly correlated with SES-CD (p < 0.01), in particular for the ileal (p < 0.01) and ceacum-ascending colon subscores (p < 0.05). Severity of the disease at endoscopy did not correlate to severity at MEGS (p = 0.7). Both MEGS and SES-CD show significant correlations with CDAI (p < 0.01) and CRP (p < 0.05), yet SES-CD only correlated significantly with FC (p < 0.001). The extramural involvement subscore, observed in half of patients, regardless of the behavior and severity at endoscopy, was associated to CRP positivity (p < 0.05), not with fecal calprotectin (p = 0.67). Increasing staging of grading at endoscopy was significantly correlated to the risk of extramural involvement (p = 0.008)
CONCLUSION: MRI is capable of identifying disease activity, although it results less accurate in the assessment of severity as measured at endoscopy. The presence of positive CPR suggests the need of MRI for the staging of patients with active luminal disease.

INTRODUCTION: Faecal calprotectin (FC), an abundant neutrophil protein, has recently been introduced as a non-invasive marker for monitoring of disease activity in inflammatory bowel disease (IBD). However, it has been difficult to define a definite threshold to discriminate between remission and active disease.
AIMS & METHODS: We, aimed to compare the results of different FC-assays in a well-characterized cohort of patients with IBD, followed over time. Patients (n = 13) with established IBD provided faecal samples and reported clinical activity every third months prospectively for a two year period. Relapse was defined as increasing symptoms and intensified treatment. FC was measured with three different assays; Calprotectin Elisa Buhlmann Laboratories AG, Basel, Switzerland; Phadia Elia Calprotectin, ThermoFischer Scientific, Freiburg, Germany; and PhiCal Calprotectin Elisa, Immundiagnostik AG, Bensheim, Germany. Disease status, defined as clinical remission or relapse, i.e. active disease, was determined at the time of collection of each fecal sample in each patient. Samples were grouped as corresponding to clinical remission or active disease. However, samples collected three months after a relapse were excluded to reduce possible bias due to prolonged intensified therapy, steroid dependent disease or ongoing subclinical inflammation.
RESULTS: In total, the 13 patients prospectively provided 91 faecal samples during the two year period. The median (IQR) concentration of FC was 187 (57 – 582) μg/g, 52 (15 – 415) μg/g and 55 (9 – 158) μg/g using the Bühlmann-, Phadia- and Immundiagnostik assay, respectively (p < 0.0001). Based on the cut-off provided by the manufactures, i.e. >50 μg/g, the FC assay was positive in 74 (81 %), 47 (52 %) and 50 (55 %) of the 91 samples when analyzed by the Bühlman-, Phadia- and Immundiagnostik assay, respectively. Modest to fairly good correlations were observed between the Bühlmann- and the Phadia assay, the Bühlmann- and the Immundiagnostik assay and the Phadia- and the Immundiagnostik assay ($R^2 = 0.70$, $R^2 = 0.80$ and $R^2 = 0.86$, respectively). However, Bland-Altman plots revealed overall poor agreement between the assays. Assay specific sensitivity, specificity and predictive values for defining clinical remission *vs.* active disease for each assay based on different cut-offs are shown in table 1.
Table 1. Assay specific sensitivity, specificity and predictive values for defining clinical remission *vs.* active disease for each assay based on different cut-offs

FC cut-off (μg/g)	Bü ≥50	Ph ≥50	Im ≥50	Bü ≥100	Ph ≥100	Im ≥100	Bü ≥150	Ph ≥150	Im ≥150
Sensitivity	86%	71%	86%	86%	64%	36%	79%	50%	14%
Specificity	26%	66%	62%	50%	72%	78%	56%	76%	80%
NPV	87%	89%	94%	93%	88%	81%	90%	84%	77%
PPV	24%	37%	39%	32%	39%	31%	33%	37%	17%

Bü; Bühlmann assay, Ph; Phadia assay, Im; Immundiagnostik assay, NPV; negative predictive value, PPV; positive predictive value
CONCLUSION: By cross-comparisons pronounced inter-assay differences were revealed. Although moderate to fairly good correlations between the FC assays were observed, Bland-Altman plots showed overall poor agreement.

INTRODUCTION: High definition(HD)- iSCAN endoscopy can characterize in details the mucosa in patients with ulcerative colitis (UC) and may provide more information about inflammation and mucosal healing (MH). However, the gold standard of mucosal healing is still histological diagnosis. More refined histologic and high definition iSCAN endoscopic criteria may redefine mucosal healing.
AIMS & METHODS: 78 patients (40 male, median age = 42y, range = 19-90y) with UC were assessed by HD–iSCAN colonoscopy (Pentax EC-3490Fi; Pentax, Japan) as well as by white light endoscopy (WLE). Mayo endoscopic subscore and UC endoscopic index of severity (UCEIS) score were assigned to patients according WLE findings. Mucosal pattern on iSCAN was graded as 1 = normal, 2 = mosaic pattern, 3 = tubular-gyrus, 4 = nodular rosette. The vascular pattern was graded as 1 = normal, 2 = spiral isolated vessels, 3 = crowded tortuous vessels, 4 = Irregular vessels. A histological grading and scoring system that assesses all changes possibly seen in IBD was developed for a detailed and comprehensive evaluation. This system (GUI-ECAP system) was designed to reflect all histologic changes in IBD categorized as 1) Extent of inflammation (focal, multifocal, diffuse), 2) Chronicity (crypt architectural alteration, Paneth cell metaplasia), 3) Activity (surface epithelium changes, neutrophilic cryptitis, crypt abscess, crypt destruction, lamina propria mononuclear cellularity, lamina propria neutrophil infiltration, and basal plasmacytosis), and 4) Plus additional findings, including eosinophilia and lymphoid follicles/aggregates. An established histologic grading system, New York Mount Sinai score was used to validate the grading of inflammation.
RESULTS: In this cohort of 78 patients with UC, 23 (29%) patients had Mayo endoscopic subscore of 0. Of these 23 patients with complete MH, 18 patients (78%) had abnormal vascular pattern on iSCAN and 7 (30%) had abnormal mucosal pattern on iSCAN. By using ECAP histologic scoring all 23 patients (100%) showed various histologic abnormalities including crypt architectural alteration [19, (83%)], surface epithelium abnormality [16, (70%)], crypt destruction [3, (13%)], increase in lamina propria mononuclear cells [15, (65%)], basal plasmacytosis [11, (48%)], lamina propria neutrophilic infiltration [5, (21%)] and other additional findings [19, (83%)].
CONCLUSION: The subtle histologic abnormalities underlying the apparently healed mucosa with Mayo endoscopic subscore of 0 can be detected by using refined histological scoring system (GUI-ECAP) in combination with iSCAN. Sensitive endoscopic techniques such as iSCAN and histologic scoring such as ECAP can detect residual abnormalities in the majority of patients with seemingly complete MH in UC.

INTRODUCTION: In murine models, blocking TNF-alpha showed efficacy in colitis-associated colon cancer. Chronic inflammation in Inflammatory Bowel Disease (IBD) colitis has been associated with colorectal cancer (CCR).
AIMS & METHODS: In a monocentric retrospective matched-pair study, the frequency of colon cancer was compared in a cohort of IBD patients treated or untreated with anti-TNFs. In a matched-pair study, the role played by clinical characteristics of IBD in determining the frequency of colon cancer was also evaluated. Clinical records of all IBD patients in follow up from 2000 to 2013 at our tertiary IBD referral center developing cancer of the lower GI tract (IBD-K)(small intestine, appendix, CCR, anal canal) were reviewed. Each IBD-K patient was retrospectively matched with 2 IBD patients with no cancer of the lower GI tract (IBD-C), for IBD type (MDC/RCU), gender, age (±5yrs). Anti-TNFs (Infliximab or Adalimumab≥1 dose) and IMM (≥6mos) use was reported. Data expressed as median (range). Student's T test and Chi squared test used as appropriate.
RESULTS: From 2000 to 2013, the study population included 2387 IBD patients: anti-TFNs use in 384 (16%). Cancer of the lower GI tract developed in 15/2387 (0.62%) patients (9CD,6UC), including 12 CCR, (6UC,6CD), 1 ileal adenocarcinoma (1CD), 1 carcinoid of the appendix (1CD), 1 anal canal carcinoma (1CD). In the 15 IBD-K patients, age at diagnosis of cancer was 51 (28-73) yrs, IBD duration 19yrs (1-47): there were 9 CD of the ileum (I) (n = 4), colon (C) (n = 2), ileum-colon (IC) (n = 3) and 6 UC distal (n = 3), left-sided (n = 1) or total (n = 2). Among the 15 IBD-K patients, 3 (20%) received anti-TNFs and/or IMM (combined in all 3). In these 3 patients, cancer included CCR (n = 2) or carcinoid (n = 1) in 2CD (2F,age 40 and 54yrs, CD duration 28 and 26 yrs; I-C, fistulizing) and 1UC (1F, CCR, age 30, duration 19yrs; pancolitis). Among the 384/2387 (16%) IBD patients treated with anti-TNFs, CCR developed in 3 (0.78%)(combined IMM in 3). Among the 2003/2387 (84%) patients anti-TNFs naïve, 12(0.6%) developed cancer of the lower GI tract,including CCR in 10 (0.5%) (p = ns *vs* anti-TNFs treated patients). IBD-C included 30 patients (18CD,12UC;14 M/16 F, age 54,range 37-75), with CD (13 I;2 C;3 I-C) or UC (distal 11, left-sided 1). Anti-TNFs use was reported in a comparable proportion of IBD patients developing or not cancer (IBD-C n = 6/30; 20% *vs* IBD-K n = 3/15; 20%). In IBD-C, IMM were used in 10 (33%)(combined anti-TNFs in 2;6.7%).
CONCLUSION: In a retrospective matched-pair study, a comparable low frequency of colon cancer was observed in IBD patients treated or untreated with anti-TNFs.

P0875 IS THERE A ROLE FOR THE NEW SEROLOGICAL MARKERS IN PREDICTING DISEASE COURSE IN AN IBD POPULATION COHORT? LESSONS LEARNT FROM A PROSPECTIVE IRISH POPULATION

M.N. Shuhaibar[1,*], C. O'Morain[1]
[1]*Department of Gastroenterology/ Clinical Medicine, AMNCH/Trinity College Dublin, DUBLIN, Ireland*
Contact E-mail Address: *mnshuh@gmail.com*

INTRODUCTION: Crohn's disease and Ulcerative colitis are the two main forms of inflammatory bowel disease. There are different disease phenotypes within those groups and yet another 10-17% of patients may not have either diagnosis and can be then be classified as indeterminate colitis until later on in their disease course when they are reclassified into either main group as symptoms progress. Furthermore, some patient with gastrointestinal symptoms may not have IBD initially, but develop it in future. Several antibodies have been linked to CD and different IBD subtypes.
AIMS & METHODS: The aim of our study was to determine the prevalence of the new anti-glycans antibody panel in a prospective homogenous IBD cohort to help differentiating those with IBD from healthy controls. We aimed to assess panel's role in discriminating between CD and UC with their different phenotype and their predictive value for disease course and treatment stratification in the future.
Antibodies against a mannan epitope of Saccharomyces cerevisiae (gASCA), laminaribioside (ALCA), Chitobioside (ACCA), mannobioside (AMCA) were tested in serum samples of 103 IBD patients, 199 healthy matched controls. Antibody response was matched to disease type and course. A backward step multiple-regression analysis was performed along with 2- sample t-test for univariate biomarker analysis.
RESULTS: The anti-glycans antibody panel was useful in differentiating IBD patients from healthy matched controls. Overall, 72% of IBD patients tested positive for anti-glycans antibodies and of those 64% were positive for gASCA, compared to 49% for ACCA antibody. gASCA was highly sensitive and specific in CD patients.
CONCLUSION: From applying the anti-glycans antibody panel, combination of gASCA IgA**,** Anti-L and Anti-C antibodies were statistically very significant in differentiating CD from UC (with a $p < 0.0001$). gASCA was very specific to CD and correlated with severe disease course requiring surgery or fistulas, requiring anti -TNF therapy in the lateral years.

INTRODUCTION: Calprotectin is a calcium binding protein of the S100 family associated with inflammation. A recent systematic review has confirmed its value in distinguishing between organic (inflammatory bowel disease - IBD) and non-organic gastrointestinal disease (irritable bowel syndrome - IBS). Those with FC levels below 50 mcg/g have a negative predictive value of >92% to exclude organic gastrointestinal disease. Conversely, FC levels greater than 250mcg/g, correlates with endoscopic disease activity in those with IBD; sensitivity of 90%. The aim of our study was to determine the clinical outcome in patients presenting with an intermediate raised level of FC between 50-250 mcg/g.
AIMS & METHODS: FC test results from July 2012 to October 2013 were reviewed. FC testing was performed using the PhiCal ELISA method. 482 patients were identified from the UHCW pathology database: 390 normal (<50mcg/g), 51 intermediate (50-250mcg/g) and 41 high (>250mcg/g). Excluding paediatric patients (under 16), left 47 intermediate and 35 high results. Where possible clinical information was obtained from the UHCW Clinical results and reporting system. If no information was found then general practitioners (GPs) were contacted for further details (long term clinical data could not be found for 5 intermediate and 9 high patients).
RESULTS: We studied a subset of 50 of the 390 normal FC values (<50mcg/g) which served as a comparator group. Of these, 9 (18%) were referred to secondary care gastroenterology, with 3 (6%) still in secondary care 6 months post FC. None were diagnosed with IBD.
Of the 26 patients with high FC (>250mcg/g), 8 did not have details provided by their GPs, 8 (31%) were known IBD patients and 3 (12%) were not investigated - declining referral or patient mortality. 6 (23%) had a new diagnosis of IBD and 1 (4%) with post infective IBS. 15 (58%) were still in secondary care 6 months after FC testing.
Of the 42 intermediate (50-250mcg/g) patients, 17 did not have information provided by their GPs and 2 (5%) were known IBD patients. 8 patients (19%) were diagnosed with colon cancer or were still under investigation. 3 (7%) had a new diagnosis of IBD and 12 (29%) with non IBD conditions (e.g. BAM,

Diverticular disease and IBS). 13 (31%) patients were still in secondary care 6 months after initial FC –see table 1.
Within the intermediate group, 10 patients had FC < 100mcg/g, none were diagnosed with IBD and 20% remained in secondary care 6 months post FCP. Of the 16 available patients with FC of 100-250, 3 (23%) had a new diagnosis of IBD and 7 (54%) were still in secondary care 6 months after FC.

Groups	<50mcg/g (subset n = 50)	50-250mcg/g (n = 42)	>250mcg/g (n = 26)
Managed in primary care	41(82%)	5 (12%)	3 (12%)
Undergoing investigations	9 (18%)	17 (40%)	6 (23%)
New diagnosis of IBD	0	3 (7%)	6 (23%)
Existing diagnosis of IBD	0	2 (5%)	8 (31%)
Still under follow-up at 6 months (from FC testing)	3 (6%)	13 (31%)	15 (58%)

CONCLUSION: 1) The majority (81%) of FC requested were normal with a similar proportion managed in primary care without any new diagnosis of IBD. 2) New diagnosis of IBD is three times more common in those with FC values > 250mcg/g and 3) A third (31%) with intermediate FC levels remain under secondary/tertiary care at 6 months but still half compared with those having high FC levels.

P0877 LONG-TERM EFFECTIVENESS, PATIENT SATISFACTION & COST-BENEFIT ANALYSIS OF A SELF-MANAGEMENT PROGRAMME FOR PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A FIVE YEAR FOLLOW-UP STUDY

S. Gethins[1], **M.S. Hanna**[1,*], B. Robinson[1], T. Duckett[1], P. Hunt[1], R.J. Robinson[1]
[1]*Department of Gastroenterology, Leicester General Hospital, Leicester, United Kingdom*
Contact E-mail Address: *minahanna@yahoo.com*

INTRODUCTION: Self management programmes enable patients with Inflammatory Bowel Disease to play a greater role in monitoring and treating their illness, allowing them to be discharged from hospital follow up. Short-term studies have shown reduced health service utilization, without compromising health outcomes[1].
AIMS & METHODS: The aim of our study was to evaluate the long-term effectiveness of a self-management programme for patients with IBD and assess patient satisfaction and health care cost benefits. Over a 12 month period in 2007, 157 patients with IBD (122 with Ulcerative colitis (UC), 31 Crohn's disease (CD) and 4 indeterminate colitis were recruited to our IBD self management programme. Stable patients on first line therapy met with a specialist IBD nurse and were provided with specific information about their diagnosis, relapse recognition and medication. A personalised written self management programme was provided with an escalation plan in the event of symptoms. The first 70 patients recruited to the study were sent a patient satisfaction questionnaire 1 year post-recruitment. A cost-saving analysis over the 5 year period was performed based on the premise of avoiding 2 hospital follow-up appointments per year and the local tariff (£103). After 5 years, the case notes of all patients re-referred were reviewed to establish the reason for re-referral and interval between discharge & re-referral.
RESULTS: Over the 5 year period 22 (14.0%) patients (22 = UC, 2 = CD) had been re-referred to our service with a flare of their IBD. Five patients required azathioprine & one patient with Crohn's disease was started on biologics. One patient was admitted as an emergency, initially responding to cyclosporine but required a colectomy 1 year later. The remainder were treated with increased 5-ASA, topical therapy or oral steroids. Median time from discharge to re-referral was 31 months (range 11-60 months). 62/70 (88.6%) patients completed their patient satisfaction surveys; 58 (93.5%) being satisfied with the programme and 58 (93.5%) feeling involved in their treatment decisions. Over the 5 year period, there was an estimated health-care cost saving of £147290. (Table 1)

Year	No. of patients in self-management programme at start of year – No. of patients re-referred to service in each year	Local follow-up appointment tariff x estimated appointments per year	Estimated Cost-savings
Year 1	157- 2 = 155	£103 x 2	£31930
Year 2	155- 6 = 149	£103 x 2	£30694
Year 3	149- 7 = 142	£103 x 2	£29252
Year 4	142- 6 = 136	£103 x 2	£28016
Year 5	136- 3 = 133	£103 x 2	£27398
Overall savings			**£147290**

CONCLUSION: This study shows that self-management is an effective long term strategy for selected stable patients with IBD and is acceptable to patients. Few patients are re-referred and the substantial 5-year cost savings could be re-invested in developing specialist IBD services.

INTRODUCTION: Circulating hepcidin is proposed to regulate iron absorption by modulating iron export by ferroportin at the basolateral membrane of the duodenal mucosal cells and/or uptake into the cells at the apical membrane by DMT1. To date, no data have shown a relationship between plasma hepcidin concentrations and iron absorption in IBD patients.
AIMS & METHODS: We used stored samples from a human iron absorption study to further test the hypothesis that plasma hepcidin may explain interindividual variation in iron absorption in IBD patients. Serum ferritin (SF) and serum markers of inflammation [high-sensitivity C-reactive protein (hsCRP) and IL-6] were measured in stored samples from a human iron absorption study using commercially available immune-assays. Hepcidin-25 concentrations were determined in fasting samples from 71 adult subjects with IBD (31 UC, 40 CD) and 26 healthy controls. Hepcidin was measured by LC-MS.
RESULTS: There was a positive correlation between hepcidin (mean: 2.3; range: 0.1–7.8nmol/L) and hsCRP ($p < 0.005$), but not between hepcidin and serum ferritin ($p > 0.05$). Whereas iron absorption was negatively correlated with serum ferritin only in patients with inactive disease (hsCRP < 5md/dl; $p < 0.001$), a negative correlation was observed with serum hepcidin in both active and inactive disease ($p = 0.006$), independent of IBD phenotype. Multiple linear regression models showed that serum hepcidin in isolation significantly predicted the interindividual variation in iron absorption.
CONCLUSION: Concentration of serum hepcidin, but not serum ferritin, was highly correlated with intestinal iron absorption in IBD patients.

P0879 LONG TERM OUTCOME OF CROHN'S DISEASE ACTIVITY – A PROSPECTIVE STUDY-

N. Bounab[1,*], L. Kecili[1], A. Balamane[1], K. Belhocine[1], K. Layaida[1], L. Gamar[1], T. Boucekkine[1]
[1]*Faculty of Medicine, Algiers, Algeria*

INTRODUCTION: Crohn's Disease (CD) is a chronic and heterogeneous inflammatory bowel disease affecting the gastrointestinal tract; its etiology is unknown and its outcome is unpredictable
AIMS & METHODS: To analyze the long term outcome of the disease activity, we studied a cohort of 226 consecutive cases of CD hospitalized from 01/01/2000 to 31/12/2004. These patients, enrolled at diagnosis, underwent initial complete investigation. CD diagnosis was based on international criteria. All patients were included in a prospective study and followed-up from 01/01/2005 to 31/12/2009 during at least 5 years or until the first surgical resection. A systematic clinical control was performed every 6 or 12 months and on demand; complete investigation comprising endoscopy was done when needed. Statistical study: Student – Fisher's t test and Mann Withney U test.
RESULTS: The cohort included 103 males and 123 females (mean age was 30, 3 years at diagnosis); 41 patients were smokers (18.1%). At the end of follow-up: 1/ The overall annual activity which was defined as the percentage of active disease per year has showed a progressive decrease (from 59.3 % the first year to 46.5% the last year $p < 0.05$) associated with a decrease of the number of severe flares (from 34.7% to 15% $p < 0.05$). 2/the age at onset of the disease didn't influence the disease activity: 62%; 59.3%; 59.7% at diagnosis and 50%; 45.3%; 45.4% at the end of follow- up in patients aged <20 years, 20-40 years, >40 years respectively ($p > 0.05$).3/ the rate of activity tends to decrease over time when lesions were located in both small intestine and colon (59.5% to 46.5% $p < 0.05$) whereas it remained stable when lesions were located exclusively in the colon (from 48.8% to 44.1%;$p > 0.05$). 4/decrease of activity was more often observed in inflammatory type lesions (from 50% to 41.3% $p < 0.05$). 5/smoker (S), non smoker (NS) and previous smoker (PS) statutes didn't influence activity outcome (from:S = 60%;PS = 60%; NS = 57.6% to S = 45.4%; PS = 43.4%; NS = 47%: $p > 0.05$).6/ however, the need for surgery increased progressively over the time (from 4% the first year to 7% the last year).
CONCLUSION: This prospective study showed that the overall Crohn's Disease activity decreased and became less severe over time, which probably expresses a slight tendency to a disease extinction. The course of disease hasn't been significantly influenced neitherby the age at onset of disease, nor by tobacco consumption. The outcome of initial inflammatory type lesions was more favourable than stricturing or penetrating lesions.

P0880 PREVALENCE OF ANAEMIA IN A COHORT OF PATIENTS WITH IBD AND ITS RELATIONSHIP TO FAECAL AND SERUM BIO-MARKERS OF INFLAMMATORY BURDEN, AND MARKERS OF IRON STATUS

N.S. Taylor[1,*], D.A. Lloyd[1], S. Cotton[1], L.-A. McCabe[1], J.N. Gordon[1]
[1]*Gastroenterology, Hampshire Hospitals NHS Foundation Trust, Winchester, United Kingdom*
Contact E-mail Address: *john.gordon@hhft.nhs.uk*

INTRODUCTION: Anaemia is common in IBD and usually due to either iron-deficiency or anaemia of chronic disease. Serum ferritin is a frequently used marker of iron status in patients with IBD. It is influenced by inflammatory status with CRP commonly used in clinical practice to aid in determining the presence or absence of iron deficiency. However, the correlation of ferritin with markers of mucosal disease activity such as faecal calprotectin (FC) is unknown and may have important implications in determining the effect of inflammation on the diagnosis of iron deficiency. The aim of this study was to investigate the prevalence of anaemia and its relationship to markers of iron stores and faecal and serum markers of inflammation in IBD.
AIMS & METHODS: We performed a computer database search of all IBD clinic patients who had paired blood tests (including Hb, mean cell volume, CRP, ferritin) and FC in the last 12 months. Blood and faecal samples were accepted as paired if taken within 7 days of each other. Anaemia was defined using WHO criteria, with a ferritin of <30ng/ml taken to indicate iron-deficiency. An FC of <50 ug/g was taken to indicate inactive disease, an FC of 50-200 ug/g a borderline result and an FC >200 ug/g as active disease. Results were analysed to assess for prevalence of anaemia and iron deficiency and their correlation with faecal and biochemical markers of disease activity.
RESULTS: 124 patients (79 Crohn's disease, 45 Ulcerative Colitis) with a diagnosis of IBD and paired blood tests and faecal inflammatory markers were identified and their data analysed. 30/124 (21%) of the whole cohort were anaemia, and 34% were iron-deficient. There was a clear negative correlation between disease activity and both haemoglobin and ferritin levels. 20/30 (66%) of the anaemic patients had a ferritin of <30 and could clearly be classified as iron-deficient. The average CRP in this group was 11.4mg/l and calprotectin 686ug/g. 9/30 (30%) of patients had a ferritin of >30 with one patient having a ferritin of >100. The average CRP in this group was 17.8 and calprotectin 832ug/g. 40% of anaemic patients with a ferritin >30 had a CRP <5 and would not be classified as iron deficient. All these patients had a raised calprotectin (av 1030). Use of a raised Calprotectin of >500ug/g as a marker of inflammatory burden rather than CRP would have resulted in half these patients being classified as iron deficient which was supported by other markers of iron stores.
CONCLUSION: Anaemia (21%) and iron deficiency (34%) were common in this cohort of patients with IBD. There was a clear negative correlation between markers of anaemia and iron deficiency and faecal calprotectin. There was a closer correlation between calprotectin and anaemia than CRP and anaemia. Calprotectin may be a more effective marker of inflammatory burden than CRP in the assessment of IDA in patients with active IBD.

INTRODUCTION: Faecal calprotectin (FCP) is a non-invasive marker of gastrointestinal inflammation. Its utility in the clinical management of inflammatory bowel disease (IBD) is still under evaluation. We aimed to perform a meta-analysis of prospective studies in assessing the ability of baseline FCP for predicting disease relapse with 12 months in patients with Crohn's disease (CD) and ulcerative colitis (UC) in clinical remission.
AIMS & METHODS: Multiple electronic databases were searched including Pubmed, Embase and Ovid looking for studies providing data on relapse prediction in IBD using FCP. Pooled sensitivity, specificity, negative (LR-) and positive (LR+) predictive value diagnostic odds ratio (DOR) and pooled area under the receiver operating characteristic (AUROC) was calculated using MetaDiSc ver1.4 software. A random effects model was used and publication bias was assessed using Funnel plots and Egger's test and heterogeneity was assessed using Cochran's Q and the I^2 test.
RESULTS: 8 studies involving 507 patients with CD and 8 studies involving 587 patients with UC were included. The predictive value for a relapse within 12 months for baseline FCP in patients with CD was sensitivity 73%(64-80), specificity 78% (74-82), LR+ 2.9 (1.9-4.5), LR- 0.4 (0.2-0.6), DOR 10.1 (4.5-22.6) and AUROC 0.83 ($\pm$0.04). The cut off for baseline FCP used for the CD studies ranged from 130-340 µg/g. The predictive value for a relapse within 12 months for baseline FCP in patients with UC was sensitivity 72%(65-77), specificity 78% (74-83), LR+ 3.0 (2.3-4.0), LR- 0.4 (0.2-0.6), DOR 9.2 (5.4-15.7) and AUROC 0.82 ($\pm$0.03). The cut off for baseline FCP used for the UC studies ranged from 130-250 µg/g. There was significant heterogeneity ($I^2 > 50\%$) for all the analysis likely because of the differences in relapse rates and FCP cut off values used.
CONCLUSION: FCP is a simple non-invasive marker with the potential to predict relapse in CD and UC. With pooled sensitivity and specificity under 80% for both CD and UC but with a likelihood ratio of a negative test being 0.4, its value may be mainly to identify low risk patients. However wide variations in the cut off values for FCP used in these studies makes it difficult to apply this to routine clinical practice. Serial measurements of FCP to check for a rise from baseline may be the way forward for future studies.

P0882 IS THERE ANY RELATION BETWEEN RED BLOOD CELL DISTRIBUTION WIDTH AND MUCOSAL REMISSION IN ULCERATIVE COLITIS?

O. Kocaman[1,*], A. Danalioglu[1], A.T. Ince[1], K. Turkdogan[1], H. Senturk[1], B. Baysal[1], M. Tozlu[1], Y. Kayar[1]
[1]*Department of Gastroenterology, Bezmialem Vakif University, Istanbul, Turkey*
Contact E-mail Address: *drokocaman@hotmail.com*

INTRODUCTION: A higher red blood cell distribution width (RDW) has been shown as an indicator of disease activity in ulcerative colitis (UC). However, the relation of mucosal remission with RDW has not been investigated. We aimed to determine if RDW level as a categorical variable (high or normal) could be used as a parameter for predicting mucosal remission in UC.
AIMS & METHODS: This study was conducted prospectively at a university hospital with high volume of inflammatory bowel disease patients. C-reactive protein (CRP), RDW value and colonoscopic findings were analyzed in UC patients. The endoscopic procedures were performed by a dedicated IBD endoscopist. Mucosal remission was defined as a Mayo score of 0 for UC. The groups were compared using chi-square test. SPSS version 16 was used for statistics.
RESULTS: A total of 178 patients (102 male, 76 female; age range: 19 to 82 years) were included in the study. The number of patients with mucosal-remission was 57 (normal or inactive disease). No correlation between CRP levels and mucosal remission was found. Of the patients in mucosal remission, 46 had normal RDW level. Of the 121 patients with no mucosal remission, 75 had normal RDW level. RDW was found as a significantly useful parameter for identifying mucosally active UC patients ($p<0.005$).
CONCLUSION: This study shows that categorical RDW value is a useful parameter for identifying mucosally active UC patients and could be used as a marker for non-invasive monitoring of mucosal activity in UC patients.

P0883 PREVENTION OF OPPORTUNISTIC INFECTIONS IN PATIENTS ON BIOLOGICAL AGENTS FOR MANAGEMENT OF INFLAMMATORY BOWEL DISEASE

H. Gordon[1,*], A. Steel[1]
[1]*Gastroenterology, Chelsea and Westminster Hospital, London, United Kingdom*
Contact E-mail Address: *hannah.gordon@chelwest.nhs.uk*

INTRODUCTION: Patients with inflammatory bowel disease are at increased risk of infection; this is especially true of the 20% on biological agents. ECCO guidelines recommend the following vaccines: Influenza (annual), Pneumococcal, Hepatitis B, Varicella, HPV (women under 26). The guidelines also highlight the need to exclude latent TB; local policy is to perform an interferon gamma release assay. Within the UK vaccination services are provided by primary care.
AIMS & METHODS: The measures taken to prevent opportunistic infection in patients prescribed anti-TNFs for IBD at Chelsea and Westminster Hospital in 2013 were audited against the ECCO OI Guidelines. The following were retrieved from electronic records: age, sex, anti TNF prescribed, pneumococcal antibodies, hepatitis B core and surface antibodies, varicella IgG, Elispot®. Attempts were made to retrieve vaccination history from General Practice.
RESULTS: 60 patients were prescribed infliximab and 15 patients were prescribed adalimumab. 46 GPs were able to provide vaccination history.
Influenza: 50% (23/46) patients received vaccination against influenza within the past year.
Pneumococcus: 55% (47/85) patients demonstrated immunity. 6% (5/85) were not immune and the remainder were not tested. The vaccination history of 26 patients who were not immune or not tested was retrieved. 27% (7/26) had since been vaccinated.
Hepatitis B: No patients were core Ab positive. Surface Ab levels demonstrated immunity in 7% (6/85). 53% (45/85) were not immune, and the remainder were not tested. Vaccination history of 44 patients who were not immune or not tested was retrieved. Of these, 25% (11/44) had since been vaccinated.
HPV: 4 patients were women under 26 years old. 25% (1/4) had confirmed HPV vaccination.
Varicella: 21% (18/85) patients demonstrated immunity to varicella. 2% 2/85 were not immune.
Elispot: 65% (55/85) patients had a nonreactive assay. 1% (1/85) had a positive result and the remainder were not tested.
CONCLUSION: The standards set out by ECCO to protect patients from opportunistic infection are not being met.
Problems obtaining accurate vaccination history from GP records include incorrect surgery details, lack of availability of staff able to review records and incomplete records. HPV vaccination usually takes place at school and is not routinely recorded by primary care.
Potential service improvements include provision of vaccines at clinic, improved patient education regarding the importance of vaccination and a check list to review bloods at first anti-TNF prescription.

INTRODUCTION: Ulcerative colitis (UC) is a form of chronic inflammatory bowel disease and is characterized by periods of remission and episodes of relapse. The pathogenesis of UC remains unclear. This study aims to evaluate the efficacy and safety of tacrolimus (TAC).
AIMS & METHODS: Aims: To evaluate the safety and efficacy of oral TAC in Japanese patients with refractory (corticosteroid-resistant or -dependent) active UC in a real clinical setting.
Methods: The observation period of this study was 6 months. Six hundred and sixty-six UC patients were enrolled between 2009 and 2011 in 145 medical institutions. Efficacy was evaluated using the Disease Activity Index (DAI) score (1), clinical remission and endoscopic remission. DAI score improvement was defined as either a reduction in DAI of more than 4 points with improvement of all categories (Stool frequency, Rectal bleeding, Mucosal appearance, Physician's global assessment) or complete resolution of all categories (2). Clinical remission was defined as stool frequency ≤ 3 per day and no rectal bleeding. Endoscopic remission was defined as mucosal appearance ≤ 1.
RESULTS: Mean DAI score was 8.9 ± 1.97 at baseline. Adverse drug reactions (ADRs) occurred in 39% of the patients. The most frequent ADRs were Nervous system disorders (serious: 2 patients, non-serious: 71 patients) such as finger tremor (50 patients), and the most frequent serious ADRs were infections and infestations (20 patients) such as cytomegalovirus-related events (7 patients) and pneumonia-related events (5 patients). In 18 out of 20 patients, serious infections and infestations were resolved or became mild during the observation period. When serious infections and infestations occurred, 6 patients discontinued the TAC treatment and 11 patients continued after they occurred. One patient had discontinued before the event. In another 2 patients, one patient (age 81) developed sepsis and died 2 days after it occurred. One patient (age 56) developed herpes zoster and didn't improve during the observation period. TAC treatment was continued after it occurred. Serious renal and urinary disorders were reported in 8 patients. Seven out of 8 patients were resolved or became mild during the observation period. One patient (age 62) developed renal impairment and didn't improve during the observation period. All of the 8 patients discontinued the TAC treatment when serious renal and urinary disorders occurred. DAI score improvement was observed in 63% of the patients during the observation period. Sixty-seven percent of the patients had clinical remission during the observation period. The endoscopic remission rate increased with time during the observation period (17% after 3 months, 31% after 6 months).
CONCLUSION: Oral TAC therapy, with monitoring of blood trough concentration was well tolerated and induced clinical and endoscopic remission with time in Japanese patients with refractory active UC.

P0885 WITHDRAWAL OF AZATHIOPRINE IN PATIENTS WITH CROHN'S DISEASE IN STABLE CLINICAL REMISSION: A DOUBLE-BLIND, PLACEBO-CONTROLLED 2 YEARS TRIAL

H.H. Wenzl[1,*], C. Primas[2], G. Novacek[2], A. Teml[2], A. Öfferlbauer-Ernst[2], C. Högenauer[1], H. Vogelsang[2], W. Petritsch[1], W. Reinisch[2]
[1]*Internal Medicine, Medical University of Graz, Graz,* [2]*Internal Medicine, Medical University of Vienna, Vienna, Austria*

INTRODUCTION: Many patients with quiescent Crohn's disease are maintained on long-term treatment with azathioprine (AZA), but controlled data are limited. The aim of the present study was to evaluate the efficacy of AZA therapy for more than 4 years to maintain clinical remission.
AIMS & METHODS: We performed a randomized double-blind placebo-controlled AZA withdrawal trial with a follow-up period of 24 months. Patients had to have continuous AZA therapy for a minimum of 4 years without exacerbation of disease during the previous 12 months before enrollment, and a Crohn's disease activity index <150 at baseline. Patients were randomized to continue on AZA ($n=26$) or switch to placebo ($n=26$). The primary endpoint was time to clinical relapse during follow-up.
RESULTS: During the 2-year follow-up clinical relapse occurred in 4 patients on continued AZA and in 8 patients on placebo. Time to clinical relapse averaged 22.3 months (95% CI 20.6-24.0) in the AZA group, and 19.2 months (95% CI 16.4-22.1) in the placebo group ($p=0.20$). According to life-table analysis, the proportion of patients in remission after 12 and 24 months was $96\pm4\%$ and $86\pm7\%$ in patients receiving AZA versus $76\pm8\%$ and $68\pm9\%$ in patients receiving placebo (month 12, $p=0.035$; month 24, $p=0.30$). A higher AZA dose at enrollment was an independent predictive factor for relapse ($p<0.05$).
CONCLUSION: In patients with clinically inactive Crohn's disease on maintenance therapy with AZA for $>$ 4 years discontinuation of AZA resulted in a numerically higher relapse rate compared to further AZA treatment. Our results are in line with previous observations.

P0886 COST-EFFECTIVENESS OF ADALIMUMAB IN MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS (SUB-ACUTE) IN THE UK

H. Yang[1], A. Curry[2], **S. Wang**[3,*], M. Yang[1], M. Skup[3], J. Chao[3], Y. Bao[3]
[1]*Analysis Group, Inc., Boston, United States,* [2]*AbbVie Ltd, Berkshire, United Kingdom,* [3]*AbbVie Inc., North Chicago, United States*
Contact E-mail Address: *song.wang2@abbvie.com*

INTRODUCTION: The objective was to compare the cost-effectiveness of adalimumab (ADA) versus standard of care (SOC) for the treatment of patients with moderately to severely active ulcerative colitis (UC) (sub-acute) who have an inadequate response to SOC in the UK. The base case was conducted for a UC patient population including patients who are naïve to the cytokine inhibitors affecting tumour necrosis factor alpha (anti-TNF-α) and patients who have previously been exposed to anti-TNF-α agents other than ADA.
AIMS & METHODS: A Markov model was constructed to simulate the treatments and disease course of adults with moderately to severely active UC (including both anti-TNF-α naïve and experienced patients) who had an inadequate response to conventional therapies receiving ADA therapy, or receiving SOC. SOC refers to conventional treatments including anti-inflammatory drugs or immunosuppressants. The model estimated the direct health care costs and quality-adjusted life years (QALYs) over a 10-year time horizon. The model was conducted from the perspective of the U. K. National Health Service. Only direct costs were considered. Eight health states were defined in the Markov model, including three pre-surgery states (i.e. remission, mild, and moderate-to-severe), surgery state, and four post-surgery states (i.e. post-surgery without complication, transient complication, chronic complication, and surgery-related death). The transitional probabilities of the pre-surgery states were primarily derived from the randomized, controlled clinical trials of ADA in the treatment of moderately to severely active UC patients [the Ulcerative Colitis Long-term Remission and Maintenance with Adalimumab M06-827 (ULTRA 2) trial and M10-223 (the ULTRA 1/2 extension trial)]. The transitional probabilities for the surgery and post-surgery states were derived based on published literature. Utility values were specified for each disease state, and were based on published literature. The model considered drug costs, disease states costs, hospitalization costs, surgery costs, surgery-related complication costs, and costs associated with surgery-related death. These costs inputs were derived from published literature. Results were expressed in the incremental cost-effectiveness ratio (ICER) per QALY gained. The impact of uncertainty of model parameters was examined using deterministic sensitivity analyses (DSA) and probabilistic sensitivity analyses (PSA).
RESULTS: The ICER per QALY gained for ADA vs. SOC was £34,417 over a 10-year time horizon in the base case (in 2013 GBP pounds). DSA varying key model inputs produced ICER per QALY gained in the range of £29,437 to £38,073. The probability for ADA to be cost-effective at the willingness-to-pay threshold of £30.000 was 30%.
CONCLUSION: With no NICE recommended biologic options, there is currently a high unmet need for patients in England and Wales with moderately to severely active UC (sub-acute) who have failed on standard of care. This economic evaluation demonstrated that when compared to SOC, the ADA therapy has a reasonable cost-effectiveness ratio. The cost-effectiveness result of the ADA strategy was shown to be robust in a range of sensitivity analyses.

P0887 MAINTENANCE OF REMISSION OF ULCERATIVE COLITIS: PREBIOTICS AND DIETARY FIBER

I. Copaci[1,*], G. Chiriac[1]
[1]*Center of Internal Medicine, FUNDENI CLINICAL INSTITUTE, Bucharest, Romania*
Contact E-mail Address: *laurentiumicu2000@yahoo.com*

INTRODUCTION: Butyrate enemas may be effective in the treatment of active distal ulcerative colitis (UC). Colonic fermentation of Plantago Ovata seeds (dietary fiber) yields butyrate. UC patients have an altered intestinal flora which can be modified by administration of prebiotics such as fructo-oligosaccharides, and probiotics like bifidobacterium longum w11, which promote selective growth of saccharolytic bacteria with low inflammatory potential.
AIMS & METHODS: We conducted an open-label, parallel group, randomized clinical trial. A total of 36 patients with ulcerative colitis who were in remission for over 3 months (4 < C. A. I. Rachimilewitz) were randomized into 3 groups to receive oral treatment with mesalamine (group A), Plantago Ovata (Colon help) + mesalamine (group B) and fructo-oligosaccharides/bifidobacterium longum w11 + mesalamine (group C). All patients were 18-65 years old. At day 0 and weeks 12 and 24 we determined the clinical activity index (C. A. I.) and the endoscopic index. Clinical safety was monitored using the Gastrointestinal Symptom Rating Scale (GSRS) questionnaire every 4 weeks.
RESULTS: After 6 months, treatment failure was 35% in group A, 28% in group B ($p = 0.02$) and 30% in group C ($p = 0.05$). Probability of continued remission was similar (Mantel Cox test, $p = 0.76$; Breslow test, $p = 0.52$). Mean times to treatment failure were 4.34±0.44, 4.57±0.76 and 4.62±0.81 months, respectively for groups A, B and C. It was shown that patients with total colitis as compared to those with left-sided colitis had an increased probability of relapse during the 1 year follow-up. Patients of group B experienced more asymptomatic nights (90% vs 77% in group C vs 58% in group A, $p = 0.0011$) during the first 3 months. Fecal calprotectin was lower in group C vs A and B ($p < 0.05$).
CONCLUSION: Plantago Ovata seeds and the combination of fructo-oligosaccharides/bifidobacterium longum w11 maintain UC remission and increase the response to mesalamine.

INTRODUCTION: Since its introduction, anti-TNF therapy has shown to be effective for the treatment of IBD in several clinical trials. However, its long-term effectiveness and reasons for discontinuation in clinical practice might be different from those observed in clinical trials
AIMS & METHODS: Aims: To evaluate the drug survival and reasons for discontinuation of the first anti-TNF therapy in IBD patients in clinical practice.
Methods: IBD patients under anti-TNF therapy from 2000 to 2012 in our center were included. Data regarding the first anti-TNF treatment were extracted from clinical records fulfilled prospectively. Kaplan-Meier method was used to estimate the long-term drug survival of the treatment.
RESULTS: 160 IBD patients were included: 130 with Crohńs disease (mean age 42±14 years; 47% male) and 30 with ulcerative colitis (mean age 45±17 years; 63% male). The distribution of first biologic in Crohn's disease was 76 (58%) adalimumab and 54 (42%) infliximab, while in ulcerative colitis it was 1 (3%) adalimumab and 29 (97%) infliximab. Time to a probability of 50% discontinuation was 3.94 years in Crohńs disease compared with 0.97 years in ulcerative colitis ($p < 0.001$). The reasons for discontinuation of the drug, respectively in Crohn's disease and ulcerative colitis, were: intolerance (20% and 19%), lack of response (30% and 24%), loss of response (22% and 19%), remission achievement (17% and 29%), and others (11% and 10%). The probability of maintaining (retention rate) the anti-TNF treatment in Crohn's disease was 69% at 1 year, 59% at 2 years, 52% at 3 years, 50% at 4 years, 45% at 5 years, and 41% at 10 years. The corresponding figures for ulcerative colitis were 48% at 1 year, 41% at 2 years, 36% at 3 years, 31% at 4 years, and 15% at 5, 6 and 7 years
CONCLUSION: The probability of maintaining the first anti-TNF drug in Crohn's disease patients is around 50% after 5 years of treatment. Discontinuation rate was even higher in ulcerative colitis, with only 15% of patients maintaining anti-TNF therapy at 5 years. The most frequent reasons for discontinuation of anti-TNF therapy were lack of response, loss of response, remission achievement and intolerance

P0889 CLINICAL BENEFIT OF ADALIMUMAB DOSE ADJUSTMENT FOR PATIENTS WITH MODERATELY TO SEVERELY ACTIVE CROHN'S DISEASE IN EXTEND

J.-F. Colombel[1,*], P. Rutgeerts[2], W.J. Sandborn[3], D. Wolf[4], W. Reinisch[5], G.Van Assche[2], S. Eichner[6], Q. Zhou[6], J. Petersson[6], A.M. Robinson[6], R.B. Thakkar[6]
[1]*Icahn School of Medicine at Mount Sinai, New York, United States,* [2]*University of Leuven, Leuven, Belgium,* [3]*UCSD, La Jolla,* [4]*Atlanta Gastroenterology Associates, Atlanta, United States,* [5]*McMaster University, Hamilton, Canada,* [6]*AbbVie Inc, North Chicago, United States*

INTRODUCTION: Weekly dosing was shown to have a clinical benefit for adalimumab (ADA)-treated patients with Crohn's disease enrolled in the clinical trial CHARM who had flares or lost response to every other week (EOW) ADA dosing[1]. The clinical outcomes of dose escalation in patients enrolled in the EXTEND[2] trial are evaluated.
AIMS & METHODS: EXTEND was a 52-week double-blind (DB) trial in which patients received open-label (OL) ADA 160/80 mg at weeks 0/2. At week 4, patients were randomized to placebo or ADA 40 mg EOW. Patients with flares/non-response could move to OL ADA 40 mg EOW beginning at week 8, followed by escalation to 40 mg weekly (EW) for continued flare/non-response. Week 52 clinical remission (CDAI < 150), clinical response (decrease in CDAI ≥ 70 from baseline), and mucosal healing (absence of mucosal ulceration) were assessed in patients who moved to and remained on OL ADA EOW and in those who moved to OL ADA EW. Endpoints are reported using non-responder imputation (NRI) for patients with missing data and as observed for patients remaining in the study at week 52. Logistic regression analysis was used to determine predictors of moving to OL EW ADA.
RESULTS: In EXTEND, 42.2% (27/64) of patients randomized to DB ADA moved to OL ADA, and 23.4% (15/64) escalated to EW dosing. The only significant predictor of dose escalation was week 4 non-response (odds ratio 24.2, 95% CI 1.6, 365.2, $p = 0.021$). Week 52 outcomes for patients who completed the study on OL ADA (EOW or EW) are shown in the table. Increased adverse event rates were not observed with OL EW dosing.
Table. Week 52 efficacy in patients randomized to ADA who completed the study on OL EOW or EW ADA dosing

	NRI		Observed	
	OL EOW n/N (%)	OL EW n/N (%)	OL EOW n/N (%)	OL EW n/N (%)
Remission	3/12 (25.0)	3/15 (20.0)	3/6 (50.0)	3/9 (33.3)
Response	6/12 (50.0)	6/15 (40.0)	6/6 (100)	6/9 (66.7)
Mucosal healing	1/12 (8.3)	2/15 (13.3)	1/7 (14.3)	2/7 (28.6)

CONCLUSION: Escalation to weekly ADA dosing demonstrated clinical benefit in patients who met protocol criteria for dose escalation. No new safety risks were observed with EW ADA dosing.

P0890 CLINICAL OUTCOMES IN CONTINUOUS CLINICAL RESPONDERS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS: SUB-ANALYSES FROM THE PURSUIT-SC MAINTENANCE STUDY

J. Colombel[1,*], W. Reinisch[2], P. Gibson[3], W.J. Sandborn[4], B.G. Feagan[5], C. Marano[6], R. Strauss[6], J. Johanns[6], H. Zhang[6], H. Weng[7], R. Yao[7], D. Tarabar[8], Z. Hebzda[9], P. Rutgeerts[10]
[1]*Hôpital Claude Huriez, Lille Cedex, France,* [2]*Universitätsklinik für Innere Medizin III/McMaster University, Vienna/Hamilton, Austria,* [3]*Alfred Hospital, Melbourne, Australia,* [4]*University of California San Diego, La Jolla, United States,* [5]*Robarts Research Institute, University of Western Ontario, London, Canada,* [6]*Janssen Research & Development, LLC., Spring House,* [7]*Merck Sharp & Dohme, Kenilworth, United States,* [8]*Military Medical Academy, Belgrade, Serbia,* [9]*Klinika Chorob Wewnetrznych, Krakow, Poland,* [10]*University Hospital, Gathuisburg, Belgium*

AIMS & METHODS: The objective was to evaluate long-term clinical outcomes in patients with moderately to severely active UC who achieved complete continuous response (CCR) compared with patients who did not achieve CCR (non-CCR) through Wk54 of SC golimumab (GLM) maintenance therapy. During PURSUIT-Maintenance, GLM induction responders (464 patients) were randomized to receive PBO, SC GLM 50mg, or SC GLM 100mg at baseline (Wk0) and q4wks through Wk52. The primary endpoint was clinical response through Wk54 (CCR). Clinical remission, mucosal healing, corticosteroid use, and IBDQ outcomes and fecal markers at Wk54 among CCR versus non-CCR were assessed. All sub-analyses are based on patients randomized at Wk0 of maintenance (n = 456).

RESULTS: On all of the selected endpoints evaluated, CCR patients had better results when compared with non-CCR patients (Table). Among patients receiving corticosteroids at baseline, a greater proportion of CCR patients were not receiving corticosteroids at Wk54 versus non-CCR patients. Greater proportions of CCR patients were also in clinical remission versus non-CCR patients. Additionally, mean decreases in fecal lactoferrin and fecal calprotectin at Wk54 from Wk0 of maintenance were greater for CCR patients compared with non-CCR patients. Data between the GLM groups were similar and thus were pooled in the table.

Table: Clinical outcomes based on continuous clinical response at Wk54 in the PURSUIT-SC maintenance study*
Table to abstract P0890

Clinical endpoints	Non-CCR: PBO	Non-CCR: Combined GLM	CCR: PBO	CCR: Combined GLM
Randomized pts receiving concomitant steroids at Wk 0 (n)	60	87	27	73
Pts not receiving corticosteroids at Wk54(%)	1.7	4.6	66.7	75.3
Remission: Randomized pts(n)	106	156	48	146
Pts in clinical remission at Wk54(%)	0.9	1.9	68.8	67.1
Mucosal healing:Randomized pts(n)	106	156	48	146
Pts with mucosal healing at Wk54 (%)	1.9	2.6	87.5	90.4
IBDQ score:Randomized pts (n)	105	156	48	144
Change from Wk0 through Wk54 [mean(SD)]	-38.9(32.1)	-36.9(37.6)	10.6(18.2)	11.3(28.1)
Pts with IBDQ score >170 at Wk54 (%)	18.1	24.4	81.2	75.0

CONCLUSION: These data continue to support that patients induced into clinical response who maintain a clinical response through Wk54 are more likely to have better clinical outcomes.

INTRODUCTION: Crohn's disease (CD) may be complicated by a sealed-off perforation that results in the development of an abscess typically located next to adjacent loops of bowel. Traditional treatment has been antibiotics, surgical or CT-guided drainage of drainable collections, bowel rest, and, ultimately, in some patients, resection of the affected bowel segment. Most gastroenterologists avoid immune suppression in this setting because of the potential for disseminated and systemic infection. Data regarding use of anti-tumor necrosis factor (TNF) in this situation are scarce. The aim of this study was to examine outcomes for patients with CD who developed an abdominal abscess that was subsequently treated with infliximab without initial drainage in order to evaluate its safety and efficacy in a larger number of patients than previously reported.

AIMS & METHODS: We retrospectively reviewed the records of all CD patients attending the Mount Sinai Medical Center in New York City, between 2000 and 2013, with an intra-abdominal abscess who were treated with infliximab in order to evaluate its safety and efficacy.

RESULTS: There were 18 patients with CD complicated by an intra-abdominal collection treated with antibiotics and infliximab at our center between 2000 and 2013. The median age was 25.5 (18-46) years and eleven patients were males. Seventeen patients had ileal disease. Fourteen patients developed an intra-abdominal abscess (size ranging from 1.1 cm to 7.9 cm) and four had a phlegmon only. In addition to anti-TNF therapy, all patients were treated with broad-spectrum antibiotics. No complications following infliximab therapy were reported including sustained fever or sepsis. None required a surgical drainage but four patients required abscess drainage by interventional radiology. Eight patients underwent surgery within 6 months after initiating anti-TNF therapy.

CONCLUSION: Penetrating CD complicated by intra-abdominal abscess formation may be safely and effectively managed with a combination of antibiotics and infliximab therapy without drainage. Prospective trials are required to confirm these findings.

P0893 HIGH SERUM CRP PREDICTS FASTER CLEARANCE OF INFLIXIMAB AND POOR OUTCOME IN MODERATE-SEVERE ULCERATIVE COLITIS

J.F. Brandse[1,*], G.R. van den Brink[1], D.van der Kleij[2], T. Rispens[3], K. Bloem[3], Y. Ashruf[1], J.M. Jansen[4], M. Löwenberg[1], C. Ponsioen[1], R.A. Mathot[5], G.R. D'Haens[1]

INTRODUCTION: Insufficient serum concentrations have been suggested as a cause of lack of response to infliximab (IFX) in Ulcerative Colitis (UC) and may be associated with a high inflammatory load. Early pharmacokinetics (PK) of IFX related to inflammatory markers and response to induction therapy have been poorly studied.
AIMS & METHODS: We studied the PK of IFX induction therapy and markers/predictors for response in patients with moderate-to-severe UC (endoscopy Mayo 2 or 3) in a multicenter prospective study. Serum IFX concentrations and antibodies to IFX (Radioimmunoassay, Sanquin Laboratories, Amsterdam), serum CRP and albumin and fecal samples (for calprotectin and IFX concentrations) were collected at 10 serial time points during the first 6 weeks of therapy. Endoscopic response was defined as improvement by at least 1 Mayo point at week 6-8.
RESULTS: Twenty patients were included, all but one receiving IFX according to standard induction regime (5mg/kg at week 0.2,6). 11/19 patients showed endoscopic improvement. The median IFX serum concentration at week 6 was 2.9 (0.01-5.8) ug/ml for endoscopic non-responders versus 8.1 (3.0-13.7) ug/ml for responders ($p=0.03$). Serum IFX$\leq$7ug/ml at week 6 was defined as a predictive cut-off (OR:18.67, 95%CI 1.56-223.1, $p=0.02$) for endoscopic non-response. The presence of antibodies to IFX at week 6 ($n=4$) was associated with a 2.93 fold increased clearance of the drug. Fecal IFX concentrations at day 1 were 4.1 (1.3-20.1) ug/ml in non-responders compared to 1.3 (0-5.8) ug/ml for responders (P[GD1]$=0.10$). Median area under the curve (AUC), IFX concentration versus time, was 1229 mg/L/day in the endoscopic non-responders compared to 1352 mg/L/day for the responders ($p=0.65$). Patients with a baseline CRP$>$50mg/l had a significantly smaller AUC than those below 50mg/l (578 vs. 1361 mg/L/day, $p=0.001$), with IFX clearance 1.63 fold increased ($P<0.001$, multivariate analysis).
CONCLUSION: Ulcerative Colitis patients with a high baseline serum CRP have increased clearance and lower serum IFX concentrations during IFX induction therapy, predicting poor outcome as early as week 6. These patients can be selected for more intensive induction regimens.

P0894 PULMONARY INVOLVEMENT AND THE EFFECT OF TNF-ALPHA-INHIBITORS ON PULMONARY FUNCTION IN IBD-PATIENTS

J. Bethge[1,*], M. Ellrichmann[1], C. Conrad[1], S. Nikolaus[1], R. Noth[2], D. Schuldt[1], S. Zeissig[1], S. Schreiber[1,2]
[1]*Medical Department I, Gastroenterology,* [2]*Medical Department I, Pulmonology, University Medical Center, Schleswig Holstein, Campus Kiel, Kiel, Germany*
Contact E-mail Address: *jbethge@1med.uni-kiel.de*

INTRODUCTION: Extraintestinal manifestations are a frequent complication in patients with Inflammatory-Bowel-Disease (IBD). Pulmonary involvement is commonly recognized but describe as a rare manifestation. Of note, increased mortality from respiratory diseases was observed in patients with ulcerative colitis. This may be due to an overlap between genetic causes in IBD and various chronic inflammatory lung diseases. Therefore, pulmonary involvement may be overlooked in IBD patients.
AIMS & METHODS: The aim of this prospective study was to assess pulmonary-function-abnormalities in IBD patients in comparison to healthy controls and investigate the effect of TNF-a-inhibitors on pulmonary-function-test (PFT). 90 consecutive patients with IBD (51 Crohńs disease (CD), 39 UC) were included. 47 patients were in remission and 43 had active disease. Out of these, 25 patients were seen for initiating anti-TNF therapy. 40 matched healthy controls were included. Pulmonary function was evaluated using the Medical Research Council (MRC) dyspnea index and a standardized spirometry. IBD activity was assessed using Harvey-Bradshaw index for CD and partial-Mayo-score for UC. In patients treated with anti-TNF all parameters were reevaluated 6 weeks later. Data are presented as Median/25thpercentile/75thpercentile.
RESULTS: Patients with active IBD showed significantly reduced parameters in their PFT. Tiffeneau index-values (FEV1%) were significantly reduced in IBD patients with active disease (78,9/73,7/85,1) compared to controls (86/81,8/88,3; $p=0.001$) and IBD patients in remission (84,5/81,2/89,4; $p=0.0002$). No difference was found between IBD patients in remission and controls ($p>0.05$). Parameters of peripheral airway obstruction (MEF 75-25%) showed comparable changes (MEF75: IBDactive vs. controls $p=0.01$; IBDactive vs. IBDremission $p=0.002$). Clinically significant peripheral airway obstruction was seen in 19.1%, obstructive dysfunction in 12.8% and restrictive dysfunction in 2.1% of IBD patients with an active disease (IBDremission: 4.6%/2.3%/6.9%; Control: 5%/0%/0%). Patients treated with anti-TNF showed a significant improvement of obstructive parameters ($p=0.003$ FEV1%) compared to baseline levels.
CONCLUSION: IBD patients with active disease showed significant abnormalities in their obstructive PFT-parameters in comparison to healthy controls and IBD patients in remission. Anti-inflammatory therapy with anti-TNF improves obstructive abnormalities. Pulmonary obstruction and chronic broncho-pulmonary inflammation might be the cause of reduced exercise levels during active disease and may be overlooked in the majority of patients. Further studies are necessary to determine whether chronic obstruction should be treated and whether it contributes to the observed mortality from lung problems in IBD.

INTRODUCTION: Peri-anal fistulas are an incapacitating complication of Crohn's disease affecting approximately 25% of patients in population-based estimates. Since the introduction of anti-TNF agents (infliximab and adalimumab), the treatment for Crohn's fistulas has changed from almost exclusively surgical to placing a much larger emphasis on medical therapy.
AIMS & METHODS: The purpose of this systematic review is to provide an overview of the literature evaluating the success rate of perianal fistula treatment with anti-TNF. PubMed, Embase and Biosis were searched. Randomized controlled trials on the effect of anti-TNF treatment on Crohn's perianal fistulas were included. Studies assessing perianal fistulas in children, rectovaginal fistulas and costs were excluded. The primary outcome of interest was complete fistula closure with partial closure as a secondary outcome parameter. A subgroup analysis for complete fistula closure was performed based on studies with a follow-up longer than 4 weeks.
RESULTS: Four studies comparing placebo with anti-TNF therapy regimens were included in the meta-analysis: one study on infliximab (ACCENT study) and three studies analysing adalimumab (CLASSIC, CHARM and GAIN trial). All patients with fistulising disease were included in the trials (peri-anal, entero-cutaneous and entero-enteral fistulas). In total, 179 patients were treated with anti-TNF medication whereas 109 patients received placebo. All studies assessed complete closures rates and three studies reported partial closure rates. The mean follow-up time was 13 weeks (range 4-26). In the anti-TNF group, 54 of 179 (30%) patients responded to treatment with complete fistula closure, whereas complete healing was seen in 13 of 109 (12%) patients in the placebo group. Partial fistula closure was seen in 48 of 109 (44%) patients in the anti-TNF treatment group and in 15 of 62 (24%) patients in the placebo group. There was no significant difference in complete or partial closure rates between the two groups (RD 0.12, -0.06-0.30, I^2 74% and 0.09, 95% CI -0.23-0.41, I^2 78%, respectively). The subgroup analysis showed a significant advantage for complete fistula closure with anti-TNF in the two trials with follow-up longer than 4 weeks (ACCENT: 46% versus 13%, $p=0.003$ and CHARM: 30% versus 13%, $p=0.03$) when compared to the placebo group.
CONCLUSION: Meta-analysis of 4 randomized controlled trials did not show a significant advantage for (partial) fistula closure with anti-TNF treatment as compared to placebo. However, subgroup analysis showed an advantage of anti-TNF treatment on complete fistula closure rates in the two trials with a follow-up longer than 4 weeks.

INTRODUCTION: Significance
Budesonide MMX is a novel drug developed for the treatment of ulcerative colitis using multi-matrix system. The effects on remission of disease would help to form recommendations for efficacy and safety profile. Most of these trials conducted have relatively small size, limited data and a meta-analysis for this drug could have stronger conclusion.

AIMS & METHODS: Manual search through MEDLINE & PUBMED using "ulcerative colitis" and "Budesonide MMX" were merged yielding 9 studies. Six studies were shown which was limited to human. Excluded were two reviews and a comment. Three multicenter, randomized, placebo-controlled trials were included & Cochrane Review Manager Software Version 5 was used.
RESULTS: There was a significant remission of symptoms in patients using the combined Budesonide MMX 9 & 6 mg with a p-value of 0.02. Sensitivity analysis using Budesonide MMX 9 mg is effective in the remission compared to Budesonide 6 mg alone and placebo with p-value 0.0005 at 95% confidence interval. Adverse effects showed no significant difference between Budesonide MMX group and the placebo group with a p value of [illegible].
CONCLUSION: Budesonide MMX, [illegible] meta-analysis, is beneficial in assessing the response to treatment in remission of symptoms. The adverse effects have no significant difference with placebo thus further study is needed to assess the safety profile of the drug.

INTRODUCTION: Penetrating Crohn's disease (CD) can be complicated by sealed-off perforation resulting in the development of an inflammatory mass or phlegmon. This typically involves the mesentery and adjacent bowel loops, and can be further complicated by an abscess or a fistula. The optimal management strategy and long-term outcomes of phlegmons in CD remains unknown.
AIMS & METHODS: Patients with CD and confirmed phlegmons on MRI/CT between January 2009 and December 2012 were identified retrospectively. Radiographic evidence of co-existing strictures, abscess, fistula and/or perforation was recorded. Medical records were reviewed and demographic data, CD phenotype, CD therapy prior to and following presentation, requirement for abscess drainage or surgical resection, and clinical status at most recent follow-up were recorded. Clinical remission was defined as a Harvey -Bradshaw index of <5. Repeat imaging was evaluated to assess phlegmon resolution.
RESULTS: 13 patients (7 male) were identified with median follow up of 40 months (range 33-61 months). 3 had ileal and 10 had ileocolonic CD. 11 had co-existing strictures, 5 had co-existing abscess, and 4 had co-existing enteroenteric fistula. 4 patients were receiving a thiopurine at presentation with phlegmon. 12 patients reported significant abdominal pain with 8 requiring admission. In 4 of these, imaging studies confirmed perforation. 2 patients required short-term parenteral nutrition and 6 were managed with exclusive liquid diet.
7 patients were treated primarily with medical management (2 with prolonged courses of antibiotics, 5 with thiopurine and corticosteroids, and subsequently 2 escalated to an anti-TNF agent) and this led to phlegmon resolution in 4 patients, and clinical remission in 3 patients. 2 patients have subsequently required surgery, and 2 persist with low grade obstructive symptoms treated conservatively. 6 patients were managed with primary surgery. All received a thiopurine as post-operative prophylaxis, of whom 3 escalated to an anti-TNF agent for significant post-operative recurrence. Repeat surgical resection or abscess drainage was not required subsequently.
2 of 4 patients presenting with perforation and phlegmon at presentation were treated surgically, 2 of 4 patients with enteroenteric fistula and phlegmon at presentation were treated surgically, and 3 of 5 patients with abscess and phlegmon at presentation were treated surgically. All 4 patients on thiopurine at presentation required surgery.
CONCLUSION: Phlegmonous disease remains challenging to treat. Medical and surgical management are both viable options, however phlegmon resolution was more likely in the surgically treated group. Medically treated patients remain at risk of need for future surgery. Surgically treated patients require aggressive medical treatment post-operatively, to limit recurrence of CD.

P0898 COMBINED USE OF AZATHIOPRINE/6-MERCAPTOPURINE ARE ASSOCIATED WITH DECREASED RISK OF ANTI-TNF INDUCED SKIN LESIONS

K.-J. Kim[1,*], J.S. Soe[1], S. Hyun[1]
[1]*Gastroenterology, Asan Medical Center, Seoul, Korea, Republic Of*
Contact E-mail Address: *capsulendos@gmail.com*

INTRODUCTION: Anti-tumor necrosis factors (anti-TNF) agents are given for treating patients with moderate to severe active inflammatory bowel disease (IBD). Among various adverse events during anti-TNF therapy, skin lesions such as psoriasis or eczema could be a reason for discontinuation of anti-TNF therapy.
AIMS & METHODS: We aimed to identify the risk factors for skin lesion occurrence and compared the cumulative incidence of skin lesions in relation to concomitant use of azathioprine/6-mercaptopurine during being treated with anti-TNF agents in IBD patients. Methods: Between June 2002 and July 2013, 500 patients (404 Crohn's disease and 96 ulcerative colitis) were treated with anti-TNF at Asan Medical Center. Among them, new skin lesions occurred in 47 IBD patients at the department of dermatology. We retrospectively reviewed the medical records. To identify risk factors for skin lesions, we compared 47 patients with skin lesions to 443 patients without any skin disease or history.
RESULTS: The incidence of skin lesions during anti TNF therapy was 9.4%. The skin lesions were listed in Table 1. Face was the most common involved site ($n=21$, 45%), followed by trunk ($n=18$, 38%) and upper extremities ($n=18$, 38%). Thirty three (70%) patients were treated with topical steroids with or without antihistamine and showed good response. Four subjects (9%) discontinued anti-TNF because of eczematiform ($n=2$), psoriasiform ($n=1$), linear IgA dermatosis ($n=1$). On univariate analysis, skin lesion occurred more in female (HR: 1.794, 95% CI: 1.011-3.181, $p=0.046$) than in male. Also, combined use of azathioprine/6-mecaptopurine was associated with decreased risk of the occurrence of skin lesions (HR: 0.452, 95% CI: 0.251-0.814, $p=0.008$). However, only combined use of azathioprine/6-mercaptopurine (HR: 0.437, 95% CI: 0.242-0.790, $p=0.006$) decreased the risk of occurrence for skin lesions on multivariate analysis. Thus, we compared the cumulative incidence of skin lesions according to the use of azathioprine/6-mercaptopurine. Combined use of azathioprine/6-mercaptopurine at the time of starting anti-TNF agents tended to be lower cumulative incidence of skin lesions ($p=0.009$ by log rank test) during follow-up period.
Multivariate analysis of factors associated with skin lesion occurred during treatment of anti-TNF agents in patients with inflammatory bowel disease

Variables		HR	95% CI	p-value
Sex	Male	1		
	Female	1.741	0.978-3.105	0.059
Age				0.129
Concomitant use with IMM (azathioprine / 6-mecaptopurine)	No concomitant use	1	0.941-1.008	
	Continue to concomitant use during follow-up period	0.441	0.215-0.905	0.025
	Stop IMM during follow-up period	0.433	0.214-0.879	0.020
IBD group	CD	1		
	UC	0.672	0.230-1.961	0.467

HR, hazard ratio; CI, confidence interval; IMM, immunomodulator; IBD, inflammatory bowel disease
CONCLUSION: Combined use of azathioprine/6-mercaptopurine may reduce the occurrence of skin lesions on anti-TNF therapy at the time of starting anti-TNF agents.

INTRODUCTION: Pharmacokinetics of anti-TNF therapy is increasingly used to treat inflammatory bowel disease (IBD). Whether this approach is associated with significant cost savings beyond one year in a large cohort of patients with IBD has yet to be determined (1,2).
AIMS & METHODS: We compared two cohorts of patients with Crohn's disease treated with anti-TNF therapy (infliximab and then adalimumab in case of infliximab failure) and presenting loss of response. The first cohort followed a process management based on current practice, with drug optimization (increasing dose and/or shortening the interval) not taking into account pharmacokinetics of anti-TNF. In the second cohort, results of trough levels and antibodies against anti TNF were integrated when patient was not responding for the first time to an anti TNF agent. We used a selected mathematical model to describe the trajectories of Crohn's disease patients in the management of their disease based on a discrete event system. This allows tracking over a given period (1, 3 or 5 years) a double cohort of patients (10.000 patients) who move randomly and asynchronously from one state to another while keeping the whole information on their entire trajectory. Both cohorts were modeled by a state diagram parameters where transition probabilities from one state to another are derived from literature data. A stochastic sensitivity analysis on the transition probabilities was conducted in order to assess the stability of results. In the second analysis, we used the cost of an Elisa test from Theradiag (France, 100 euros) and no other indirect costs were included in this test based strategy. The costs of anti TNF therapy integrated in this model were reported by the French healthcare system.

RESULTS: There was a dramatic decrease in overall costs within the cohort of Crohn's disease patients benefiting from a test-based strategy (table 1)

	Decrease in total costs (n = 10.000)	Percentage of decrease in direct costs	Decrease in costs per patient
One year	**23 847 619 €**	**14.1%**	**2 385 €**
Three years	**88 588 892 €**	**22.4%**	**8 859 €**
Five years	**131 300 293 €**	**24.6%**	**13 130 €**

For this simulation, the mean decrease in costs was similar when testing a population of 3 000 or 10 000 patients. At 5 years the mean decreased costs were 12 899 (95% CI:11820 - 13977) for 3 000 patients and 13 130 euros (95% CI:12535 - 13725) for 10 000 patients. After a stochastic sensitivity analysis (30 simulations with random choice of transition probabilities and a bootstrap analysis), these results were comparable with a decreased costs at 5 years for each patient using tests with a 95CI [13 251,74 € - 13 565,05 €]. The impact of the direct cost of test is not significant and our results were similar using cost of test of 2.000 euros.
CONCLUSION: A test-based strategy is associated with major cost savings among Crohn's disease patients treated with anti-TNF strategy. These findings should be taken into account to guide decision making in clinical practice and also by French healthcare system.

INTRODUCTION: Infliximab has been shown to be effective in acute severe ulcerative colitis (UC) reducing the risk of colectomy. The ACT studies proved efficacy for IFX in patients with a more chronic type of UC, However, long-term data on clinical outcome of anti-TNF therapy are scarce. We assessed long-term outcome in patients with chronic UC started on IFX.
AIMS & METHODS: METHODS: Retrospective data capture from local registries at 9 Swedish IBD centers from November 2004 to December 2011. Inclusion criteria were: a) IFX treatment on an ambulatory basis. b) age ≥18 years, c) 8 weeks or more on continuous steroid use or more than 12 weeks during the last 6 months, d) steroid intolerance, e) insufficient response to, or intolerance to thiopurine therapy. Patients were eligible if followed at least 12 months or until colectomy.
RESULTS: 243 patients (145 males, 98 females) were included; median age 26.3 years (8-71.7) at diagnosis and a median disease duration of 5.0 years (0.2-39.5 years). 114/243 patients (47%) were on steroids and 116/243 (48%) were on concomitant thiopurines, 25/243 (10%) started a thiopurine together with IFX at inclusion and 90/243 (37%) patients had a previous thiopurine exposure. Median follow-up was 3.3 years (0.1 –8.9 years) during which a median of 6 (1-41) infusions were given. At 12 months 114/243 (46.9%) patients were in steroid-free remission and 46/243 (18.9%) had a steroid-free response. Lack of response was noted in 39/243 (16%) and 32/243 (13.2%) underwent colectomy. The corresponding figures at a median follow-up of 3.3 years were steroid-free remission: 114/243 (46.9%), steroid-free response 31/243 (12.8%), no response 14/243 (5.8%) while 75/243 (30.9%) had undergone colectomy. Of non-responders at 1 year, 21/39 (53.8%) had a colectomy during follow-up compared to 22/172 (13%) patients with response or remission at 12 months. At last follow-up, 44 patients were on IFX maintenance treatment with a median of 24 (11-54) infusions. The remaining 199 patients had a first course of IFX treatment with a median of 4 (1-41) infusions, 41 patients had a second course with a median of 5 (1-29) infusions, 9 patients a third course with a median of 5 (1-14) infusions and one patient a fourth course with 4 infusions. The main reasons for stopping IFX at the first course was remission in 32%, loss of response 28%, non-response 18% and adverse events 10%. Overall 62 (25,5%) patients were switched to adalimumab.
CONCLUSION: Anti-TNF is an efficacious long-term treatment in chronic active UC with 47% of patients in steroid-free remission at 12 months and sustained at 3.3 years. 66% had at least a clinically significant steroid-free response at 12 months with a slight decrease to 60% at 3.3 years. In contrast, non-response at 12 months was associated with a high risk of subsequent colectomy.

INTRODUCTION: Infliximab (IFX) trough levels (TLI) vary greatly between inflammatory bowel disease (IBD) patients. This variability is relevant because there is a relationship between IFX concentration and clinical response.
AIMS & METHODS: Main objective: estimate individual pharmacokinetic parameters and predict trough IFX levels. Secondary objective: evaluate the association between IFX exposure and covariates that could modify trough levels.
(a) Observational and prospective study of patients on IFX treatment from July 2013 to March 2014. TLI and antibodies toward infliximab (ATI) were measured by ELISA at steady-state. Variables recorded: demographic, disease location C-reactive protein levels (CRP), serum albumin concentrations (SAC), immunomodulatory treatment (IMM) and smoking. Individual pharmacokinetic parameters were estimated and TLI were predicted using population PK modelling (Nonmem® 7.2).
RESULTS: 55 patients (49% women) were included. 93 TLI and ATI were measured. Mean age: 43 yr (18-75); weight: 74 kg (IC95%: 71-77.5). Diagnose: 58.5% CD and 41.5% UC. 70 % received IMM. 27% patients were under intensified IFX doses. Mean CRP: 6.45 mg/L (IC95%: 4.56-8.35), mean SAC: 4.70 g/dL (IC95% 2.55-6.84).
Mean TLI: 3.34 mg/L (CD: 3.62. UC: 2.49) (IC95%:2.66-4.02). TLI: <3: 56 % and 3-7: 31.2%. ATI status: 4.3% of patients tested positive. All patients who developed ATI had undetectable trough levels. 68.5% of patients with trough levels<3 were in remission. Mean estimated peak levels: 114.35 mg/L (IC95%: 107.37-121.305); mean estimated AUC: 27105.77 mg/h/L (IC95%: 24835-29376.54).
Fasanmade et al (2011) population PK model for CD was used in both CD and UC patients. Mean predicted TLI: 3.1 mg/L (IC 95%: 2.49-3.69). Bias –5.55% (IC95 %: -7.98-(-3.129)) and precision 10.4% (IC95 %: 8.85-11.95). Fasanmade et al (2009) population PK model for UC was not precise enough.
Individual estimated PK parameters (mean): central clearance (Cl) 5.65 ml/kg/day (IC95%: 5.13-6.16), volume of distribution (central) (Vd) 50.59 ml/kg (IC95%: 49.97-51.21), half-life ($t_{1/2}$): 11.7 days (IC95%: 10.7 -12.7). Population PK parameters: Cl 5.42 ml/kg/day, Vd 52.4 ml/kg. Difference between individual and population PK parameters: 4% in Cl and 3.4% in Vd. Comparison of exposures achieved showed that patients with positive ATI, SAC< 3.9 g/dL, non receiving IMM and smokers had significant lower trough IFX levels, higher Cl and lower $t_{1/2}$. Patients with PCR>6 mg/L and ileo-colonic CD had lower IFX levels.
CONCLUSION: High interindividual variability in IFX PK and trough levels exists in IBD patients. The influence of IMM, SAC, smoking and inflammation on infliximab clearance suggests that individual adjustment of infliximab doses according to disease activity may be useful in IBD.

INTRODUCTION: Mesenchymal stem cells (MSCs) are potent immune regulators, proposed for local and systemic use in human IBD. Recent studies reported that MSCs can promote tumorigenesis, warning their use in clinical condition associated to increased cancer risk, such as IBD.
AIMS & METHODS: To evaluate the cancer risk associated to the therapeutic effect of MSCs in murine model of colon cancer associated to chronic colitis.
MSCs were isolated from adipose tissue of C57BL/6 mice, and analyzed for MSCs markers and for adipocyte and osteogenic differentiation. An MTT assay was used to explore the direct effects of MSCs on tumor intestinal epithelial cells proliferation and vitality. CT26 cells were incubated with TNF-a for 48 h and then exposed to the surnatant of TNF-alfa pre- treated AMSC. C57BL/6 mice were injected intraperitoneally with azoxymethane (AOM) and exposed to 3 weekly cycles of 2.5% DSS.1 million of MSCs were injected intra-peritoneally at day 3 of each DSS cycle, control (CT) mice received saline. Body weight, occult blood test and stool consistency were used to calculate the Disease Activity Index (DAI). Mice were sacrificed at week 10 and colon was analyzed macroscopically and microscopically for number of cancer and degree of inflammation. Nude mice were subcutaneously engrafted respectively with murine (CT26) or human

(HCT116) tumor cells lines alone or in combination with MSCs to evaluate their role in tumor cell growth. CT nude mice received MSCs alone.
RESULTS: MSCs differentiated into adipocytes and osteocytes, and expressed low levels of CD31, CD34, LIN and cKIT markers, and highlevels of SCA-1, CD44 and CD106. MSCs proliferation was increased when stimulated with TNF. Their surnatant leaded to a not significant reduction of CT26 growth. MSCs injection significantly reduced DAI in treated mice vs. CT. MSCs treated mice showed lower body weight loss and better survival rate. Treated mice had a not significant reduced rate of colon cancer development vs. CT. In nude mice, there was no significant difference in tumor size between groups. No lesions were found in CT mice.
CONCLUSION: MSCs did not increase cancer risk in this colitis model and did not affect the progression of pre-existing tumor lesions. MSCs exerted an immune-modulatory effect in vivo, by decreasing the severity of colitis in mouse, suggesting that their anti-inflammatory effects may contra-balance their pro-carcinogenetic potential, even in pre-cancer condition such as chronic colitis. Further analyses are required to define mechanisms of action underlying these findings.

INTRODUCTION: Currently, safety and economic issues have increasingly raised concerns about the long term use of biologics as maintenance therapies.
AIMS & METHODS: To evaluate the role of azathioprine (AZA) on mucosal healing in patients with inflammatory bowel disease (IBD). Two thousand seven hundred patients with IBD were evaluated from January 1995 to April 2014. The searching criteria were as follows: (1) endoscopic records before the AZA and during the AZA therapy; (2) AZA naïve patients with severe IBD. The data included patients and disease demographics and the efficacy of AZA. Patients with a minimum duration of 4 months of AZA were included in this study.
RESULTS: A total of 120 patients treated with AZA for IBD were enrolled. AZA therapy reduced the number of the surgical interventions in patients with IBD* (*: $p<0.05$). Male gender had a negative impact on the efficacy of AZA therapy*. IBD patients with responce were older than the nonresponder*. There was no difference between the operated CD patients and nonoperated for the AZA responce rates (32% vs 34%, $p> 0.05$ respectively). Then, 33 AZA non-responder patients with CD were put on biologics. Responce rate was 30%. Of the nonresponders, intestinal resection performed in 35% .

	number	mucosal healing by AZA	Nonresponce %
Patients with IBD	120	37 %	63%
UC	38%(45p)	42%	58%
CD	62%(75p)	33%	67%
Male	60%	25%	67%*
Operated after AZA	13%	4.5%	18.4*
AZA used (months)	31.5±24.7 (4-113)	31.2±25.7 (4-90)	31.6±24.3 (4-113)
Age at IBD diagnose (years)	36.8±12.3 (11-72)	38.1±12.3 (17-58)	36.1±12.3 (11-72) *
Period (AZA started-IBD diagnosed (months)	39.8±52.5 (0-264)	56±69 (0-264)	30±37 (0-204)

CONCLUSION: In this study, we showed that AZA therapy increased endoscopic mucosal healing rates and decreased the frequency of the surgical interventions in AZA naïve patients with severe IBD. We believe that there is still room for the AZA therapy in the management of severe IBD patients. Of the 33 CD patients with no previous AZA responce, biologics failed in 70%.

P0904 EFFICACY OF ADALIMUMAB TREATMENT IN STEROID-DEPENDENT ULCERATIVE COLITIS PATIENTS

M. Barreiro-De Acosta[1,*], F. Muñoz[2], M. Sierra[2], M. García Alvarado[3], A. Lorenzo[1], J.E. Dominguez-Munoz[1]
[1]*University Hospital, Santiago,* [2]*Hospital de Leon, Leon,* [3]*Hospital de Zamora, Zamora, Spain*

INTRODUCTION: Steroid dependency develops frequently (more than 30%) with regards to ulcerative colitis (UC) patients. Limited data exists concerning adalimumab (ADA) administration in steroid-dependent UC patients.
AIMS & METHODS: Our aim was to evaluate the clinical efficacy of ADA in steroid-dependent UC patients.
We designed an open-label, retrospective, consecutive, and multicentre study. Inclusion criteria were patients over 18 years old with UC and ECCO criteria of steroid-dependency: Patients who are either unable to reduce corticosteroids below the equivalent of prednisolone 10 mg/day within three months of starting corticosteroids, without recurrent active disease or who have a relapse within three months of stopping corticosteroids. All patients received ADA treatment for induction (160/80 mg) at weeks 0 and 2 and 40 mg every 2 weeks thereafter. In the event of loss of response patients received higher doses of ADA. The main endpoint evaluated was clinical remission without steroids during all the treatment. Clinical response, mucosal healing and varying levels of C-reactive protein (CRP) and calprotectine were also evaluated. Results are shown in percentages; associations were analyzed by Cox regression whenever appropriate.
RESULTS: 37 steroid-dependent UC patients were treated with ADA: 67% female, mean years since UC diagnosis being 11 years, 40% presenting extraintestinal manifestations and 65% with extensive colitis (E3). 12 patients (32%) were naïve to anti-TNF and 25 (68%) had previously received infliximab. Mean follow-up was 25.9 months. 83% received concomitant treatment with immunosuppressive drugs. 43% needed higher doses of ADA treatment due to loss of response. After induction 35% of patients were in remission and after 12 months. 40% of patients were in remission without steroids. The mean partial mayo score was 6.89 basal, 3.13 at month 6 and 2.33 at month 12 ($p<0.001$). Mucosal healing was achieved in 48% of patients. Mean calprotectine decreased from 563 basal to 218 at month 6 ($p<0.05$) and to 61 at month 12. CRP decreased from 19.13 to 6.13 at month 12 ($p<0.001$). Only 3 patients (8%) needed a colectomy during the first year. We did not observe any association between concomitant treatment with immunosuppressive drugs and response to ADA, but after Cox regression patients with need of intensification with ADA (HR = 48.1 95%IC:1.46-1589.1; $p=0.03$) and with previous IFX (HR = 12.8; 95%CI: 2.24-73.54, $p=0.004$) had a lower remission rates.
CONCLUSION: Adalimumab can be effective for clinical remission without steroids and mucosal healing in steroid-dependent UC. Previous IFX or need of intensification are predictive factors of poorer efficacy.

INTRODUCTION: Infliximab therapy in patients with inflammatory bowel disease (IBD) requires intravenous administration in over 2 hours, with a further 1 hour of post-infusion observation. Recent studies demonstrated the safety and the tolerance of a shortened 1-hour infusion in IBD patients under scheduled maintenance infliximab treatment. We report our experience in order to evaluate if repeated 1-hour infliximab infusions could affect the antibodies to infliximab (ATI) and the infliximab trough levels (TL).
AIMS & METHODS: This was a prospective cohort study on patients with IBD receiving infliximab with shortened 1-hour infusions. All patients were treated with scheduled maintenance infliximab therapy, after at least 5 well tolerated 2-hours infusions before enrolment. For each patient we recorded diagnosis, vital signs. All patients were routinely premedicated with 20 mg i.v. methylprednisolone and oral antihistaminics. We analyzed serum samples collected before starting the first shortened infusion and after one year of maintenance scheduled infliximab treatment for ATI and TL by a commercial ELISA kit according to the manufacturer instructions (DRG Diagnostics GmbH, Marburg, Germany). All samples were analyzed simultaneously at the end of the collection period. Statistical analysis was performed by Wilcoxon test for paired samples and Fisher's exact test.
RESULTS: Fifty-seven IBD patients (28 Crohn's Disease, 29 Ulcerative Colitis) were treated at our IBD Outpatient clinic with 1-hour infliximab infusion protocol: out of them 24 (42%) at the dose of 10 mg/kg and 18 (31.6%) with a shortened interval of 6 weeks. Eleven patients (19.3%) were on concomitant immunosuppressants. In total, 396 maintenance 1-hour infliximab infusions were administered. Adverse reactions were reported in 2 out of 396 (0.5%) 1-hour infusions: these reactions were considered as severe, resulting in infliximab discontinuation. Both patients had elevated ATI at the time of the first 1-hour infusion. No significant difference was found between median ATI (17.5 AU/ml versus 17.7 AU/ml) and TL (3.1 mcg/ml versus 2.26 mcg/ml) measured before and after 1 year of shortened infliximab infusions. The percentage of patients with ATI positive (scoring higher than 10 AU/ml) and of patients with undetectable TL were unchanged after one year of 1-hour infusions. We found no correlations of ATI positivity and detectable TL measured after one year of shortened infusions with the infliximab dose (5 mg/kg or double dose 10 mg/kg), the dose interval (every 8 or 6 weeks) and the concurrent immunosuppressive therapy. Five out of 55 patients (9%) changed their ATI status from negative to positive, while 10/55 (18%) from positive to negative, at the end of the study period ($p=$ n.s.).
CONCLUSION: In our experience, shortened 1-hour infliximab infusions were safe and well tolerated in IBD patients under scheduled maintenance therapy also with dose and interval optimisation and did not affect ATI and TL.

P0906 TUBERCULOSIS INFECTION IN INFLAMMATORY BOWEL DISEASE PATIENTS AFTER ANTI-TNF THERAPY IN A HIGH TUBERCULOSIS PREVALENCE RATE AREA

M.L. De Castro[1,*], V. Rodil[2], V. Hernández[1], J.R. Pineda[1], L. Sanromán[1], S. Pereira[1], J. Martínez-Cadilla[1], J. I. Rodríguez-Prada[1]
[1]*Gastroenterology,* [2]*Internal Medicine, Universitary Hospital of Vigo-CHUVI, Vigo, Spain*
Contact E-mail Address: *maria.luisa.decastro.parga@sergas.es*

INTRODUCTION: Galicia is a region located in the north west of Spain. It has an estimated incidence of 27 new cases of tuberculosis per 100000 population, that is higher than the Spanish average rate of 15.5/100000. On the other hand cases of active tuberculosis have been reported worldwide with the use of therapeutic agents that inhibit tumor necrosis factor (TNF) alpha. Our aim was to study the prevalence of latent tuberculosis infection and active tuberculosis in inflammatory bowel disease (IBD) patients before and during TNF therapy in this geographical area.
AIMS & METHODS: We conducted a retrospective study collecting clinica data of IBD patients on anti TNF therapy from January 2000 to December 2012, identifying the cases with latent tuberculosis and active tuberculosis infection. Latent tuberculosis was defined as a positive tuberculin cutaneous test (TCT) or Booster re-test (> 5 mms). Active tuberculosis infection was confirmed by positive culture to Mycobacterium tuberculosis.
RESULTS: 225 patients received TNF alpha drugs, 136 male (60.4%), 173 (76.9%) Crohńs disease. Nine patient had suffered from previous lung diseases. Tuberculin cutaneous test was done in 190 patients, and Booster re-test in 100. Latent tuberculosis was diagnosed in 20 and 1 patients whether TCT or Booster were > 5 mms respectvely and all of them received oral isoniacide prophylaxis (9.3%). Seven patients suffered from active tuberculosis infection (3.1%): 4 male (57.1%) mean age 49.6 years 57.1% ulcerative colitis. Four of them had negative TCT and Booster but they were on inmunosuppresant but no corticosteroids when these tests were performed, and the other 3 patients had received oral quimioprofilaxis (3-6 months) because TCT was positive. Time from last TNF dose to symptoms and from symptoms to tuberculosis diagnose were and days respectively. Active tuberculosis were generally disseminated (85.5%) and required hospitalization until diagnose and clinical stabilization. Multidrug therapy was continued for 6-8 months but one patient eventually died. Anti TNF-alpha was no restarted in these patients.
CONCLUSION: Active tuberculosis in IBD patients on antiTNF therapy in a high prevalence area was 3.1%. The infection was generally disseminated, required hospitalizations and even caused death.
TCT test and previous oral quimioprofilaxis failed to eliminate risk of active infection in these patients, so any other tests or preventive measures should be develop.

P0907 COMBINATION THERAPY WITH LOW DOSE THIOPURINE AND ALLOPURINOL IN PATIENTS WITH ULCERATIVE COLITIS

M. Kiszka-Kanowitz[1,*], K. Theede[1], A.M. Nielsen[1]
[1]*Hvidovre Hospital, Hvidovre, Denmark*
Contact E-mail Address: *marianne.kiszka-kanowitz@regionh.dk*

INTRODUCTION: Thiopuine is used as a second line therapy in patients with ulcerative colitis (UC) failing 5-ASA treatment. However up to 50 % of patients treated with thiopurine fail this treatment due to intolerance or to lack of efficacy. A high ratio between Methylmercaptopurine (MeMP) and the active metabolite 6-Thioguanine-nucleotide (6-TGN) can be the explanation for intolerance and thiopurine-faliure in some patients.
Adding Allopurinol to a low dose of thiopurine changes the ratio between MeMP and 6-TGN, thereby decreasing the risk of some adverse events and at the same time increasing the efficacy.
AIMS & METHODS: To determine the tolerance and efficacy of combination therapy with low dose of thiopurine and allopurinol in patient with UC.
A retrospective analysis of patient with CU starting combination therapy between October 1th 2010 and October 1th. 2013 in a single IBD-center in Denmark.
36 UC patients were identified. 21 males and 15 females. Disease duration was mean 7 years (range 2 – 28 years). 2 patients had proctitis, 22 patients had left-sides colitis and 12 patients had pancolits.
The reason for starting combination therapy was: abnormal liver test in 8 patients, high MeMP/6-TGN ratio in 24 (14 were proven to fail mono-treatment with thiopurine), 3 other adverse events and 2 patient failing thiopurine treatments, but without a high MeMP/6-TGN ratio.
When starting combination therapy 20 patients had active disease despite of treatment with systemic steroid in 2 patient, anti-TNFa treatment in 5, steroid and anti-TNFa treatment in 3 patients. 16 patients had inactive disease, but 3 patients were receiving steroid and 7 anti-TNFa treatment.
RESULTS: Six (17 %) patients were intolerant to combination therapy and had to stop treatment. 5 patients had the same adverse event as in mono-therapy and 1 patient had an unspecific event not thought to be related to treatment.
The active metabolite increased from mean 130 pmol/nmol Hgb (range 62-220) to mean 243 pmol/nmol Hgb (range 115-434) and MeMP decreased from 4158 pmol/nmol Hgb (range 487-12150) to mean 134 pmol/nmol Hgb (range: 0-419) and ratio between MeMP and 6TGN decreased from 31 to 0, 55 upon changing from thiopurine mono-therapy to combination-therapy.
Four (11 %) patients had no or poor response to combination therapy, 2 had a colectomy and 2 started treatment with anti-TNFa.
Twenty-six (70 %) patients responded to combination treatment and have since start of treatment been in steroid and anti-TNFa free clinical remission.
CONCLUSION: Combination therapy with low dose thiopurine and allopurinol is well tolerated, cheap and a highly effective treatment in patients with CU and a high MeMP/6-TGN ratio experience intolerance or having poor or no response to thiopurine mono-therapy.

P0908 CAN MINDFULNESS-BASED COGNITIVE THERAPY IMPROVE THE QUALITY OF LIFE FOR PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD)?

M. Schoultz[1,*], I. Atherton[1], R. Kyle[1], A. Watson[1]
[1]*University of Stirling, Inverness, United Kingdom*
Contact E-mail Address: *ms84@stir.ac.uk*

INTRODUCTION: Around 30% of patients with IBD report depression and anxiety and require psychological support. A prolonged effect of such comorbidities has been associated with poorer quality of life (QoL) and exacerbation of IBD symptoms. Mindfulness-Based Cognitive Therapy (MBCT) is a psychological intervention successful in improving depression and anxiety scores in depressed patients, but no previous randomised controlled trial has tested its possible effects on IBD patients.
AIMS & METHODS: The aim of this study was to evaluate the feasibility and acceptability of MBCT with IBD patients and assess its possible effect on QoL, depression, anxiety, disease activity and dispositional mindfulness.
IBD patients (n = 44) recruited from outpatient gastroenterology clinics in two Scottish NHS Boards were randomised to receive MBCT (intervention group n = 22) or allocated to a wait-list (control group n = 22). The intervention was 16 hours of structured group MBCT training over 8 consecutive weeks plus guided home practice and an hour of monthly follow up session for four months. Primary outcome was feasibility and acceptability of MBCT assessed by a self-complete questionnaire. Secondary outcomes included: QoL, depression, anxiety, disease activity and dispositional mindfulness assessed at three points: baseline, post intervention and six month follow up.
RESULTS: 24 patients completed the trial. All patients described the MBCT program as a feasible and useful method and 100% would recommend MBCT to other IBD patients. Dispositional mindfulness significantly improved ($p = .03$) in the intervention group at post intervention and follow up. QoL, depression, anxiety and disease activity scores also showed promising improvement in the intervention group.
CONCLUSION: A larger randomised controlled trial of MBCT for patients with IBD is feasible and pilot data suggests that MBCT significantly improved dispositional mindfulness in IBD patients and also has the potential to improve QoL, depression, anxiety and disease activity scores. MBCT offered in combination to standard care holds a potential to benefit IBD patients.
Disclosure of Interest: M. Schoultz: none, I. Atherton: none, R. Kyle: none, A. Watson: none

P0909 ARE HIGH INFLIXIMAB TROUGH LEVELS ASSOCIATED WITH IMPAIRED QUALITY OF LIFE IN IBD PATIENTS IN CLINICAL AND BIOCHEMICAL REMISSION ON INFLIXIMAB MAINTENANCE THERAPY?

M. Löwenberg[1,*], J.F. Brandse[1], L.M. Vos[1], C. I. Ponsioen[1], G.R. Van den Brink[1], G.R. D'Haens[1] on behalf of IBD group AMC Amsterdam

INTRODUCTION: Preliminary evidence suggests a therapeutic window for infliximab (IFX) trough levels (TLs) in patients with inflammatory bowel disease (IBD). It remains unknown if higher or presumably 'supra-therapeutic' TLs are associated with adverse effects. The aim of this study was to identify a possible association between high TLs, side effects of IFX treatment and quality of life.
AIMS & METHODS: We performed a cross-sectional study in IBD patients in clinical and biochemical remission whilst receiving IFX maintenance therapy. Clinical remission was defined as HBI < 5 for Crohn's disease (CD) and CCAI < 5 for ulcerative colitis (UC). Biochemical remission was defined as a fecal calprotectin < 250 ug/g. IFX TLs and biochemical markers (Hb, Ht, TSH, CRP and vitamin D) were assessed to rule out alternative diagnoses for fatigue. Patients were excluded in case of pregnancy or diseases such as cancer, infections or rheumatologic disorders. Quality of life was assessed by IBDQ and SF-36. Fatigue and joint pain were measured by visual analogue scores (VAS) and for skin lesions a skin questionnaire was completed. The patient cohort was separated in groups consisting of patients with 'therapeutic' (IFX TL 3-7 ug/ml) and 'supra-therapeutic' (IFX TL > 7 ug/ml) TLs. Patients and investigators were unaware of TL results when completing the questionnaires and during the assessment of clinical and biochemical remission. In total 115 patients on IFX maintenance treatment (5 or 10 mg/kg) were approached of which 46 patients (CD n = 33, UC n = 13) were deemed fit for inclusion.
RESULTS: We did not find a significant correlation between the severity of side-effects and IFX TLs. Moreover, no correlation was observed between quality of life and IFX TLs. Patients with supra-therapeutic TLs had lower median scores (although not significant) compared to the therapeutic TL group on several SF-36 domains: e.g. SFphysical, SFsocial, SFpain, SFrole-physical and SFperception. The supra-therapeutic group scored lower on the physical

component score (PCS) (43.9 vs. 49.7; p = 0.18) while both groups scored equally on the mental component score (MCS) (47.2 vs. 48.3; p = 0.98). The supra-therapeutic TL group had lower scores on the IBDQ (178 vs. 183; p = 0.35) and joint pain VAS (10 vs. 6; p = 0.67) compared to the therapeutic TL group. Skin problems were more often seen in the therapeutic group versus patients in the supra-therapeutic TL group, but this difference did also not reach statistical significance, Skin score (4 vs. 6; p = 0.097).

CONCLUSION: CD and UC patients who were in clinical and biochemical remission with supra-therapeutic IFX TLs did not show an increase in side-effects nor impaired quality of life compared to patients with therapeutic IFX TLs.

P0910 THE RELATIONSHIP BETWEEN REMISSION STATUS AND HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH MILD-TO-MODERATE ULCERATIVE COLITIS RECEIVING SHORT-TERM AND LONG-TERM DAILY THERAPY WITH MULTIMATRIX MESALAZINE

M.K. Willian[1,*], A. Yarlas[2], A. V. Joshi[1]

Contact E-mail Address: *MWillian@shire.com*

INTRODUCTION: Studies of patients with ulcerative colitis (UC) have found an inverse relationship between disease activity and health-related quality of life (HRQL): Decreases in disease severity predict improvement in HRQL. The current analysis examines whether this association holds at various levels of disease activity by testing whether HRQL differs among patients in complete clinical and endoscopic remission, in partial remission, or not in remission after treatment with multimatrix mesalazine.

AIMS & METHODS: Data were from a multinational, open-label, prospective trial of multimatrix mesalazine (ClinicalTrials.gov ID: NCT01124149). In the initial (acute) treatment phase, patients with active mild-to-moderate UC received 4.8 g/day of multimatrix mesalazine once daily (QD) for 8 weeks. Patients in complete or partial remission at Week 8 were eligible to receive 12 months of maintenance treatment with 2.4 g/day of multimatrix mesalazine QD. Remission status at Week 8 and Month 12 was determined using a modified UC-Disease Activity Index (UC-DAI). Complete remission was defined as UC-DAI $\leq$1 with scores of 0 on both rectal bleeding (RB) and stool frequency (SF) components and $\geq$1-point reduction from Baseline in the endoscopy component. Partial remission was defined as UC-DAI $\leq$3, RB+SF $\leq$1, and not in complete remission. At Baseline, Week 8, and Month 12, patients completed measures of generic HRQL (12-item Short-Form survey [SF-12v2]) and disease-specific HRQL (Shortened Inflammatory Bowel Disease Questionnaire [SIBDQ]). Analysis of variance models tested whether HRQL scores at Week 8 and Month 12 differed by remission status. Repeated-measures mixed-effects models (RMMM) tested if changes in HRQL scores across Baseline, Week 8, and Month 12 visits varied by remission status. Analyses of each phase included only patients who fully completed treatment during that phase.

RESULTS: The numbers of patients in complete, partial, and no remission, respectively, were 186 (30.0%), 282 (45.4%) and 153 (24.6%) at Week 8 for acute phase completers, and 159 (50.6%), 103 (32.8%) and 52 (16.6%) at Month 12 for maintenance phase completers. At both Week 8 and Month 12 visits, patients in complete or partial remission scored better on all SF-12v2 and SIBDQ domains than those not in remission (all Bonferroni-adjusted $P < 0.001$). At Week 8, scores on most HRQL domains (all but the SF-12v2 pain domain, and social functioning domains on both instruments) did not statistically differ between patients in complete vs. partial remission. HRQL scores also did not differ between complete and partial remission groups at Month 12 (all Bonferroni-adjusted $P \geq 0.130$). Estimated parameters and means from RMMM models indicated that patients who achieved or maintained complete or partial remission showed similarly larger improvements and better maintenance of HRQL than patients not in remission.

CONCLUSION: Patients with UC in complete or partial remission who completed short-term and long-term daily treatment with multimatrix mesalazine had similar HRQL. Both groups had better HRQL than completers not in remission. These results indicate that achievement of partial remission of UC provides advantages comparable to those of complete remission with respect to improvement and maintenance of HRQL.

P0911 DISEASE BURDEN AND TREATMENT IMPACT IN PATIENTS WITH MILD-TO-MODERATE ULCERATIVE COLITIS: A COMPARISON OF RESULTS FROM TWO OPEN-LABEL TRIALS

M.K. Willian[1,*], A. Yarlas[2], A. V. Joshi[1]
[1]*Shire, Wayne, PA,* [2]*Optum, Lincoln, RI, United States*
Contact E-mail Address: *MWillian@shire.com*

INTRODUCTION: Data addressing the burden of ulcerative colitis (UC) on health-related quality of life (HRQL) and the impact of multimatrix mesalamine treatment on HRQL and work-related outcomes (WRO) of patients with UC were compared across 2 similarly-designed clinical trials. The objective of this comparison was to examine the robustness and relative magnitudes of these effects among multiple samples.

AIMS & METHODS: Trials 409 (ClinicalTrials.gov ID: NCT01124149) and 404 (NCT00446849) were each multicenter, open-label, prospective studies of multimatrix mesalazine treatment for adults with active mild-to-moderate UC. Both trials included an 8-week acute treatment phase followed by a 12-month maintenance treatment phase. This analysis includes acute phase data only. Patients received 4.8 g/day (Trial 409) or 2.4 to 4.8 g/day (Trial 404) of multimatrix mesalazine once daily for 8 weeks. At Baseline and Week 8 visits, all patients completed 3 patient-reported outcomes (PRO) instruments, measuring HRQL (the 12-item Short-Form survey [SF-12v2] and the Short Inflammatory Bowel Disease Questionnaire [SIBDQ]) and WRO (Work Productivity and Activity Impairment Questionnaire: UC [WPAI:UC]). Within each trial, burden of UC on HRQL was estimated as the deficits in patients' SF-12v2 scores relative to scores from a US general population sample (USGPS). Analysis of variance (ANOVA) models compared the magnitude of pre-treatment disease burden, and differences in Baseline PRO scores, between trials. ANOVA models also tested between-trial differences in burden at Week 8 for patients who completed treatment. Analysis of covariance (ANCOVA) models tested for between-trial differences in PRO scores at Week 8, controlling for Baseline scores for treatment completers.

RESULTS: In Trial 404, 42.4% (56/132) of patients completed treatment at 8 weeks, compared to 89.1% (639/717) in Trial 409. Patients in Trial 409, compared to Trial 404, showed greater burden on several SF-12v2 domains (general health, limitations due to emotional problems, social functioning, and mental health; $P < 0.05$ for differences). Comparisons of Baseline PRO scores between trials found worse scores for Trial 409 than Trial 404 on several domains of the SF-12v2 (general health, limitations due to emotional problems, and mental health), SIBDQ (social and emotional function), and WPAI:UC (presenteeism and overall work impairment); $P < 0.05$ for differences. Comparison of burden at Week 8 for treatment completers found no trial differences for any SF-12v2 domains (all $P > 0.05$); burden at Week 8 was similarly small for each trial, with most domain scores at least equivalent to those scores of the USGPS. Direct comparisons of Week 8 post-treatment scores between trials found no significant differences for any PRO measure (all $P > 0.05$).

CONCLUSION: Patients in Trial 409 entered treatment with a larger disease burden on HRQL and with generally worse HRQL and WRO than patients in Trial 404. At Week 8, there were no between-trial differences in burden on HRQL or for direct comparisons of all HRQL and WRO measures for treatment completers. Further, for patients in both trials, Week 8 scores on most SF-12v2 domains were not below scores from the USGPS, indicating that patients with UC achieved near-normal levels of most aspects of HRQL following 8 weeks of daily multimatrix mesalazine treatment.

P0912 EFFICACY AND SAFETY OF INFLIXIMAB SALVAGE THERAPY IN PATIENTS WITH ULCAERATIVE COLITIS AFTER FAILURE OF TACROLIMUS INDUCTION THERAPY

M. Sugimura[1,*], M. Iwabuchi[1], H. Takahashi[1], K. Shishikura[1], K. Ukai[1], K. Tadokoro[1]
[1]*Gastroenterology, Sendai medical center, Sendai, Japan*

INTRODUCTION: Tacrolimus and anti-TNFα therapy like infliximab have been shown to be effective for the treatment of patients with moderate to severe corticosteroid-refractory/dependent ulcerative colitis. However, currently, there are no guidelines pertained to the order or the timing of these medications.

AIMS & METHODS: In our hospital, tacrolimus precedes infliximab as a second-line therapy for patients of ulcerative colitis. This study was to investigate the efficacy and safety of infliximab in patients with moderate to severe corticosteroid-refractory/dependent ulcerative colitis who failed to respond to tacrolimus induction therapy. We enrolled twenty-nine patients (16 male, 13 female; mean age 43.9) treated with tacrolimus between January 2010 and January 2014, and 11 (4 male, 7 female; mean age 47.6) out of these patients were treated with infliximab because of refractoriness or loss of response to tacrolimus, or no tolerance. We assessed therapeutic outcomes at baseline, 8, and 30 weeks for 11 patients treated with infliximab using Lichtiger index, a score of which less than or equal to 4 was defined as clinical remission.

RESULTS: Mean Lichtiger index was significantly decreased to 11.6, 6.7, and 5.1 at baseline, 8, and 30 weeks, respectively ($P < 0.05$). Five patients (45%) showed clinical remission at 8 weeks and six (54%) showed clinical remission at 30 weeks. Three patients who did not respond to infliximab were all over 60 years old, and finally underwent colectomy. Rates of clinical remission at 8 and 30 weeks were 42.4% and 53.1% in tacrolimus responders (2 loss of response; 4 no tolerance), 46.3% and 56.4% even in tacrolimus nonresponders (4 patients). There was no significant difference in clinical remission rate between tacrolimus responders and nonresponders. No serious adverse events were encountered.

CONCLUSION: Infliximab salvage therapy following tacrolimus appeared to be efficacious in both tacrolimus responders (loss of response or no tolerance) and in nonresponders (refractoriness), and 8 (72.7%) of 11 patients could avoid colectomy. Infliximab salvage therapy is considered to be useful and well tolerated.

INTRODUCTION: Faecal microbiota transplant (FMT) is a novel highly effective treatment for Clostridium difficile infection (CDI).* Initial clinical trials and case reports suggest that this may be a promising therapy for patients with inflammatory bowel disease (IBD).** As part of a patient audit regarding our FMT treatment for CDI we performed a survey to evaluate patient attitudes to potentially receiving FMT as treatment for IBD and gauged attitudes towards participation in a future clinical trial evaluating the effectiveness of FMT in IBD.
AIMS & METHODS: We conducted a structured survey on patients attending gastroenterology clinics to assess perceptions of effectiveness, tolerability, safety and thresholds for considering FMT as a treatment.
RESULTS: We collected 105 responses (M:F 46:59, Median age 36 years) including 80 (76%) from patients with IBD. 91% (96/105) felt that this treatment would be effective and 56% (59/105) did not consider it unpleasant. 96% (101/105) patients perceived it to be safe. 72% (76/105) and 82% (86/105) would be comfortable with having FMT via an NG tube or rectal enema route respectively. 78% (82/105) did not have any concerns regarding the faecal transplant being obtained from a screened unrelated donor. 74% (78/105) of the patients would be willing to have FMT as a first line treatment of CDI. 50% (40/80) of IBD patients surveyed would consider FMT as a first line treatment of their IBD, 85% (68/80) if steroid resistant or dependant, 89% (71/80) if failing on biologics and 94% (75/80) as a salvage treatment option prior to surgery. Importantly 75% (60/80) would consider taking part in a clinical trial evaluating faecal microbiota transplantation for treatment of their IBD.
CONCLUSION: In this survey of patient attitudes to FMT amongst patients from the UK, we found that patients perceived FMT as a potentially effective, safe, tolerable treatment and were inclined to consider this as part of conventional medical therapy for IBD. In our cohort we did not discover reluctance to take part in a trial of FMT for treatment of IBD.

P0914 ADALILMUMAB SERUM CONCENTRATION AS A PREDICTOR FOR CLINICAL EFFICACY - ROC ANALYSES

N.M. Mostafa[1,*], A.M. Robinson[1], S. Sharma[1], W.J. Sandborn[2], S. Ghosh[3], S.B. Hanauer[4], J.-F. Colombel[5], R.B. Thakkar[1], W.M. Awni[1]

INTRODUCTION: The relationship between adalimumab trough concentration and efficacy (clinical remission and response) in patients with ulcerative colitis has been previously characterized[1]. The purpose of this analysis was to explore whether an adalimumab concentration threshold is predictive of adalimumab efficacy in ulcerative colitis.
AIMS & METHODS: Data from 242 patients with moderate to severe ulcerative colitis enrolled in the adalimumab treatment arm in ULTRA2 were included in the analysis. Patients received 160/80 mg adalimumab at Week 0/ 2 and 40 mg eow thereafter. Adalimumab trough concentration at Week 8 was used to predict clinical remission and response per Full Mayo scores at Week 8, 32 or 52. In case of dropouts or missing Week 8 concentrations, values were imputed using last-observation-carried-forward method. For Week 8, 32 and 52, efficacy, non-responder imputation was implemented such that subjects were considered not in remission/response if they were discontinued or moved to open-label prior to the time point of efficacy assessment or if they had a missing Mayo score at the time point of efficacy assessment. Receiver operating characteristic (ROC) curves were constructed and area-under the ROC curves (AUC) were calculated using R Ver 3.0.3. Determination of predictive adalimumab trough concentration thresholds was based on the choice of corresponding specificity and sensitivity pair determined from the ROC curves.
RESULTS: Mean (range) adalimumab trough concentrations at Week 8 were 8.7 (0-22.8 mcg/mL). ROC curves showed AUC values ranging from 0.64 to 0.67 for remission and 0.55 to 0.63 for response at Week 8, 32 and 52. No concentration threshold exhibited a combination of specificity and sensitivity that was highly predictive of remission or response at Week 8, 32 or 52. The highest value for AUC (0.67) was associated with Week 52 remission, for which the algorithm-determined threshold showed a specificity and sensitivity of 0.52and 0.78, respectively.
CONCLUSION: ROC analyses were conducted and did not identify an adalimumab trough concentration threshold that predicts clinical remission or response at Week 8, 32 or 52 in UC.

P0915 EFFICACY OF CONCOMITANT MESALAMINE SUPPOSITORY IN PATIENTS WITH ACTIVE ULCERATIVE COLITIS WHO SHOWED INADEQUATE RESPONSE TO ORAL 5-AMINOSALICYLIC ACID PREPARATIONS: A PROSPECTIVE STUDY

N. Yoshimura[1,*], T. Kawaguchi[1], M. Sako[1], M. Takazoe[1]
[1]*Department of Internal Medicine, Division of IBD, Tokyo Yamate Medical Centre, Tokyo, Japan*

INTRODUCTION: Oral 5-aminosalicylic acid (5-ASA) preparations have been widely given as first-line medications for inducing and maintaining remission in patients with mildly to moderately active ulcerative colitis (UC). Further, for distal UC, topical salicylate preparations as enema or suppository have been applied. However, up to now, there is no widely accepted evidence for efficacy of concomitant mesalamine suppository in patients with active UC who do not respond well to oral 5-ASA preparations.
AIMS & METHODS: We were interested to evaluate the efficacy of concomitant Pentasa suppository as remission induction therapy in patients who had active UC while on oral mesalamine preparations for at least 4 weeks. In a single-centre prospective setting, 114 consecutive patients with mildly to moderately active UC with rectal inflammation who had shown inadequate response to oral 5-ASA preparations were included. All patients received concomitant Pentasa 1g suppository rectally once a day for 4 weeks together with the ongoing oral 5-ASA preparations. No patient received corticosteroid or immunosuppressant. At week 4, clinical efficacy for Pentasa suppository was evaluated by the UC-Disease Activity Index (UC-DAI), including the 3 sub-scores. Clinical remission was defined as the bleeding sub-score = 0.and a decrease of $\geq$ 3 in the UC-DAI score, while clinical response meant a decrease of $\geq$ 1 in the UC-DAI score.
RESULTS: Of the 114 patients, 41 (36.0%) achieved clinical remission, 37 (32.4%) achieved response level. The UC-DAI fell from 3.2±0.8 at entry to 1.6±1.7 at week 4 ($n = 114$, $P < 0.001$). The bleeding sub-score fell from 1.0±0.2 to 0.4±0.5 ($P < 0.001$). Regarding the response rate vs extent of UC, the UC-DAI fell from 3.2±0.8 to 1.5±1.7 in patients with proctitis ($n = 101$, $P < 0.001$), and from 3.0±0.6 to 1.8±1.5 in patients with left-sided colitis ($n = 12$, $P < 0.05$), and one patient with pancolitis worsened. Further, by concomitant Pentasa suppository, the bleeding sub-score in patients who did not respond well to oral 5-ASA preparations alone ($n = 60$) fell from 1.0±0.1 to 0.4±0.5; in sulphasalazine-treated subgroup ($n = 21$), mean dose 3.7±1.2g/day, range 1.5-6.0/day fell from 1.0 ± 0.0 to 0.4±0.5 ($P < 0.01$); in Pentasa ($n = 7$) 1.7±0.6g/day, range 1.5-3.0/day fell from 1.0 ± 0.0 to 0.3±0.5 ($P < 0.05$); in Asacol ($n = 32$) 3.5±0.3g/day, range 2.4-3.6/day fell from 1.0 ± 0.2 to 0.4±0.6 ($P < 0.001$), reflecting significant efficacy for concomitant Pentasa suppository in patients who did not respond well to high dose oral 5-ASA preparations alone. No serious adverse events were observed.
CONCLUSION: This is the first study in Japan that has investigated the efficacy of Pentasa suppository in patients who did not respond well to oral 5-ASA preparations. Based on the outcomes of the present investigation, we believe that patients with distal UC who remain with active UC while on oral 5-ASA preparations alone should benefit from receiving concomitant Pentasa suppository.

P0916 PREDICTORS AND FREQUENCY OF ANTI-TNF DOSE ESCALATION AND DE-ESCALATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

N. Viazis[1], T. Koukouratos[1], J. Anastasiou[1], M. Giakoumis[1], C. Triantos[2], C. Tsolias[2], G. Theocharis[2], E. Vienna[1], **D.G. Karamanolis**[1,*]
[1]*Department of Gastroenterology, EVANGELISMOS HOSPITAL, Athens,* [2]*Department of Gastroenterology, University Hospital of Patras, Patras, Greece*
Contact E-mail Address: *nikos.viazis@gmail.com*

INTRODUCTION: The role of anti-TNF therapy in patients with Inflammatory Bowel Disease (IBD) is well established; however in some patient dose needs to be intensified in order to maintain remission. We aimed to determine predictors and frequency of anti-TNF dose escalation and de-escalation in patients treated with infliximab or adalimumab for ulcerative colitis (UC) or Crohn's disease (CD).
AIMS & METHODS: Since September 2010, all consecutive patients treated with infliximab or adalimumab for active Crohn's disease or ulcerative colitis at the IBD clinics of the two participating centers (both tertiary referral hospitals) were prospectively included in this cohort study. All patients were anti-TNF

naïve, while concomitant azathioprine was administered for 6 months. The outcome of anti-TNF therapy was consequently evaluated every 2 months throughout the follow up period. Secondary loss of response was defined in those patients who initially responded to anti-TNF therapy and subsequently lost clinical response. Patients were considered to initially respond to anti-TNF therapy if they experienced a clear improvement in symptoms and drop in CRP if elevated at baseline at week 6 through week 14. Absence of primary response precluded the patient from further analysis. Patients were considered to lose response if symptoms reappeared and CRP re-elevated at any time period after the first 14 weeks of anti-TNF therapy. For patients losing response, anti-TNF dose escalation was scheduled. During the follow up period and after 1 year of intensified administration, anti-TNF was de-escalated in patients in remission (absence of symptoms, normal CRP).
RESULTS: During the study period 161 IBD patients (CD = 133, UC = 28) were started on infliximab (n = 96) or adalimumb (n = 65) in the participating centers; however 29 (18.0%) did not respond to therapy (absence of primary response) and were excluded from further analysis. From the remaining 132 patients (CD = 113, UC = 19, infliximab = 77, adalimumab = 5), 31 (23.5%) needed a dose escalation for maintenance of remission (CD = 30, UC = 1), during the median follow up period of 26 months (range 2 to 36 months). Factors associated with the need for anti-TNF dose escalation were azathioprine discontinuation earlier than 6 months in all patients and smoking in CD patients. Most patients achieved clinical remission (n = 25, 80.6%) without any other intervention and among them, 16 (64%) were successfully de-escalated to the standard maintenance infliximab or adalimumab dose schedule, after 1 year of intensified anti-TNF administration.
CONCLUSION: A substantial number of UC and CD patients (23.5%) initially responding to anti-TNF therapy required dose escalation to maintain disease remission. Factors associated with anti-TNF loss of response were discontinuation of azathiorpine co-administration earlier than 6 months in all patients and smoking in Crohn's disease patients. Dose escalation was successful in 80.6% of the patients studied and among them dose de-escalation was possible in 64%, after 12 months of intensified anti-TNF administration

P0917 THE IMPACT OF ANTI-TNF THERAPY AND SURGERY ON PERIANAL CROHN'S FISTULAS

N.A. Yassin[1,*], A. Askari[1], J. Warusavitarne[1], O. Faiz[1], T. Athanasiou[2], R. Phillips[1], A. Hart[1]
[1]*St Mark's Hospital and Academic Institute,* [2]*St Mary's Hospital, London, United Kingdom*
Contact E-mail Address: *nayassin@gmail.com*

INTRODUCTION: The management of perianal Crohn's fistulae represents a significant challenge. Combination medical and surgical therapy, guided by radiology is often required. The aim of this systematic review and meta-analysis is to assess healing rates between medical treatment (anti-TNF-a therapies +/- immunomodulators) or surgical treatment alone compared to combined medical and surgical treatment in fistulating Crohn's Disease (CD).
AIMS & METHODS: This review was carried out according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Two independent reviewers searched PubMed (January 1966 to January 2014), the Cochrane Database, and EMBASE (January 1980 – January 2014). All studies investigating anti-TNF-α therapy combined with surgery as a treatment for Crohn's perianal and rectovaginal fistulas were included. Meta analysis was carried out using a random effects model. Odds ratios and confidence intervals were generated.
RESULTS: A total of 24 articles were included. Six were amenable to quantitative data synthesis and were meta-analysed. The total population was 1138 patients; 460 (40.4%) received single treatment with either biological or surgical therapy, and 682 (60%) received combined biological and surgical therapy. Forty four percent of the patients were male (n = 503) and 48.6% were female (n = 553). Across the studies, the mean age ranged from 28 years to 46 years of age. Similarly the median age reported, ranged from 25 years to 43 years old. The mean follow up ranged from 2.5 to 68.8 months whilst the median was 8 to 62.5 months.
Within the six studies, the total population was 686 patients (single therapy, n = 382, combination therapy n = 304). In the single therapy group (either biologics alone or surgery), out of 382 patients, 184 patients were in complete remission (48.2%). This was lower than the healing rate of the combined therapy group 170/304 (56.0%). Patients who had single therapy were less likely to go into complete remission when compared with the combination therapy group (OR 0.69, CI 0.50-0.95, p = 0.02).
CONCLUSION: Combined surgical and anti-TNF-a therapy has an additional beneficial effect on perianal fistula healing in patients with Crohn's disease, compared with surgery or medical therapy alone. A well-designed Crohn's perianal fistula clinical trial is required in a multidisciplinary medical and surgical setting with clearly defined end points of clinical and radiological healing.

P0918 LONG TERM OUTCOMES OF ANTI-TNF THERAPY FOR FISTULISING PERIANAL CROHN'S DISEASE

N.A. Yassin[1,*], A. Askari[1], L. Ferrari[1], J. Warusavitarne[1], C. Vaizey[1], O. Faiz[1], R. Phillips[1], A. Hart[1]
[1]*St Mark's Hospital and Academic Institute, London, United Kingdom*
Contact E-mail Address: *nayassin@gmail.com*

INTRODUCTION: Fistulising perianal Crohn's disease (CD) is a challenging condition to treat and a multidisciplinary approach to treatment is required. Little is known regarding long-term efficacy of anti-TNF therapy for this group of patients.
AIMS & METHODS: We evaluated the clinical and radiological outcomes and the effects of biological therapy on our cohort of CD patients.
A database of 173 consecutive patients with Crohn's disease treated at our institution between 2005 and 2014 was established. Data on patient demographics and relevant outcomes were collated from medical, electronic and radiological reports. Chi-Squared, Cox regression and binary logistic analysis were used for statistical analyses.
RESULTS: Patients received Infliximab therapy (61%), Adalimumab therapy (6%) or switched between the two (33%) for the treatment of perianal fistulas. Forty-five percent of the patients were male and 55% female, with 13.5% being current smokers and 68% previous smokers. A fistula diagnosis and treatment occurred in 8% of patients prior to Crohn's diagnosis with a 10-year gap between a diagnosis of fistula and a diagnosis of CD in 65% of patients. Montreal classification identified that 40% of patients had L1 disease, 76% L2, 28% L3 and 2% L4, and 3.5% had perianal disease only. Proctitis was noted in 36% of patients.
At the start of anti-TNF therapy, 32% of patients had a simple fistula, 68% had a complex fistula at the baseline MRI. Combined therapy with thiopurines was observed in 58% of patients. Seton drainage was performed for 51% of patients at the start of anti-TNF therapy.
Overall, after a median follow-up period of 52 months (range 1-163), 32% of patients were in clinical remission, 74% of patients had a clinical response to treatment and the recurrence rate after remission was 12%. Radiological remission was noted in 14% of patients, response in 62% of patients and recurrence of 4.7% over a median of 37 months (range 3-101) MRI follow-up.
With regards to complexity of fistula, Cox Regression analysis demonstrated that clinical remission was seen in 47% of patients with a classification of a simple fistula, and 22% of those with a complex fistula ($p < 0.01$). Radiological remission however was noted in 28% of patients with a simple fistula and 5% of those with a complex fistula ($p < 0.01$). Factors influencing the time to clinical response were fistula duration ($p = 0.03$), and the concomitant use of immunomodulators ($p = 0.02$).
Multivaraite binary logistic regression revealed that patients who have a Montreal classification of L1 disease are 64% less likely to achieve clinical remission (OR = 0.36, CI = 0.17-0.79 p = 0.01), and those who have L3 disease are 60% less likely to achieve remission (OR = 0.40, CI = 0.17-0.93, p = 0.03). Having proctitis at the start of biological therapy predicts a 60% decrease in the likelihood of clinical remission in this group of patients (OR = 0.40, CI = 0.16-0.98, p = 0.04).
CONCLUSION: About three-quarters of patients with fistulising perianal Crohn's disease had clinical response to biological therapy, whereas two-thirds had a radiological response. Fistula complexity and the presence of ileal and ileocolonic disease were predictors of a worse clinical and radiological outcome. Radiological remission is an important outcome measure to assessment in predicting sustained fistula healing.

P0919 ANAEMIA DEVELOPS IN PATIENTS FOLLOWING ILEOANAL POUCH ANASTOMOSIS (IPAA): A SINGLE CENTRE STUDY REVIEW OF IPAA PATIENTS

E.Van Blankenstein[1,*], M.F. Jaboli[1], T.C. Shepherd[1], M. Hamilton[1], E. Despott[1], G. Erian[1], O. Epstein[1], C. Murray[1]
[1]*Gastroenterology, Royal Free London, London, United Kingdom*
Contact E-mail Address: *emily.blankenstein.09@ucl.ac.uk*

INTRODUCTION: Anaemia is reported in 17% of patients following IPAA[1]. However, few studies specifically report the prevalence of iron deficiency anaemia (IDA) following IPAA: One small study of 18 patients report 56% developed IDA[2]. There are no specific guidelines on investigating IDA in IPAA.
AIMS & METHODS: Retrospective demographic and pre and post-operatively medical data from IPAA patients at the Royal Free Hospital was collected to analyse the frequency of anaemia, specifically IDA, and its subsequent investigation and treatment. Anaemia was defined as Haemoglobin (Hb) < 13g/dL for males or <12g/dL for females; iron deficiency defined using CRP adjusted ferritin.
RESULTS: 80 patients (51% [41] male), median age 38 years (range 19 to 74) were included. Pre-operatively all 80 had a diagnosis of ulcerative colitis (UC), although subsequent histological analysis was most consistent with Crohn's Disease in 5% [4/80] and Indeterminate Colitis in 2.5% [2/80]. Median age at diagnosis 17.5 years, and median age at pouch formation 28 years.
16% [13/80] were anaemic pre-operatively, while 64% [51/80] developed anaemia within a 6 month period post-operatively. 53% [42/80] patients were iron deficient and 21% [17/80] patients had IDA post-operatively. Most (76% [13/17]) were treated with either oral or parenteral iron. 82% [14/17] were investigated with sigmoidoscopy, 29% [5/17] with OGD, 65% [11/17] had a TTG checked and 29% [5/17] with video wireless capsule endoscopy. 94% [16/17] had pouchitis.
CONCLUSION: We report that anaemia develops many months post IPAA in a large proportion of patients. Many patients are iron deficient and some have IDA. IDA was well treated, but investigated predominantly with only sigmoidoscopy; invariably pouchitis was discovered and felt to be the aetiology of IDA. We suggest that there is a need for further research into the mechanisms of anaemia following IPAA. IDA, even when pouchitis is discovered, should still be investigated following BSG guidelines, given 20% of patients will have dual pathology.

P0920 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR DYSPLASTIC LESIONS IN LONG-STANDING ULCERATIVE COLITIS: LESION DEFINITION AND CURATIVE RESECTION

F. Iacopini[1,*], C. Grossi[1], T. Gotoda[2], T. Matsuda[3], Y. Saito[3], G. Costamagna[4], A. Scozzarro[1]
[1]*Gastroenterology and Endoscopy Unit, Ospedale S. Giuseppe, Albano L; Rome, Italy,* [2]*Department of Gastroenterology and Hepatology, Tokyo Medical University,* [3]*Endoscopy Unit, National Cancer Center Hospital, Tokyo, Japan,* [4]*European Endoscopy Training Center, Catholic University, Rome, Italy*
Contact E-mail Address: *federico.iacopini@gmail.com*

INTRODUCTION: Long-standing inflammatory bowel diseases (IBD) are associated to an increased risk of dysplasia and cancer, and proctocolectomy is recommended for flat dysplasia and dysplastic lesions associated with dysplasia in the surrounding flat mucosa (DALM) due to the risk of synchronous / metachronous advanced cancer. Contrary to resection by snare, endoscopic submucosal dissection (ESD) achieves curative resections with wide margins of normal mucosa regardless lesion size and submucosal (SM) fibrosis.
AIMS & METHODS: To assess ESD feasibility of curative resection of IBD dysplastic lesions and differentiate DALM from sporadic adenomatous-like mass (ALM). From May 2011, consecutive patients with long-standing (>8 yrs) extended ulcerative colitis (UC) and a superficial dysplastic lesion within the colitic mucosa were prospectively enrolled. Dysplastic lesions were characterized by chromoendoscopy (CE) with indigo-carmine 0.4% and acetic acid 1%, and narrow band imaging (NBI) with no magnification. ESD was performed according to the standard technique. Mucosal incision was planned at >5 mm from lesion margins. SM fibrosis was graded from 0 to 2. Follow-up with pan-CE colonoscopy was planned every 6 months after curative resection (low-risk for lymph node metastasis after en bloc R0 resection).
RESULTS: Five patients with 6 lesions were included. Patient mean age was 63 (55-69), UC duration 13 yrs (9-22). Lesion morphology was LST-G homogeneous type in 3, LST-NG flat type in 3. Lesions were located in the right, left colon, and rectum in 3, 2, and 1, respectively. Median diameter was 28 mm (20-40). The rectal lesion had a wide scar from previous transanal endoscopic microsurgery. Acetic acid CE permitted to better delimitate lesion margins; peripheral markings were used in two cases. SM fibrosis was observed in 3 cases during dissection. ESD achieved en bloc, R0 and curative resection in 5 (83%) cases, and failed in the rectal case. Histology showed a T1 cancer with SM-slight invasion in 1 case. Wide margins of normal mucosa were achieved in all successful ESD cases with no flat dysplasia. No complication occurred. No advanced cancers or flat dysplasia on random biopsies were observed within a follow-up of 20 months (16-36).
CONCLUSION: Delineation of IBD dysplastic lesion margins is difficult and requires a multimodal CE approach. The ESD en bloc R0 resection of IBD dysplastic lesions with wide margins of normal mucosa is feasible and permits to accurately differentiate DALM from ALM with important clinical implications.

P0921 INTESTINAL SURGERY FOR CROHN'S DISEASE: ROLE OF PREOPERATIVE THERAPY IN POST OPERATIVE OUTCOME

M. Scarpa[1], M. Martinato[2], E. Bertin[3], A.D. Roit[3], A. Pozza[4], C. Ruffolo[4], R. D'Incà[5], R. Bardini[3], G.C. Sturniolo[5], C. Castoro[6], **I. Angriman**[3,*]
[1]*Oncological Surgery Unit, Veneto Institute of Oncology (IOV-IRCCS),* [2]*Azienda Ospedaliera di Padova,* [3]*General Surgery Unit, University of Padova, Padova,* [4]*General Surgery Unit, Ca' Foncello Hospital, Treviso,* [5]*Gastroenterology Unit, University of Padova,* [6]*Surgical Oncology Unit, Veneto Institute of Oncology (IOV-IRCCS), Padova, Italy*

INTRODUCTION: Patients affected by Crohn's disease (CD) require life-long medical therapy but they can also often require abdominal surgery. The effect of CD therapy on postoperative course is still unclear. The aim of this study was to evaluate the effect of preoperative medical therapy on the outcome of intestinal surgery in these patients.
AIMS & METHODS: Data from a consecutive series of 186 patients with CD operated on at the University of Padova Hospital form 2000 to 2013 were retrieved. Data of their preoperative therapy during the 6 months before surgery were available for 146 patients who were enrolled in this retrospective study. Clinical data and surgical details were retrieved and postoperative complications and reoperation were considered outcome measures. Univariate and multivariate analysis were performed.
RESULTS: No significant difference was observed between patients without data about their preoperative therapy and those with them. Eight patients underwent reoperation in the first 30 postoperative days: two of them for anastomotic leak, three for bleeding, one for obstruction and two for abdominal wound dehiscence. At multivariate analysis preoperative adalimumab and budesonide resulted to be an independent predictor of reoperation (OR = 7,67 (95%CI = 1,49-39,20), p = 0.01 and OR = 6,7749 (95%CI = 0.98-46,48), p = 0.05, respectively). At multivariate analysis neither pharmacological nor clinical variables resulted to predict anastomotic leak.
CONCLUSION: In our series, adalimumab but not infliximab seemed to be associated to early reoperation after intestinal surgery. This may be due to a worst disease severity in patients who needed surgery in spite of biological therapy. Preoperative tapering of budesonide dose seems a safe option before elective abdominal surgery for CD.

P0922 LONG-TERM OUTCOME OF TERMINAL ILEOSTOMY IN CROHN'S DISEASE (CD) PATIENTS AT THE ERA OF BIOLOGICS. A RETROSPECTIVE SINGLE CENTRE STUDY

R. Akrimi-Molière[1], V. Juif[1], L. Dupont-Kazma[1], N. Herraney[1], **J.-M. Reimund**[1,*], **B. Duclos**[1]
[1]*Hépato-Gastroentérologie et Assistance Nutritive, Hôpitaux Universitaires de Strasbourg, CHU de Hautepierre, Strasbourg Cedex, France*

INTRODUCTION: Anti-TNF antibodies (mAbs) significantly changed CD treatment strategy. However, despite their efficacy, several patients failed all available medical therapy and require surgery, in some cases coloproctectomy with terminal ileostomy. By contrast to ileocolonic resection with ileocolonic anastomosis where postoperative relapse risk factors are known, for terminal ileostomy - often considered as at low risk of recurrence, such factors have not been clearly identified.
AIMS & METHODS: We aimed to analyze the long-term outcome of CD patients with terminal ileostomy and to try to find predictive factors of relapse, since anti-TNF mAb were largely used.
All patients with coloproctectomy/terminal ileostomy performed between 1995 and 2010 were considered for this single center study (to ensure homogeneity of the studied group, with a same treatment and follow-up strategy). The following items were recorded: demographic, clinical, biological and therapeutic patients characteristics, frequency and characteristics of disease relapse after ileostomy (defined by the association of clinical symptoms, at least one endoscopic or radiologic result confirming CD relapse, and the need to introduce/change a medical treatment), factors potentially predictive of relapse (including anti-TNF mAb use previous to surgery). Statistical significance was set at $p < 0.05$.
RESULTS: The charts of 1414 patients were reviewed. 51 CD patients with terminal ileostomy were found. Nine were excluded from analysis (5 lost for follow-up, 4 with discharge ileostomy). Among the remaining 42 patients, 23.8% relapsed. Recurrence at 5 and 10 years was of 21.7 and 30.7% respectively, with a mean delay between ileostomy and the first recurrence of 36±37 months (mean follow-up: 8±5 years). 42.9% of patients needed at least one new surgical procedure (for ileostomy complications or CD relapse). Anti-TNF mAb treatment before terminal ileostomy (n = 20/42) did not change the risk to need terminal ileostomy despite ileostomy was performed at a younger age in these patients (40.6±10.6 vs. 51.5±10.6 years; p = 0.01). Multivariate analysis showed that age at ileostomy [Hazard ratio (HR): 0.92 - 95% confidence interval (95% CI): 0.84-1; p = 0.05), presence of granuloma at resection (HR: 6.31 - 95% CI: 1.49-26.75; p = 0.01) and ongoing smoking after ileostomy (HR: 9.11 - 95%CI: 2.19-37.83); p = 0.01) were independent factors associated to CD relapse after ileostomy.
CONCLUSION: In conclusion, despite an increasing use of anti-TNF mAb for CD treatment, long-term CD relapse after terminal ileostomy occurred in 24% of patients. We identified three factors being predictive of risk of recurrence. Among those, presence of granulomas on resected tissue at the time of ileostomy and continuing smoking after ileostomy may allow to identify patients at high relapse risk. These patients are susceptible to need a close long-term postoperative surveillance.

P0923 ENDOSCOPIC BALLOON DILATION OF STRICTURES IN CROHŃS DISEASE PATIENTS: SAFE AND EFFECTIVE ALTERNATIVE TO REPEATED SURGERY

M. Bortlík[1,2,*], D. Duricova[2], M. Lukas[2], N. Machkova[2], V. Hruba[2], I. Romanko[2], K. Mitrova[2], M. Lukas[2]
[1]*Department of Internal Medicine, 1st Medical Faculty, Charles University,* [2]*IBD Clinical and Research Center, ISCARE and 1st Medical Faculty, Charles University, Prague, Czech Republic*
Contact E-mail Address: *mbortlik@seznam.cz*

INTRODUCTION: Endoscopic balloon dilation is frequently used to avoid repetitive surgery in patients with Crohńs disease.
AIMS & METHODS: The aim was to evaluate efficacy and safety of endoscopic balloon dilations in patients with Crohńs disease-related strictures. This was a retrospective study in patients who underwent endoscopic balloon dilation between May 2007 and December 2013 at a single tertiary IBD center. We assessed both short- and long-term efficacy and safety of this procedure as well as relationship between efficacy and specific disease and patients´characteristics.
RESULTS: We performed 220 dilations in 108 patients with Crohńs disease (49 women, median age 37 years, range 13-75), majority of procedures (85%) were performed in anastomotic strictures. Obstructive symptoms preceded only 53% of dilations, remaining procedures were either coincidental, or resulted from regular endoscopic check-up. Technical success (passage with endoscope through the stricture after dilation) was achieved in 77% of procedures, 75% of dilations were effective clinically (relief of obstructive symptoms). Median duration of symptomatic relief was 10 months (range 1-59). Significantly more patients with end-to-end anastomosis lost their obstructive pain after dilation as compared to those with end-to-side anastomosis (89% vs. 61%, resp., p = 0.01, Fisheŕs exact test). In contrary, patients with end-to-side anastomosis had significantly longer clinical effect (median duration 17 months, range 3-55) compared to patients with end-to-end anstomosis (median duration 10 months, range 1-38, p = 0.006, Mann-Whitney test). Technical success was associated with longer duration of symptomatic relief. We have not found any relationship between age, smoking or medical therapy at the time of procedure, and clinical efficacy of dilation. Mild bleeding occured after 9% of dilations, it was stopped

endoscopically in all cases. Serious complications, such as delayed bleeding or perforation were rare (2%), and no patient died.
CONCLUSION: Endoscopic balloon dilation is highly effective and safe therapeutic modality of Crohńs disease-related strictures, especially when the passage of the scope is achieved. Effectiveness of dilation seems not to bee associated with medical treatment.

P0924 FACTORS AFFECTING THE INCIDENCE OF AN EARLY ENDOSCOPIC RECURRENCE AFTER ILEOCOLONIC RESECTION FOR CROHN'S DISEASE: A MULTICENTRE STUDY

T. Yamamoto[1,*], P. Kotze[2], A. Spinelli[3], Y. Suzuki[4], F. Teixeir[5] on behalf of the MULTIPER Study Group
[1]*Inflammatory Bowel Disease Centre, YOKKAICHI HAZU MEDICAL CENTRE, Yokkaichi, Japan,* [2]*Colorectal Surgery Unit, Cajuru University Hospital, Curitiba, Brazil,* [3]*IBD Surgery Unit, Humanitas Research Hospital, Milano, Italy,* [4]*Internal Medicine, Toho University, Sakura, Japan,* [5]*Colorectal Surgery, Gastrosaude, Marilia, Brazil*

INTRODUCTION: An early endoscopic recurrence is frequently observed in patients following resection for Crohn's disease (CD). However, factors affecting the incidence of an early endoscopic recurrence have not been fully determined.
AIMS & METHODS: The aim of this study was to evaluate risk factors for an endoscopic recurrence after ileocolonic resection for CD. This was a retrospective, international multicentre study. All consecutive patients who underwent ileocolonic resections for CD in 7 IBD referral centres from 3 countries (Japan, Brazil, Italy) were initially included in our MULTIPER database. In this study, 127 patients with the first ileocolonoscopy conducted between 6 and 12 months after resection were included. The endoscopic activity score at the proximal site of the ileocolonic anastomosis was determined according to Rutgeerts, and an endoscopic recurrence was defined as a Rutgeerts sore of $\geq$ i2. The following variables were investigated as potential risk factors for an early endoscopic recurrence: sex, age at surgery, location and behaviour (perforating vs non-perforating) of CD, smoking, concomitant perianal lesions, preoperative use of steroids, immunosuppressants and biologics, previous resection, blood transfusion, surgical procedure (open vs laparoscopic), length of resected bowel, type of anastomosis (side-to-side vs end-to-end), postoperative complications, granuloma, and postoperative biologic therapy. To identify risk factors for an endoscopic recurrence, both univariate and multivariate analyses were conducted.
RESULTS: Forty-three patients (34%) developed an endoscopic recurrence which was confirmed at the time of ileocolonoscopy between 6 and 12 months after resection. In the univariate analysis, only preoperative steroid use was significantly associated with a higher rate of an early endoscopic recurrence. Twenty-one of 45 patients (47%) on steroids and 22 of 82 patients (27%) without steroids developed an endoscopic recurrence ($p = 0.04$). In the multivariate analysis, no factors were associated with the incidence of an endoscopic recurrence.
CONCLUSION: This study failed to find any significant factors associated with an endoscopic recurrence after ileocolonic resection for CD. However, prospective studies are necessary to precisely evaluate the impact of perioperative medications on an early endoscopic recurrence.

P0925 HAND-ASSISTED LAPAROSCOPIC VERSUS OPEN COLECTOMY FOR ULCERATIVE COLITIS: SAFETY AND FEASIBILITY

T. Yamamoto[1,*], S. Nakayama[1], K. Matsumoto[1]
[1]*Inflammatory Bowel Disease Centre, YOKKAICHI HAZU MEDICAL CENTRE, Yokkaichi, Japan*

INTRODUCTION: Laparoscopic surgery is now becoming widely used in the management of colorectal cancer. However, safety and feasibility of laparoscopic colectomy for ulcerative colitis (UC) have not been fully evaluated.
AIMS & METHODS: Since 2005, we have introduced hand-assisted laparoscopic surgery (HALS) for patients with UC and extensive Crohn's colitis. This study was to assess safety and feasibility of HALS for UC. Seventy UC patients were treated with HALS (HALS group). The outcomes of HALS were compared with those of open surgery conducted for 70 age-, sex- and disease severity-matched patients (OPEN group).
RESULTS: In both groups, 37 elective patients were treated with a total proctocolectomy and ileal pouch-anal (canal) anastomosis with a loop ileostomy, and 33 emergency patients with a total colectomy (rectal closure) with an end-ileostomy. In the HALS group, intra-operative complications were experienced in two patients (duodenal injury 1, colonic perforation 1). None of the patients required conversion to open procedure, and laparoscopic procedure was successfully completed in all patients. In the HALS group, the mean operative time was 293 minutes, which was significantly longer than 258 minutes in the OPEN group. The mean intra-operative blood loss was not significantly different between the groups. Eighteen patients (26%) in the HALS group and 20 patients (29%) in the OPEN group experienced postoperative complications (not significant). Six patients in the HALS group and 7 patients in the OPEN group required laparotomy for postoperative complications (not significant).
CONCLUSION: Although HALS takes longer time as compared with open surgery, it can be safely conducted without conversion to open procedure. HALS is a feasible option in the surgical management of UC.

P0926 URGENT LOWER GASTROINTESTINAL BLEEDING: IS THERE A PLACE FOR COLONOSCOPY WITHOUT ORAL PREPARATION IN ELDERLY PATIENTS? – A SINGLE CENTRE EXPERIENCE

A.R. Alves[1,*], S. Giestas[1], R. Cardoso[1], S. Lopes[1], P. Figueiredo[1], F. Portela[1], C. Sofia[1]
[1]*Gastroenterology Department, Coimbra Hospital and University Centre, Coimbra, Portugal*
Contact E-mail Address: *alvess.anarita@gmail.com*

INTRODUCTION: In urgent lower gastrointestinal bleeding (LGIB), bowel preparation for colonoscopy is highly influenced by logistic factors, patient tolerance and adverse reactions, particularly in elderly patients. In these cases a colonoscopy can be performed without preparation (WP) or after a cleansing enema (CE).
AIMS & METHODS: The aim of this study was to compare diagnostic accuracy of urgent colonoscopy WP and after CE in elderly patients. It was performed a retrospective study involving patients aged over 70 years with acute LGIB, submitted to colonoscopy WP and after CE, according to the gastroenterologist option, for a 6-month period. Cases with known inflammatory bowel disease or recent polipectomy were excluded. Data related with demographics, clinical information, colonic segment reached in the exam and diagnostic findings in the two groups were compared.
RESULTS: Seventy-four patients (mean age 81.6±6.6 years, 54.4% male) were included. Chronic medication: antiaggregants - 50.0%, anticoagulants - 10.8% and nonsteroidal anti-inflammatory drugs - 4.1%. Mean hemoglobin value at admission was 11.1±2.9g/dl and red blood cell transfusion was required in 24.3% patients. Colonoscopy was performed WP in 70.3% and after CE in 29.7%. Colonic segment reached: cecum - 5.4%, ascending colon - 2.7%, transverse colon - 12.2%, descending colon - 23.0%, sigmoid colon - 52.7% and rectum - 4.1%. Diagnostic findings: ischemic colitis - 29.7%, diverticula - 20.3%, hemorrhoids - 10.8% and neoplasia - 6.8%. There were no statistically significant differences between WP and CE colonoscopies regarding the colonic segment or diagnostic findings. Globally, including the diagnosis considered as definitive by the gastroenterologist, the diagnostic yield of colonoscopy without oral preparation, (WP and after CE) was 56.8%. Transfusion requirement at admission was an independent risk factor for absence of diagnosis, in both groups (OR 11.5; $p < 0.001$).
CONCLUSION: Comparing WP and post CE colonoscopy, there were no differences in the colon segment achieved or in endoscopic findings. Colonoscopy without oral bowel preparation showed to have a limited diagnostic yield. In more severe LGIB (with transfusion requirement) should be considered diagnostic colonoscopy after oral preparation ab initio.

INTRODUCTION: Data on rates of recurrence and mortality throughout the course of colonic angiodysplasia are limited. The aim of this study is to determine rates and risk factors for recurrence and mortality in long-term in a cohort of patients.
AIMS & METHODS: In 2007, data from 2462 patients with lower gastrointestinal bleeding were collected prospectively in 102 french general hospitals; 79 patients (3.2%) bled on colonic angiodysplasia. We retrospectively studied in 2013 the follow up of these patients. Collected data were: rates of death and reccurence, taking anticoagulant and antiplatelets treatments, comorbidity Charlson's score, ischemic and valvular diseases. Data were obtained by contacting the referent gastroenterologist, the general practitionner and sometimes the patient. Predictive factors of recurrence and mortality were studied by univariate analysis.
RESULTS: Data of 46 patients (58.2% of the initial population) were collected; it was 22 women (47.8%). Six patients were excluded because of an early death, 13 patients were lost to sight and in 14 cases no data were available. The median duration of follow up was 3.3 years (OQR 25-75% :1.5-5.4 years). The average age of patients at the end of follow up was 76.8 +/- 9 years; 8 (17.4%) had a valvular disease. Twenty-three patients died (50%), including 4 from bleeding recurrence. Mortality rates at 1 year, 3 years et 5 years were respectively 19.6%, 34.8% and 43.5%. Eighteen patients (39.1%) had at least a bleeding recurrence. Reccurence rates at 1 year, 3 years and 5 years were respectively 19.6%, 34.8% and 39.1%. These reccurences were complicated by 4 deaths. One patient has needed an hemostatic colectomy. Seven patients (38.8% of recurrences) had to stop anticoagulant and antiplatelet treatments because of a recurrence, and 3 have developed after that an ischemic disease (2 strokes and one myocardial infarction). No risk factors of recurrence and mortality was found, especially taking anticoagulant and antiplatelets treatments or a valvular disease. Charlon's score was not higher in dead patients.
CONCLUSION: Bleeding colonic angiodysplasia are a rare cause of lower gastrointestinal bleeding and concern an elderly population. In this study, after a

median follow-up of 3.3 years, the cumulated rate of recurrence was 39.1% and the mortality rate was 54.3%. The continuation of antiplatelet and anticoagulant treatment is not associated with a higher risk of recurrence and conversely stopping aspirin may increase the risk of death because of ischemic diseases.

INTRODUCTION: Data on rates of recurrence and mortality in patients with diverticular bleeding (DB) are limited. The aims of this study were to determine rates and risk factors for recurrence and mortality in a large cohort of patients with previous DB.
AIMS & METHODS: In 2007, data from 2462 patients with lower GI bleeding were collected prospectively in 102 French general hospitals, 789 (32%) had DB. We retrospectively studied in 2013 the follow up of these patients. The following data were collected: recurrence and mortality rates, drug intake (anticoagulants, antiplatelet agents, NSAIDs), rate of surgery and comorbidities (evaluated by the Charlson's score). These data were obtained by contacting the gastroenterologist, the attending physician and sometimes the patient himself. Predictive factors of recurrence and mortality were studied by univariate and multivariate analyses.
RESULTS: Data of 365 patients (47.3 % of the initial population) were collected, including 181 women (49.6 %). Mean age of patients was 84.7±9.7 years. Median duration of follow-up was 3.9 years. Hundred forty eight patients died (40.5%) nine of them after bleeding. Mortality rate at 1, 3 and 5 years were 22 %, 36 % and 52 % respectively. Sixty-nine patients (19.2%) had at least one recurrent bleeding. Recurrence rate at 1, 3 and 5 years were 11 %, 21% and 30% respectively. Among patients with recurrence, 9 died (12.8 % mortality of recurrences) and 3 (4.3%) had surgical hemostasis procedure. Anticoagulation or antiplatelet therapy were discontinued in 17 (19.2%) cases.
Risk factors for mortality by multivariate analysis were: age > 80 years ($p < 0.001$) and a Charlson comorbidity score > 2 ($p = 0.003$). Discontinuation of anticoagulation or antiplatelet therapies was not associated with an excess risk of death by cardiovascular events.
No risk factors for rebleeding were identified in particular taking antiplatelet or anticoagulant therapy. A past history of DB was almost significant ($p = 0.078$).
CONCLUSION: In this population, cumulative recurrence rate was 19.2 % after a median follow up of 3.9 years, and the mortality rate of 40.5 %. The majority of deaths were not related to bleeding. Continuation of anticoagulant and antiplatelet treatment was not associated with an excess risk of rebleeding conversely discontinuation did not significantly increased mortality from ischemic injury.

P0929 OUTCOMES OF URGENT COLONOSCOPY IN PATIENTS WITH LOWER GASTROINTESTINAL BLEEDING

G. Muzzaffar[1,*], **S.M. Gill**[1], A. Nawaz [1], T. Niaz [1] on behalf of Gastroenterology, Maroof International Hospital, Islamabad
[1]*Gastroenterology, Maroof International Hospital, Islamabad, Pakistan*
Contact E-mail Address: *gill95@yahoo.com*

INTRODUCTION: Early endoscopy is the standard of care in upper gastrointestinal bleeding. However most patients with lower gastrointestinal bleeding (LGIB) have favorable outcomes and majority will stop bleeding spontaneously. Therefore the role of urgent colonoscopy in LGIB remains controversial.
AIMS & METHODS: We wanted to study, diagnostic yield and clinical outcome of urgent colonoscopy in patients with Lower gastrointestinal bleed. We prospectively enrolled 140 consecutive patients who presented to our facility with lower gastrointestinal bleed. Study was conducted from January 2012 to December 2012. All patients who had malena, upper GI endoscopy was normal (was not source of bleed) were considered eligible for this study.
RESULTS: 120 urgent colonoscopies were performed for LGIB during study period. 70 (59%) were male. Mean age was 56.5 years and median age was 56.6 years (range 18:8 to 90.0 years). Caecal intubation rate was (60% n 70). 10% (n 12) of patients needed repeat colonoscopy due to inadequate visualization of bowel for definite clinical decisions. (25.0% n 30) had an endoscopic therapy done. 40% (n 12) of them altered the immediate clinical management. Causes were found in (60%n 70) of patients. However only 40% (n - 24) of them had endoscopic therapy and (60% n 46) had no clinical impact on immediate management of patients though the cause was identified. The causes were colorectal ulcers (n 30, 25%), diverticular disease (n 40, 34%), hemorrhoid (n 20, 17 %), colitis (n 20, 17 %), carcinoma (n 10, 8%).
CONCLUSION: Urgent colonoscopy for LGI bleed results in high rate of incomplete examinations. Even when causes were found, only half of them had an impact on the clinical management in terms of endoscopic intervention or change in immediate clinical decision. Therefore, decision to perform urgent colonoscopy for LGIB should be individualized, taking into consideration relative importance of timing of intervention versus colonic preparation and overall impact on Clinical management of patients.

P0930 ENDOSCOPIC BAND LIGATION FOR COLONIC DIVERTICULAR HEMORRHAGE: A LARGE CASE SERIES

K. Nakano[1,*], M. Ego[1], Y. Shimamura[1], T. Ikeya[1], N. Ishii[1]
[1]*Gastroenterology, St. Luke's International Hospital, Tokyo, Japan*

INTRODUCTION: Endoscopic band ligation (EBL) has been performed for haemostasis in colonic diverticular haemorrhage[1]. However, the number of the patients who have colonic diverticular haemorrhage and have been treated by EBL is not sufficient, and the safety and efficacy of EBL in the colon have not been fully established.
AIMS & METHODS: The aim of this study is to evaluate the safety and efficacy of EBL for colonic diverticular haemorrhage. EBL was applied as an initial treatment in 91 consecutive patients (67 males and 24 females; age range: 34-93 years) who presented between June 2009 and March 2014 with definitive colonic diverticular haemorrhage. This type of haemorrhage involves the diverticula with stigmata of recent haemorrhage (SRH) such as active bleeding (AB), non-bleeding visible vessels (NBVV), or adherent clots (AC). We retrospectively evaluated these patients to determine the success rates of EBL and the rates of early re-bleeding (re-bleeding within 30 days of the initial EBL) and to outline any complications such as perforation and abscess formation. Informed written consents for EBL were obtained from all the patients.
RESULTS:

Location in colon (right / left), no	68 / 23
SRH (AB / NBVV / AC), no	33 / 22 / 36
Success rate of EBL (%)	93 (85/91)
Median procedural duration (range) (min)	36 (15-101)
Rate of early re-bleeding after EBL (%)	15.3 (13/85)
Median time to early re-bleeding (range) (days)	2 (0-21)
Complications (%)	0 (0/85)

The results of performing EBL for colonic diverticular haemorrhage are presented in the table. The success rate of EBL was 93% (85/91). Five lesions that had a small orifice and large dome and one lesion with an orifice that was too large could not be adequately suctioned into the suction cup of the endoscopic ligator, and EBL was not successful. Endoscopic clipping or epinephrine injection was performed in these cases, and in one of the cases interventional radiology was also performed for haemostasis. The rate of early re-bleeding after EBL was 15.3% (13/85). Re-bleeding was managed conservatively and/or endoscopically (repeat EBL or endoscopic clipping) except in one case where a right hemicolectomy was performed because of the patient's preference. There were no complications such as perforation or abscess formation after EBL.
CONCLUSION: EBL can be considered to be a safe and effective endoscopic treatment for colonic diverticular haemorrhage.

P0931 GI BLEEDING IN THE MODERN ERA - A 3-YEAR REVIEW AT TALLAGHT HOSPITAL

P. Moore[1,*], D. McNamara[1]
[1]*Tallaght Hospital, Tallaght, Ireland*
Contact E-mail Address: *moorepe@tcd.ie*

INTRODUCTION: Gastrointestinal bleeding is a common clinical condition accounting for up to 13% of Gastroenterology referrals. It frequently requires hospitalization with subsequent intervention and is associated with significant morbidity and mortality. Determining the origin of bleeding can be a challenge. Newly available modalities in both gastroenterology and radiology are available to address obscure bleeding cases.
AIMS & METHODS: a) To examine the role of endoscopic and radiological investigations in a cohort with GI bleeding.
b) To assess the diagnostic performance of available radiological and endoscopic techniques in cases of GI bleeding, including obscure bleeding.
Methods:
A Retrospective analysis was undertaken of patients admitted with Gastrointestinal bleeding at Tallaght Hospital from 2010-2013 via HIPE (Primary discharge diagnosis – Malaena, Haematemesis, Gastrointestinal haemorrhage or IDA due to bleeding). Discharge summaries were reviewed and patients were excluded if they were <18 yrs or had no evidence of bleeding. All radiological and endoscopic investigations were identified from cross-referencing with ''Keogh'' Radiology, Capsule Endoscopy (CE) and Unisoft Endoscopy Reporting Systems. Outpatient investigations were included if prompted by the index admission. Patient demographics, procedures and positivity rates for the various modalities were recorded
RESULTS: In all, 418 patients were identified from HIPE, 106 (25%) were excluded following discharge review. Of the 312 remaining cases the majority were male 176 (56%) with a mean age of 59 years (Range 18-97). In all 294 (94%) presented with overt bleeding vs 18 (6%) with occult bleeding. Of note 18 (6%)

underwent no investigation for bleeding. Of the 294 who had tests, 163 (55%) had either a colonoscopy or OGD and 122 (41%) had both and 39 (13%) proceeded to have additional endoscopic tests, CE and/or Enteroscopy. In all 110 (37%) had a specialized radiological test. After any investigation, 122 (41%) had negative tests with no etiology found. While 77 (26%) had obscure GI bleeding defined as a negative gastroscopy and colonoscopy. In this obscure cohort, only 26 (34%) had 2nd line GI Investigations and disregarding standard CT, only 27 (35%) had a specialized radiological test. Overall 66 (22%) remained obscure despite all investigations. The frequency of investigations by type and positivity rate is illustrated in table 1. Diagnostic yield was highest for standard endoscopy at 48% OGD and 28% Colon whilst also significant for CE (31%), Enteroscopy (50%) and Angiography (50%).
CONCLUSION: Obscure GI bleeding remains common (26%) and the diagnosis often remains elusive despite advanced endoscopic and radiological tests. The diagnostic yield for many commonly employed less specific modalities is poor and suggests changes to the diagnostic paradigm are appropriate.

P0932 HOW TO DETERMINE THE NEED FOR EMERGENCY COLONOSCOPY TO ACHIEVE TIMELY HEMOSTASIS OF LOWER GI BLEEDING

S. Umezawa[1,*], S. Koyama[2], T. Kato[1]
[1]*Division of Gastroenterology,* [2]*Endoscopy Center, Tokyo Metropolitan Hiroo Hospital, Tokyo, Japan*
Contact E-mail Address: *p0a4p7a3n1e8k4o1@yahoo.co.jp*

INTRODUCTION: We occasionally perform endoscopic hemostasis during emergency colonoscopy for lower gastrointestinal (GI) tract bleeding, but endoscopic hemostasis is not always necessary. Making the correct decision about the need for emergency colonoscopy is very important from the perspective of preparation and examination time.
AIMS & METHODS: To investigate how to determine the need for endoscopic hemostasis in cases of lower GI bleeding, 241 cases of lower GI bleeding (excluding post polypectomy bleeding) that underwent CT and emergency colonoscopy between January 2008 and February 2014 were reviewed retrospectively. Glasgow-Blatchford scores (usually used in upper GI bleeding) and the results of CT and colonoscopy were analyzed. The indications for hemostasis were active bleeding, a visible vessel, and adherent clot.
RESULTS: High-frequency colonic bleeding sources included diverticular bleeding (122 cases, 51%), ischemic colitis (52 cases, 22%), and rectal ulcer (15 cases, 6%). Hemostasis was required in 41 (17%) cases. CT findings consisted of extravasation of contrast medium showing active bleeding (group A; 23 cases) and colonic wall thickening showing inflammation (group C; 47 cases). Group B was defined as neither extravasation nor wall thickening (171 cases). Endoscopic hemostasis was performed in 83% of group A (19/23), 13% of group B (22/171), and none of group C. The Glasgow-Blatchford scores without melena were significantly higher in hemostasis cases (7.6 ± 3.8) than in no hemostasis cases (4.3 ± 4.0) ($P<0.01$). Scores of hemostasis cases varied from 1 to 15, and 37 of 41 hemostasis cases had scores of four or more, whereas 109 of 200 of no hemostasis cases had scores of three or less ($P<0.01$). If one takes both group B cases with scores of three or less and group C cases as non emergency cases, there were 119 non-emergency cases. Of these, 116 (97%) were actually no hemostasis cases, that is, use of this criterion would avoid emergency colonoscopy in 58% of no hemostasis cases. The remaining three hemostasis cases all had slight bleeding.
CONCLUSION: CT findings and Glasgow-Blatchford scores are useful for determining the need for emergency colonoscopy to achieve timely hemostasis of lower GI bleeding.

INTRODUCTION: Long-term recurrence in lower gastrointestinal bleeding (LGIB), particularly benign diseases, has not been extensively studied. This study aimed to ascertain the rate of recurrence in LGIB and associated risk factors.
AIMS & METHODS: A cohort of 312 patients hospitalized for overt LGIB from benign sources was analyzed. All patients underwent colonoscopy. The Charlson comorbidity score and the use of non-steroidal anti-inflammatory drugs (NSAIDs), low-dose aspirin, other antiplatelet drugs, and warfarin were assessed. The Kaplan–Meier method was used to estimate the cumulative recurrence of LGIB. The Cox proportional hazards model was used to estimate hazard ratios (HR).
RESULTS: Rebleeding was identified in 84 patients with a mean (SD) follow-up of 19 (22) months. The cumulative rebleeding rate at 1 and 5 years was 21% and 51%, respectively. Associations with recurrence by univariate analysis were as follows: age ≥65 years ($p<0.01$), Charlson comorbidity index ≥2 ($p<0.05$), and the use of NSAIDs ($p=0.02$), low-dose aspirin ($p=0.03$), non-aspirin antiplatelet drugs ($p<0.02$) and warfarin ($p=0.59$). Multivariate analysis revealed age ≥65 years (HR, 1.9; $p=0.02$) and the use of NSAIDs (HR, 1.8; $p=0.03$) and non-aspirin antiplatelet drugs (HR, 2.0; $p=0.02$) as independent risk factors for rebleeding. Dual antiplatelet therapy carried a higher risk than single therapy (adjusted HR, 1.8; $p<0.05$).
CONCLUSION: There is a substantial recurrence rate among patients hospitalized for LGIB. Besides advanced age, various antithrombotic drugs increased the risk of recurrence in LGIB. Dual users of those drugs have a higher risk than single users.

P0934 WHAT FACTORS ARE RELATED TO DEATH FROM INTESTINAL ISCHEMIA IN THE PATIENTS WITH RENAL FAILURE UNDERGOING CONTINUOUS HEMODIALYSIS?

Y. Goto[1,2,*], K. Yasuda[3], H. Kasuga[4], H. Seno[5], S. Maruyama[6], K. Wakai[2]
[1]*Gastroenterology, Nagoya Kyoritsu Hospital,* [2]*Preventive Medicine, Nagoya University Graduate School of Medicine,* [3]*Nephrology, Masuko Memorial Hospital,* [4]*Nephrology, Nagoya Kyoritsu Hospital,* [5]*Nephrology, Kaikoukai Josai Hospital,* [6]*Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

INTRODUCTION: It has been reported that end-stage renal disease (ESRD) patients on hemodialysis (HD) were at risk for intestinal ischemia (II). Some severe cases of II die from transmural gangrenous necrosis of the intestine. Other mild cases develop ulceration and colitis, and can be treated with conservative management. In this study, we tried to identify factors associated with death from II in patients on HD.
AIMS & METHODS: Approximately 2,500 patients at our dialysis clinics underwent HD three times weekly from January 2009 to October 2013. The diagnosis of II, which includes mesenteric ischemia, non-occlusion mesenteric ischemia, and ischemic colitis, was made from endoscopy, pathology, computed tomography, ultrasound findings, and/or clinical condition. The subjects were divided into two groups of the fatal II group and the non-fatal II group. The latter included some who died from other causes than II. Continuous variables were compared by *t*-test, while qualitative variables by Fishers exact test.
RESULTS: Twenty-six of 2,500 longterm HD patients developed II for the first time during the study period. The fatal and the non-fatal group consisted of 7 and 19 subjects, respectively. Six of the non-fatal group died from the following causes: cerebral hemorrhage, infective endocarditis, heart failure, pneumonia, suicide, and unknown. The frequencies of those who had each of warfarin and laxative were higher in the fatal group than in the non-fatal (57.1% vs 5.26%, respectively, $p=0.01$). Two fatal cases used both of the drugs. Then, we needed avoid the effect of laxative on II, to focus on the effect of warfarin only. After removal of the two, the corresponding result still remained to be significant (66.7% in the fatal vs 5.56% in the nonfatal, $p=0.04$). Three of 4 who had warfarin suffered from atrial fibrillation (Af) in the fatal group. In the non-fatal group, 3 had Af but 1 of them took warfarin. There was no significant difference in the frequency of Af between the two groups. The fatal group more frequently underwent laparotomy than the non-fatal (42.9% vs 5.26%, respectively, $p=0.05$). Regarding the location of II, 71.4% of the fatal group developed the ischemic colitis on the right-sided, while 5.26% of the non-fatal on the right-sided ($p<0.01$).
CONCLUSION: This study showed that there was a possibility that warfarin causes the fatal II regardless of Af, as well as laxative. Therefore, considering the previous reports that warfarin provokes calciphylaxis on ESRD, warfarin could facilitate ischemia based on calcification of the feeding-artery. In addition, the fatal group involved the right-sided colon, and undertook laparotomy more frequently as the previous studied reported. Further studies with larger number of the subjects are required to confirm our results.

P0935 COMPARISON OF MICROWAVE COAGULATION WITH MONOPOLAR AND BIPOLAR COAGULATION IN A PORCINE MODEL

Z.P. Tsiamoulos[1,*], C. Hancock[2], P. Sibbons[3], B.P. Saunders[1]
[1]*Wolfson unit for Endoscopy, St Mark's Hospital/Academic Institute, London,* [2]*School of Electronic Engineering, University of Bangor, Bangor,* [3]*Division of Surgical Science, Northwick Park Institute for Medical Research, London, United Kingdom*

INTRODUCTION: Intra-procedural bleeding is considered an immediate serious adverse event and a major concern for the endoscopist and the patient. Current endoscopic devices utilise monopolar or bipolar energy to treat acute bleeding vessels and/or pre-coagulate visible vessels. Monopolar/Bipolar devices have proven safe in clinical practice to control acute arteriolar bleeding but there are no ex vivo comparative studies assessing the safety profile with histology.
AIMS & METHODS: The optimal time of application for the microwave modality of a new endoscopic device "Speedboat-RS2, Creo Medical Ltd, UK" was initially assessed compared to a standard mono-polar endoscopic device, Coagrasper, Olympus, USA. After histological assessment of the optimal time range, a comparison of the Speedboat RS2 to a standard bipolar endoscopic device, Gold Probe, Boston Scientific, USA, and to standard monopolar device, Coagrasper, was performed to assess the safety profile of coagulation with histology and the endoscopic performance of pre-coagulation in the porcine colon. The Speedboat-RS2 blade delivers microwave coagulation (5.8GHz) for hemostasis, and also has an insulated hull to prevent thermal injury to the underlying muscle layer. Cold snare polypectomy (9mm) was performed to reveal the submucosal layer and video recorded on 3 consecutive 60kg pigs. The colonic resection sites were aligned in cranial-caudal direction. The following parameters were measured: histological assessment and pre-coagulation endoscopic performance. All animals were recovered for 2days, 5days and 7days.

RESULTS: In animal one, microwave bursts of 5sec, 10sec and 15sec were applied to the revealed submucosa compared to standard monopolar bursts of a 1sec. Histology showed that 5sec and 10sec of microwave has equivalent histological appearance with standard monolopar preserving the serosal integrity with mild muscle alteration. In animal 2 and 3, microwave was applied for 9 sec in 6 lesions, standard monopolar was applied for 1-2sec in 6 lesions and standard bipolar was applied for 3-4sec in 6 more lesions. Histology showed viable serosa with no muscle alterations in microwave group, viable serosa with mild muscle alterations in standard bipolar and viable serosa with mild/moderate muscle alterations in standard monopolar group. In all cases muscle layer cells were contiguous. During the pre-coagulations endoscopic assessment, all modalities were applied to coagulate vessels with median calibre of 2mm before and after dissection. Effective pre-coagulation was achieved in 3 out of the 6 visible vessels (microwave group) and in 2 out of the 6 visible vessels (standard monopolar and bipolar groups). Effective coagulation (defined when blood flow stopped) was achieved after the dissection, in all three groups.
CONCLUSION: Compared to Coagrasper (monopolar) and Gold Probe (bipolar), the microwave modality of Speedboat RS2 appears to be equivalent during the pre-coagulation phase. The safety profile of coagulation phase resembles the profile of the other two modalities but with less muscle alterations in the histological specimens.

P0936 BPREDICT: BURGENLAND PREVENTION TRIAL OF COLORECTAL DISEASE WITH IMMUNOLOGICAL TESTING

G. Leeb[1,*], P. Hofer[2], A. Gsur[2], G. Böhm[3], G. Puhr[1], K. Mach[1]
[1]*Hospital Oberpullendorf, Oberpullendorf,* [2]*Department of Medicine I, Medical University of Vienna, Institute of Cancer Research, Vienna,* [3]*Hospital Oberwart, Oberwart, Austria*
Contact E-mail Address: *gernot.leeb@gmail.com*

INTRODUCTION: Colorectal cancer (CRC) is the third most common cancer and cause of cancer death in Europe and continues to be among the most severe health problems in the EU. In Austria, 4,600 new cases are diagnosed per year. Ten years ago there used to be a remarkable east west decline in CRC incidence with the highest incidence rates in Burgenland, a province in the very east of Austria, with about 300.000 inhabitants. Therefore, 2003 the screening project Burgenland PREvention trial of colorectal Disease with ImmunologiCal Testing (bPREDICT) was initiated.
AIMS & METHODS: This screening project utilizing fecal immunochemical testing (FIT) was first implemented in the district Oberpullendorf in 2003. Since 2006, the screening program has been expanded to the whole province Burgenland. Between 2003 and 2010, a qualitative fecal occult blood test was applied. Since 2010 this test was replaced by a quanitiative FIT test (OC sensor, Mast Diagnostica Germany).
Annually, 150.000 residents aged between 40 and 80 (50% of the population) receive a stool sample container and are invited to take part in bPREDICT. Stool samples are processed and evaluated in a central laboratory. Individuals with positive testing (cutoff level 50ng hemoglobin/mL) are advised to undergo colonoscopy.
RESULTS: The target group from 2003 to 2012 was 1.2 million. In this time period 100.000 colonoscopies were performed, 20,292 (25%) were triggered by the screening program. The participation rate was about 35 percent, 8.3 percent of the participants had a positive FIT. Within this group we found CRC in 314 persons, high grade intraepithelial neoplasias in 225, high risk adenomas in 2,673 and low risk adenomas in 3,379 individuals.
Age-standarized incidence rates per 100.000 decreased from 43.4 (average 1998-2000) to 25.7 (average 2009-2011) in Burgenland (Statistic Austria).
Within bPREDICT FIT positive participants are also invited to take part in the Colorectal Cancer Study of Austria (CORSA), yielding a large biobank (DNA and plasma) comprising more than 10.000 CRC patients and colonoscopy-negative controls. This biobank is the basis for several molecular epidemiology research projects.
CONCLUSION: Most recent data of "Statistic Austria" show that the incidence pattern has changed in Austria, Burgenland is now on the last but one position, this may due to the effect of bPREDICT.

INTRODUCTION: The literature on colorectal cancer screening and ethnic diversity is dominated by studies from the USA. There is no such published data from the UK BCS population. 10.3% of the Black Country BCS population are of South Asian (SA) ethnicity. We aimed to determine the effect of ethnicity and gender on the risk of polyp or cancer detection over a 5 year period (2007-11).
AIMS & METHODS: Data was collected from the BCS cohort retrospectively. SA patients were identified and compared to those of Non South Asian (NSA) ethnicity and colonoscopy outcomes were determined.
RESULTS: 3552 subjects underwent BCS colonoscopy (NSA = 3363; SA = 189). The incidence of colorectal cancer within the SA population was 7.4 per 100.000 per year compared with 36 per 100 000 per year in NSA ($p < 0.05$). The probability of colon cancer is higher (OR = 3.84; $p < 0.05$) in NSA compared with SA patients. Similarly patients in the 65-70 age group have the highest risk (OR = 1.60; $p < 0.05$) of colorectal cancer.

		95% confidence interval	
Parameter	Risk odds ratio	Lower	Upper
Male	2.26021*	1.72979	2.953527
NSA	3.846221*	1.894585	7.806838
South Staffordshire	0.517331*	0.318861	0.839457
Walsall	1.124037	0.827787	1.526534
Wolverhampton	1.130742	0.818731	1.562051
Age 65-70	1.602908*	1.18412	2.170592
Age 70-75	1.449215*	1.051271	1.997707
Intercept (SA female aged 60-65 years living in Dudley is the baseline and all groups are deviations from this estimate)	4.54E-05	3.06E-05	6.75E-05

Table: Factors predicting risk of colorectal cancer in BCSP. *denotes statistical significance ($p < 0.05$).
CONCLUSION: The colorectal cancer risk is significantly higher in the male NSA BCS population in this regional study. This is the first such study in the BCS population.

Contact E-mail Address: *alinamircea.popescu@gmail.com*

INTRODUCTION: While a population-based colorectal cancer screening program is not implemented, probably any other method of early detection of this disease is welcome.
AIMS & METHODS: The aim of our study was to assess which were the findings in regard to neoplastic pathology (polyps or colorectal cancer) of opportunistic colorectal cancer screening by colonoscopy (asymptomatic subjects in whom we performed a colonoscopy for colorectal cancer screening).
We included in our study the colonoscopies performed in asymptomatic subjects in whom the indication was screening for colorectal cancer, in 3 endoscopy centers from Timișoara and Tg. Mureș. We excluded the colonoscopies performed in patients with previous history of polyps and colorectal cancer. We studied the prevalence of polyps, significant polyps (polyp ≥1cm) and colorectal cancer, globally and in different age groups.
RESULTS: 2537 colonoscopies were performed in asymptomatic subjects in the 3 endoscopy centers between January 2008-December 2013; from these 95.9% (2433 cases) were total colonoscopies. The statistic analysis was performed only on total colonoscopies.
The 2433 total colonoscopies performed in asymptomatic subjects led to the discovery of polyps in 32.1% (783/2433) of cases, of significant polyps in only 7.2% (175/2433) of cases and of colorectal cancer in 2% of cases (50/2433). Most often we found neoplastic pathology in the 60-69 years age group: 38.5% (302/785) polyps, 8.4% (66/785) significant polyps, 2.5% (20/785) cancers.
CONCLUSION: The detection rate of significant pathology (significant polyps and cancer) in asymptomatic subjects' colonoscopy was 9.2% in the studied group, which confirms the need for colorectal cancer screening.
Disclosure of Interest: None declared

P0939 RADIATION PROCTOCOLITIS AND THE RISK OF COLORECTAL NEOPLASIA

J.S. Mcgrath[1,*], E. Randell[1], S. Antle[1], D. Pace[1], S. Stone[1], M. Borgaonkar[1]
[1]*Medicine, Memorial University, St. John's, Canada*
Contact E-mail Address: *jmcgrath@mun.ca*

INTRODUCTION: A mainstay in the treatment of prostate and some gynecological cancers is the use of external beam radiation therapy. Radiation proctocolitis is a common complication of this treatment. Little is known about the association between external beam radiation, radiation proctocolitis, and the risk of colonic neoplasia.
AIMS & METHODS: The current study is a prospective analysis of patients with radiation proctocolitis referred from the Newfoundland and Labrador Bliss Murphy Cancer Centre from Jan. 2010 to Dec. 2013. The current study investigated the relationship between radiation proctocolitis at index colonoscopy and the detection of colorectal polyps. These results were then compared to data

collected for colonoscopies conducted on (i) average risk individuals and (ii) fecal immunohistochemical test (FIT) positive patients. Data was recorded on a standardized data sheet and entered into SPSS version 20.0 for analysis.
RESULTS: Data was collected on 81 individuals who had radiation proctocolitis, 130 individuals who were average risk, and 109 FIT positive individuals. At colonoscopy the adenoma detection rate (ADR) was 60.5% for patients with radiation proctocolitis, 21.5% for individuals at average risk and 55.6% for FIT positive individuals. The colon cancer rate was 6.2% for individuals with radiation proctocolitis, 0% for individuals at average risk and 1.8% for FIT positive individuals.
There was a significant difference in the ADR between the patients with radiation proctocolitis and average risk individuals 60.5% vs. 21.3 ($p<0.0001$) and the corresponding colon cancer rate was 6.2% vs. 0 respectively ($p<0.002$). There was no significant difference in the ADR or colon cancer rate in patients with radiation proctocolitis compared to FIT positive.

Histiopathology	ADR	Colon Cancer Rate
Patients with Radiation Proctocolitis (n = 81)	60.5%	6.2%
Average Risk Individuals (n = 130)	21.5%	0%
FIT Positive Individuals (n = 109)	55.6%	1.8%

CONCLUSION: Pelvic radiation exposure is known to be associated with the development of proctocolitis. This study also shows it is associated with an extremely high prevalence of colorectal neoplasia. Patients with a history of radiotherapy require screening for colonic neoplasia.

P0940 HEIGHT AND RISK OF COLORECTAL ADENOMA: A COHORT STUDY OF A KOREAN MEN

J. Pyo[1,*], Y.H. kim[1], S.N. Hong[1], D.K. Chang[1], P.-L. Rhee[1], J.J. Kim[1]
[1]*Gastroenterology, Samsung medical center, Seoul, Korea, Republic Of*
Contact E-mail Address: *tyoma@hanmail.net*

INTRODUCTION: Increasing cancer risk with increasing adult height has been reported for all cancers combined and for several common site specific cancers, including colon and rectum. The underlying mechanism is unclear, but it has been suggested that increased cell turnover mediated by insulin like growth factor or increased cell number might increase cancer risk by increasing the amount of tissue available to undergo malignent transformation. Evidence is limited, however, for adenomatous polyps, precursors to colorectal cancer.
AIMS & METHODS: The aim of this study was to evaluate the associations between height and risk of colorectal adenomas at the various stages of the adenoma-carcinoma pathway.
We conducted a retrospective study using data from who had undergone a complete colonoscopy as part of a health examination at the Health Promotion Center of Samsung Medical Center between October 13, 2009 and December 31, 2011. A total of 1356 male subjects were included. Multivariable logistic regression analysis was used to evaluate the association between height and colorectal adenoma.
RESULTS: Each 5-cm increment in height was associated with 19.4% and 9.8% higher risk of advanced colorectal adenoma and high risk colorectal adenoma, after adjusting for age, BMI, metabolic syndrome, smoking, drinking, family history of colorectal cancer, and regular use of aspirin. Still, there was clearly no significant association. (p-vaule 0.4404 and 0.6852 each)
CONCLUSION: Unlike colorectal cancer, there is no clear association between colorectal adenoma and height. The difference between the patterns associated with cacner and adenoma could be explained as some cancers may not arise from an adenoma, and only a limited portion of subjects with adenomas will eventually have cancer.

P0941 RECTAL NEUROENDOCRINE TUMOURS: MANAGEMENT AND SURVIVAL IN 60 PATIENTS

K. Naik[1,*], R.E. Rossi[1], D. Mandair[1], C. Toumpanakis[1], M. Caplin[1]
[1]*Neuroendocrine Tumour Unit, Centre of Gastroenterology, Royal Free Hospital, London, United Kingdom*
Contact E-mail Address: *keval.naik@nhs.net*

INTRODUCTION: Rectal neuroendocrine tumours (rNETs) are increasing in incidence, with more found incidentally on routine colonoscopy.
AIMS & METHODS: To retrospectively analyse a cohort of rNETs to characterize diagnostic features and clinical behaviour. Patients (pts) with confirmed diagnosis of rNET were identified from a database
RESULTS: 60 pts evaluated, median age 55 years (range 23-78). Most common presentation was rectal bleeding n = 29 (48%). 29/60 pts had tumour <1cm, 7/60 pts 1-2cm, 22/60 >2cm, 2/60 size was unknown. Of patients with tumour size <1cm, 3/29 did not require endoscopic follow-up (pT1a) and of the other 26, none had evidence of recurrence on endoscopic follow-up (follow-up range 6 to 88 m). 24/60 pts had metastases at presentation, 5/60 developed metastases during follow-up (of these 29 pts 86% liver, 40% bone, 10% lung). Of 29 pts with metastases, 24/29 had somatostatin receptor imaging with 62% avid uptake. Chromogranin A available in 23/29 pts and was not elevated in 83%. Of 29 pts with metastases, 19/29 had chemotherapy, 10/29 somatostatin analogues (SST), 15/29 surgery and 10/29 peptide-receptor-radionuclide-therapy (PRRT). Chemotherapy: 1/19 pts partial response, 2/19 stable disease (SD), 12/19 progressive disease (PD) (median time to progression 4 months (m)); 4/19 no data. PRRT: 4/10 had SD (follow-up range 24 to 53m), 4/10 PD (median time to progression 4m, range 2-9), 2/10 no data. SST: 2 sustained SD (range 12-27m), 7/10 PD, (median time to progression 3m, range 2-5); 1/10 no data. During median follow-up of 20m (range 3–170m), 100% of pts with primary tumour <1cm, 86% with tumour size 1-2cm, and 25% with size >2cm are currently alive. Tumour size >2cm have poorer outcome than the other 2 groups ($p<0.001$).
CONCLUSION: Tumours larger than 2cm are associated with poor prognosis. Chromogranin A is mostly normal even in advanced disease. Prospective studies are needed to determine progression free survival data for systemic therapy.

P0942 CANCER INVADING THE SUBMUCOSAL LAYER: SOMETHING IS MISSING. A SINGLE CENTER EXPERIENCE

L. Peraro[1,*], E. Rosa-Rizzotto[1], M. Lo Mele[2], E. Guido[1], D. Caroli[1], F. Ancona[1], F. Polato[1], M. Rugge[2], F. De Lazzari[1]
[1]*Dpt of Specialized Medicine, Gastroenterology Unit, St Anthony Hospital,* [2]*Surgical Pathology and Cytopathology Unit, Department of Diagnostic, Medical Sciences and Special Therapies, University of Padua, Padua, Italy*

INTRODUCTION: Actually we don't know how long does it takes for a preneoplastic lesion to became a cancer invading the submucosal layer (pT1). We don't know, also, how long a pT1 lesion rest in the submucosal layer before going deeper to reach the muscolaris propria becoming pT2. Qualitative parameters to determinate high metastatical risk in pT1 as showed in Europeans Guidelines in Colorectal Cancer (CCR) screening[1] and Japanese Society for Cancer of the Colon and Rectum (JSCCR) guidelines[2] are: high tumor grade, deep extent of invasion, vascular invasion, presence of high grade budding, polipectomy resection margin <1mm. The presence of none (low risk) or one (high risk) of these parameters involves a metstatical risk from 0.7% to 36%, and a overall average of 13%.
AIMS & METHODS: to assess the metastatical risk in pT1 lesions diagnosed during routine colonoscopies and in those found during the colorectal cancer screening program. We retrospectively enrolled in the study 15.252 consecutive patients gone for colonoscopy in our Endoscopy Unit from april 2009 to april 2014. 4.970 patients were Fecal Occult Blood Test (FOBT) positive and enrolled in the CCR screening program. pT1 patients gone for a strict follow-up with CT scan, CEA and colonoscopy. Fisher exact test and Student's T-test for unpaired data were used for statistical analysis.
RESULTS: in 5 yr 119 pT1 (67M, 52F) tumors were detected, 96 during screening colonoscopies (SC) and 23 during routine colonoscopies (RC). Overall pT1 prevalence was 1,9% in SC and 0.3% in RC. 60/119 (50.4%) patients underwent for surgery because considered at high metastatic risk, of those only 3 patients (3.3%) presented limphnode metastasis, 1/5 (20%) in RC and 2/55 (3.6%) in SC (p = ns). The mean follow-up was 132 months. During the follow-up none other patient had metastasis. Population mean age was higher in RC 71.87 vs 61.24 ($p<0.0001$). High risk pT1 were more frequent in SC (56.2% vs 26.1%, $p=0.01$). No differences were found in the two populations for: polyp dimension, tumor grading, deep/extent of invasion, vascular invasion, polypectomy resection margin (p = ns). The presence of tumor budding was higher in male (23.1% 15/65 vs 6.1% 3/49, $p=0.01$) and in RC pT1 gone for surgery (60% 3/5 vs 16% 8/50, $p<0.05$).
CONCLUSION: The probability to find a pT1 tumor is 6 times higher during SC. Colorectal pT1 lesions found during the screening colonoscopy program seams to be at less metastatic risk compared to analogue pT1 lesions found during routine colonoscopies, probably because are diagnosed at an early stage; for this reason we must find new parameters to better predict the real metststic risk for these kind of tumors. The controversial budding parameter is probably affected by gender.

INTRODUCTION: In Croatia in 2012 colorectal cancer was the second leading cause of cancer mortality in males, (1.136 or 55.0/100.000) as well as women (868 or 39.1/100.000). According to Croatian Cancer Registry in 2011 it was diagnosed in 19% of cases at the localised stage, and 61% with regional metastases or distant metastases at time of diagnosis.
AIMS & METHODS: Faecal occult blood testing (FOBT) is an evidence based, cost-effective screening approach in organised population-based colorectal cancer screening programmes throughout the world. The hypersensitive guaiac-based Hemognost (Biognost, Zagreb) card test was used to screen population age between 50-75 years in Croatia.
RESULTS: By the end of September 2012 a total of 1,419.639 persons (born between 1933-1957) were received three FOBT test cards. Among them, 15,339 persons were ineligible for testing. 288,935 (21%) sent test packages with correctly applied specimens which is in accordance to the response rate according to EU guidelines (17.2 to 70.8%) in the first round.
Within the program, more than 10.000 colonoscopy examinations were conducted (80% response rate) and 576 people with colon cancer were discovered (2.3‰ of total number of tested persons, which is consistent with the expected: EU guidelines 1.2-2,3/1000). In 4223 people polyps were found (39.7% of incurred colonoscopy) and removed. The largest number of polyps were found in the left half of the colon: 64% (19%, 37% and 8% in the rectum, sigma, and descendens, respectively). The other 36% were detected in the proximal part (17% in the transverse colon and 19% in ceco-ascending colon). Small polyps in the rectum (5-10 mm in diameter), sigmoid and descending colon were histologically found to be tubular adenomas in 60% of cases, with a low degree of dysplasia, and 40% were classified as hyperplastic. Polyps of this size in the transverse or ceco-ascending colon in almost 20% had a histologically villous component, but still had a low degree of dysplasia. Polyps sized 10-20 mm in diameter were in 43% cases tubulovillous, and among them, 32% had areas with a high degree of dysplasia, especially those polyps in the ceco-ascending or transverse part
CONCLUSION: According to first cycle results and organisational obstacles it was suggested a need for intervention strategies in order to improve compliance. A number of organizational changes are performed together with educational and promotional activities to improve awareness of CRC screening usefulness and increase participation rates.

P0944 RISK FOR COLORECTAL ADENOMAS AMONG PATIENTS WITH INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS OF THE PANCREAS (IPMNS): A CASE-CONTROL STUDY

N. Panic[1,*], G. Capurso[2], F. Attili[3], S. Boccia[1], G. Costamagna[3], G. Vitale[3], G. Delle Fave[2], S. Stigliano[2], A. Larghi[3]

Contact E-mail Address: *nikola.panicmail@gmail.com*

INTRODUCTION: It is well documented that patients with IPMN are at the incresed risk of colorectal cancer.
AIMS & METHODS: Aim of the study was to investigate if risk of colorectal cancer development in patients with IPMN may be related to an increased propensity to harbor colorectal adenomas. A two centers case–control study. Cases were prevalent IPMN without history of colorectal cancer, who underwent screening colonoscopy for the first time in their life. Matched controls were enrolled along side between individuals who underwent colonoscopy for screening and evaluation of non specific abdominal pain.
RESULTS: During the study period, 122 IPMN cases and 246 controls were enrolled. IPMNs were more frequently branch-duct (87.7%), multifocal (67.2%) with a mean diameter of greater lesion of 16.1 mm ± 8.1. First-degree family history of colorectal cancer was more frequently among controls (14.1% vs. 37.8%, $p<0.001$), while 2nd degree family history of any cancer (18.2% vs. 10.3%, $p=0.035$), as well as pancreatic ductal adenocarcinoma (3.3% vs. 0%, $p=0.01$) was more frequent among cases. Colorectal polyps were found in 52 IPMN (42.6%) and 78 controls (31.7%). In 29 cases (23.8%) and 55 controls (22.5%) histological examination disclosed adenomatous polyps, which were multiple in 11 cases (9%) and 20 controls (8.2%). Three cases of cancer were found, 2 in IPMNs (1.6%) and 1 in controls (0.4%). We observed a significantly increased risk for harboring colorectal polyps among IPMN cases than IPMN-free controls [adjusted odds ratio (OR): 1.60, 95% confidence interval (CI): 1.10-2.59]. However, IPMN was not significant risk factor for harboring adenomatous polyps (OR: 1.05, 95% CI: 0.61-1.80). Due to the small number of discovered cancers it was not possible to conduct the same analysis for colorectal cancer as an outcome.
CONCLUSION: Increased risk of colorectal cancer in patients with IPMNs do not seem to be related to an increased propensity to harbor adenomatous polyps.

P0945 DIMINUTIVE POLYPS: RESECT AND DISCARD STRATEGY IS NOT ENOUGH. A DIFFERENT FOLLOW UP IS NEEDED IF THERE IS A CONCOMITANT PRESENCE OF LARGER POLYPS

D. Caroli[1,*], L. Peraro[1], E. Rosa-Rizzotto[1], M. Lo Mele[2], E. Guido[1], F. Ancona[1], F. Polato[1], M. Rugge[2], F. De Lazzari[1]
[1]*Dpt of Specialized Medicine, Gastroenterology Unit, St Anthony Hospital,* [2]*Surgical Pathology and Cytopathology Unit, Department of Diagnostic, Medical Sciences and Special Therapies, University of Padua, Padua, Italy*

INTRODUCTION: Oncological significance of diminutive polyps alone (DPA) is controversial as the association of diminutive polyps with other types of larger polypoid or non-polypoid lesions (DPP). The resect and discard strategy for diminutive polyps appears to be cost effective but the post polypectomy follow up, that is crucial for colonoscopy screening programs, still remain uncertain[1]. Colonoscopy intervals are based on pathological assessment of all polyps detected during colonoscopy and several elements contribute to assess the risk to develop colon cancer: polyps dimension, colon side, histology, number of polyps detected at the index colonoscopy and colonoscopy quality.
AIMS & METHODS: to establish the appropriateness and safety of the ''resect and discard'' strategy in a colorectal cancer screening population undergone for index colonoscopy in 2010 and subjected at least a survaillance colonoscopy within 3 years. We retrospectively analyzed 585 patients positive for FOBT undergone for colonoscopy during a Colorectal Cancer Screening Program in Padua in 2010 and with polyps. Subsequently among this initial population were identified 387 patients with detection of DPA or with DPP. These patients were divided into two groups: DPA (184 pts) and DPP (203 pts). The number, dimension, colon side and histology of all the polyps were assessed at first colonoscopy and during the follow up. Only clean colonoscopies were considered in the study. Statistical analysis used: Fisher exact test and Student's T-test for paired and unpaired data.
RESULTS: A regular follow up was observed in 82 pts (M 60-F 22, mean age 66 y) with DPA and in 158 pts (M 113- F 45, mean age 66 y) with DPP. Quality index of colonscopy: adenoma detection rate 57.2% and coecal intubation 98%. 1150 polyps resected at index colonoscopy, 397 (34.3%) DPA and 758 (65.7%) DPP. 450 polyps were resected during the follow up, 125 (27.7%) in DPA and 325 (72.2%) in DPP. The total number of patients with advanced adenomas was higher in DPP vs DPA 108-83% vs 21-17% ($p<0.0001$) at index colonoscopy, but in the follow up colonoscopy the difference about advanced adenomas was not significant ($p=0.342$). Also the right side was predominantly in DPP at the index colonoscopy (113-59.8% vs 76-41.2%, $p<0.0001$). Finally the two group as expected are different for mean number of total polyps at index DPA 2.17 vs DPP 3.72 ($p<0.0001$) and subsequent colonoscopy DPA 1.52 ± DPP 2.06 ($p<0.05$), mean number of colonoscopies at follow up was similar 1.37 vs 1.39 ($p=$ ns). One interval cancer was found in the group of DPP in the right colon, this event was statistically consistent with literature data[2].
CONCLUSION: The ''resect and discard'' strategy appears to be safe, cost effective and adequate in the context of colorectal screening programs against data of follow up in patients with **only** diminutive polyps, in who prevails not advanced adenomas. A closer follow up program should be performed according to the presence of **non** diminutive polyps, where prevails advanced adenomas and frequently the lesions are in the right colon with consequent high risk of interval cancer.

INTRODUCTION: *MUTYH*-associated polyposis (MAP) is an autosomal recessive inherited condition commonly showing an attenuated familial adenomatous polyposis phenotype. It represents about 1% of all CRC although is thought that it might be underdiagnosed. Apparent sporadic cases not fulfilling clinical and pathological criteria are being described, though no screening marker is widely adopted.
AIMS & METHODS: We aimed to approach the analytical and clinical validation of *KRAS*_G12C somatic mutation as screening marker for MAP diagnosis. Sensitivity, specificity, positive and negative predictive values were calculated.
A total number of 103 patients were included in this study: 75 patients with polyposis (EPIPOLIP cohort) and 28 CRC patients (EPICOLON and

Hereditary Cancer Program Comunidad Valenciana, cohorts). All patients were tested for germline mutations at *MUTYH* gene (Sanger sequencing of the whole coding region and intron-exon boundaries); and *KRAS*_G12C mutation at polyps or CRC microdisected tissues (Sanger sequencing).
RESULTS: *MUTYH* biallelic mutation was present in 13 and 19 of the polyposis and CRC patients, respectively. No *MUTYH* mutation was detected in 62 and 9 of the polyposis and CRC patients, respectively. Eleven out of 13 (84.6%) *MUTYH* biallelic carriers and 2 out 62 (3.2%) wildtype *MUTYH* polyposis patients harboured *KRAS*_G12C mutation in at least one of their polyps. In the CRC cohort, 13 out of 19 (68%) *MUTYH* biallelic mutation carriers and none of the nine *MUTYH* wildtype patients had *KRAS*_G12C mutation. Taking together these results, we found that the diagnostic value of *KRAS*_G12C for screening of MAP syndrome shows a specificity and sensibility of 0.972 and 0.75 respectively, with positive and negative predictive values of 0.923 and 0.896, respectively.
CONCLUSION: Our results suggest that *KRAS*_G12C mutation is an effective screening marker for MAP syndrome in both, polyps and tumor tissues. Larger studies are needed to confirm the clinical value of this marker for its potential use in the universal screening for MAP-syndrome.

P0947 SHOULD ALL BARIUM ENEMAS BE CONVERTED TO COLONOSCOPY? ANALYSIS OF 300 BARIUM ENEMAS BY INDICATION AND OUTCOME

F. Rana[1,*], D. Tate[1], P. Hanson[1]
[1]*Gastroenterology, Great Western Hospital, Swindon, United Kingdom*
Contact E-mail Address: *fahdrana@outlook.com*

INTRODUCTION: Historically in the UK barium enemas have played a greater role in clinical diagnosis than in countries where colonoscopy is more available. It is now the policy of the Department of Health and thr National Institue for Health and Care Excellence (NICE) to improve access to colonoscopy and phase out barium enemas[1]. At the Great Western Hospital 2,700 barium studies were done in 2012; to switch all of these to colonoscopy would have major implications for colonoscopy workload. Furthermore, the switch might not always be clinically appropriate.
AIMS & METHODS: We retrospectively studied the stated indications for 300 consecutive barium enemas in patients over 45 years (older age group) and those 45 years and younger (younger age group). We looked at the outcome for each age group and indication: a **Relevant Positive** examination revealed pathology considered relevant to the stated indication; a **Diagnostic Negative** was a negative result with no further colonic investigations (these 2 groups constitute **Useful Results**). A **Disbelieved Negative** was a negative result followed up with lower gastrointestinaI endoscopy. **False Positives** and **False Negative** results were based on subsequent revision of findings on colonoscopy.
RESULTS: Five indications accounted for 83% of all studies in both age groups cumulatively: altered bowel habit (ABH) 42%; Per Rectal bleed (PRB) 22%; abdominal pain (AP) 15%; anaemia (An)14% and diarrhoea (Dia) 7%.
ABH comprised the majority of indications in both age groups when combined together (42%). In the younger age group, this, together with abdominal pain, yielded mostly diagnostic negatives (63% & 78% respectively) and only 12% relevant positives, all diverticulosis. The yield of relevant positives doubled in the older age group to 25% (mostly diverticulosis but 18% neoplasms, 5% strictures, 5% rectocele).
PRB was more common than other indications in the younger age group (38%) compared with older age group (20%). In the younger age group all patients with PRB who had positive results were found to have neoplasms, whereas in the older age group, 33% were neoplasms and 67% diverticulosis. The rectal bleeding groups also provided the most disbelieved negatives (55%) prompting clinicians to request a colonoscopy.
In the older age group, anaemia and diarrhoea had low yields (6% and 18% respectively) and a significant number of disbelieved and false negatives necessitating further investigation with colonoscopy.
CONCLUSION: Colonoscopy is preferable in patients with rectal bleeding, diarrhoea or anaemia. For young patients with altered bowel habit and/or abdominal pain a negative barium result was common and accepted as reassuring; colonic investigation should therefore be used sparingly in these patients and where used, should be less invasive and expensive than colonoscopy.

INTRODUCTION: In neuroendocrine tumors (NET), the therapeutic strategy is highly dependent on tumor grade assessed according to the WHO classification. The decision is commonly based on the histological characteristics of the primary tumor, even in the patients in whom metastatic disease developed several years after resection of the primary tumor. It is possible, however that metastatic lesions present characteristics different from the primary tumor which could have important clinical implications. The aim of the present study was to compare the tumor grade between the primary tumors and their liver metastases in patients with entero-pancreatic NETs, and to determine the consequences in terms of survival
AIMS & METHODS: Patients with entero-pancreatic NETs treated in our institution from 1995 until 2012, for whom both the samples from the primary tumor and from the liver metastases were available, were included. Clinical data were collected and 3 markers of tumor cell proliferation (reflecting the tumor grade) were evaluated: a) mitotic index (MI), measured by counting the number of mitoses in 10 HPF presenting the highest mitotic activity, b) mitotic index measured with a new metaphase specific marker: phosphohistone 3 (PPH3), assessed in the same conditions, and c) the Ki67 index, expressed as percentage of MIB1-positive cells per 2000 tumor cells in the areas of the highest proliferation activity. Statistical analyses were performed using the exact Mc Nemar test. Survival was analysed using logrank test.
RESULTS: Twenty-five patients (12 males, median age 58 years, range 33-79) were included. Primary NETs were pancreatic in 7 patients and intestinal in 18 patients. Liver metastases were synchronous in 20 patients and metachronous in 5 patients. 44% and 56% of primary lesions were of grade 1 and 2, respectively, while 20%, 68% and 8% of the metastatic lesions were of grade 1, 2 and 3, respectively. Tumor grade differed between the primary and the metastatic lesion in 12 patients (48%): out of 10 patients who had a Ki67$\leq$2% in the primary lesion, 8 had a Ki67$>$2% in the metastatic lesion, out of 22 patients who had a MI $<$ 2 in the primary lesion, 10 had a MI $\geq$ 2 in the metastatic lesion, and out of 14 patients who had a PPH3 $<$ 2 in the primary lesion, 9 had a PPH3 $\geq$ 2 in the metastatic lesion. The median Ki67 and MI in metastases were statistically higher than in primary tumors ($p = 0.01$). Ki67 of metastases, but not of primary lesions, tended to correlate with mortality: 0% of mortality if Ki67$\leq$2 % and 66% if Ki67$>$2% on metastases, vs 60% and 47%, respectively, on primary lesions, for the median follow-up of 87 months. A good correlation was found between Ki67 and PPH3 ($p = 0.0001$), but not between Ki67 and MI ($p = 0.4$).
CONCLUSION: In about half of the patients with entero-pancreatic NETs, there is a significant difference in tumor grade between the primary and the metastatic lesions. Metastatic histology seems to better correlate with the survival. The prognostic and therapeutic impact of systematic biopsies of metastatic lesions needs to be further investigated.

INTRODUCTION: SSA/P (sessile serrated adenoma/polyp), the precursor of MSI positive colorectal cancer proposed by serrated pathway, has recently attracted attention. We pathologically and genetically investigated serrated lesions including SSA/P based on the findings of magnifying endoscopy. We have reported *BRAF* mutation presence in the right colon in SSA/P, CpG island methylator phenotype (CIMP)-positive and characteristic findings of magnifying endoscopy (Kimura T, et al. Am J Gastroenterology 107:460-469, 2012). It is essential to investigate the precursor of SSA/P.
AIMS & METHODS: According to the WHO classification, hyperplastic polyps (HPs) were sub-classified and pathologically and genetically investigated. The aim of this study was to investigate the precursor of SSA/P.
Subjects were 46 HPs endoscopically resected at our center. According to WHO classification proposed in 2010, microvesicular variant (MVHP), goblet cell rich variant (GCHP) and mucin poor variant (MPHP) were classified. We investigated genetic mutation and methylation from samples extracted from lesions by location.
RESULTS: Classification of 46 HPs and locations was as follows; 33 MVHPs (14 lesions in the right colon and 19 in the left colon), 13 GCHPs (3 lesions in the right and 10 lesions in the left), and absence of MPHP. In investigation of genetic mutation, 7 MVHPs were observed in *kras* mutation, 22 MVHPs in *BRAF* mutation and 4 MVHPs in wild type. Conversely, 8 GCHPs were observed in *kras* mutation, 5 GCHPs in wild type and lesions were not observed in *BRAF*

mutation. Regarding investigation of methylation, CIMP-positive was confirmed in 10 lesions out of 22 lesions indicating *BRAF* mutation in MVHPs and the other lesions were CIMP-negative. In *BRAF* mutation, CIMP-positive was observed in 8 lesions (66.7%) out of 12 lesions in the right colon and 2 lesions (20.0%) out of 10 lesions in the left colon and difference between the left and right was confirmed. On the other hand, all of the GCHPs were CIMP-negative.
CONCLUSION: The findings indicated that MVHP presence in the right colon was considered to be similar to SSA/P by clinical pathology and generic background and may be the precursor of SSA/P.

INTRODUCTION: First-degree relatives (FDR) of colorectal cancer (CRC) patients have an increased CRC risk [1] and are likely to show advanced neoplasia [AN: CRC and advanced adenomas (AA)] despite a negative FIT [2]. Consequently, there is an imperative need to find new non-invasive screening tests to identify patients with AN after a false-negative FIT result. Based on our previous results we propose the proteins sCD26 and NDK-A as serum candidate biomarkers [3-4].
AIMS & METHODS: To find a risk prediction model combining serum sCD26 and NDK-A proteins, and clinical variables to identify AN in FIT negative subjects at familial risk. The studied cohort included 486 asymptomatic individuals with at least one FDR with CRC and a negative FIT result, recruited from the "Complejo Hospitalario de Ourense". All individuals underwent a colonoscopy and a blood extraction. Concentration of sCD26 and NDKA in serum was measured with ELISA kits.
RESULTS: According to the colonoscopy findings patients were classified as: 335 with no neoplasia, 116 with non-advanced adenomas and 36 with AA. The risk of AN associated with the molecular and clinical variables was evaluated with a univariate analysis (see table).
Risk factors associated with the presence of AN in a FIT negative family-risk cohort.

Variable	Odds Ratio (95% IC)	*P*
sCD26 (≤330ng/mL)	7.38 (3.57-15.28)	<0.001
NDK-A (≥66.5 pg/mL)	2.78 (1.40-5.52)	0.003
Age (≥50 years)	2.90 (1.18-7.10)	0.020
Sex (male)	2.00 (1.01-3.97)	0.047
Number of FDR (2 or more)	1.20 (0.50-2.88)	0.679
Age of younger FDR (≤60 years)	1.03 (1.00-1.07)	0.055

The variables associated with an increased risk for AN ($P<0.1$) were included in the logistic regression model. The ROC curve obtained had an AUC of 0.820 (95% IC 0.758-0.891). The proposed risk model at a 0.122 cut-off predicts the presence of AA with a sensitivity of 48.6% and a specificity of 89.4%. Accordingly, 18 cases of AA originally not detected by FIT would be identified.
CONCLUSION: The risk prediction model proposed including serum sCD26 (≤330 ng/mL) and NDK-A (≥66.5 pg/mL), and the variables sex (male), age (≥50 years) and age of younger FDR (≤60 years) has the capability to re-classify FIT negative individuals who are at risk of having AA in a family-risk population.

INTRODUCTION: Evidence has accumulated that approximately 20% of colorectal cancer (CRC) arises from a serrated polyp (SP) precursor lesion via the serrated neoplasia pathway. Therefore CRC population screening should not only focus on detecting advanced adenomas and CRC, but also on detecting advanced SPs (ASPs). Risk stratification for the detection of ASPs could contribute to target colonoscopy screening towards a population of increased risk.
AIMS & METHODS: The aim of this study was to identify diagnostic risk factors associated with ASPs in a colonoscopy screening program for CRC. Data were collected from the colonoscopy arm of a multicenter randomized trial conducted in the Netherlands comparing colonoscopy with CT-colonography for primary population screening. 6600 Asymptomatic men and women between the age of 50 and 75 years were randomly selected from a population registry and invited to undergo a screening colonoscopy. Information on patient risk factors was obtained before colonoscopy through an extensive and validated risk questionnaire. A literature review was conducted to identify possible risk factors for ASPs. For these risk factors, the diagnostic odds ratio (OR) for the detection of ASPs during colonoscopy was calculated using multiple logistic regression analysis. SPs were defined as hyperplastic polyps, sessile serrated lesions or traditional serrated lesions. ASPs were defined as SPs ≥10mm or SPs with dysplasia.
RESULTS: Of 6600 screening participants, 1426 underwent a colonoscopy; 1236 (86%) also completed the questionnaire. Of all participants, 636 (52%) were male and the average age was 60.3 (SD 6.2). Colonoscopy detected an ASP in 53 (4.3%) participants.
The evaluated diagnostic risk factors are presented in table 1. The following risk factors were significantly associated with ASPs detected at colonoscopy: current smoking (OR: 4.36; 95% CI: 2.93–7.95), BMI (OR: 1.08 per kg/m^2; 95% CI: 1.02–1.15) and fiber intake (OR: 1.02 per gram; 95% CI: 1.01–1.03).
Table 1. Association of risk factors and the detection of advanced serrated polyps

Risk factor	OR (95% CI) univariate advanced SP	OR (95% CI) multivariate advanced SP
Male gender	1.15 (0.66-2.00)	
Age (years)	1.019 (0.98-1.07)	
First degree relative with CRC	1.38 (0.68-2.79)	
BMI (kg/m^2)	**1.07 (1.01-1.14)**	**1.08 (1.02-1.15)**
Current smoking	**4.00 (1.95-8.22)**	**4.36 (2.93-7.95)**
Alcohol consumption (units/week)	1.01 (0.98-1.04)	
Fiber intake (g/week)	**1.01 (1.00-1.02)**	**1.02 (1.01-1.03)**
Calcium intake (mg/week)	1.00 (0.99-1.01)	
Aspirin/NSAID use	0.94 (0.48-1.86)	

CONCLUSION: Current smoking, elevated BMI and elevated fiber intake are diagnostic clinical risk factors for the detection of ASPs during colonoscopy in asymptomatic patients. These risk factors could be combined with risk factors for the detection of advanced adenomas and CRC to optimize targeting CRC population screening towards a high-risk population.

P0952 CIRCULATING GALECTIN-1 AND 90K/MAC-2BP CORRELATED WITH THE TUMOR STAGES OF PATIENTS WITH COLON CANCER

K.-L. Wu[1,*], E.-Y. Huang[2], **C.-M. Liang**[1]
[1]*Division of Hepatogastroenterology,* [2]*Department of radiooncology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*
Contact E-mail Address: *kengliang_wu@yahoo.com.tw*

INTRODUCTION: The simultaneous correlation of serum galectin-1,-3, 90K/Mac-2BP levels with clinical stages of patients with colon cancer has not yet been clarified.
AIMS & METHODS: To measure the serum levels of galectin-1,-3 and 90K/Mac-2BP of patients at different stages of colon cancer and analyze the correlation of these galectins with stages of colorectal cancers. One hundred ninety-eight colorectal cancer patients (62 ± 13 (range 31-85) years old, 43.6 % female) were recruited for this study. Subjects were checked blood samples for serum galectin-1, galectin-3, 90K/Mac-2BP and CEA by sandwich ELISAs. We determined the correlation between plasma concentrations with pathologic TNM stages.
RESULTS: Our study found colon cancer patients with larger cancer sizes (stage T3, 4 than T1, 2) have higher serum 90K/Mac-2BP levels ($p=0.014$) and patients with lymph node metastasis have higher serum galectin-1 levels ($p=0.002$) but there was not a significant correlation between galectin-3 levels and patients with prognosis of colon cancer patients. In colon cancer patients with normal CEA levels, serum galectin-1 levels could predict more lymph node metastasis.
CONCLUSION: We found 90K/Mac-2BP correlated with the size of colorectal cancer. Galectin-1 but not galectin-3 was associated with lymph node metastasis. Galectin-1 could predict more lymph node metastasis of colon cancer when colon cancer patients had normal serum CEA levels.

INTRODUCTION: Methylated Septin 9 (SEPT9) was evaluated as a sensitive and specific biomarker for colorectal cancer (CRC) in plasma samples. However, it has not been investigated how methylated DNA detected in plasma relates to the occurrence of methylated DNA in colon tissue.
AIMS & METHODS: The goal of this study was to quantitatively compare levels of methylated SEPT9 in matched plasma and tissue samples of healthy, adenoma and CRC cases; and to determine the amount of circulating free DNA (cfDNA) and the expression of Septin-9 protein in tissue. Plasma and matching biopsy samples were collected from 24 patients with no evidence of disease (NED), 26 adenomas and 34 CRC. A commercial real-time PCR assay was used to determine the total amount of DNA in each sample and the portion of DNA methylated at a specific locus of SEPT9 after bisulfite conversion of DNA. In a subset of tissue samples, Septin-9 protein expression was determined using immunohistochemistry.
RESULTS: In tissue samples, percent of methylated reference (PMR) values of SEPT9 above a selected PMR threshold of 1% were detected in 4.2% (1/24) of NED, 100% (26/26) of adenoma and 97.1% (33/34) of CRC. PMR differences were found highly significant ($p<0.001$) between NED vs. adenoma and NED vs. CRC comparisons.
In matching plasma samples SEPT9 PMR values, using a cut-off level of 0.01%, were detected in 8.3% (2/24) of NED, 30.8% (8/26) of adenoma and 88.2% (30/34) of CRC cases. Significant PMR differences were observed in comparisons between NED vs. CRC ($p<0.01$) and adenoma vs. CRC ($p<0.01$).
Significant differences ($p<0.01$) in the amount of cfDNA (circulating cell-free DNA) were found between NED and CRC and a modest correlation was observed between mSEPT9 concentration and cfDNA in plasma of cancer patients ($R^2=0.48$).
Protein expression of Septin-9 in tissues determined by IHC was inversely correlated to SEPT9 methylation levels with abundant expression in normals, and diminished expression in adenomas and tumors.
CONCLUSION: Methylated SEPT9 was detected in healthy tissue samples only at low levels, but significantly elevated in adenoma and CRC tissues. In plasma samples, elevated mSEPT9 values were detected in CRC, but not in adenomas. Tissue levels of mSEPT9 alone are not sufficient to predict mSEPT9 levels in plasma. Parameters like degree of vascularisation of the lesions, the amount of cfDNA in plasma and probably additional factors seem to be equally important.

INTRODUCTION: The biology of colorectal carcinomas has been reported to differ by location. Although the investigation of clinicopathological diversities between colon and rectal carcinomas could provide useful information for more effective clinical treatment, there is not adequate evidence of the differences.
AIMS & METHODS: The aim was to compare the clinicopathological features of T1 carcinomas between colon and rectum and to reveal whether these carcinomas should be considered as a single entity or two distinct entities. This study was performed at Showa University Northern Yokohama Hospital in Japan (UMIN Clinical Trials Registry number, UMIN000010979). A total of 21060 colorectal neoplasms were resected endoscopically or surgically at our institution between April 2001 and September 2013. Of these, 580 surgically resected T1 carcinomas, 475 colon and 105 rectal were evaluated. Factors analyzed included patient age, gender, tumor size, morphology, recurrence, depth of invasion, histologic type, vascular invasion, lymphatic invasion, tumor budding, and lymph node metastasis.
RESULTS: Rectal T1 carcinomas were significantly larger (19.9 ± 10.9 mm vs. 23.7 ± 12.9 mm, $p<0.001$) and were accompanied by significantly higher rates of vascular invasion (30.7% vs. 47.6%, $p<0.001$) and recurrence (0.4% vs. 2.9%, $p<0.05$) than colon T1 carcinomas. None of the other clinicopathological factors, including lymph node metastasis, differed significantly.
CONCLUSION: Rectal T1 carcinomas were significantly larger in size, with a significantly higher rate of vascular invasion and recurrence, than colon T1 carcinomas. However, the tumor location was not a risk factor for lymph node metastasis. These suggest that additional surgery after endoscopic resection be recommended for rectal T1 carcinomas with high risk for lymph node metastasis as well as colon ones even if rectal surgery is more invasive and rectal T1 carcinomas need more careful management after treatment.

INTRODUCTION: Circulating tumor DNA (ctDNA) is a very promising marker for non-invasive management of patients with cancer (1). The main clinical significance of ctDNA is in monitoring of patients after tumor resection, detection of recurrence or progression of disease and predicting and monitoring of the response to treatment. Most methods for ctDNA detection and monitoring are based on highly dedicated technologies, mainly utilizing digital PCR with subsequent detection by flow cytometry or next-generation sequencing (2). The high cost of equipment as well as sample processing prevents wide application of ctDNA testing in a clinical practice.
AIMS & METHODS: In a multicentric setting consisting of seven clinical collaborators we have optimized methodology for the collection and processing of samples and isolation and detection of ctDNA by PCR followed by denaturing capillary electrophoresis (DCE). In total, we have prospectively examined presence of ctDNA in 210 patients including 186 patients with colorectal cancer (CRC) at various stages and 24 patients with colorectal adenomas. Subsequent samplings were carried at 2-6 month intervals to monitor the ctDNA dynamics. Results were correlated with clinical data of patients (stage R0/R2 surgery, tumor markers, response to treatment, recurrence or progression of the disease).
RESULTS: The overall ctDNA detection rate in cancer patients was 28% (52/186), with the highest rate of 68% (19/28) in stage IV. In subsequently monitored patients levels of ctDNA correlated with the R0/R2 resection radicality, response to (neo)adjuvant chemotherapy, recurrence or eventual disease progression. Tumor markers CEA and CA19-9 correlated with ctDNA in 62% (65/104) of cases, in 13% (13/104) of ctDNA-positive cases the markers were negative.
CONCLUSION: A routine procedure has been implemented for the ctDNA analysis applying a simple methodology available to standard molecular laboratory. The ctDNA detection rates are ca. 20% below the rates produced by dedicated techniques and at 10 – 50x lower cost per patient. Our results confirm a significant potential of ctDNA in monitoring patients after resection of the primary tumor / metastasis and prediction of the response to biological treatment. The work was supported by IGA Ministry of Health No. NT 13660.

Contact E-mail Address: *rogalidoum@yahoo.com*

INTRODUCTION: Familial Adenomatous Polyposis is an autosomal dominant inherited disorder in 80% of cases, characterized by the early onset of hundreds to thousands of adenomatous polyps throughout the colon. If left untreated, all patients develop colon cancer by age 35-40 years. In children with FAP colectomy is advised at the age of 17-18 years.
AIMS & METHODS: Aim of presentation was to study the characteristics of pediatric patients with FAP from our centre.
7 patients with Familial adenomatous polyposis, aged 7.5-17 years {5 boys (B) & 2 girls (G)} were included. All patients had positive familial history of FAP. One patient has Turcot syndrome, while the rest of patients have no other pathological findings or associated conditions. They were asymptomatic, with normal growth, and normal blood tests.

RESULTS: P0956

Patients	Genetic study	Endoscopy	Histological findings
B /12.5 y	(-)	~1000-10.000 polyps	Adenomatous polyps with moderate grade epithelial dysplasia
B/7.5 y	P. Ser1213X (c3638 C>A)	~ 10-100 polyps	Adenomatous polyps
G /14 y Sdr Turcot	P. Ser1213X (c3638 C>A)	~ 100 polyps	Tubular-vilous adenoma (median grade differentiation) with high grade dysplasia & focal signs of adenocarcinoma
B /16 y	(-)	~1000 polyps	Adenomatous polyps with low to moderate grade epithelial dysplasia
G/16 y	p. Ser583X (c.1748 G>A)	~ 10-100 polyps	Adenomatous polyps with moderate grade epithelial dysplasia
B /17 y	p. Ser583X (c.1748 G>A)	~ 100-1000 polyps	Adenomatous polyps with low grade epithelial dysplasia
B/14 y	p. Ser583X (c.1748 G>A)	~ 100-1000 polyps	Adenomatous polyps with low grade epithelial dysplasia

CONCLUSION: The development of colon adenocarcinoma in patients with FAP could occur also in pediatric age even without any previous alarming symptom. Children with a positive family history should be checked regularly and in the presence of FAP an intensive follow-up & eventually early intervention should be considered.

INTRODUCTION: This study was conducted to evaluate efficacy and safety of celecoxib versus placebo in paediatric subjects with familial adenomatous polyposis (FAP).

AIMS & METHODS: The standard of care for FAP has long been prophylactic colectomy, a major surgical procedure associated with up to 2% mortality. Colonoscopic polypectomy has a role in maintaining a minimal polyp burden, in order to delay surgery in the typically young (age 10-16 y) patient. Elevated levels of cyclooxygenase-2 (COX-2) in colorectal adenomas suggest that COX-2 inhibitors may help maintain the polyp burden within the limits of endoscopic management, as has been demonstrated in clinical trials.

METHODS: This was a randomised, double-blind, multicentre, placebo-controlled, 5-year study in subjects aged 10-17 years, with a confirmed diagnosis of FAP (based on mutation testing) and no more than 30 colorectal polyps at screening, all of which had to be removed such that no subjects initiated treatment with an adenoma > 2 mm. Approximately 200 subjects were to be randomized in a 1:1 ratio to the 2 treatment arms: celecoxib 16 mg/kg/d or placebo. Subjects had yearly visits, with colonoscopies at each visit. The primary end point was the time-to-treatment failure, defined as the time from randomisation to the earliest occurrence of ≥ 20 polyps (> 2 mm in size) at any colonoscopy during the study or diagnosis of colorectal malignancy.

RESULTS: The study was terminated, at the recommendation of the Data Monitoring Committee, due to lower than expected enrolment and end point accumulation rate. At the time of study termination, 106 subjects had been randomised. There were 7 (13%) subjects in the celecoxib group and 13 (26%) in the placebo group who met the primary end point. Among them, the median time to disease progression was 2.1 years in the celecoxib group and 1.1 years in the placebo group, respectively. None of the subjects in any treatment group developed colorectal malignancy. The proportion of subjects reporting all causality treatment-emergent adverse events (TEAE) was similar between the treatment groups: 40 (76%) subjects in the celecoxib group and 35 (73%) subjects in the placebo group. The proportion of subjects with treatment-related TEAEs was also similar: 18 (34%) subjects in the celecoxib group and 15 (31%) subjects in the placebo group. The most common AEs (occurring in more than 10% of subjects in a group) were abdominal discomfort, abdominal pain, diarrhoea, nausea, vomiting, fatigue, seasonal allergy, influenza, nasopharyngitis, upper respiratory tract infection, pain in extremity, headache, cough, and oropharyngeal pain.

CONCLUSION: Treatment with celecoxib in children with FAP was generally well tolerated, with a safety and tolerability profile similar to that observed in previous studies, and with no new or unexpected safety results. Although a trend toward delay in progression of adenomas was seen in the celecoxib arm, it was not statistically significant, which was likely to be related to low sample size and event rate.

Contact E-mail Address: *shungtang@hotmail.com*

INTRODUCTION: Endoscopic stenting with self-expandable metallic stent (SEMS) is a widely accepted procedure for the palliative management of malignant colonic obstruction and as a bridge to surgery, however, was not able to be performed under Japanese insurance system. We conducted prospective feasibility study, after this procedure was covered by government medical insurance in Jan. 2012.

AIMS & METHODS: Our objectives were to estimate safety and feasibility of SEMS placement for malignant colorectal obstruction in general clinical practice in Japan.

We conducted a prospective, observational, single-arm and multicenter clinical trial from Mar. 2012 to Oct. 2013. This study was registered with UMIN Clinical Trial Registry (UMIN000007953). Forty five facilities consisted of 12 academic and 33 community hospitals participated this study. Ahead of the start-up of the study, we launched a website (http://colon-stent.com/) and pronounced the standard methods based on previous published data to standardize the maneuver of SEMS placement. Each patient was treated with an uncovered WallFlex Enteral Colonic Stent (Boston Scientific Corporation). SEMS were placed under fluoroscopy and endoscopy. Technical success was defined as deployment of the stent across the entire length of the stricture on the first attempt. Clinical success was defined as a resolution of symptoms and radiological relief of the obstruction within 24 h. Patients undergoing the stenting as a bridge to surgery (BTS) were followed until surgery, and incurable patients undergoing palliative treatment (PAL) were followed until death or 12, whichever came first. The following conditions were considered to be complications: stent occlusion, stent migration, colonic erosion or ulcer, perforation, hematochezia, tenesmus, and bacteremia. Complications were categorized as early (within 7 days) or late (after 7 days).

RESULTS: We registered 518 patients. Six patients were excluded, because of loose stenosis with passed by colonoscope (3), benign stricture (1), unknown indication (1) and placement with another SEMS (1). We enrolled 512 patients for a BTS (311) and PAL (201) indication. In an intension-to-treat analysis, technical and clinical success was 98% (97% BTS, 99% PAL) and 96% (96% BTS, 95% PAL). The overall early complication rate was 8% (7% BTS, 9% PAL), including stent occlusion 1.2% (0.3% BTS, 2.5% PAL), stent migration in 1.5% (0.5% BTS, 2.3% PAL), perforation in 1.9% (2.3% BTS, 1.5% PAL).

CONCLUSION: This large multicenter, prospective study demonstrates the feasibility of SEMS placement for malignant colorectal obstruction within 7 days after SEMS placement. Despite of short period experience of this procedure in Japan, the incidence of complications including perforation was relatively low.

P0959 EICOSAPENTAENOIC ACID (EPA) SUPPRESSES COLORECTAL ABERRANT CRYPT FOCI (ACF) AND CELL PROLIFERATION IN COLORECTAL EPITHELIUM VIA GPR120

T. Higurashi[1,*], S. Uchiyama[1], S. Umezawa[1], E. Sakai[1], H. Ohkubo[1], H. Endo[1], H. Takahashi[1], A. Nakajima[1]

[1]*Department of Gastroenterology and Hepatology, Yokohama City University, Yokohama, Japan*

INTRODUCTION: Eicosapentaenoic acid (EPA), the omega-3 polyunsaturated fatty acid (ω3PUFA) that is widely used in the treatment of hyperlipidemia and

prevention of cardiovascular disease, has recently been suggested to have a suppressive effect on tumorigenesis and cancer cell growth. However, the mechanism of EPA chemopreventive effect was still unclear. Recently, G-protein coupled receptor 120 (GPR120) functions as a receptor forω3PUFA and has a critical role in various physiological homeostasis mechanisms. It is known that GPR120 is expressed abundantly in the intestinal tract and in adipocytes. However, it is unclear that the role of GPR120 in intestinal tract, especially in anti-carcinogenesis effect against EPA. In the present study, we explore the colon chemopreventive effect of EPA focused on via GPR120 pathway using GPR120 deficient mice.
AIMS & METHODS: We produced and used GPR120 deficient mice and the littermate wild type mice. Both mice were fed with normal diet or EPA containing chow. Then we investigated carcinogen-induced formation of aberrant crypt foci ACF and tumors in the colon.
RESULTS: In WT, mice fed with EPA were significantly suppressed ACF formation. On the other hand, in GPR deficient, both mice fed with normal diet and EPA containing chow were present similar ACF formation.
CONCLUSION: We demonstrated the importance of EPA/GPR120 signaling in the colon in colorectal carcinogenesis.

P0960 DOES THE UBIQUITIN PROTEASOME SYSTEM IS INVOLVED IN THE EFFECTS OF PAR2 RECEPTORS ACTIVATION IN THE INTESTINE?

I. Ghouzali[1,2,*], S. Azhar[1], C. Bôle-feysot[1], P. Déchelotte[1,3], M. Coëffier[1,3]
[1]*UMR 1073 nutrition, inflamation, brain gut axis dysfunction,* [2]*Institute for Research and Innovation in Biomedicine, University of Rouen,* [3]*Department of Nutrition, University Hospital, Rouen, France*

INTRODUCTION: The irritable bowel syndrome (IBS) is a functional disorder in which chronic digestive discomfort or abdominal pain are the primary symptoms. Dysfunction of the intestinal barrier has been observed leading to changes in the immune system and visceral hypersensitivity. Protease-activated receptor type 2 (PAR2) and ubiquitin-proteasome system might play contribute to the pathophysiology of IBS. Thus, we aimed to investigate whether ubiquitin proteasome system might be involved in the effects of PAR2 activation in human intestinal epithelial Caco-2 cells and in C57BL/6 mice.
AIMS & METHODS: Caco-2 cells were grown on microporous filters to obtain a monolayer of polarized cells and were then incubated with the agonist peptide PAR2 (PAR2-AP, 100μM) and/or IL-1β (1ng/ml) and/or a proteasome inhibitor, MG132 (10 μM). Production of proinflammatory IL-8 chemokine was measured by ELISA in apical and basolateral culture media. Proteolytic activities of proteasome, paracellular permeability and the expression of subunits of proteasome have been evaluated. C57BL/6 Mice also received intraperitoneal injection of a proteasome inhibitor MG132 (15μmol/kg) or "vehicle". After one hour, under anesthesia, mice received intracolic injection of a solution of 100μl of PAR2-AP (1mg/ml) or saline. After 4 hours, production of proinflammatory CXCL1/KC chemokine was measured by ELISA in colonic washes and in portal serum.
RESULTS: Addition of PAR2-AP alone did not influence the ubiquitin-proteasome system, both in its activity and in its composition. However, when PAR2-AP was combined with IL-1β, chymotrypsin-like and caspase-like proteasome activities were increased (2.85 and 1.37 fold changes, respectively) as well as the composition of proteasome. Indeed, the ratio β5i / β5 was significantly decreased. Production of IL-8 and its mRNA level was increased in presence of PAR2-AP ($p < 0.05$). In Caco-2 cells polarized model, production of IL -8 was apical or basolateral differentially modulated when PAR2-AP was applied in apical or basolateral media. Proteasome inhibitor, MG132, exacerbated effects of PAR2-AP on production of IL-8 and barrier function. In mice, intracolonic injection of PAR2-AP decreased production of CXCL1/KC in both luminal and portal sides. This effect was blocked by injection of MG132.
CONCLUSION: In conclusion, we have shown in a cell model that PAR2 agonist peptide alone did not affect the ubiquitin-proteasome system under basal conditions but can modify proteasome activities in presence of an inflammatory stimulus (IL-1β). Furthermore, complete inhibition of proteasome enhances effects of PAR2 activation on inflammatory response and intestinal barrier. In contrast, in mice, inhibition of proteasome blocks effects of agonist peptide PAR2 on production CXCL1/KC. Further studies are needed to explain these results.

INTRODUCTION: It has been shown that interventions on the gut microbiota affect behaviour in rodents and healthy human volunteers. This has led to establish what is now recognized as the microbiota-gut-brain axis. However, the mechanisms of communication between microbes and nerve cells or nerve endings in the gastrointestinal tract (GIT) remain largely unknown.
The intestinal microbiota is composed by a large number of microorganisms, including gram-positive lactic acid bacteria, which are able to interact with several cell types within GIT, including epithelial cells. Due to their ability to express neuropeptides, epithelial cells might act as intermediaries capable of transducing signals from luminal bacteria to nerve cells or sensory nerve endings in the GIT wall. One candidate neuropeptide is urocortin 2 (UCN2), which is known to regulate visceral nociception and gastric emptying.
AIMS & METHODS: We aimed to evaluate whether human colonic epithelial cells (Caco-2 cell line) are able to increase UCN2 mRNA expression upon stimulation with three types of *Lactobacillus* species: *L. rhamnosus* GG, *L. casei* L54-2-33 and *L. plantarum* L46-1-12. For this, Caco-2 cells were stimulated with 10^3, 10^5 and 10^7 colony forming units (cfu) per millilitre (cfu/mL) of each *Lactobacillus* strain for 3 hours. Control Caco-2 cells were exposed to broth alone. Then, total mRNA was extracted and UCN2 mRNA expression was analyzed using RT-PCR.
RESULTS: Caco-2 cells stimulated with 10^5 and 10^7cfu/mL of *L. casei* L54-2-33 displayed increased levels of UCN2 mRNA in comparison to control Caco-2 cells. On the other hand, stimulation of Caco-2 cells with 10^7cfu/mL of *L. plantarum* L46-1-12 reduced UCN2 mRNA expression in comparison to controls, while *L. rhamnosus* GG was not able to affect UCN2 expression at any of the analyzed doses.
CONCLUSION: These findings show that lactic acid bacteria are able to modulate neuropeptide expression (i.e.: UCN2) in intestinal epithelial cells, suggesting a potential pathway of communication with the nervous system. Modulation of UCN2 expression was strain specific suggesting that alterations in the intestinal microbiota and/or interventions through the use of antibiotics or probiotic bacteria would differentially affect this communication and potentially have differential effects on the gut-brain axis.

P0962 ACUTE PSYCHOLOGICAL STRESS INCREASES PARACELLULAR PERMEABILITY IN THE SIGMOID COLON OF HEALTHY VOLUNTEERS

L. Gerdin[1,2,*], M. Persborn[3], Y. Braaf[1,2], C.D. Ley Magana[1], M. Olsson[4], A.-C. Ericson[1], S. Walter[5], J. Dabrosin Söderholm[1]

INTRODUCTION: Psychological stress (PS) has been shown to have an effect on the course of both irritable bowel syndrome (IBS) and ulcerative colitis (UC). The mechanisms behind these effects are as yet unknown. Animal studies have shown that PS increases the intestinal barrier function. Our group has previous preliminary data showing that in vivo PS increases paracellular permeability in the rectum of healthy volunteers (HV). Whether or not the same is true for the sigmoid colon is unknown.
AIMS & METHODS: 18 HV (11 women and 7 men) were stressed using the method modified dichotomous stress for 60 minutes. Stress was monitored as blood pressure (BP), pulse (HF) and subjectively using a visual analogue scale (VAS). The control session was 60 min listening to calm music and the same HV were their own controls. Immediately following the stress/control sessions biopsies were taken from the sigmoid colon. The biopsies were mounted in modified Ussing chambers and passage of the paracellular permeability marker CrEDTA was measured for 120 min.
RESULTS: VAS, BP and HF were significantly higher at the stress than at the control session. There was a significant increase in passage of CrEDTA (6.2E-06 (5.3 E-06 -8.3 E-06)cm/s vs 4.4 E-06 (3.3-6.2) cm/s (median(IQR) ($p(<0.05)$.
CONCLUSION: Vanuytsel et al have recently shown that PS increases paracelluar premability in the small intestine in HV. Our results show similar permeability results in the colon. The mechanisms should be further investigated.

INTRODUCTION: Visceral hypersensitivity is an important pathophysiological mechanism of stress-related FGIDs. In recent years, abnormalities of brain activity are thought to play important roles in the pathogenesis of visceral hypersensitivity. The insula as one important center processing visceral sensory and regulating emotion is inferred to be closely related with the pathogenesis of visceral hypersensitivity induced by chronic stress. However, the role of insula in visceral hypersensitivity has not been clearly defined.
AIMS & METHODS: We aimed to determine if insular neuron activation plays an important role in visceral hypersensitivity induced by chronic stress. Chronic water avoidance stress (WAS) was used to establish visceral hypersensitivity rat models. Visceral sensitivity was determined by measuring visceromotor response (VMR) amplitude to graded colorectal distention (20mmHg, 40mmHg, 60mmHg CRD). The bilateral insula was stimulated electrically, and insular lesions were generated with n-methyl-d-aspartate (NMDA).
RESULTS: Compared with sham WAS (2.07±0.61) and normal rats (2.15±0.46), the VMR to graded CRD in WAS rats (4.22±0.35) significantly

increased (p = 0.000). Bilateral insular lesions caused a significant decrease of the VMR in WAS rats (2.17±0.56) comparing with that in sham-lesion (4.02±0.84) and non-lesion WAS (4.35±0.87) rats (p = 0.000). The VMR to 60mmHg in insular lesion WAS rats have no significant differences with that in normal rats (p = 0.691). Electrically stimulating (ES) the left or right insula all enhanced the VMR of WAS rats (left: ES-before 4.62±1.51, ES-after 13.59±4.27 p = 0.000; right: ES-before 4.54±0.62, ES-after 13.95±4.77 p = 0.000) and the increase level of VMR amplitude had no significant differences between bilateral insula electrically stimulated (p > 0.05)

CONCLUSION: Insula plays a critical role in the modulation of visceral hypersensitivity induced by chronic stress, without unilateral advantage phenomenon in modulating process. After insular lesions, the pathological hypersensitivity symptoms in visceral hypersensitivity rats disappearance, but it keeps "natural state" visceral sensitivity.

P0964 IN IBS PATIENTS WITH SEVERE POSTPRANDIAL BLOATING AND ABDOMINAL DISTENTION, COLONIC TONE IS REDUCED IN POSTPRANDIAL PERIOD

M. Di Stefano[1], **M. Bergonzi**[1,*], C. Mengoli[1], E. Pagani[1], E. Miceli[1], G.R. Corazza[1]

[1]*1st Department of Internal Medicine, IRCCC Policlinico S. Matteo, University of Pavia, Pavia, Italy*

Contact E-mail Address: *m.distefano@unipv.it*

INTRODUCTION: Bloating is a very frequent complaint, is frequently associated to IBS and, in a subgroup of patients, is accompanied by a severe, visible abdominal distention. These subgroup of patients is characterized by different clinical presentations: bloating and abdominal distention onset may be related or not to food ingestion, they may be absent on waking and progressively worsen during the day, they may occur immediately after meal ingestion. The characteristics of the onset suggest a different pathophysiology.

AIMS & METHODS: Accordingly, we studied colonic tone in fasting condition and after a meal in a group of IBS patients with bloating and abdominal distention and we compared the results of patients with a meal-related and a meal unrelated occurrence of symptoms.

A group of 38 consecutive IBS patients (mean age 38.4±9.4 years, range 21-60, IBS-C = 20; IBS-D = 5 IBS-M = 13) with severe bloating and abdominal distension, diagnosed according to Rome III criteria was enrolled. Twenty-one patients suffered from postprandial onset of bloating and severe abdominal distention and 17 had meal-unrelated symptoms. In all subjects, recto-sigmoid tone was monitored with barostat, during a 30-min fasting period and a 60-min period after meal consumption (200 Kcal, 200 ml liquid meal). Every ten minutes, the occurrence of abdominal distention was monitored by abdominal girth measurement.

RESULTS: In the subgroup of patients with postprandial occurrence of bloating and abdominal distention, meal intake induced a significant decrease of recto-sigmoid tone as mean postprandial recto-sigmoid volume modification was +26.6±4,4% in these patients; on the contrary and as expected, in the subgroup with meal unrelated symptoms, mean recto-sigmoid volume modification was -4,1±4.0% (p = 0.001). Moreover, in patients with postprandial symptoms a meal-induced increase of the balloon volume higher than 10% of the fasting value was present in 14/21 (66.7%) vs 2/17 (11.7%) of the other subgroup (p = 0.0009) and postprandial abdominal girth significantly increased (85.0 cm ± 7.7 cm) vs the other subgroup (83.4 cm ± 7.2; p < 0.01).

CONCLUSION: A reduction of intestinal tone in the postprandial period may represent an important pathophysiological mechanism for the occurrence of abdominal distention in functional patients with bloating. An inappropriate, diffuse activation of a nitrergic pathway might be responsible for this alteration.

P0965 DIFFERENTIAL EFFECTS OF EXTRACELLULAR CYCLIC GMP (CGMP) AND THE GUANYLATE CYCLASE-C (GC-C) AGONIST, LINACLOTIDE, ON MOUSE GASTRIC VAGAL AFFERENT MECHANOSENSITIVITY

S.J. Kentish[1], T.A. O'Donnell[1], S.M. Brierley[1], C. Kurtz[2], A. Silos-Santiago[2], **A. Page**[1,*]

[1]*University of Adelaide, Adelaide, Australia,* [2]*Ironwood Pharmaceuticals Inc., Cambridge, United States*

Contact E-mail Address: *amanda.page@adelaide.edu.au*

INTRODUCTION: cGMP is a second messenger produced in intestinal epithelial cells in response to GC-C activation. GC-C is expressed in the epithelium of the stomach (1). In addition, the endogenous peptide ligand for GC-C, uroguanylin, is located in enterochromaffin-like cells within the stomach (2). These findings suggest the stomach mucosa may be capable of producing cGMP in response to a GC-C agonist. In mouse colon both extracellular cGMP and linaclotide inhibit colonic nociceptor mechanosensitivity. Vagal afferents are associated with reflexes commonly altered in diseases such as functional dyspepsia. However, little is known about the effects of GC-C receptor activation and cGMP on these afferents.

AIMS & METHODS: We aimed to determine the effect of extracellular cGMP and linaclotide on gastric vagal afferent mechanosensitivity. Single fibre *in vitro* recordings of gastric vagal mechanoreceptors from 8wk old female C57BL/6 mice were recorded (3). The response of mucosal receptors to mucosal stroking with von Frey hairs (10-1000mg) and tension receptors to circular stretch (1-5g) in the absence and presence of cGMP (30-1000μM) or linaclotide (10-300nM) was determined. An increase or decrease in response to mucosal stroking (50mg)/circular tension (3g) of ≥ 20% in the presence of cGMP or linaclotide was considered to be potentiation or inhibition, respectively.

RESULTS: The effect of cGMP and linaclotide on gastric vagal afferent mucosal and tension receptor mechanosensitivity is illustrated in the table below:

	cGMP (30-1000μM)			Linaclotide (10-300nM)		
	Inhibit	**Potentiate**	**No effect**	**Inhibit**	**Potentiate**	**No effect**
% gastric mucosal receptors	27% (n = 7)	31% (n = 8)	42% (n = 11)	36% (n = 5)	41% (n = 9)	23% (n = 8)
% gastric tension receptors	0%	44% (n = 7)	56% (n = 9)	18% (n = 6)	55% (n = 12)	27% (n = 4)

The inhibitory and excitatory effects of linaclotide occurred close to the limiting ridge in the corpus and along the lower curvature of the stomach respectively. In contrast, there was no relationship between cGMP effects on vagal afferents and the location of these afferents in the stomach.

CONCLUSION: Linaclotide and extracellular cGMP can both inhibit and enhance responses of gastric vagal afferents to mechanical stimulation. The functional significance of these effects on gastric sensory signalling remains to be determined.

INTRODUCTION: Linaclotide, a guanylate cyclase C (GC-C) agonist, reduces abdominal pain and improves constipation in patients with irritable bowel syndrome with constipation (IBS-C).[1] We recently showed that linaclotide activates GC-C expressed on intestinal epithelial cells, resulting in the production and release of cyclic GMP (cGMP), which accelerates gastrointestinal transit and inhibits colonic nociceptors.[1] We have also shown that key components of the GC-C/cGMP signalling pathway are expressed within human colonic mucosa.

AIMS & METHODS: We investigated whether components of the GC-C/cGMP signalling pathway are differentially expressed in different IBS patient subtypes. Recto-sigmoid mucosal biopsies were obtained from healthy subjects (N = 10) and IBS patients (N = 14), as per Rome II criteria. We compared IBS patients with mixed (constipation and diarrhoea) bowel habits (IBS-M; N = 7) and patients with IBS-C (N = 7). RNA was extracted from biopsies and Taqman qRT-PCR used to assess mRNA expression of: GC-C (*GUCY2C*); the endogenous GC-C agonists, guanylin (*GUCA2A*) and uroguanylin (*GUCA2B*); and the cGMP transporters, MRP4 (*ABCC4*) and MRP5 (*ABCC5*). Expression of these targets was determined relative to the housekeeping genes 18S RNA and GAPDH. In separate biopsies, immunohistochemistry determined localisation of GC-C/cGMP signalling pathway components to cellular structures.

RESULTS: In mucosal biopsies from healthy controls, guanylin was the most abundantly expressed component of the GC-C/cGMP signalling pathway, followed sequentially by uroguanylin ($P < 0.01$), GC-C ($P < 0.001$), MRP5 ($P < 0.001$) and MRP4 ($P < 0.001$), respectively. In IBS-M biopsies, both of the endogenous GC-C agonists (guanylin and uroguanylin) were significantly reduced compared with healthy controls ($P < 0.05$). By contrast, in IBS-C patient biopsies, MRP4 was significantly down-regulated compared with expression in biopsies from healthy controls ($P < 0.001$). No significant change in either MRP5 or GC-C expression was observed between IBS patient subtypes and healthy controls. Immunohistochemistry revealed MRP4 expression on the apical side of colonic epithelial cells, whilst MRP5 displayed basolateral expression.

CONCLUSION: Distinct alterations in the GC-C/cGMP pathway are evident between different subtypes of IBS patients and may contribute to the pathophysiology of IBS. In IBS-M, reduced expression of the endogenous hormones guanylin and uroguanylin may contribute to alternating bowel habits. In IBS-C, a reduction in apically expressed MRP4 may result in reduced release of cGMP into the colonic lumen. Overall, these changes may help to explain some aspects of the pathophysiology associated with IBS and the differential stool frequency and symptom patterns between IBS subtypes, which are under further investigation.

P0967 EXTRACELLULAR CYCLIC GMP, THE DOWNSTREAM MEDIATOR RELEASED IN RESPONSE TO LINACLOTIDE-INDUCED ACTIVATION OF GUANYLATE CYCLASE C, REDUCES EXCITABILITY OF MURINE AND HUMAN DORSAL ROOT GANGLION NEURONS

J. Castro[1,2], G.Y. Rychkov[3], A. Ghetti[4], A.M. Harrington[1,2], C. Kurtz[5], **I. Silos-Santiago[5,*], S.M. Brierley[1,2]**

INTRODUCTION: Linaclotide, a guanylate cyclase C (GC-C) agonist, reduces abdominal pain and improves constipation in patients with irritable bowel syndrome with constipation (IBS-C).[1] Cyclic GMP (cGMP) is a second messenger produced in intestinal epithelial cells in response to GC-C activation. We have recently shown that both linaclotide and exogenous extracellular cGMP inhibit colonic nociceptor mechanosensitivity with greater efficacy during chronic visceral hypersensitivity (CVH) compared with healthy nociceptors.[1] However, the effects of exogenous cGMP on sensory neuron function remain to be determined in isolation.
AIMS & METHODS: We investigated the effects of exogenous extracellular cGMP on dorsal route ganglion (DRG) neurons isolated from both mice and humans. For mouse DRG studies we performed whole-cell patch-clamp recordings in current-clamp mode from retrogradely traced colonic DRG neurons. We compared the effect of cGMP (100 nM-50 μM) on the rheobase, or threshold for action potential firing, of DRG neurons from healthy C57BL/6 mice and mice with CVH, 28 days post-trinitrobenzene sulphonic acid administration.[1] For human DRG studies we performed calcium-imaging studies and compared the effects of cGMP (10 μM-300 μM) on Ca^{2+} influx in response to hypo-osmotic stimuli of DRG neurons from healthy donors.
RESULTS: Colonic DRG neurons from CVH mice displayed a significantly reduced rheobase ($P<0.001$, n = 13-23) and fired significantly more action potentials ($P<0.05$, n = 13-23) compared with healthy mice. In a subpopulation of colonic DRG neurons, cGMP inhibited the neuronal excitability of putative nociceptors, significantly increasing the rheobase ($P<0.01$) and reducing action potential discharge ($P<0.01$). This effect was evident in both healthy and CVH DRG neurons, was most apparent in CVH DRG neurons, and occurred at concentrations as low as 100 nM cGMP. In human DRG neurons, cGMP induced an overall reduction in the number of cells responding to hypo-osmotic stimulation. In addition, in human DRG neurons cGMP caused, in a concentration-dependent manner, up to 60% inhibition of the Ca^{2+} influx induced by hypo-osmotic stimulation.
CONCLUSION: Exogenous cGMP directly decreases the excitability of sensory DRG neurons isolated from both mice and humans. These results complement our previous findings in mice, which demonstrated that cGMP inhibited the peripheral endings of nociceptors within the wall of the colon. These current findings also provide further mechanistic insight into how linaclotide, through GC-C agonism and the release of cGMP from mucosal epithelial cells, reduces nociceptive signalling from the colon.

P0968 EFFECT OF TOLL LIKE RECEPTORS 2 AND 4 ON THE SEROTONIN INDUCED MOTOR RESPONSE MEDIATED BY 5-HT2 AND 5-HT3 RECEPTORS IN MOUSE ILEUM

INTRODUCTION: The recognition of intestinal microbiota is in part carried out by toll-like receptors (TLR), which are responsible for initiating the innate immune response. Alterations in the intestinal microbiota may contribute to the development of intestinal inflammatory pathologies. Moreover, it has been described that the serotonergic system may result also altered in situations of intestinal inflammation. Serotonin (5-HT) has been shown to regulate gastrointestinal motility by binding to several receptors ($5\text{-}HT_{1\text{-}7}$). However, the influence of TLRs in 5-HT intestinal motor response mediated by 5-HT receptors in the intestine remains unknown.
AIMS & METHODS: The aim of this study was to investigate the role of $5\text{-}HT_2$ and $5\text{-}HT_3$ receptors in the motor response induced by 5-HT in the mouse ileum, and the involvement of TLR2 and TLR4 in this response.
Segments of ileum from male C57/BL10 wild-type (WT), TLR2 $^{-/-}$ and TLR4 $^{-/-}$ mice of 8-12 weeks old were suspended in an organ bath in the direction of longitudinal smooth muscle fibres. The effects of ritanserin ($5\text{-}HT_2$ receptor antagonist) or ondansetron ($5\text{-}HT_3$ receptor antagonist) on motor responses induced by 5-HT in the WT, TLR2 $^{-/-}$ and TLR4 $^{-/-}$ mice were studied. The gene expression (mRNA) of $5\text{-}HT_2$ and $5\text{-}HT_3$ receptors was determined in ileum from WT, TLR2 $^{-/-}$ and TLR4 $^{-/-}$ mice by quantitative RT-PCR.
RESULTS: Expression of $5\text{-}HT_{2A}$, $5\text{-}HT_{2B}$ and $5\text{-}HT_3$ receptors was found in ileum from WT mice. The contractile response induced by 5-HT 100 μM in ileum from WT mice was partially reverted by ritanserin 1 nM and ondansetron 10 nM, suggesting that $5\text{-}HT_2$ and $5\text{-}HT_3$ may be involved in this response. Expression of $5\text{-}HT_{2A}$, $5\text{-}HT_{2B}$ and $5\text{-}HT_3$ in ileum from TLR2 $^{-/-}$ mice, was not modified compared with WT mice. 5-HT-induced contractile response in TLR2$^{-/-}$ mice was partially reverted by ritanserin but not by ondansetron, indicating that $5\text{-}HT_2$ but not $5\text{-}HT_3$ may be involved in this response. In TLR4 $^{-/-}$ mice ileum, the expression of $5\text{-}HT_{2A}$, $5\text{-}HT_{2B}$ and $5\text{-}HT_3$ resulted increased compared with WT mice. The 5-HT-induced contractile response in TLR4$^{-/-}$ was blocked by ritanserin and ondansetron, suggesting that $5\text{-}HT_2$ and $5\text{-}HT_3$ may be involved in this response.
CONCLUSION: These results suggest that $5\text{-}HT_2$ and $5\text{-}HT_3$ receptors are involved in the contractile response evoked by serotonin in mouse ileum. Furthermore, TLR2 and TLR4 seem to interact with $5\text{-}HT_2$ and $5\text{-}HT_3$ receptors.

P0969 ELECTROPHYSIOLOGICAL PROPERTIES OF COLON BIOPSIES FROM PATIENTS WITH IRRITABLE BOWEL SYNDROME ARE ALTERED BY EXPOSURE TO E. COLI

S.M. P. Bennet[1,*], M. Sapnara[1], H. Sjövall[1], J.K. Gustafsson[2], H. Eutamene[3], B.L. Neve[4], H. Törnblom[1], L. Öhman[1], M. Simrén[1]

INTRODUCTION: Prior research indicates altered basal bowel permeability in IBS patients and aberrations in the expression of tight junction proteins (TJP). We therefore studied the electrophysiological characteristics of colon biopsies using square wave current analysis *in vitro*.
AIMS & METHODS: Sigmoidal colonic biopsies (unprepared colon) from 35 IBS patients (female = 27, median age 29 years (27-37)), (Rome III; IBS-C = 4, IBS-D = 6, IBS-M = 25) and 20 healthy controls (female = 14, median age 36 years (27-47)) were mounted in miniaturized Ussing chambers and a solution with or without *E. coli* ($1x10^8$ CFU/ml) was added to the luminal side. The electrical properties of the mucosa were assessed by square wave current analysis that enables quantification of epithelial/tight junction resistance, net current generated by the membrane, and membrane capacitance reflecting the process of exocytosis. To induce epithelial chloride secretion and/or release of mucin from goblet cells, carbachol (Cch, 1mM) was added on the serosal side. In addition, TJP, claudin and occludin expression in 114 IBS patients (female = 72, median age 32 years (27-39)) (Rome III; IBS-C = 14, IBS-D = 26, IBS-M = 74) and 37 healthy controls (female = 25, median age 27 years (23-35)) was analysed using qRT-PCR. Immunohistochemistry was used to determine the tight junction protein ZO-1 (TJP1) in 56 IBS patients (female = 38, median age 30 years (24-36)) and 19 healthy controls (female = 12, age median age 33 years (26-48)). Data is shown as median, range 25-75 percentile.
RESULTS: Carbachol addition evoked similar changes in electrophysiological parameters in IBS patients and healthy controls, with no differences seen between IBS subgroups. However, IBS biopsies exposed to *E. coli* had an increased basal membrane resistance (10.4 Ohm *cm^2(9.2-12.5) vs. 8.3 Ohm*cm^2 (7.5-10); p = 0.01) and net membrane current (-203.7 uA/cm^2 (-311.9 – -115.9) vs. -121 uA/cm^2 (-210.3 – -79.7); p = 0.005) compared to unexposed IBS biopsies. *E. coli* exposed IBS biopsies also had an increased response to CCh compared to unexposed IBS biopsies (-321.5 uA/cm^2 (-411.3 – -216.5) vs. -236.8 uA/cm^2 (-335.8 – -102.3); p = 0.01) and a reduced capacitance response (4.3 uF/cm^2 (2.5-8.2) vs. 7.8 uF/cm^2 (6.2-11.7); p = 0.04). qRT-PCR analyses, demonstrated a tendency

towards lower expression of claudin ($p = 0.07$) and TJP1 ($p = 0.06$) in IBS patients compared to healthy controls. Occludin expression was similar in IBS patients and healthy controls, but was higher in IBS-C compared to IBS-M ($p = 0.004$). No significant difference was seen in levels of TJP1 ZO-1 protein expression between IBS patients and healthy controls ($p = 0.4$).
CONCLUSION: Colon mucosa from IBS patients reacts differently to mucosal exposure to E. coli, with increased basal membrane resistance and net membrane current as well as an increased reactivity to the muscarinic agonist CCh. The exact mechanisms behind these phenomena remain unknown but may reflect altered reactivity of epithelial ion channels and/or tight junctions.

INTRODUCTION: The pathophysiology behind gastrointestinal dysmotility in diabetes mellitus is unknown. Both esophageal dysmotility and gastroparesis have been shown to be associated with retinopathy, suggesting microangiopathy as important also for dysmotility.
AIMS & METHODS: The aim of the present study was to examine whether patients with diabetes mellitus exhibit microangiopathy in the large intestine, and if present, to correlate this to the clinical picture.
Consecutive patients subjected to surgery of the large intestine at any of the Departments of Surgery in the southernmost districts of Skåne between January 2011 and May 2013 were identified. All medical records were scrutinized, and patients with a history of diabetes mellitus were reconsidered for histopathologic reevaluation, according established criteria (1, 2). Morphometric examination of the vessels was compared with biopsies from non-diabetic patients. Gender, age, type of diabetes, diabetic complications, type of diabetes treatment, and other concomitant diseases were registered from the medical records.
RESULTS: Of 1135 identified patients during the studied time period, 94 patients suffered from diabetes mellitus and were finally examined. Twenty-nine non-diabetic patients served as controls. The mean age was 71.8 ± 10.3 and 70.0 ± 12.1 years in patients and controls, respectively. Microangiopathy was found in 68% of patients and in 17% of controls ($p < 0.001$). The wall-to-lumen relation was 0.31 (0.23–0.46) in patients with diabetes mellitus compared with 0.18 (0.13–0.24) in controls ($p < 0.001$). The records did not include any information about gastrointestinal symptoms. There was no association between microangiopathy and clinical picture available.
CONCLUSION: Microangiopathy in the large intestine is more common in patients with diabetes mellitus than in controls. This may contribute to dysmotility secondary to diabetes mellitus.

P0972 CHARACTERISATION OF NAUSEA IN WELL-CONTROLLED AND LONG-TERM, OPEN-LABEL STUDIES OF LUBIPROSTONE FOR CHRONIC IDIOPATHIC CONSTIPATION, OPIOID-INDUCED CONSTIPATION, AND IRRITABLE BOWEL SYNDROME WITH CONSTIPATION

INTRODUCTION: Lubiprostone (LBP) has been studied for the treatment of chronic idiopathic constipation (CIC) in adults, opioid-induced constipation (OIC) in adults with chronic non-cancer pain who are taking full-agonist opioids other than diphenylheptanes, and irritable bowel syndrome with constipation (IBS-C). LBP has a favourable overall safety profile, with nausea being the most common adverse event (AE). Here, we provide a detailed characterization of nausea in pivotal studies of LBP across all 3 indications.
AIMS & METHODS: The CIC analysis includes data pooled from 3 short-term (3–4 weeks' duration), randomised, placebo (PBO)-controlled and 3 long-term (one 24-week and two 48-week), open-label studies of LBP. Overall, 316 CIC patients received PBO and 1113 received LBP 24 mcg twice daily (BID). The OIC analysis includes data pooled from three 12-week, randomised, PBO-controlled studies and one 36-week, open-label extension study. OIC patients received PBO ($n = 652$) or LBP 24 mcg ($n = 889$) BID. The IBS-C analysis includes data pooled from three 12-week, randomised, PBO-controlled studies and one 36-week, open-label study. In total, 435 IBS-C patients received PBO and 1011 received LBP 8 mcg BID.
RESULTS: The crude incidence of nausea in patients receiving LBP was 31.1%, 13.9%, and 11.4% in the CIC, OIC, and IBS-C populations, respectively, when exposed to LBP for up to 12 months; corresponding rates in patients treated with PBO over 4- and 12-week periods ranged from 5.1%–6.7%. For the same time-periods, the incidence of severe nausea in patients receiving LBP was 3.5%, 1.0%, and 0.9% in the CIC, OIC, and IBS-C populations, respectively, with corresponding rates in patients treated with PBO ranging from 0%–1.1%. Nausea led to discontinuation in 8.7%, 2.1% and 1.3% of the CIC, OIC, and IBS-C populations receiving LBP, respectively, with corresponding discontinuation rates in patients treated with PBO ranging from 0%–0.7%. Of those CIC, OIC, and IBS-C patients who received LBP and reported nausea at any time during the treatment period, 83.6%, 87.9%, and 88.7%, respectively, reported only 1 event of nausea. Of these patients, 62.1%, 75.2%, and 63.7% did not require a change to their assigned dosing regimen for CIC, OIC, or IBS-C, respectively, with nearly three-quarters of these patients completing the full treatment period with LBP (72.7%, 70.7%, and 73.8%, respectively). Of those CIC, OIC, and IBS-C patients who reported only 1 nausea event, 12.0%, 8.3%, and 17.7%, respectively, either reduced their intake to once daily (QD) dosing or temporarily withheld medication, which allowed for 54.5%, 66.7%, and 100% of these patients, respectively, to complete LBP dosing in the clinical trial. Across the 3 indications, the majority of reported nausea events occurred during the first 5 days after beginning LBP treatment (66.9%).
CONCLUSION: Most patients report only a single event, with a majority of events being mild-to-moderate severity and occurring early in the treatment period. In addition to an emphasis on dosing with meals, dose reduction and/or temporary withholding of doses are strategies that may be employed for management of nausea in patients taking lubiprostone.

P0973 PUBORECTALIS MUSCLE AND EXTERNAL ANAL SPHINCTER DO NOT, BY DEFINITION, BEHAVE AS ONE FUNCTIONAL UNIT IN PATIENTS WITH FUNCTIONAL DEFECATION DISORDER

H.K. De Boer[1,2,*], E. Heineman[1,2], P.M. Broens[2]
[1]*University of Groningen,* [2]*Department of Surgery, University Medical Center Groningen, Groningen, Netherlands*
Contact E-mail Address: *p.m.a.broens@umcg.nl*

INTRODUCTION: Functional defecation disorder (FDD) is common and underlies about half of the cases of chronic constipation. Rome III-classification distinguishes dyssynergic defecation and inadequate defecatory propulsion, which can be further subdivided according to a classification proposed by Rao et al.[1,2]
Both classifications are based on the unsubstantiated assumption that puborectalis muscle and external anal sphincter behave as one functional unit during attempted defecation. What if it turns out that puborectalis muscle and external anal sphincter do not, by definition, function as one unit and are therefore not, by definition, equally affected in patients suffering from FDD? That could have an impact on both classification, diagnostics and treatment of FDD.
AIMS & METHODS: Anorectal manometry and defecometry test were performed in 124 adult patients suffering from FDD. Pressure changes were recorded at three levels: rectum, puborectalis muscle and external anal sphincter.
RESULTS: Defecometry test revealed that puborectalis muscle and external anal sphincter do not consistently contribute equally to FDD. Three main groups can be identified: congruent FDD (puborectalis muscle and external anal sphincter are more or less equally affected; $n = 105$), anal sphincter-dominated FDD (external anal sphincter is significantly more affected than puborectalis muscle; $n = 10$) and puborectalis-dominated FDD (puborectalis muscle is significantly more affected than external anal sphincter; $n = 9$).
Defecatory propulsive force (increase in rectal pressure that is required for defecation) is stronger correlated to pressure increase at the level of the puborectalis muscle ($\rho = 0.794$) than to pressure increase at the level of the external anal sphincter ($\rho = 0.488$).
Male patients generate a higher defecatory propulsive force than female patients ($p < 0.001$). They also build more pressure on the level of the puborectalis muscle ($p = 0.003$) and suffer relatively more often from puborectalis-dominated FDD.
CONCLUSION: Puborectalis muscle and external anal sphincter do not, by definition, behave as one functional unit in patients suffering from FDD and may thus differ in degree of dyssynergia. This understanding might have some important consequences for classification, diagnostics and treatment of FDD. It questions, for example, the reliability of the single probe electromyographic devices currently used in treatment of FDD.

P0974 CONFIRMATORY FACTOR ANALYSIS OF THE PATIENT ASSESSMENT OF CONSTIPATION-SYMPTOMS (PAC-SYM) IN PATIENTS WITH CHRONIC CONSTIPATION

L. Neri[1,*], P.M. Conway[2], G. Basilisco[3] on behalf of Laxative Inadequate Relief Survey (LIRS)
[1]*Clinical Science and Community Health, University of Milan, Milano, Italy,* [2]*Psychology, University of Copenhagen, Copenhagen, Denmark,* [3]*Gastroenterology and Endoscopy Unit, Fondazione IRCCS "Ca' Granda – Ospedale Maggiore Policlinico", Milano, Italy*
Contact E-mail Address: *luca.neri@unimi.it*

INTRODUCTION: PAC-SYM is widely adopted to evaluate constipation severity. However it has been validated in a small sample, few items have been included based on expert opinion and not on empirical grounds and its factor structure has never been replicated. We sought to assess its psychometric

properties, its responsiveness to clinical changes and characterizing its relationship with key outcomes such as quality of life and treatment satisfaction in a large sample of patients with chronic constipation.
AIMS & METHODS: We enrolled 2203 outpatients with chronic constipation in two waves. We used the wave I sample to test psychometric properties and construct validity of the PAC-SYM and wave 2 sample to cross-validate the factor structure with confirmatory factor analysis (CFA), and to assess criterion validity, responsiveness to clinical changes and the minimal clinically important difference.
RESULTS: We observed a large floor effect for rectal tearing (62%). Deletion of such item lead to a 11-item version (M: PAC-SYM). Exploratory Factor Analysis revealed a bifactor model with 2 subscales (stool and abdominal symptoms) and a general severity factor. CFA consucted on the second wave dataset supported this solution. The M:PAC-SYM demonstrated excellent reliability ($\alpha = 0.89$), moderate correlation with SF-12 and treatment satisfaction (r = 0.28-0.45), discrimination across Rome III criteria for functional constipation and abdominal pain (table 1), and responsiveness to clinical change (β -0.49; $\omega^2 = 0.25$). M:PAC-SYM minimal clinically important difference was 0.24.

Clinical Characteristics*	M-PAC-SYM Δ (σ)	M-ABD	M-STO
Rome III			
Lumpy/Hard Stools	**0.32 (0.40)**	0.16 (0.17)	**0.39 (0.42)**
Incomplete Evacuation	**0.44 (0.63)**	**0.29 (0.36)**	**0.52 (0.65)**
Obstruction	**0.57 (0.74)**	**0.29 (0.33)**	**0.68 (0.78)**
Manual Maneuvers	**0.26 (0.33)**	0.04 (0.04)	**0.39 (0.43)**
<3 defecations/wk	0.03 (0.04)	0.13 (0.15)	0.13 (0.14)
Strain	**0.29 (0.37)**	**0.22 (0.25)**	**0.33 (0.36)**
Abdominal Pain	**0.26 (0.32)**	**0.44 (0.48)**	0.16 (0.17)

CONCLUSION: We developed a modified version of the PAC-SYM which might better represent symptom severity of most patients seeking care in gastroenterology referral centers.

P0975 DIFFERENT INNERVATIONS FOR CONSCIOUS AND AUTONOMIC ANAL SPHINCTER CONTRACTIONS IN ADULT PATIENTS

M.M. van Meegdenburg[1,2,*], E. Heineman[1,2], P.M. Broens[1,2]
[1]*Surgery, University Medical Center Gorningen,* [2]*University of Groningen, Groningen, Netherlands*
Contact E-mail Address: *m.van.meegdenburg02@umcg.nl*

INTRODUCTION: Fecal continence is partially maintained by external anal sphincter contraction and the anal-external sphincter continence reflex[1,2]. Whereas the first system is supplied by the pudendal nerve[3], it is unknown if the reflex part of the external anal sphincter is also mediated by the pudendal nerve.
AIMS & METHODS: The present study aims to determine if in patients with pudendal neuropathy both continence systems, concerning the external anal sphincter, are malfunctioning. Retrospectively, we reviewed the medical records of all patients older than seventeen who had undergone an anorectal function test between January 2010 and March 2013 and in which nerve supply to and functional anatomy of the external anal sphincter was not damaged by surgery, trauma, and/or polyneuropathy (N = 70). The study was conducted at University Medical Center Groningen, the Netherlands.
RESULTS: The patients were divided into two groups, one group without signs of pudendal neuropathy (anal electrosensibility ≤ 4 mA at one and two centimeter into the anal canal, PudNP-), and the other group with signs of pudendal neuropathy (anal electrosensibility > 4 mA at one and two centimeter into the anal canal, PudNP+). Of the seventy patients, 76% had pudendal neuropathy. PudNP+ were significantly older than PudNP- ($P = .013$). Maximum anal sphincter contractility, i.e. conscious contraction, was significantly lower in PudNP+ than in PudNP- (median: 165 versus 235 mm Hg, $P = .007$). By contrast, pressure in the anal canal at maximum tolerable or retainable sensation, i.e. autonomic contraction, did not significantly differ between the two groups (median: 135 versus 153 mm Hg). Furthermore, no relation was found between maximum anal sphincter contractility and pressure in the anal canal at maximum tolerable or retainable sensation. Multiple linear regression analyses demonstrated that age and electrosensibility, measured at two centimeters into the anal canal, significantly predicted conscious contraction, but not autonomic contraction.
CONCLUSION: Autonomic reflex contraction of the external anal sphincter is most probably mediated by nerve fibers different from those responsible for conscious contraction (the pudendal nerve). A potential source might be a direct branch from the fourth sacral nerve. This needs to be elucidated in a prospective study set up.

P0976 LUBIPROSTONE IS WELL TOLERATED FOR TREATMENT OF OPIOID-INDUCED CONSTIPATION IN CHRONIC NON-CANCER PAIN PATIENTS: RESULTS OF THREE PHASE 3, RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIALS

P. Lichtlen[1,*], T. Losch-Beridon [2], M. Wang [2]
[1]*Sucampo AG, Zug, Switzerland,* [2]*Sucampo Pharma Americas, LLC, Bethesda, MD, United States*
Contact E-mail Address: *plichtlen@sucampo.com*

INTRODUCTION: Chronic opioid use is often associated with the common adverse effect of serious constipation; however, there are limited treatment options for patients with opioid-induced constipation (OIC) in patients with non-cancer pain. The efficacy and safety of lubiprostone (LBP), a selective ClC-2 activator, for treating OIC in subjects taking opioids for chronic, non-cancer pain was evaluated in three multicentre, 12-week, randomised, double-blind, placebo-controlled, Phase 3 trials. An integrated analysis of data from those 3 trials was conducted to determine the overall safety profile of LBP in this population.
AIMS & METHODS: Adults on chronic opioid therapy with documented OIC (i.e., defined as having, on average < 3 spontaneous bowel movements/week), were randomised to receive double-blind LBP 24 mcg or placebo twice daily (BID). Adverse events (AEs) were recorded electronically by the subject or investigator; graded as mild, moderate, or severe; and assessed for seriousness and relationship to study drug.
RESULTS: The combined safety population from the 3 trials (N = 1315; LBP, n = 663; placebo, n = 652; mean age, 50.4 years) comprised mostly female (62.7%) and white (82.6%) subjects. The most common (≥5% in the LBP arm) treatment-emergent AEs (TEAEs) were gastrointestinal (GI) disorders, with nausea, diarrhea, and abdominal pain reported 2.1, 2.5, and 3.3 times more with LBP than with placebo. Incidences of other TEAEs were comparable with LBP and placebo. In both the LBP and placebo arms, most subjects experienced mild (38.3% vs 36.5%) or moderate (31.5% vs 26.7%) TEAEs, with few severe TEAEs (8.9% vs 8.0%); the rest had no TEAEs. The incidence of severe TEAEs was similar with LBP or placebo, except for diarrhea (1.8% vs 0.3%), vomiting (0.3% vs 0.8%), and abdominal distension (0% vs 0.6%). Significantly more subjects in the LBP arm had ≥1 treatment-related AE (TRAE; 30.8% vs 20.2%; P < 0.0001) or ≥1 GI TRAE (24.7% vs 12.9%). The most common (≥5% in the LBP arm) TRAEs were GI disorders, with nausea and diarrhea reported 2.5 and 4.3 times more in the LBP arm. The other TRAEs (≥1% of LBP arm) were, in order of decreasing frequency, abdominal pain, abdominal distension, flatulence, vomiting, headache and oedema peripheral experienced 3.5, 2.2, 1.3, 1.9, 1.4 and 3.7 times more in the LBP-treated patients vs placebo, respectively. Percentages of subjects experiencing ≥1 serious AE (SAE) were similar in the LBP and placebo arms (3.9% vs 3.2%; p = 0.554). The only SAEs reported in >1 subject were migraine and back pain (LBP arm) and upper abdominal pain, fecaloma, and back pain (placebo arm). No SAEs were attributed to LBP; 3 SAEs (pneumonia, hypersensitivity, and fecaloma) were attributed to placebo. One death was reported in the LBP arm (multiple drug toxicity), but was assessed as unrelated to study drug by the investigator. Significantly more subjects treated with LBP (7.2%) compared with placebo (3.1%) withdrew from the studies because of AEs (p = 0.001), most commonly GI AEs (LBP, 4.4% vs placebo, 0.9%; P < 0.001).
CONCLUSION: An integrated safety analysis from 3 randomised, double-blind, placebo-controlled trials demonstrates that LBP, when used in chronic non-cancer pain subjects with OIC, is well tolerated.

INTRODUCTION: Lanreotide has an inhibitory effect on gastrointestinal secretions and motility. We evaluated the efficacy and safety of the prolonged-release somatostatin analogue lanreotide Autogel 120 mg for the treatment of persistent diarrhea in a multicenter, prospective, open label study.
AIMS & METHODS: The study was performed in 10 centers between July 2009 and August 2012. The study protocol was approved by the Ethics Committee of

UZ Leuven, Belgium (V). Male or female adult patients with refractory diarrhea (mean of > 3 stools/24 h) for at least 1 month after workup to rule out inflammatory, infectious causes, and rectum disorders, and insufficient /non-response to standard anti-diarrheal were treated for 8 weeks with lanreotide autogel 120 mg deep s.c. every 4 weeks. Patients' stool frequency and consistency (Bristol Stool Form Scale) were recorded in a daily diary. Quality of life (QOL) was assessed using the SF-36 and IBS-QOL questionnaires. Responders were patients with a ≥50% decrease or a normalization of the mean number of stools. Adverse events (AEs) were recorded during the entire study.
RESULTS: In total, 36 patients (24 women, 12 men) with chronic refractory diarrhea were studied. The mean age was 55.2 ± 16.4 years. Four weeks after the first injection (Day 28), 44.4% of patients were responders, which increased to 54.3% at Day 56. Response rates were higher in male patients (58.3%) compared to females (37.5%). Overall, the mean number of stools decreased significantly from 5.5 ± 2.3 at baseline to 3.6 ± 2.2 at Day 56 (-30.7%) (p = 0.0006). In the responder subgroup at Day 56 this number changed significantly from 5.3 ± 2.4 to 2.2 ± 0.8 (p < 0.0001). The median percentage of days per week with less than 3 stools/day increased from 7.1% at baseline to 57.1% at Day 56. In the responder subgroup at Day 56, the mean stool consistency score dropped significantly from 6.4 ± 0.7 to 5.2 ± 1.2(p = 0.0005). At Day 56, the mean IBS-QOL score increased with 16.3 points. Similarly, the SF36-QOL scores improved at Day 56, especially in the domains of social functioning (+14.0), physical role (+11.8) and mental health (+10.1). The improvement in IBS-QOL was very significant in the responder group with an increase from 48.4 to 76.7 (p = 0.0001), indicating that the improvement in stool consistency and frequency resulted in an improvement of QOL. In total, 93 treatment emergent AEs were reported, of which the majority (79) were mild to moderate and 9 were serious. The most frequently reported AEs were gastrointestinal disorders (abdominal pain, 25% of patients; nausea, 11.1% and steatorrhea, 8.3%), injection site reactions (16.7%) and asthenia/fatigue (11.1%).
CONCLUSION: This study showed improvement of diarrheal symptoms and QOL during therapy with lanreotide autogel 120 mg treatment, which suggest it is effective for the management of persistent refractory diarrhea. Confirmatory studies are needed.

P0978 SMALL-BOWEL ABNORMALITIES IN PATIENTS WITH IRRITABLE BOWEL SYNDROME - A CAPSULE ENDOSCOPY STUDY

S. Oka[1,*], S. Tanaka[1], M. Nakano[2], A. Igawa[2], T. Aoyama[2], M. Ito[2], K. Chayama[2]
[1]Endoscopy, [2]Gastroenterology and Metabolism, Hiroshima University Hospital, Hiroshima, Japan
Contact E-mail Address: *oka4683@hiroshima-u.ac.jp*

INTRODUCTION: Irritable bowel syndrome (IBS) is the most common functional digestive disorder globally, affecting 10-20% of the adult population in several western countries. IBS is diagnosed when the symptoms fulfill the Rome III criteria, however, the small bowel was not examined.
AIMS & METHODS: We conducted a case-control study to determine whether capsule endoscopy (CE) detects small-bowel abnormalities in IBS patients. Study subjects were 57 patients who met the Rome III criteria for IBS and were scheduled to undergo CE (PillCam SB or SB2; Given Imaging Ltd., Yoqneam, Israel) for investigation of their symptoms at Hiroshima University Hospital between April 2006 and December 2013 (IBS group) and 57 patients with occult obscure gastrointestinal bleeding (OGIB) were selected as control (OGIB [control] group). Patients in the IBS group were further classified according to the type of IBS: constipation–prevalent IBS (subgroup A, n = 40); diarrhea-prevalent IBS (subgroup B, n = 26); or mixed IBS (subgroup C, n = 9). CE was evaluated in all groups according to the total enteroscopy achievement rate, mean small-bowel transit time, small-bowel lesion detection rate, and the types of small-bowel lesions detected. All statistical analyses were carried out with JMP statistical software version 5.0.1J (SAS Institute Inc., Cary, NC, USA). $P < 0.05$ was considered significant.
RESULTS: Total enteroscopy was achieved by CE in 82% (47/57) of patients in the IBS group and 80% (45/57) of patients in the OGIB group; the difference between the two groups was not significant. For patients in whom total enteroscopy was achieved by CE, mean small-bowel transit time was 270 minutes in the IBS group and 268 minutes in the OGIB group, with no significant between-group difference. In the IBS group, total enteroscopy was achieved per subgroup as follows: subgroup A, 76% (22/29); subgroup B, 89% (17/19); and subgroup C, 89% (8/9). The mean small-bowel transit times were 280 minutes, 254 minutes, and 277 minutes, respectively, with no significant difference among them. The small-bowel lesion detection rates were 29% (20/57) and 28% (16/57) in the IBS group and OGIB group, respectively. Small-bowel lesions detected by CE in the IBS group were non-specific enteritis (n = 16), non-specific ulcer (n = 1), eosinophilic enteritis (n = 1), ischemic enteritis (n = 1), and lesioning due to a parasitic worm (n = 1); otherwise, no abnormality was found (n = 37). Small-bowel lesions detected by CE in the OGIB group were non-specific enteritis (n = 6), non-specific ulcer (n = 6), submucosal tumor (n = 3), and diverticulum (n = 1); otherwise no abnormality was found (n = 41). The prevalence of non-specific enteritis was significantly high in the IBS group versus the OGIB group ($p < 0.05$). Small-bowel lesion detection rates in the IBS subgroups were as follows: subgroup A, 17% (5/29); subgroup B, 68% (13/19); and subgroup C, 22% (2/9). The detection rate in subgroup B (versus subgroup A and subgroup C) was significantly high ($p < 0.05$).
CONCLUSION: CE detected no significant abnormalities that explained the symptoms in the majority of our patients with IBS; thus, the use of CE in IBS patients is not supported by the current data.

P0979 A PHASE 1 STUDY TO INVESTIGATE THE ABSORPTION, METABOLISM AND EXCRETION OF 14C PRUCALOPRIDE AFTER A SINGLE ORAL DOSE

S. Flach[1,*], S. Troy[2], T. Pankratz[3], J. Ding[1], G. Scarfe[4], J. Getsy[2]
[1]Covance, Madison, [2]Shire, Wayne, [3]Xceleron Inc, Germantown, United States, [4]Shire, Basingstoke, United Kingdom

INTRODUCTION: Prucalopride is a 5-hydroxytryptamine receptor agonist that stimulates intestinal motility and is approved in Europe for the treatment of women with chronic constipation in whom laxatives fail to provide adequate relief. The absorption, metabolism and excretion (AME) of prucalopride has been reported previously; however, poor recovery of total radioactivity led to uncertainty regarding the mass balance properties of the drug.
AIMS & METHODS: The aim of this phase 1 study (NCT01807000) was to use microtracer dosing (200 nCi radioactivity) with accelerator mass spectrometry (AMS) to investigate the AME profile of ^{14}C-radiolabelled prucalopride after a single oral dose and to obtain more robust data. Healthy men aged 18–50 years were enrolled in the study. A single oral dose of 2 mg ^{14}C-prucalopride (200 nCi radioactivity) was administered on day 1. Blood samples were collected at 0, 0.5, 1, 1.5, 2, 2.5, 3, 4, 6, 8 and 12 hours on day 1, and once daily thereafter until day 11. Urine and stool samples were collected and electrocardiogram and vital signs were recorded on every day of the study. Pharmacokinetic parameters were calculated from concentrations of prucalopride measured by liquid chromatography–tandem mass spectrometry (LC–MS/MS). Total radioactivity and metabolites from LC fractions were measured using AMS. Metabolites were identified using authentic standards, when available, and by LC coupled with high resolution MS. Results presented are mean ± standard deviation unless otherwise specified.
RESULTS: Six men were enrolled in the study (mean age: 35.5 ± 10.45 years). Following oral administration, ^{14}C-prucalopride was absorbed rapidly (median time to maximum plasma concentration [t_{max}]: 2.75 h [range: 1.13–4.00 h]) and was eliminated with a half-life ($t_{½}$) of 20.6 ± 5.35 h. For prucalopride, the maximum plasma concentration (C_{max}: 3.79 ± 1.10 ng/mL) and area under the concentration–time curve ($AUC_{0-\infty}$: 96.5 ± 9.64 ngh/mL) accounted for 92% and 95% of the total radioactivity in plasma, respectively. The blood:plasma radioactivity concentration ratios ranged from 1.74 to 2.06 up to 48 hours post-dose. Most of the administered dose of prucalopride (84.2 ± 8.9%) was recovered in urine, and an additional 13.3 ± 1.7% of the dose was recovered in faeces (total recovery: 97.5 ± 8.6%). Approximately 65% of the dose recovered in urine and 5% in faeces was intact prucalopride. Quantitatively important metabolites identified in the urine and faeces were products of O-demethylation, N-dealkylation and oxidation.
CONCLUSION: The AMS with microtracer approach was used successfully in this study, with good total recovery of radioactivity in urine and faeces (97.5 ± 8.6% of the administered radioactive dose). Following oral administration of a 2 mg dose of prucalopride, at least 84% of the drug was absorbed. The observed blood:plasma ratio of radioactivity indicates that there was moderate uptake of prucalopride (and metabolites) into blood cells. Systemic exposure to prucalopride metabolites was low, and both prucalopride and its metabolites were eliminated in urine and, to a lesser extent, faeces. This shows that renal clearance is the primary route of elimination of prucalopride.

INTRODUCTION: Prucalopride (PRU) is a high-affinity serotonin receptor (5-HT_4) agonist approved in Europe for the symptomatic treatment of chronic constipation (CC) in women in whom laxatives fail to provide adequate relief.
AIMS & METHODS: The aim of this phase 3, multicenter, parallel-group, double-blind trial was to evaluate the efficacy and safety of PRU in men (NCT01147926). Men aged ≥18 years with CC who had ≤2 spontaneous complete bowel movements (SCBMs) per week were randomized to receive placebo (PLA) or PRU 2mg (starting dose of 1mg for patients ≥65 years) once daily for 12 weeks. The primary endpoint was the proportion of patients achieving a mean of ≥3 SCBMs per week over 12 weeks. Secondary endpoints included the Patient Assessment of Constipation-Symptoms (PAC-SYM) and -Quality of Life (PAC-QOL) questionnaires. Safety was assessed throughout the study.

RESULTS: In total, 374 patients from 10 European countries were randomized (187 per treatment group). Baseline demographics were similar between treatment groups with an overall mean age of 58.5 (SD: 16.91) years and mean duration of CC of 9.2 (SD: 11.63) years. The primary endpoint was achieved by significantly more patients in the PRU group (37.9%) than in the PLA group (17.7%, $p<0.0001$). More patients on PRU than PLA achieved an improvement of ≥1 SCBM/week (53.7% vs 45.3%; $p=0.0743$) and an improvement of ≥1 SBM/week (65.5% vs 43.1%; $p<0.0001$). At the final on-treatment assessment, there was no significant difference between groups in the proportion of patients with a clinically relevant improvement of ≥1 point in total PAC-SYM score (PRU: 34.9%; PLA: 30.4%; $p=0.3152$), abdominal (39.1% vs 35.1%; $p=0.4874$) or rectal subscale score (34.9% vs 29.2%; $p=0.2759$). However, there was a significant difference in stool symptoms score (53.3% vs 36.3%; $p=0.0005$). The proportion of patients with an improvement of ≥1 in PAC-QOL score was higher with PRU (40.2%) than PLA (32.7%; $p=0.0755$), particularly in the satisfaction (52.7% vs 38.8%; $p=0.0035$) and physical discomfort subscales (50.3% vs 39.2%; $p=0.0249$). The overall safety profile was consistent with previous studies. The most common adverse events (AEs) were abdominal pain (PRU vs PLA: 4.3% vs 5.9%), diarrhoea (6.5% vs 1.6%), nausea (6.0% vs 2.2%), headache (9.2% vs 3.8%) and dizziness (2.2% vs 1.6%). The incidence of serious AEs and ischaemic cardiovascular adverse events was low and comparable between treatment groups.

CONCLUSION: In this first study of efficacy of PRU in an exclusively male patient population, PRU significantly increased the proportion of men achieving an average of ≥3 SCBMs per week compared with PLA. No new safety concerns were identified. These results demonstrate a positive benefit–risk profile for the use of PRU in men with CC.

P0981 EVALUATION OF A NEW DIAGNOSTIC METHOD FOR ANAL SPHINCTER RUPTURE BY THREE-DIMENSIONAL HIGH-RESOLUTION ANORECTAL MANOMETRY

A. Benezech[1,*], M. Behr[2], M. Bouvier[1], J.-C. Grimaud[1], S. Berdah[1,2], V. Vitton[1]
[1]*Hôpital Nord,* [2]*IFSTTAR, Marseille, France*
Contact E-mail Address: *benezech.alban@gmail.com*

INTRODUCTION: Anorectal manometry is the gold standard to explore anorectal disorders. Endoanal ultrasound (EUS) is commonly associated for the diagnosis of anal sphincter rupture. 3-Dimensional High-Resolution Anorectal Manometry (3DHRAM) seems able to provide new topographic information, including an assessment of the integrity of the sphincters.

AIMS & METHODS: The aim of the study was to develop a method for computerized analysis of 3DHRAM results to optimize the diagnosis of anal sphincter defect, compared with the EUS as gold standard.

All patients referred to our center to explore anal incontinence or dyschesia by 3DHRAM and EUS were eligible. 3DHRAM measured anal resting and voluntary contraction pressure which reflected internal anal sphincter and external anal sphincter respectively. A software was created to analyze 3DHRAM records. Significant pressure parameters were calculated to separate patients with anal sphincter rupture and patients without rupture. The combination of these parameters resulted in a 3DHRAM diagnostic score for anal sphincter rupture, compared with the EUS.

RESULTS: A total of 206 patients (91% females) with a mean age of 54.6 ± 14.9 years were included. The EUS diagnosed an anal sphincter defect in 130 (63%) patients, 76 (37%) patients were without rupture. 40 pressure parameters were defined from 3DHRAM records by the software. 5 most significant pressure parameters were selected for the construction of diagnostic scores. Overall, the diagnostic score for the internal anal sphincter defect had a sensitivity of 65% and a specificity of 65%, with a positive predictive value of 75% and a negative predictive value of 53%. For the external anal sphincter defect, the diagnostic score had a sensitivity of 43% and a specificity of 87%, with a positive predictive value of 82% and a negative predictive value of 53%.

CONCLUSION: A computerized diagnostic method of 3DHRAM results was developed for a systematic and comprehensive analysis. However, 3DHRAM has not shown sufficient diagnostic capacity for sphincter defect, compared to EUS. A better distinction between anal sphincter defect and neurological damage, which can also affect the pressure recorded at the 3DHRAM, could improve our diagnostic scores.

P0982 PROSPECTIVE EVALUATION OF RECTAL BOTULINUM TOXIN INJECTION IN FECAL INCONTINENCE

C. Benard[1,2,*], G. Gourcerol[2], O. Touchais[2], A.-M. Leroi[2], V. Bridoux[3], C. Melchior[1,2], P. Ducrotte[1]
[1]*Gastroenterology department,* [2]*Physiology department,* [3]*Surgery department, CHU rouen, Rouen, France*
Contact E-mail Address: *coralie.benard@yahoo.fr*

INTRODUCTION: *Botulinum Toxin* (BT) has been widely used to treat urinary incontinence in the context of overactive bladder. It has been previously suggested in 6 patients that injection of BT in the reservoir may relieve faecal incontinence (FI) in patients with either overactive rectum or colonic pouch after protectomy (1). However, the efficacy of rectal BT injection in patients with FI related to anal sphincter incompetence has never been investigated.

AIMS & METHODS: We prospectively investigated the efficacy of rectal BT injection in 21 patients with FI. In 11 patients, FI was related to anal sphincter incompetence, in 4 patients to overactive rectum and in 6 patients to overactive colonic pouch after proctectomy. All patients failed medical therapy, and 7 patients were unresponsive to sacral nerve root stimulation. BT injection consisted in a session of 10 injections of 50 UI of Dysport ® (3-4 injections every 5 cm) in the submucosa of the rectum or of the colonic pouch as previously reported (1). Clinical efficacy and quality of life were assessed at baseline, at 3 and 6 months after BT injection with the Cleveland Clinic and the FIQL scores, respectively. Anorectal manometry was performed before and 3 months after BT injection.

RESULTS: Compared to pre-operative values of the 21 patients, Cleveland Clinic (12.7 ± 1.2) and the FIQL (1.9 ± 0.2) scores improved at 3 months (9.7 ± 1.2 and 2.4 ± 0.2, respectively; $p<0.05$ for both). After a single session of injection ($n=6$), the Cleveland Clinic and the FIQL scores at 6 months returned to pre-operative values. By contrast, in patients with a second session performed 3 months after the first one ($n=8$), the Cleveland Clinic and the FIQL scores remained decreased at 6 months compared to pre-operative values ($p<0.01$ for both). At 3 months, neither anal tone and squeezing pressures, nor rectal volume and compliance were affected by BT injections. Univariate analysis failed to evidence factors associated with a poor clinical response. In particular, similar improvement was noted in patients with anal sphincter incompetence or with an overactive reservoir. No serious adverse events were reported.

CONCLUSION: Our study is the first to demonstrate that injection of BT in the rectum or in the colonic pouch is effective at 3 months to treat FI. A second injection seems to be necessary to achieve improvement at 6 months. Efficacy of BT is not related to FI origin (anal sphincter incompetence vs with an overactive reservoir) and is not explained by modification of rectal volume and/or compliance.

P0983 TRICYCLIC ANTIDEPRESSANTS FOR SYMPTOMATIC TREATMENT OF INTRACTABLE TENESMUS IN THE SETTING OF RECTAL PROLAPSE

D.M. Livovsky[1,*], T. Adar[1], J. Lysy[1]
[1]*Digestive Diseases Institute, Shaare Zedek Medical Center, Jerusalem, Israel*
Contact E-mail Address: *danlivo@szmc.org.il*

INTRODUCTION: The spurious feeling of the need to evacuate the bowels, with little or no stool passed (tenesmus) can cause severe distress and a negative impact on quality of life. Management is focused on the primary cause of tenesmus and not on tenesmus itself. Rectal prolapse is occasionally encountered as the main etiology of tenesmus, in those patients surgical consultation is warranted. Tenesmus in this setting is particularly problematic since it leads the patient to a vicious cycle of straining with deterioration of prolapse and subsequent worsening of tenesmus. Tricyclic antidepressants (TCAs) have been shown to reduce ano-rectal hypersensitivity in patients with irritable bowel syndrome (IBS), by centrally mediated mechanisms and are commonly used to treat functional chronic pelvic pain syndromes. We have used the same approach to treat patients referred to our tertiary center suffering from intractable tenesmus that are poor surgical candidates or refuse surgical correction.

AIMS & METHODS: From 2010 we created a registry of patients with rectal prolapse that were poor surgical candidates or refused surgical correction and received treatment with TCA for rectal tenesmus. Only patients with rectal mucosal prolapse or full-thickness rectal prolapse with high internal intussusception or externally visible only with straining were included. Patients with full-thickness rectal prolapse externally visible at all times or with an impending surgical indication were excluded.

RESULTS: Twenty one patients were treated by this approach, 81% were female, the mean age was 74.81+14.39 years, and symptoms were present for a mean of 9±7 months. The feeling of an anal protrusion on straining, anal pain, fecal incontinence and constipation were present in 75, 42.9, 36.8 and 26.3% of patients respectively. Full thickness rectal prolapse was present in 57% of patients, while 43% had internal rectal mucosal intussusceptions. Nortryptiline 25mg, amitriptyline 10mg and desipramine 25mg were used in 43, 38 and 19% of patients respectively. After a mean follow up of 7.18+5.5 months 76% of patients reported significant improvement in symptoms, 14% were lost to follow up and 10% ($n=3$) failed to respond. The response rates were 88% (7/8) for nortryptiline, 100% (4/4) for desipramine and 55% (5/9) for amitriptyline. Noteworthily in 5 patents, symptoms were completely resolved obviating the need for surgery, most probably due to cessation of the vicious cycle of tenesmus, straining and worsening of prolapse. Additionally the treatment was very useful in patients suffering from dementia, who could not be convinced to stop straining.

CONCLUSION: To our knowledge this is the first report to address the symptomatic treatment of tenesmus in patients with rectal prolapse. TCAs may be an acceptable option for poor surgical candidates or patients refusing surgical treatment. Nortryptiline or desiparamine had a trend to better response rates compared to amitryptiline in an uncontrolled setting.

INTRODUCTION: 3D ano-rectal high resolution manometry (3D ARHRM) has been recently developed. Closely spaced pressure sensors allow a precise definition of pressure profile within the anal canal. However normal values are scarce with this device.
AIMS & METHODS: This study aimed to determine normal values for 3D ARHRM and to compare them to those obtained in patients with fecal incontinence. Fifty seven women (29 controls and 28 patients with fecal incontinence (FI)) were included in 3 centers. Vaizey score was used to define fecal incontinence: controls had a score of 0 or 1 and patients a score greater than 6. Anal ultrasound was performed to search for anal sphincter defect in patients with FI. 3D ARHRM was performed using a rigid probe (Given Imaging, Duluth, GA). The protocol consisted of a 2-minute resting period, 2 squeezing periods and 2 bearing down maneuvers. The high-pressure zone (HPZ) corresponding to the anal canal was delineated at the 20-mmHg isobaric contour. The height and mean pressure of the HPZ were measured over a 20-s period at the end of the resting period and after the beginning of each squeezing period. Resting pressure volume and squeezing contractile volume (expressed in mmHg.cm.s) were calculated as the product of HPZ height x HPZ mean pressure x 20 seconds. Data are expressed in median (range) and compared between groups using non-parametric tests.
RESULTS: Controls were younger than FI patients (mean age 45 years (18-70) vs 58 (31-74), $p<0.01$). Fourteen women with FI presented an anal sphincter defect on ultrasound examination. All manometric variables were significantly different between controls and FI women (Table).

	Controls	FI	p
Resting HPZ height (cm)	3 (2-5)	3 (0-5)	0.02
Resting HPZ pressure (mmHg)	51 (29-74)	40 (11-70)	<0.01
Resting pressure volume (mmHg.cm.s)	3217 (1444-6512)	2552 (307-7006)	<0.01
Squeezing HPZ height (cm)	4 (3-5)	4 (1-5)	<0.01
Squeezing HPZ pressure (mmHg)	79 (49-135)	53 (14-124)	<0.01
Squeezing contractile volume (mmHg.cm.s)	7175 (4051-10536)	4195(583-11307)	<0.01

No difference was seen during the bearing down maneuvers between controls and FI women. The 2D map of the 3D sensor plot showed a constant lambda aspect at rest and during squeezing in controls: this aspect may be representative of the posterior pressure applied by the puborectal in the upper part of the anal canal, and the anterior pressure applied by the lower part of the anal sphincter. This typical aspect was much less evident in FI women, especially when a sphincter defect was present.
CONCLUSION: This preliminary study established normal values for 3D ARHRM, and clearly showed differences between controls and patients with FI. 3D data may be interpreted as a typical image pattern rather than as quantified variables.

P0985 LONG TERM OUTCOMES OF BOTULINUM TOXIN IN THE TREATMENT OF CHRONIC ANAL FISSURE 5 YEAR FOLLOW-UP

S.P. M. Barbeiro[1,*], C. Martins[1], C. Gonçalves[1], M. Canhoto[1], B. Arroja[1], F. Silva[1], I. Cotrim[1], H. Vasconcelos[1]

INTRODUCTION: Chronic anal fissure is a frequent and disabling disease, affecting especially young adults. Botulinum toxin (BT) and internal lateral sphincterotomy are therapeutic options for refractory cases. BT is minimally invasive and safer, compared to surgery, which carries a more difficult post-operative state and fecal incontinence risk. The long term effectiveness of BT is not known.
AIMS & METHODS: Evaluate the long term outcomes of BT treatment in chronic anal fissure.
Observational and retrospective study, including the patients treated with BT from 2005 to 2009, each followed over a period of 5 years. Patients were treated with injection of 25U of BT in the intersphincteric groove. The response was registered as complete (CR), partial (PR), refractory (RR) and relapse (RP).
RESULTS: One hundred and twenty-six patients were treated, of which 69.8% (n = 88) were followed over a period of 5 years [48 females (52.3%), mean age 48 years]. The majority presented with a fissure in the anal posterior midline (n = 68, 77.3%). After 3 months, 46.6% (n = 41) had CR, 23.9% (n = 21) had PR and 29.5% (n = 26) had RR. Relapse was observed in 1.2% (n = 1) at 6 months, 11.4% (n = 10) at 1 year, 2.3% (n = 2); no relapse at 5 years. Treatment with BT had a long term efficiency of 64.8%. There was no difference between the groups with CR and RR for gender, age, duration of symptoms, fissure localization and constipation. The treatment was well tolerated by all patients and there were no complications. Patients with no response were assigned to second injection with BT or surgery. The authors highlight the occurrence of two cases of fecal incontinence in the surgery group.
CONCLUSION: BT was an effective and safe alternative to chronic anal fissure long term treatment.

P0986 PATIENT PERSPECTIVES FOR ENDPOINTS IN CLINICAL TRIALS FOR FECAL INCONTINENCE

INTRODUCTION: Pivotal trials of new treatments for fecal incontinence (FI) often define responders by a 50% reduction in frequency of FI or a report of "adequate relief", but there has been no patient input into these responder definitions.
AIMS & METHODS: Our aim was to survey patient preferences for endpoints in FI treatment trials. In Phase I (focus groups), 30 patients with FI (29 women) were recruited by advertisement to participate in internet chat rooms of 1-5 persons. They were asked open-ended questions on how to define FI treatment success as well as questions about 50% improvement and adequate relief. Based on this input, 3 questions were developed for a national internet survey of individuals with FI (Phase II). This sample, stratified by age, sex, and race/ethnicity, was provided by Cint USA, Inc., a market research company. Descriptive statistics followed by regression analyses were used to identify personal characteristics that influence preferences for endpoints. Subjects also completed the Fecal Incontinence Severity Index (FISI).
RESULTS: In Phase I focus groups, most participants did not believe a 50% reduction in frequency was an adequate definition of success, but neither did they think complete cure was required. When asked how much improvement was needed, the consensus was about 75%. Some did not know what "adequate relief" meant. In the Phase II national survey, 48/234 (20.5%) of responders were excluded because they gave inconsistent responses to two questions that were repeated as a quality control, leaving 186 for analysis: 52% were women, mean age was 48.9 years (range 20-91), and race/ethnicity was 9% Hispanic and 8% African American. Post-bacalaurate education was over-represented (39.2%). Average FISI score was 29.9 on a 0-61 scale. The national survey confirmed focus group findings: only 57.5% thought a 50% reduction is enough to consider a treatment successful (only 26.2% of people over age 65) and 78% considered "adequate relief" a good measure of treatment success. Logistic regression analysis identified several significant predictors of finding a 50% reduction in the frequency of FI an acceptable endpoint in clinical treatment trials: greater severity of FI, younger age, male gender, and higher household income. These would be potential confounders when a 50% reduction is used as the definition of clinical success. For "adequate relief", bivariate analyses confirmed that better educated and wealthier subjects are more likely to accept "adequate relief" as an endpoint. However, in a multivariate logistic regression, only younger age was an independent predictor of endorsing "adequate relief". When asked how much improvement is needed to consider a treatment as successful, the average was a 77% decrease in FI episodes (95% confidence interval 74.5%, 79.5%).
CONCLUSION: Endpoints in clinical trials should be redefined as at least a 75% reduction in the frequency of FI because (a) the 50% decrease criterion is satisfactory to only 57.5% of people with FI (26% of people over age 65), (b) multiple demographic variables predict endorsement of the 50% reduction definition of a responder and are therefore potential confounders, and (c) "adequate relief" appears to be difficult to understand for patients with lower levels of education. INTRODUCTION: Some studies support that there is a significant overlap between the different functional disorders of the digestive tract[1, 2].
AIMS & METHODS: The aim of this study was to compare oesophageal motor characteristics between type 2 diabetics with and without constipation.
Oesophageal manometry was performed in 16 type 2 diabetic individuals with complaints of constipation and 20 without constipation. Glycaemia control was similar. Waves were evaluated in the 3 thirds of the oesophagus (P1 = upper, P2 = middle, and P3 = distal). Results are in mean ± standard error.
RESULTS: In constipated vs. non-constipated diabetics, oesophageal wave distribution was as follows: peristaltic waves, 85.54±3.85% vs. 91.45±2.32%, $p = 0.16$; simultaneous waves, 3.50±%1.19% vs. 0.93±0.28%, $p = 0.015$. The percent of no transmitted waves and of retrograde waves between groups were similar. Wave amplitude did not reveal significant differences between groups. Wave duration (sec.) in constipated vs. non-constipated was as follow: P1-P2, 4.76 ±0.67 vs. 4.15±0.53, $p < 0.47$; P2-P3, 7.24±0.93 vs. 4.90±0.47, $p < 0.017$ and P1-P3, 6.71±1.20 vs. 3.37±0.42 p = 0.013. Wave velocity (cm/s) registered in constipated vs. non-constipated was: P1-P2, 2.93±0.64 vs. 4.03±0.58, $p < 0.21$; P2-P3, 3.42±0.67 vs. 5.07±0.51, $p < 0.05$ and P1-P3, 2.69±0.58 vs. 4.27±0.37, $p < 0.01$.
CONCLUSION: (1) Simultaneous oesophageal waves were significantly more frequent in constipated diabetics. (2) Wave duration was significantly higher within the middle and distal oesophagus of constipated diabetics. (3) Wave velocity was significantly higher within the esophagus of non-constipated individuals. (4) There are some differences in esophageal motility in type 2 diabetic patients with or without constipation

INTRODUCTION: Faecal incontinence is a complaint that some type 2 diabetic patients refer[1]. For some authors, alterations in recto-anal sensory-motor thresholds may be present[2].
AIMS & METHODS: The aim of this study was to compare rectal sensorial and motor characteristics of type 2 diabetics with and without faecal incontinence.
Recto-anal manometry was performed in 35 type 2 diabetics, without signs of autonomic neuropathy, 5 with complaints of faecal incontinence and 30 without this complaint, matched by age and gender. Results are in mean ± standard error.
RESULTS: In diabetics with faecal incontinence vs. without faecal incontinence the values were the follow: rectal resting pressure, 11.5±1.8 vs 12.1±2.3mmHg; p = 0.27 internal anal sphincter resting pressure, 40.0±20. vs 43.6±23.3mmHg, p = 0.24; 39.8±7.02 vs. 47.7±3.30, p = 0.36; minimum rectal sensibility, 56.7±6.7% vs. 80.0±7.6ml, $p = 0.28$; first urge, 80.8±6.1 vs. 132.3±13.5ml, $p = 0.69$; Intense urge,108,3±6.0 vs. 152.8±14.7, $p = 0.80$; maximum tolerable rectal capacity, 169.2±15.6 vs. 225.5 ±20.8ml, $p = 0.95$. The relaxing percent during the recto-anal reflex and the sphincters pressures during the squeeze and squeeze endurance were statistically similar. The anal sphincter fatigue during the squeeze endurance was 0.15±0.70 vs. 0.04±0.32 mmHg/sec, p > 0.05.
CONCLUSION: 1-In type 2 diabetics with faecal incontinence the rectal resting pressure, the resting internal and external sphincter pressures, the volume for minimum rectal sensibility and for maximum tolerable rectal capacity were similar to diabetics without the symptoms. 2-The anal sphincter fatigue was similar between groups. 3-There is no significant differences in recto-anal sensory-motor characteristics in type 2 diabetics with or without faecal incontinence studied.

INTRODUCTION: Constipation is a very frequent complaint in type 2 diabetic patients[1] and some authors believe that alterations in recto-anal thresholds may be present in individuals with these symptoms[2].
AIMS & METHODS: The aim of this study was to compare rectal sensorial and motor characteristics of type 2 diabetics with and without constipation.
Recto-anal manometry was performed in 35 type 2 diabetics, without signs of autonomic neuropathy, 15 with complaints of constipation and 20 without this symptom, matched by age and gender. Results are in mean ± standard error.
RESULTS: In diabetics with complaints of constipation vs. without constipation, the values registered were the follow: rectal resting pressure, 11.5±1.8 vs. 12.1±2.3mmHg; p = 0.8; internal anal sphincter resting pressure, 40.0±4.7 vs. 43.6±6.1mmHg, p = 0.6; minimum rectal sensibility, 65.5±6.8 vs. 78.6±9.2ml, $p = 0.2$; first urge, 107.5.8±14.1 vs. 119.3±13.1ml, $p = 0.5$; Intense urge, 132.0±14.2 vs. 145.3±15.5ml, $p = 0.5$; maximum tolerable rectal capacity, 197.0±22.6 vs. 208.6 ±19.0ml, $p < 0.7$. The relaxing percent during the recto-anal reflex was 40.9±6.0% vs. 30.5±4.5%, p > 0.05. The sphincter pressure during the squeeze was significantly lower in diabetics with symptoms 67.2±11.2 than without it, 109.7±16.4, p < 0.03; but during the squeeze endurance, 88.0±11.7 vs. 114.9±17.4, was statistically similar. The anal sphincter fatigue during the squeeze endurance, 0.29±0.41 vs. -0.26±0.40 mmHg/sec, was similar. When comparing the recto-anal characteristics according to the severity of constipation, there were no statistic differences between diabetics with slight to moderate or severe to very severe symptoms.
CONCLUSION: 1-In type 2 diabetics with complaints of constipation the resting rectal pressure, the volume for minimum rectal sensibility, first urge, intense urge and maximum tolerable rectal capacity, and the relaxing degree during the recto-anal inhibitory reflex were statistically similar to diabetics without the symptoms. 2-The pressure augment during the squeeze was higher in diabetics without constipation. 3-In general recto-anal sensorial and motor thresholds were similar in type 2 diabetics with or without constipation.

P0991 INTERACTIONS OF HERBAL CONSTITUENTS INFLUENCES THE EFFECTS OF STW 5 ON INFLAMMATORY PROCESSES AND DISTURBED MOTILITY

K. Nieber[1,*], S. Hoser[1], V. Winkelmann[1], A. Baumgärtel[1], N. Mishenzon[1], S. Okpanyi[2], H. Abdel-Aziz[2], D. Weiser[2], O. Kelber[2]
[1]*Institute of Pharmacy, UNIVERSITY OF LEIPZIG, Leipzig,* [2]*Scientific Department, Steigerwald Arzneimittelwerk GmbH, Darmstadt, Germany*
Contact E-mail Address: *nieber@rz.uni-leipzig.de*

INTRODUCTION: The multi-herbal drug STW 5 (Iberogast®) was effective for treatment of symptoms in patients with functional dyspepsia or irritable bowel syndrome (IBS). Its mode of action is still not fully elucidated. Modulation of gastric motility and an anti-inflammatory action were hypothesized. These findings provide the basis for investigating STW 5 and its components in inflamed small and large intestinal preparations to identify novel anti-inflammatory pathways.
AIMS & METHODS: The aim of this study was to investigate the effect of individual constituents as well as selected combinations on different parameters related to inflammatory processes in the gastrointestinal tract.
For analysis of lactate dehydrogenase (LDH) activity using a commercially available LDH cytotoxicity assay (Roche). TNFa concentration was detected by ELISA in the supernatants. The inflammation was elicited by intraluminal preincubation with TNBS (10 mM). The herbal extracts were applied together with TNBS. For analysing synergism or antagonism the isobologram method was used.
RESULTS: STW 5, STW 5-II (a combination containing only 6 of the 9 extracts) and lemon balm reduced LPS (10 ng/ml)-induced lactate dehydrogenase (LDH) release from CaCo-2 cells by 74-75 %. *Iberis amara*, peppermint, chamomile, angelica and milk thistle inhibited this parameter by 25-37 %. Liquorice, caraway and celandine had no effect. The combinations of *Iberis amara* and peppermint as well as peppermint and milk thistle revealed synergistic or additive effects, whereas the combination of chamomile and angelica evoked additive or antagonistic effects depending on their compositions (i.e. relative ratios of individual extracts).
STW 5, STW 5-II, *Iberis amara*, peppermint, liquorice, caraway, milk thistle and lemon balm inhibited LPS (100 ng/ml)-induced TNFa release from THP-1 cells to 51-67 %. Chamomile and angelica revealed a more potent effect. The combinations of *Iberis amara* and peppermint as well as chamomile and liquorice had additive or antagonistic effects depending on their compositions.
STW 5 and STW 5-II reduced the acetylcholine (ACh)-induced contractions in rat ileum preparations to 81-83 %. The individual components inhibited the contractions to 83-91 % except for lemon balm which had no effect. The combinations of *Iberis amara* and peppermint as well as liquorice and caraway had additive or antagonistic effects depending on their compositions.
CONCLUSION: Our results indicate that synergistic, additive and antagonistic interactions exist between the constituents within STW 5 and STW 5-II. The overall effects depend on their combination and therefore confirm that combined extracts produce an effect different from or greater than the sum of their individual effects. Our results allow greater insight into the interactions between individual herbal constituents of STW 5 and confirm the concept of multi-target actions.

P0992 NON-GSHR1A MEDIATED EFFECTS OF ULIMORELIN IN ISOLATED RODENT ARTERIES

J. Broad[1,*], B.P. Callaghan[2], G. Sanger[1], J. Furness[2], J. Brock[2]
[1]*National Centre for Bowel Research and Surgical Innovation, London, United Kingdom,* [2]*Anatomy and Neuroscience, University of Melbourne, Melbourne, Australia*
Contact E-mail Address: *j.broad@qmul.ac.uk*

INTRODUCTION: Ghrelin receptor agonists cause changes in blood pressure in humans (1) and rodents. The ghrelin receptor agonist ulimorelin (TZP101), recently in clinical trials for the treatment of gastroparesis, has been shown to cause alterations in blood pressure and mesenteric artery tone in rats (2). Here we investigate the role of the canonical ghrelin receptor, GHSR1a, in mediating this effect.
AIMS & METHODS: Saphenous, mesenteric and basilar arteries from Sprague-Dawley rats (male, 8 weeks), and saphenous arteries from mice lacking the GHSR1a receptor or littermates (male, 6-8 weeks) were studied. Arteries were suspended between steel wires in myography chambers containing an oxygenated modified Krebs solution (36.5°C) and given an effective transmural pressure of 100mmHg- mesenteric and basilar arteries were then reduced in diameter by 10%. Phenylephrine (PE) 3-10μM, or 60mM $[K^+]$ in basilar arteries, was used to confirm tissue viability. Ulimorelin was applied non-cumulatively following increases in artery tension induced by application of PE 3-10μM or 60mM $[K^+]$. To investigate direct changes in artery tension, ulimorelin was applied cumulatively. Responses were measured as the % change from the plateau response of the stimulus applied prior to application of agonists. Changes between groups were investigated using 2-way ANOVA and Bonferroni post-tests.
RESULTS: PE 3-10μM contracted saphenous (n = 19 rat, n = 4 mouse) and mesenteric (n = 6) arteries, but had no effect on basilar arteries (n = 4). Ulimorelin (0.03-30μM) caused concentration-dependent inhibition of PE-induced contractions of rat saphenous (IC50 = 697nM; Imax = 66±5% PE response; n = 3-6) and mesenteric arteries (IC50 = 5μM, Imax = 113±16%; n = 3-4), but had no effect on contractions induced by 60mM [K+] in basilar arteries. In rat saphenous and basilar arteries ulimorelin 10-100μM caused an increase in artery tension (EC50 = 9.9μM Emax = 50±7%; and EC50 = 8 μM Emax = 99±16% respectively) but had no effect in mesenteric arteries. These effects were not attenuated by the ghrelin receptor antagonist YIL 781 3μM (e.g. ulimorelin 10μM inhibited the PE response by 62±5% in the absence and 48±8% in the presence of YIL 781 respectively; $P > 0.05$; n = 4) or mimicked by ghrelin 0.001-1μM (n = 3-4), desacyl ghrelin 0.001-1μM (n = 3-4), capromorelin 0.01-10μM (n = 3-4) or AZP-531 0.001-1μM (n = 3-4). In mesenteric arteries pre-incubation of ulimorelin 1-10μM caused a parallel rightward shift in the cumulative response to PE (0.01-1000μM; pA2 = 5.7; n = 3-4). No differences were observed between wild type mice and mice lacking the GHSR1a receptor in the ability of ulimorelin 1-10μM to inhibit PE responses (at 10μM by 61±17 and 51±16 respectively; $P > 0.05$; n = 3, 3) or increase in artery tension (10-100μM; EC50 = 21μM Emax = 15±3%; EC50 = 16μM Emax = 23±6%; n = 3, 3; $P > 0.05$).
CONCLUSION: Ulimorelin inhibited PE induced contractions and, at higher concentrations, increased artery tension. These effects were regionally dependent, and it is likely they were not mediated by GHSR1a as they were not mimicked by other ghrelin receptor agonists, and not attenuated in mice lacking GHSR1a or by the antagonist YIL 781. A possible competitive antagonist action at the α-adrenoceptor is suggested for the inhibition of PE-induced contractions.

INTRODUCTION: Although sigmoid volvulus (SV) causes acute obstruction, the pathogenesis and pathological mechanism of SV are unknown.
AIMS & METHODS: The aim of our study is to evaluate the clinicopathological characteristics of volvulus and factors contributing to volvulus of the sigmoid colon. Fourteen patients with SV (10 men and 4 women; median age, 78.5 years) were compared with 14 age- and sex-matched control patients with respect to differences in clinical characteristics, focusing on dysmotility (enteric visceral myopathy, neuropathy, and mesenchymopathy).
RESULTS: Of the 14 patients with SV, 7 had recurrent volvulus, 11 had an associated condition, and 5 required emergency surgery. The prevalence of atrophy and fibrosis of the inner muscle in patients with SV was higher than that of the control patients ($P = 0.041$). Median extents (per cm of muscularis propria) of the myenteric plexus (12.5 versus 17.5, $P < 0.001$) and submucous plexus (15.0 versus 25.5, $P < 0.001$) in patients with SV were lower than those of the control patients. Median numbers of myenteric (9.7 versus 30.4, $P < 0.001$) and submucous ganglion cells (10.0 versus 23.2, $P < 0.001$) were also lower than those of the controls. The prevalence of inflammatory neuropathy in patients with SV was higher than that of the control patients ($P = 0.046$). There were no differences in mesenchymopathy ($P = 0.481$).
CONCLUSION: A decrease in the extent of enteric plexus and ganglion cells may play an important role in the diagnosis and recognition of a clear mechanism leading to torsion in SV.

INTRODUCTION: Percutaneous Tibial nerve stimulation (PTNS) is a minimally invasive, well tolerated emerging treatment for patients who have not responded to conservative treatment for faecal incontinence (FI). There is limited information about the difference in its efficacy in patients with different FI symptoms. The aim of this retrospective study was to assess the efficacy of PTNS in patients with FI, comparing between patients with different faecal incontinence symptoms.
AIMS & METHODS: Consecutive patients were studied: all had improved following the initial 12 weeks of weekly PTNS treatment and were receiving maintenance. Based on initial presenting FI symptoms the patients were placed into three categories: 1) Urge incontinence 2) Passive 3) Passive + Urge incontinence. The outcome parameters were Wexner FI incontinence score, stool consistency and FI episodes per week (based on diary). Outcomes were compared between

the pre- and post-treatment, and between pre-treatment and latest maintenance (mean 12.4 (SD 7.2 months) scores.
RESULTS: Data is presented on 44 patients (6 male, mean age of 59[25 to 77]) with a mixture of aetiologies. (As there was only 3 patients in the passive incontinence group, no statistical analysis was undertaken.) There was a statistically significant improvement in both other groups when comparing pre-vs post-treatment Wexner Scores (mean and SD in table). In addition, in the pre vs maintenance analysis there was a significant improvement seen in symptoms. There was a statistically significant improvement observed in faecal continence episodes in the pre vs maintenance analysis, but no statistically significant change in stool consistency between any groups in pre vs post and pre vs maintenance analysis.
Table- Wexner Score Comparison table

	Pre-procedure	Post-procedure	Pre vs Post P value	*Maintenance*	Pre vs Maintenance
Urge Incontinence (n = 21)	14.4± 2.7	7.2 ± 2.1	< 0.0001	8.5 ± 3.4	< 0.0001
Passive incontinence (n = 3)	12.0 ± 4.0	6.3 ± 5.3		10.7 ± 8.3	
Urge + passive incontinence (n = 24)	16.1 ± 2.2	9.3 ± 3.5	< 0.0001	9.6 ± 4.4	< 0.0001

CONCLUSION: We have shown that PTNS improves symptoms in patients with urge incontinence and in also in those with a combination of urge and passive symptoms. The symptom improvement was maintained in all our patients. Larger numbers of patients with passive incontinence need to be studied.
Disclosure of Interest: None declared

P0995 THE EFFICACY OF PERCUTANEOUS TIBIAL NERVE STIMULATION IN DIFFERENT ANAL SPHINCTER DEFECTS

K. **I. Kemal**[1,1,*], L. Kumar[1], A. Alam[1], J. Liwang[1], A. Raeburn[1], E. Athanasakos[1], A. Emmanuel[1]
[1]*GI Physiology Unit, University College London, London, United Kingdom*

INTRODUCTION: Percutaneous Tibial nerve stimulation (PTNS) is an emerging 'step-up' treatment for patients who have not responded to conservative treatment for faecal incontinence (FI). There is limited information about its efficacy in patients with different sphincteric defects. The aim of this retrospective study was to assess the efficacy of PTNS in patients with FI, comparing between patients with different sphincter pathologies.
AIMS & METHODS: Consecutive patients were studied: all had improved following the initial 12 weeks of weekly PTNS treatment and were receiving maintenance. Based on baseline endoanal ultrasound patients were placed into four categories: 1) Both sphincters intact 2) External anal sphincter (EAS) defect 3) Internal anal sphincter (IAS) defect 4) Both sphincters damaged. The outcome parameters were Wexner FI incontinence score, stool consistency and FI episodes per week (based on bowel diary). Outcomes were compared between the pre- and post-treatment, and between post-treatment and latest maintenance (mean 12.3 (SD 7.2 months) scores.
RESULTS: Data is presented on 46 patients (40 female, mean age of 57[25 to 78]) with a mixture of aetiologies. There was statistically significant improvement in all groups comparing pre- vs post-treatment Wexner Scores (mean and SD in table). In the post vs maintenance analysis there was significant symptom exacerbation only for the intact sphincter groups, whilst persistent improvement was seen in the other three groups. In all groups incontinence episodes were reduced after PTNS, and remained at low levels during maintenance ($p < 0.05$ vs pre-PTNS for both). No such difference in stool consistency was seen however ($p > 0.05$ vs pre-PTNS for both).
Table- Wexner score mean ± SD in the different sphincter states

	Pre-procedure	Post-procedure	*Pre vs Post p value*	Maintenance	*Post vs Maintenance p value*
Intact sphincters (n = 23)	14.4 ± 2.5	7.4 ± 2.3	*< 0.0001*	9.7 ± 4.2	*0.0214*
EAS defecit (n = 8)	15.7 ± 1.9	7.9 ± 1.2	*< 0.0001*	7.6 ± 1.7	*0.3559*
IAS defecit (n = 7)	15 ± 3.7	7.4 ± 3.3	*0.0003*	8.1 ± 2.5	*0.1824*
Both sphincters damaged (n = 8)	16.6 ± 1.7	11 ± 4.5	*0.0063*	11.5 ± 18.3	*0.7627*

CONCLUSION: We have shown that PTNS improves symptoms in patients who have both anal sphincter defects and intact sphincters. The symptom improvement with PTNS was maintained in the sphincter damaged patients but not those with intact sphincters. The effect of PTNS on patients with sphincter disruption suggests a mechanism of action directed at the anorectal unit beyond just the anal sphincter.

P0996 THE ROLES OF LENGTH, DURATION OF ESOPHAGEAL HYPERTENSIVE CONTRACTIONS IN DIFFERENT DIAGNOSIS STRATEGIES OF NUTCRACKER ESOPHAGUS

K. Wang[1], L.-P. Duan[1], Z.-W. Xia[1], **Y.-X. Leng**[1,*], Z.-J. Xu[1]
[1]*Department of Gastroenterology, Peking University Third Hospital, Beijing, China*
Contact E-mail Address: *duanlp@bjmu.edu.cn*

INTRODUCTION: Some patients with chest pain or dysphasia present esophageal hypertensive contractions (HCs) during esophageal manometry test, but the contraction pattern did not meet any criteria of Chicago classification 2012.
AIMS & METHODS: To evaluate the esophageal segmental or short-time HCs (s-HCs) with Chicago classification criteria and conventional criterion respectively in NCCP or dysphasia patients and preliminarily analyze the roles of HCs location, pressure and duration in diagnosis strategy.
Methods: Patients with NCCP or dysphasia were enrolled. All underwent gastroscopy to exclude organic diseases. Esophageal peristalsis conditions of 10 wet swallows were recorded by HRM with 36 channels of pressure sensors. We defined the area in 180mmHg isobaric contour as hypertensive contraction area (HCA). According to Gothenburg criterion (GC), patients with peristaltic contractions of amplitude > 180mmHg at any level of the esophagus was considered as conventional nutcracker esophagus (c-NE). Patients with mean distal contraction index (DCI) > 5000 mmHgscm, normal integrity relaxation pressure and distal latency were diagnosed as Chicago NE, with DCI > 8000 mmHgscm as Chicago Jackhammer. Patients who met GC but not Chicago criteria were considered as s-HCs.
RESULTS: ①Thirty one patients present HCs and 3 of them were excluded for their EGJ obstructions. The remainder 28 patients (51.8±12.3y, M/F = 10:18) were diagnosed as c-NE (100%, 28/28). Among them, five (17.9%, 5/28) patients were diagnosed as Jackhammer and 2 NE (7.1%, 2/28). The other 21 patients (75%, 21/28) were diagnosed as ''normal'' group by Chicago criteria, which considered as s-HCs in our study. ②seventy swallows in Chicago abnormal group and 210 swallows in s-HCs group were compared. The lengths (3.8(3.3-4.9) vs. 6(5.5-9) cm, $p = 0.023$), durations (3(2.6-3.2) vs. 4.8(4.4-5.1)s, $p < 0.001$)), peak amplitudes (212.8(203.8-233.6) vs. 304.9(221.4-347.7) mmHg, $p = 0.001$) of HCA in s-HCs patients were significantly lower than that of Chicago abnormal group. The mean pressure (132(118-144.1) vs. 188.1(179.6-206.2) mmHg, $p < 0.001$) and duration (3.5(3-3.8) vs. 4.9(4.4-5.2) s, $p < 0.001$) of 3-8cm esophageal segment above LES in s- HCs group were significant lower than that of Chicago abnormal group. There were no differences in IRP 4s, upper margin of HCs, pressure of 8cm and 13cm above LES between the two groups ($p > 0.05$). Further analysis showed negative correlation ($r = -0.435$, $p = 0.021$) between the upper margin of HC area and DCI value, while the length ($r = 0.634$, $p < 0.001$), peak amplitude($r = 0.721$, $p < 0.001$) and contraction duration ($r = 0.819$, $p < 0.001$)of HC area were positively correlated with DCI.
CONCLUSION: A large proportion of c-NE diagnosed by conventional Gothenburg criterion was considered as ''normal'' in Chicago criteria because the hypertensive contractions were segmental or short-time. For patients with typical NCCP or dysphasia, the roles of s-HCs and the relationship between s-HCs and esophageal symptoms need to be clarified.

P0997 PATIENTS WITH DYSPEPSIA SYMPTOMS ARE MORE RESPONSIVE THAN HEALTHY SUBJECTS AFTER SPRAYING MENTHOL INTO THE UPPER GASTROINTESTINAL TRACT

K. Hiroaki[1,*], H. Ken[2], J. Hata[3], Y. Naohito[1], K. Honda[1], K. Tomoari[2], S. Akiko[2], K. Tomoko[1], I. Kazuhiko[1], T. Machi[1]
[1]*Department of General Medicine,* [2]*Department of Gastroenterology,* [3]*Division of Endoscopy and Ultrasonography, Kawasaki Medical School, Kurashiki, Japan*

INTRODUCTION: In Japan, the use of antispasmodics such as anticholinergic agents as pretreatment for upper gastrointestinal tract endoscopy has become standard. However, endoscopy without antispasmodics has frequently been performed in recent years; when antral contraction interferes with intragastric observation, 0.8% L-menthol (MINCLEA® 20 mL) is sprayed into the gastrointestinal tract to stop such contractions. However, the mechanism of antral contraction suppression after spraying menthol into the stomach has not been fully elucidated, and differences in gastric and duodenal responsiveness have also not yet been sufficiently studied.
AIMS & METHODS: By focusing on post-spray responsiveness, we separately applied menthol to the antrum and the duodenal bulb using a spray tube and studied associations between changes in antral contractile activity and dyspepsia symptoms. [Subjects] The 18 subjects who underwent endoscopy without antispasmodics consisted of nine patients with dyspepsia symptoms (patient group) and nine healthy subjects without abdominal symptoms (healthy group). [Method] The subjects fasted for a minimum of 12 hours starting the day before the examination and underwent endoscopy without receiving pre-administration of drugs into the stomach or injection of antispasmodics. Prior to detailed intragastric observation, an endoscope was fixed to the site where antral contraction could be evaluated; after spraying 2 mL of menthol solution into the antral region using a spray tube, changes in contraction were observed for two minutes. A tube was then inserted into the duodenal bulb and 2 mL of menthol solution were sprayed in a similar manner, and changes in contraction were observed for two minutes thereafter. In patients in whom antral contractions did not stop, the antral region was again sprayed with another 16 mL of menthol solution. After menthol spraying, we continued normal endoscopy in the subjects and recorded dilatation of the proximal stomach, opening/closing of the pyloric ring, the frequency and intensity of antral contractions, the presence or

absence of hernia, and the presence or absence of bile retention in the stomach and the duodenum.
RESULTS: After menthol spraying we found that the examination time was extended by approximately six minutes on average as compared to normal endoscopy. However, there was no major interference with intragastric observation. In the patient group, antral contraction stopped after spraying menthol into the duodenum in eight of nine patients, while it stopped in only three of nine subjects in the healthy group. No clear difference was identified in responses after menthol spraying between the stomach and duodenum.
CONCLUSION: Although no differences in responses after spraying were identified between the stomach and duodenum, it was revealed that there are differences in responsiveness after menthol spraying which depend on the presence or absence of dyspepsia symptoms. Accordingly, after further improvement and accumulation of patients, this could become a useful examination method for elucidating the pathology of dyspepsia symptoms.

P0998 IMPLICATION OF THE ENTERIC GLIAL CELLS IN THE IMMUNOREGULATORY PROCESSES

L. Kermarrec[1,*], T. Durand[1], M. Neunlist[1], I. Neveu[1], P. Naveilhan[1]
[1]*inserm U913, inserm U913, Nantes, France*
Contact E-mail Address: *laetitia.kermarrec@etu.univ-nantes.fr*

INTRODUCTION: The enteric nervous system (ENS), also referred as the second brain, is well-known for its role in the control of intestinal functions such as motility, secretion and absorption. A growing bulk of evidence suggests that cells of the ENS such as the enteric glial cells (EGC) may play an important role in case of inflammatory bowel diseases (IBD). Indeed, astrocytes, their counterparts in the central nervous system, have immunomodulatory properties that might be shared by the EGC.
AIMS & METHODS: To study the immunoregulatory properties of the EGC, glial cells were isolated from the myenteric plexus of the rat digestive tract (rEGC), and their effects were tested in vitro, on activated rat T lymphocytes. Spleen-derived T cells stimulated by anti-CD3 and anti-CD28 antibodies were labeled with CFSE and incubated for three days with increasing ratios of rEGC. The rate of T cell proliferation was analyzed by flow cytometry. Similar approaches were used with human EGC isolated from the myenteric plexus of colonic biopsy. The immunoregulatory properties of human EGC were tested on human peripheral blood mononuclear cells (PBMC) activated with phytohemagglutinin (PHA).
RESULTS: The results show that rEGC inhibit the proliferation of activated T cells. Pretreatment of rEGC with pro-inflammatory stimuli (LPS, interleukine-1/TNFalpha) does not modify these immunomodulatory effects. Preliminary experiments with EGC derived from a human colonic biopsy suggest similar properties as the cells inhibit the proliferation of PHA-activated CD3+ cells in a dose-dependent manner. Investigations are currently performed to determine whether EGC derived from other control patients have the same properties. We also are also analyzing if EGC derived from IBD patients have similar potentialities.
CONCLUSION: The present data show that EGC are able to modulate the proliferation of T cells in vitro. They suggest that neuroimmune interactions between EGC and T cells could occurr in vivo.

P0999 USE OF CONSENSUS DEFINITION OF FAILURE OF A TREATMENT TO PROVIDE ADEQUATE RELIEF (F-PAR) FOR CHRONIC FUNCTIONAL CONSTIPATION IN CLINICAL PRACTICE

L. Kumar[1,*], S. Butt[1], A. Aalam[1], D. Chatoor[1], A. Emmanuel[1]
[1]*GI Physiology Department, UCLH, London, United Kingdom*

INTRODUCTION: Chronic constipation is a common condition characterized by multiple inter-related symptoms. Treatments range from initial self-management by lifestyle modification and laxatives, through to prokinetic drugs, bowel irrigation and complex surgical options. However rates of objective and subjective treatment success are low and the subjective nature of symptoms means that success itself is hard to define. A recent consensus process (funded by Shire) Delphi- has yielded a tool to identify failure of a treatment to provide adequate relief (F-PAR).
AIMS & METHODS: Aims: To establish utility of F-PAR scoring system in identifying treatment failures amongst patients with constipation. Find out specificity of the F-PAR scoring system. Methods: The 5-item self-report F-PAR tool was offered to 236 consecutive patients attending a tertiary care center with Rome III defined functional constipation. Only one patient could not complete it and a total of 281 forms were analysed (196 patients with one form, 32 patients presented twice and 7 presented three times). The form with the tool was filled in by the patient in the waiting room prior to being seen by the clinician, who then consulted ignorant of the responses on the tool, and a clinical decision ('gold standard') about treatment success made. After the consultation an independent researcher reviewed the relationship between results of the tool and clinical assessment.
RESULTS: All 235 patients (212 female, mean age 41) had completed a time-defined prescribed treatment at the time of assessment. The treatments (number, %, of successes as defined by clinic assessment in parentheses) were: 121 (42, 35%) laxatives or enemas, 76 (35, 46%) prokinetics or secretagogues, 64 (36, 56%) biofeedback, 11 (2, 18%) trans-anal irrigation, 9 (1, 11%) sacral nerve stimulation. In total 165 (59%) were deemed not to have responded to treatment. There were 5 'false positives' and 7 'false negatives' generated by the F-PAR. Of 163 F-PAR identified patients, 136 (83%) had 1 item positive, 21 (13%) had 2 items positive, 7 (4%) had ≥3 items positive. This gives specificity 96% (CI 91-98%) and sensitivity 96%(CI 90-99%), a positive predictive value of 97% (CI 93-99%) and negative predictive value 94% (CI 88-98%).
CONCLUSION: The F-PAR is a highly sensitive instrument to identify treatment failure in chronic constipation in
setting.
a tertiary care setting. A single positively reported item out of five in this easy to use tool can identify patients who need a change of treatment. Further validation will come from utilization of the tool in a primary care setting.

Contact E-mail Address: *natalia.pedersen@zeniavej.dk*

INTRODUCTION: Low fermentable Oligo-Di- and Mono- saccharides and Polyols (FODMAP) diet (LFD) may be effective in patients with irritable bowel syndrome (IBS), and these patients may have altered microbiota (MB). The aim of the study was to investigate the impact of LFD and *lactobacillus rhamnosus* GG (LGG) on fecal MB.
AIMS & METHODS: Fecal samples were collected from IBS patients (Rome III criteria) and randomized to LFD, LGG or normal Western/Danish diet (ND). IBS severity score (IBS-SSS) was registered by patients at week 0 and 6 on an e-health application, www.ibs.constant-care.dk. Bacteria in fecal samples were analyzed by Genetic Analysis AS's GA-map^{TM} Dysbiosis Test, a test utilizing 16SrRNA DNA to recognize the gut bacteria found to best correlate with dysbiosis in IBD/IBS patients. Dysbiosis Index (DI) is calculated by an algorithm based on bacterial abundance and profile in a fecal sample. DI is measured on a scale from 1-10, where values above 2 is considered dysbiotic. Dysbiosis class is defined as either non-dysbiotic or dysbiotic. Change in DI and dysbiosis class between week 0 and 6 were investigated.
RESULTS: In total 58 patients (median age 39, range 20-74 years, 81% females) were included in the study: 17 LFD, 20 LGG and 21 ND. A significant improvement in IBS-SSS total score in LFD and LGG patients was observed at week 6 compared to week 0, 308 [150-460] vs. 189 [25-478], $p<0.001$ and 296 [157-431] vs. 212 [11-471], $p<0.01$. No significant improvement was observed in ND patients, 303 [82-450] vs. 289 [62-428], $p=0.28$. There was no significant improvement in DI at week 6 compared to week 0 in LFD (6 vs 6, $p=0.53$), LGG (5 vs 8, $p=0.88$) or ND (7 vs 6, $p=0.4$). However, a substantial part of the patients (35-43%) changed dysbiosis class (dysbiotic, non-dysbiotic) following the 6 week intervention and alterations in DI were observed in all three groups, both as decreased and increased DI. At week 0, 88% LFD, 65% LGG and 76% ND patients were dysbiotic ($DI>2$), while 76% LFD, 75% LGG and 81% ND patients were dysbiotic at week 6.
There was no correlation between change in IBS-SSS and DI in either LFD or LGG group.
CONCLUSION: Both LFD and LGG groups reported significant reduction in IBS-SSS from week 0 to 6. High proportions (65-88%) were dysbiotic at week 0, and alteration in MB was observed in 35-43% of the patients who changed dysbiosis class following dietary intervention. LFD did not significantly alter the gut MB in this study population, however, the test provides information on alterations in bacterial abundance and profiles that may prove valuable for individual patients.

INTRODUCTION: *H. pylori* is known to play a paramount role in the development of both gastric and extragastric diseases.
However, human stomach harbours also a broad variety of microorganisms, often not cultivable with conventional microbiology methods. Metagenomic techniques are improving our understanding of gut microbiota composition, using the 16S rRNA gene as a molecular fingerprint to analyze microbial diversity. Chronic therapy with proton-pump inhibitors is known to increase the risk of gut microbiota-related diseases such as C. difficile infection and spontaneous bacterial peritonitis. Influence of proton-pump inhibitors (PPIs) in modifying gastric microbial ecosystem has not yet been described.
AIMS & METHODS: Our aim is to assess, through metagenomic tools, the composition of gastric microbiota in subjects with upper gastrointestinal symptoms either taking or not PPIs. We analyzed gastric biopsy samples from 10

consecutive patients undergoing upper endoscopy. We enrolled 5 patients taking PPIs (group A) and 5 ones free from gastrointestinal drugs (group B). We collected two biopsy samples for each patient. Roche 454 GS Junior was used for metagenomic analysis. Obtained data were assessed by Qiime suite.
RESULTS: Main indications to upper endoscopy were epigastric pain and/or heartburn and/or dyspepsia. Bacteria amplicons were detected in all samples. *H. pylori* was found in 3 patients from group A and 2 patients from group B, respectively. Overall, prevalent bacteria classes were Epsilonproteobacteria (26.5%), Bacilli (21%), Bacteroidia (19.3%), and Gammaproteobacteria (7.8%). Generally, a higher number of microorganisms was found in group A. Differences in gut microbiota composition were observed between two groups of patients. Respectively, higher abundance of Actinobacteria (9.74% VS 0.98%), Bacilli (27.78% VS 14.22%), Betaproteobacteria (7.68% VS 1.32%) and Gammaproteobacteria (13.86% VS 1.86%) and a lower presence of Epsilonproteobacteria (1.06% VS 51.8%) were found in group A when compared with group B.
CONCLUSION: Until a short time ago the uncultivability of microorganisms did not allow the assessment of gastric microbiota composition. The diffusion of metagenomics tools, not depending on microbial culture, has incredibly enlarged our knowledge on gut microbiota. In this preliminary report, we demonstrated that PPIs modify gastric microbiota composition in subjects with upper gastrointestinal symptoms. Such phenomenon may explain the role of PPIs in the development of many gut-microbiota related diseases. Further investigations are needed to improve our understanding of this cutting-edge topic.

INTRODUCTION: Cdx2 is expressed in human intestinal metaplastic mucosa and induces intestinal metaplastic mucosa in Cdx2-transgenic mouse stomach. In humans, atrophic gastritis and intestinal metaplasia due to *Helicobacter pylori* (*H. pylori*) infection commonly lead to gastric achlorhydria. These conditions predispose the stomach to bacterial overgrowth. To date, the few studies have been reported that explored the microbiota of the stomach in negative or positive status for *H. pylori* using molecular methods. However, the studies on characterization of the gastric microbiota in severe atrophic gastritis or intestinal metaplasia have not been published.
AIMS & METHODS: The aim of the present study was to determine the differences in the gut microbiota between normal and Cdx2-transgenic mice using a quantitative RT-PCR method with 16S rRNA-genetargeted species-specific primers.
Twelve normal and twelve Cdx2 transgenic mice (7 weeks age, 6 male and 6 female respectively) were sacrificed, and the gastric, jejunal, ileac, cecal and colonic mucosa, and feces were collected. To analyze bacterial microbiota quantitatively, we used a real time RT-PCR method with 16S rRNA-gene-targeted species-specific primers. Seven primer sets for obligate anaerobes (*Clostoridium coccoides* group, *Clostridium leptum* subgroup, *Bacteroides fragilis* group, *Bifidobacterium*, *Atopobium* cluster, *Prevotella*, *Clostridium perfringens*), 5 sets for facultative anaerobes (*Lactbacillus*, *Enterobacteriaceae*, *Enterococcus*, *Streptococcus*, *Staphylococcus*) and 1 set for a obligate aerobe (*Pseudomonas*) were used.
RESULTS: The total bacterial numbers in the gastric ($\log_{10}(7.7 \pm 0.4)$/g), jejunal ($\log_{10}(6.7 \pm 0.7)$/g), ileac ($\log_{10}(6.3 \pm 0.4)$/g), cecal ($\log_{10}(7.6 \pm 0.3)$/g) and colonic ($\log_{10}(7.7 \pm 0.4)$/g) mucosa of Cdx2-transgenic mice were significantly higher than those ($\log_{10}(5.3 \pm 1.0)$ / g, $\log_{10}(3.4 \pm 1.2)$/g, $\log_{10}(4.9 \pm 0.8)$/g, $\log_{10}(6.6 \pm 0.4)$/g and $\log_{10}(5.4 \pm 1.3)$/g, respectively) of normal mice. *Bacteroides fragilis* group and *Prevotella* were not detected in the stomach of normal mice while they were detected in that of Cdx2-transgenic mice. Moreover, *C. coccoides* group, *C. leptum* subgroup, *Bacteroides fragilis* group and *Prevotella* were not detected in the jejunum and ileum of normal mice while they were detected in that of Cdx2-transgenic mice. In contrast, the fecal microbiota in normal mice was similar to that in Cdx2-transgenic mice.
CONCLUSION: Gastric achlorhydria due to intestinal metaplasia makes an obvious effect on gastrointestinal microbiota.

P1003 TOLL-LIKE RECEPTOR 7-DEPENDENT MODULATION OF COLONIC PERMEABILITY DEPENDS UPON THE INTEGRITY OF THE EPITHELIAL BARRIER

J. Estevez[1], **V. Martinez**[1,*]
[1]*Dept. of Cell Biology, Physiology and Immunology, Universitat Autonoma de Barcelona, Bellaterra, Spain*
Contact E-mail Address: *javier.estevez@uab.es*

INTRODUCTION: Toll-like receptors (TLRs) are a key component in host-bacterial interactions within the gut. TLRs have been implicated in the regulation of epithelial permeability through the modulation of tight junctions.
AIMS & METHODS: To assess *in vivo* changes in colonic permeability associated to the local stimulation of TLR7 and the implication of tight junctions-related proteins. Adult SD rats were treated intracolonically with the selective TLR7 agonist imiquimod (300 μg/rat) or its vehicle (0.2 ml). In some cases, 4 h after imiquimod administration, the colonic epithelium was challenged with 100% dimetilsulfoxide (DMSO). Colonic epithelial permeability to macromolecules was determined assessing the accumulation of 4 kDa fluorescein isothiocyanate–dextran (FD4; 10 mg/animal, 0.2 ml, intracolonically) in the colonic wall and the passage to blood and urine. Expression of tight-junction-related proteins [occludin, Zona Occludens-1 (ZO-1), claudin-2 and -3, tricellulin and junctional adhesion molecule 1], inflammatory markers (IFNα1 and IL-6) and the barrier modifier factors [Glucagon-Like Peptide 2 (GLP-2) and Myosin Light-Chain Kinase (MLCK)] was assessed by RTqPCR.
RESULTS: Acute stimulation of TLR7 with imiquimod did not alter the colonic passage of FD4. Challenge of the colonic mucosa with DMSO slightly increased colonic permeability (Table). TLR7 stimulation after the challenge with DMSO resulted in an enhancement of FD4 accumulation in colonic tissues and an increased passage to blood and urine (Table). Neither macroscopical nor microscopical nor molecular signs of inflammation were observed, regardless the treatment considered. Intracolonic imiquimod did not modify the expression of the main tight-junction-related proteins or the barrier modifier factors (proglucagon and MLCK).

FD4	Vehicle-Vehicle	IMQ-Vehicle	Vehicle-DMSO	IMQ-DMSO
Serum (μg/ml)	0.49 ± 0.07	0.45 ± 0.07	0.74 ± 0.11	1.12 ± 0.10**
Urine (μg/ml)	0.79 ± 0.27	1.06 ± 0.20	3.14 ± 0.68	6.66 ± 1.21**
Colon (% of FD4 in tissue)	7.93 ± 2.31	4.16 ± 1.78	5.73 ± 3.14	14.25 ± 4.12

CONCLUSION: Local stimulation of TLR7 results in an enhanced colonic permeability only in states of epithelial disruption. The mechanisms mediating these effects seem to be independent of a modulation of the expression of the main tight junction-related proteins or the expression of GLP-2 and MLCK. These observations suggest that microbial factors do not trigger, per se, epithelial alterations, but they can contribute, as enhancing factors, in states of epithelial disruption. Similar mechanisms might operate in functional and inflammatory gastrointestinal disorders. In these conditions, after an initial disturbance of the epithelial barrier, the microbiota would act as an enhancing and/or perpetuating factor.

P1004 THE PERSISTENCE OF COLON CANCER-ASSOCIATED ESCHERICHIA COLI WITHIN HUMAN MACROPHAGES INDUCES COX-2 EXPRESSION

J. Raisch[1], A. Darfeuille-Michaud[1], **M.-A. Bringer**[1,*]
[1]*M2iSH, UMR1071 Inserm-Université d'Auvergne; INRA USC2018, Clermont-Ferrand, France*
Contact E-mail Address: *m-agnes.bringer@udamail.fr*

INTRODUCTION: Independent studies have shown that colonic adenomas, carcinomas and the mucosa of patients with colorectal cancer are abnormally colonized by *Escherichia coli* belonging to the B2 phylogroup, with a high prevalence of *E. coli* producing a genotoxin termed colibactin. Macrophages are one of the predominant cellular components of tumor-infiltrating immune cells where they support key processes in tumor progression through the expression of protumoral factors such as the cyclooxygenase-2 (COX-2).
AIMS & METHODS: In the present study, we aimed to analyze the interaction of B2 phylogroup *E. coli* isolated from tumors of patients with human macrophages and the subsequent COX-2 expression.
The ability of B2 *E. coli* isolated from colon cancer to resist macrophages killing was assessed in human THP-1 macrophages using gentamicin assay and microscopy analysis. COX-2 expression and PGE2 secretion were quantified by Western blot and ELISA, respectively. Involvement of MAPK signaling pathways were analyzed by Western blot using specific inhibitors.
RESULTS: Colon cancer associated-*E. coli* were able to survive within human THP-1 macrophages at 24h post-infection indicating that these bacteria are able to resist macrophages killing. Transmission electron microscopy revealed that bacteria are enclosed in two kinds of compartments, some vacuoles containing single bacteria and other ones containing numerous bacteria. In addition, colon cancer-associated *E. coli* induced COX-2 expression and PGE2 secretion to levels significantly higher than those induced by the commensal *E. coli* strain ED1a belonging also to B2 phylogroup. Induced-COX-2 expression by colon cancer-associated *E. coli* was not related to the production of colibactin, since we observed similar COX-2 levels in macrophages infected with wild-type strain

11G5 or a *clbQ* mutant unable to produce colibactin. Interestingly, when macrophages were treated with ofloxacin, a fluoroquinolone antibiotic with intracellular tropism, a decrease in the number of intracellular *E. coli* was observed together with a decrease in COX-2 expression. In addition, in infected macrophages with colon cancer-associated *E. coli*, the p38 MAPK signalling pathway was involved in the control of the number of intracellular bacteria and in COX-2 expression.
CONCLUSION: Colon cancer-associated *E. coli* strains belonging to B2 phylogroup are able to resist macrophages killing and the presence of live intracellular bacteria induces COX-2 expression. We identify the p38 MAPK signalling pathway as a target to control the number of intracellular bacteria within macrophages and to limit the expression of the pro-tumoral factor COX-2.

INTRODUCTION: A balanced gut microbiota, is essential for host well-being. Radiation proctitis (RP) may develop following radiation treatment of pelvic malignancies. Microbial changes may occur following radiation and impact radiation-induced tissue damage.
AIMS & METHODS: Aim: To investigate gut microbiota dynamics during different stages of RP in a mouse RP model.
Methods: The microbiome was analysed using fingerprinting and high-throughput approaches, based on fecal samples and colonic biopsies for up to 36 weeks. Biologic effects of microbiota at different stages were investigated using coculture of bacteria with HT-29 cells.
RESULTS: A shift in the gut microbiome during RP was observed (*p-value* Bonferroni-corrected < 0.0001 based on unweighted UniFrac mesure) and each clinical stage was represented by a unique microbial signature. These signatures were correlated with disease progression and immunologic parameters, as analyzed by colonic mRNA expression of several cytokines including TNFα, IL1β, IL6 and TGFβ (*p-value* < 0.05), histopathology (*p-value* < 0.001) and macroscopic symptoms of body weight, diarrhea and rectal bleeding in irradiated mice Vs controls. Using cocultures, RP-induced fecal microbiome obtained from active disease stages was found to induce secretion of TNFα (3.6-fold increase, *p-value* < 0.05) from the intestinal epithelial cells as compared to control flora, while naïve flora caused a decrease in IL1ß secretion (2.3-fold, *p-value* < 0.05). Supernatants and UV inactivated bacteria had no effect on cytokine secretion from the cells.
CONCLUSION: Rectal irradiation alters the local microbiota which have proinflammatory effects and loss of anti-inflammatory activity. Live bacteria are needed in order to mediate these effects. Better understanding of the mucosal-microbiome interaction may aid in future attemps to control disease severity and may potentially allow for manipulation of the microbiota in a clinically beneficial manner.

P1006 PEG-GUT LAVAGE MAY INDUCE CHANGES IN THE FAECAL MICROBIOME OF HEALTHY VOLUNTEERS

V. Robles[1,*], S. Panda[1], A. Santiago[1], E. Navarro[1], C. Herrera[1], N. Borruel[1], F. Casellas[1], C. Manichanh[1], F. Guarner[1]
[1]*GASTROENTEROLOGY, VALL DHEBRON UNIVERSITY HOSPITAL, BARCELONA, Spain*

INTRODUCTION: Dysbiosis may play a role in some gastrointestinal conditions such as IBD, IBS and *C diff* diarrhoea. Metagenomic studies indicate that such conditions are associated with reduced bacterial diversity of the gut microbial ecosystem. Using high-throughput 16S rRNA sequencing technique, we explored whether intestinal cleansing with a polyethylene glycol solution (PEG) induces changes in the faecal microbiome of healthy individuals, and whether the eventual changes are reversible over time.
AIMS & METHODS: We analysed the faecal microbiome of 12 healthy volunteers through 7 time points before and after bowel cleansing with PEG. Faecal samples obtained at day -30 (T1) and day -1 (T2) before PEG evaluated stability. A solid sample was obtained during PEG lavage (T3), and further samples on days +1 (T4), +15 (T5), +30 (T6), and +60 (T7) were used to investigate changes induced by PEG and eventual resilience. DNA extracts were analysed by pyrosequencing of the 16S rRNA gene (V4). Raw sequence data collected were analysed with Qiime. We use Chao1 as species richness estimator and Unifrac as Phylogenetic Similarity Index.
RESULTS: Regarding the overall structure of bacterial communities, main enterotype drivers (Bacteroides genus for enterotype 1 and Prevotella genus for enterotype 2) did not change with PEG or during the follow-up. Interestingly, principal component analysis based on the weighted Unifrac distance metric indicated three different outcomes from the intervention. First, six individuals (Group A) showed no change of microbiome structure after PEG. Second, three individuals (group B) showed a clear change in community structure after PEG, since T4 samples did not cluster with T1 and T2. During the follow-up, T7 returned to baseline community structure but in one subject, where the change persisted. In the third group (Group C), there was variability in community structure over time that could not be ascribed to PEG intervention. The table shows species richness according to Chao1 in the three groups.

Chao 1	Timepoint 2 Mean and CI95%	Timepoint 4 Mean and CI95%	Timepoint 7 Mean and CI95%
Group A	744,92 (685,24-804,60)	713,57 (609,94-824,21)	713,99 (685,62-762,35)
Group B	694,12 (481,86-906,32)	520,80 (385,61-656)	610,46 (232,11-988,80)
Group C	878,55 (846,68-910,43)	663,86 (537,86-789,86)	638,91 (138,89-1138,93)

At species level, counts of *Faecalibacterium prausnitzii* (Fprau) markedly increased in T4 samples from group A and C individuals ($p = 0.07$), but decreased in all samples from group B. The increase may be explained by the flushing effect of PEG, since Fprau is usually abundant at ileo-caecum. On the other hand, *Akkermansia muciniphila* was detected at baseline in 6 out of 12 individuals, but only in 3 out of 12 T4 samples and in 4 T7 samples. Mean (±SEM) relative abundance decreased (T2 3.8±2.3; T4 0.13±0.09; T7 and 0.90±0.72).
CONCLUSION: PEG exposure did not modify the overall microbial community structure. In most subjects, detectable changes fell within the expected over time fluctuations. However, changes may persist in a subset of individuals.

P1008 THE CLINICAL CHARACTERISTICS AND MANIFESTATION OF CMV ESOPHAGITIS

C.J. Kuo[1,*], H.-W. Wang[1], M.-Y. Su[1], C.T. Chiu[1]
[1]*Department of Gastroenterology and Hepatology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*
Contact E-mail Address: *m7011@adm.cgmh.org.tw*

INTRODUCTION: Esophagitis is the second most common gastrointestinal (GI) manifestation of cytomegalovirus (CMV) infection after colitis. CMV esophagitis has been reported in patients who have undergone transplantation, long-term renal dialysis and human immunodeficiency virus (HIV) infection
AIMS & METHODS: This study aimed to investigate the clinical characteristics of CMV esophagitis in patients undergoing diagnostic endoscopy.
A total of 23 patients with histologically proven cytomegalovirus infection from 1539 cases with esophageal ulcers (2003-2013) were identified and analyzed retrospectively. Patients' personal data (age, smoke, alcohol drinking), underlying systemic disease (diabetes mellitus, end stage renal disease, COPD), malignancy, indication of EGD, endoscopic characteristics in viral esophageal ulcer and diagnostic methods (pathological or serological finding) were collected for further analysis.
RESULTS: Among this data base, 23 patients were diagnosed to have cytomegalovirus esophageal ulcers. The age range was 23-84 yr and the male/female ratio 2.3/1. Odynophagia and epigastralgia were common symptoms. Most (15 of 23) of the CMV related ulcers were located at middle to lower third or distal esophagus. 21.7% (5/23) patients were infected with the human immunodeficiency virus. 47.8% (11/23) patients have underlying malignancy, including lung cancer (4), esophageal cancer (4), gastric cancer (1), ampulla vater cancer (1) and lymphoma (1). Eight of 11 patients (73%) had ever received concurrent chemoradiotherapy.
CONCLUSION:
In our study, patients with malignancy who had ever received concurrent chemoradiotherapy are at increased risk for CMV esophagitis, which had not been reported before in the literature review.
Disclosure of Interest: None declared

P1009 UPPER GASTROINTESTINAL ENDOSCOPIC FINDINGS IN HIV-INFECTED ASIAN PATIENTS ACCORDING TO AGE AND CD4 LYMPHOCYTE COUNT

J. Choi[1,*], S.W. Nam[1], J.W. C. W. Chung[1]
[1]*Department of Internal Medicine, National Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Upper gastrointestinal (GI) tract diseases are common among patients infected with human immunodeficiency virus (HIV). Upper GI endoscopic evaluation of the GI tract disease remains a cornerstone of diagnosis, especially in a highly prevalent area of gastric cancer and *Helicobacter* infection.
AIMS & METHODS: The study aimed to evaluated the upper GI endoscopic findings by CD4 lymphocyte count and age. We retrospectively studied 191 HIV-infected patients who underwent upper GI endoscopy for any indications from January 1, 2010 to December 31, 2013. The patients were classified in two groups, according to CD4 cells counting ($\geq$200 cells/mm^3 or $<$200 cells/mm^3). The subjects were divided into five groups (those aged 20–29, 30–39, 40–49, 50–59, and 60–69 years old). Parameters studied included age, gender, indications for endoscopic procedure, CD4 cell counts, antiretroviral therapies, upper GI endoscopic finding and histology.

RESULTS: The median age of 191 patients was 43 years (interquartile range [IQR], 35-52 years), and 182 patients were predominantly male (95.3 %). The median CD4+ cell count was 398 cells /mm^3 (IQR, 205- 588 cells/mm^3). GI symptoms including abdominal pain, discomfort, soreness, and dyspepsia were noted in 133 patients (69.6%). The endoscopic diagnosis of upper GI disease is shown in Table. Opportunitic infections were seen exclusively in patient with CD4 < 200 cells/ mm^3 except candidial esophagitis. There was no difference in the prevalence of gastric or duodenal ulcer according to CD4 cell count groups. However, *Helicobacter pylori* related ulcers were seen in only group with CD4 ≥200 cells/mm^3.

	All (n = 191)	CD 4 ≥200 cells/mm (n = 146)	CD4 <200 cells (n = 45)	*p*
Candidal esophagitis	11(5.8)	6(4.1)	5(11.1)	.134
Cytomegalovirus disease	4(2.1)	0(0)	4(8.9)	.003
HIV-related idiopathic ulcer	8(4.2)	3(2.1)	5(11.1)	.019
Malignant lymphoma	1(0.005)	0(0)	1(0.02)	-
Reflux esophagitis, n(%)	48(29.1)	39(26.7)	19	.31
Atrophic gastirits, n(%)	28(14.7)	23(15.8)	5(11.1)	.696
Helicobacter related peptic ulcer, active stage	3(1.5)	3(2.1)	0(0)	-
Gastric adenoma/ adenocarcinoma, n(%)	2(1.0)	1 (adenoma)	1 (early gastric cancer)	-

CONCLUSION: Low CD4 count is considered to be a predictive factor for opportunity GI infection in HIV-infected Asian patients except candidial esophagitis.

INTRODUCTION: The risk scoring systems are increasingly used to evaluate patients with Upper Gastrointestinal Bleeding (UGIB). Some of these use clinical and laboratory data, which are collected at the emergency room. Most of them also use the results of procedures such as endoscopy to stratify the results. We are still looking for the optimal scoring system, which is simple, easy to use and remember by the clinicians at the time of the patient́s reception.
AIMS & METHODS: Aims. To validate externally the discriminant ability of the pre-endoscopic clinical prediction rules (CPR) (based on clinical and laboratory data) in patients with Non-Variceal UGIB (NVUGIB) in four tertiary hospitals.
Methods. We carried out an observational retrospective study using the hospital discharges registry *Minimum Basic Data Set* (MBDS) for cases of NVUGIB in Castilla la Mancha, and Valencian Community, Spain which is based on ICD-9 diagnostic codes. We estimated the predictability of ten CPR: pre-endoscopic Rockall score, Blatchford score, modified Blatchford score, AIMS65 score, Zaragoza score, Tammaro score, Rangson score, Cambridge score, Adamopoulos score and UNAL score[1-10]. We estimated the area under the ROC curve (AUC) for each CPR versus every outcome indicator (adverse clinical course, hospital mortality, interventional therapy, unstable bleeding, prolonged hospital stay).
RESULTS: 483 patients from four different hospitals were studied in two different time periods: 2003 to 2006 (Valencian Community centers), those from the oldest cohort and 2009 to 2013 (Castile La Mancha centers), those of the recent cohort. The CPR with better discrimination ability of each analyzed indicator are shown in table 1. In general, the discrimination ability is below 0.70 in almost all analyzed indicators and rules.
Table. Discriminant ability of the Clinical Prediction Rules

Discriminant ability	CPR (Scores)	Area under ROC curve
Adverse clinical course	Adamopoulos[1]	0.58 (0.50 – 0.67)
Unstable bleeding	Rockall[7]	0.62 (0.50 – 0.73)
Interventional therapy	Adamopoulos[1]	0.57 (0.49 – 0.66)
Hospital Mortality	AIMS65[8]	0.86 (0.65 – 1.00)
Prolonged hospital stay	Rockall[7]	0.67 (0.61 – 0.72)

CONCLUSION: The CPŔs discriminant ability for estimating the evolution of a NVUGIB is relatively moderate when they are externally validated in other different centers to which were derived. Rockal, Adamopoulos and AIMS 65 are the rules that best meet the evolution of these diseases and might be the most suitable for assessing their prognosis.

P1011 DABIGATRAN- A RISK FACTOR OF SEVERE BLEEDING IN DISTAL ESOPHAGUS IN ELDERLY WOMEN

M. Stefanova[1,*], M. Pelikanova[2], M. Burian[1], D. Erhart[2], R. Spacek[2]
[1]*dept of Internal Medcine,* [2]*Hospital Na Frantisku, Prague, Czech Republic*
Contact E-mail Address: *magdalena.stefanova@seznam.cz*

INTRODUCTION: A new generation of oral anticoagulants Dabigatran has been shown to be effective. New studies showed, that the risk of gastrointestinal (GI) bleeding of Dabigatran is increased compared with Warfarin, but the incidence of life-threatening or fatal GI bleeding is lower. The source and localization of the bleeding in patients took Dabigatran are not detailed studied.
AIMS & METHODS: To compare a localization and severity of upper GI bleeding of patients with Dabigatran vs Warfarin.
All anticoagulated patients on Dabigatran or Warfarin with non variceal upper GI bleeding were enrolled in our study from November 2012 to November 2013. The demographic details, laboratory studies, concomitant medication were collected. Urgent endoscopy was performed in 24 hours from admission. A localization of GI bleeding and severity according Rockall score were describe.
All enrolled patients were divided in to two groups. Group A – patients on Dabigatran 2x110 mg. Group B – patients on Warfarin 1 x 5 mg.
RESULTS: A total of 78 patients with non variceal GI bleeding were examinated in our department. Twenty of them (26%) were anticoagulated (14 women and 6 men, medium age 78 range (47-92)).
A total of 12 patients (60%) 9 women medium age 82 and 3 men medium age 75 were on Dabigatran- group A.
8 patients (40%) (5 women, medium age 80, 3 men medium age 78 was on Warfarin- group B.
The source of bleeding had been found in distal esophagus or GE junction in 9 patients (9/12 (75%) 7 women and 2 man) in the group A compared to one patient (man) 1/8 (13%) in the group B, $p < 0.05$).
Rockall score in the group A was medium 8 (range 4-8) in patients with source of bleeding in distal esophagus or GE junction compared with Rockall score 5 (range 3-8) in patients with the source of bleeding in other upper GI locality. Rockall score in the group B was 5 in patients with source of bleeding in distal esophagus compared with Rockall score 5 (range 4-7) in patients with the source of bleeding in other upper GI locality. A total of 2 patients (2/12, 17%) in the group A had a fatal bleeding from source in distal esophagus compared with no patients in the group B.
CONCLUSION: Our study results revealed that Dabigatran is significant frequent cause of severe upper GI bleeding in distal esophagus or GE junction in elderly women compared with warfarin. Dabigatran should be indicated very carefully in this group of the patients.

P1012 STANDARD PRE-ENDOSCOPIC AND REDESIGNED POST-ENDOSCOPIC GLASGOW BLATCHFORD SCORE PERFORMED BETTER IN TERMS OF PREDICTING REBLEEDING IN PATIENTS WITH BLEEDING PEPTIC ULCER AS COMPARED TO ROCKALL SCORE - RESULTS OF A PROSPECTIVE DATABASE STUDY

INTRODUCTION: We present new diagnostic scores that successfully predicted the treatment outcome and the need for early repeated endoscopy in patients with bleeding peptic ulcer.
AIMS & METHODS: The aim of the study was to determine optimal pre-endoscopic and post-endoscopic scores in order to most optimally predict mortality, rebleeding rate, as well as the necessity for surgical intervention, and blood transfusions in patients with bleeding peptic ulcer.
Patients and methods: We prospectively studied 633 patients with bleeding stomach or duodenal ulcer admitted to Department of Internal medicine at the University Hospital Center "Sestre milosrdnice" between January 2009 and December 2012. For every patient we calculated pre-endoscopic (Rockall (RS) and Glasgow Blatchford score (GBS)) as well as post-endoscopic diagnostic scores, according to urgent upper endoscopy findings. In post-endoscopic GBS, the GBS and Forrest classification with redesigned and upgraded formula were integrated.
RESULTS: In the group of patients with bleeding stomach and duodenal ulcer when comparing AUROC for pre-endoscopic GBS and RS we found that latter is superior in predicting mortality (AUROC 0.82 vs 0.67, p 0.002) while GBS was better in predicting the rebleeding rate (AUROC 0.75 vs 0.61, $p < 0.001$). Post-endoscopic RS was also better in predicting mortality (AUROC 0.82 vs 0.66, $p < 0.001$) and post-endoscopic GBS in rebleeding rate (AUROC 0.79 vs 0.70, p 0.002). Pre and post-endoscopic GBSs better predict the need for blood transfusion and surgical intervention when compared to RS in the same group of

patients. Post-endoscopic GBS was better in predicting rebleeding rate (AUROC 0.79 vs 0.75, $p<0.036$) and the need for blood transfusions (AUROC 0.83 vs 0.76, $p<0.001$) compared to pre-endoscopic GBS.
CONCLUSION: In patients with bleeding stomach and duodenal ulcer, pre-endoscopic and newly designed post-endoscopic GBSs are better in predicting the rebleeding rate, surgical intervention and the need for blood transfusion while pre and post-endoscopic RSs are superior in predicting mortality.

P1013 THE PERFORMANCE OF THE GLASGOW BLATCHFORD SCORE (GBS) DEPENDS ON PREDICTING A BLOOD TRANSFUSION

M. Horibe[1,2,*], S. Toda[2], O. Okawa[2], W. Shinomiya[2], Y. Nakatani[2]

INTRODUCTION: Among the several scoring systems currently available for calculating the risk of upper-gastrointestinal bleeding (UGIB), the best option at present is the Glasgow Blatchford Score (GBS), which is used widely for assessing the need for admission. [1] The outcome is intervention (blood transfusion, endoscopic treatment, and surgery) or death. However, blood transfusion as an outcome measurement is superfluous in any scoring system since vital signs and hemoglobin level are sufficient to determine the need for a blood transfusion,[2] which in any case does not necessarily indicate either the need for intervention or a high-risk outcome. [3]
AIMS & METHODS: For the reasons stated above, the GBS should be validated based on outcomes that do not include blood transfusion. At Tama Medical Center, Tokyo, Japan, all patients suspected of suffering from UGIB, who were seen between January, 2008 and December, 2012, were enrolled in a validation study of the GBS without blood transfusion in the outcome. The first outcome comprised endoscopic treatment, surgery or death. The second outcome added blood transfusion to this list. We compared the area under the curve (AUC) of both outcomes with the GBS using Delong's test. We then assessed the predictive value of the second outcome with hemoglobin alone against that of the GBS by comparing their respective AUCs.
RESULTS:

	Outcome	AUC	95%CI
GBS	Intervention without blood transfusion or death	0.645	0.606-0.684
GBS	Intervention or death	0.757	0.718-0.796
Hemoglobin alone	Intervention or death	0.738	0.701-0.776

Of the 763 patients, 435(57.0%) received a blood transfusion and 19 patients died (2.5%). With regard to the GBS, the AUC of the first outcome was 0.645 [95%CI(0.606-0.684)] and that of the second outcome, including blood transfusion, was 0.757 [95%CI(0.718-0.796).]It was clear that the performance of the GBS depended largely on predicting the need for blood transfusion. ($p<0001$ by DeLong's method). On the other hand, the AUC of the hemoglobin level alone for the second outcome including blood transfusion was 0.738 [95%CI(0.701.4-0.776)], which was identical to that of the GBS.
CONCLUSION: The hemoglobin level alone was as useful as the GBS when the outcome measurements for the latter included blood transfusion. The results of this study suggest that the performance of risk assessments scores for UGIB should be validated after removing blood transfusion from the outcome measurements.

P1014 ACUTE ESOPHAGEAL MUCOSAL LESIONS MIGHT NOT BE A RARE DISEASE

N. Tsuruoka[1,*], E. Takeshita[1], T. Noda[2], R. Iwakiri[1]
[1]*SAGA UNIVERSITY, saga,* [2]*Karatsu Red Cross Hospital, karatsu, Japan*

INTRODUCTION: Acute esophageal mucosal lesion (AEML) that includes acute necrotizing esophagitis (ANE) and acute erosive esophagitisis relatively rareamong upper gastrointestinal bleedings. Recently, AEML is widely recognized with the development of endoscopic techniques.
AIMS & METHODS: This study aimed to clarify clinical features of AEML. We retrospectively analyse clinical and endoscopic findings of experienced AEMLcases of between January 2008 and March 2014.
RESULTS: We experienced 19cases (16patients)of AEML with 12male patients (75%) and 4 female patients (25%) with an average age of 56 years. Among them, only one patient had repeated 4 times of AEML (once ANE and 3 times of acute erosive esophagitis). During the period, we performed 14746 upper gastrointestinal endoscopies include 807 emergent upper gastrointestinal endoscopies. The rate of AEML accounted for emergency upper gastrointestinal endoscopies was 2.35% and 0.13% for all upper gastrointestinal endoscopies. AEML predominantly affected the lower third of the esophagus, and sliding hernia was the most common (94.7%) coexisting endoscopic finding. AEML was often accompanied by gastro-duodenal mucosal lesion. Two-thirds of ANE cases were accompanied by gastro-duodenal mucosal lesion, however only 7.69% of acute erosive esophagitis cases were accompanied by gastro-duodenal mucosal lesion. All patients had some comorbidity. Thirty three percent of patients with ANE, and fifteen percent of patients with acute erosive esophagitis received non-steroidal anti-inflammatory drugs (NSAIDs). Thirty percent of patients with acute erosive esophagitis had taken PPI or H_2RA,however no ANE patient took gastric secretion inhibitor. Gastric secretion inhibitor is possible to attenuate esophageal damage because the pathology of the 2 diseases is essentially same. Five cases (26.3%) were complicated by esophageal stenosis and eventually 3 cases died. All dead cases were associated with underlying diseases.
CONCLUSION: AEML was considered to be rare disease. However, more cases might be noticed with frequent application of upper gastro-intestinal endoscopy.

P1015 THE EFFICACY OF A SECOND-LOOK ENDOSCOPY WITH OR WITHOUT CLIPPING AFTER ENDOSCOPIC RESECTION FOR GASTRIC AND DUODENAL TUMORS: INTERIM RESULTS OF ONGOING PROSPECTIVE RANDOMIZED TRIAL

R. Plakhov[1], **O. Buntseva**[1,*], E. Fedorov[1], Z. Galkova[1], E. Ivanova[1], V. Lebedeva[1]
[1]*Moscow University Hospital № 31, Moscow, Russian Federation*
Contact E-mail Address: *roma_vp@mail.ru*

INTRODUCTION: The benefit of postoperative EGD in order to control/prevent bleeding after endoscopic resection (ER) of gastric and duodenal tumors is still debatable.
AIMS & METHODS: The aim of this ongoing study is to evaluate whether second-look endoscopy (SLE) and haemostatic endoclipping is essential to prevent delayed gastrointestinal bleeding (GIB) after ER. A total of 35 patients (m-9, f-26, mean age M±s 68.3 ± 8.2 years) who underwent ER for gastric (31) and duodenal (4) tumors: endoscopic mucosal resection (EMR) – 20(57.2%), endoscopic submucosal dissection (ESD) – 9(25.7%), removal of submucosal tumor (RST) – 6(17.1%) from November 2012 to April 2014 were included in this study. All patients were randomly divided into 2 comparable groups. After ER the patients of both groups received antisecretory therapy with proton pump inhibitors (PPI): the first 3 days - pantoprazole 80 mg intravenously, the next 4 weeks - pantoprazole 80 mg per day orally. Each SLE was performed next day after the ER; endoscopic hemoclipping (EHC) was used to prevent GIB. In the group 1 (IPP+EHC) (19 pts.) endoscopic hemostasis (EH) was performed in all cases of visible vessels on the bottom and margins of the mucosal defect. In the group 2 (IPP alone) (16 pts.) EH was performed only in exceptional situations - at active bleeding or extremely high risk of bleeding (major vessels exposed on the mucosal defect). ER was performed under general anesthesia in 26 cases and local - in 9 cases. Coagulating forceps FD-410LR and argon plasma coagulation probe with electrocoagulator VIO 300 were used for hemostasis. Moreover, at the final stage clip fixing device HX-110LR with clips HX-610-135 was applied for the prevention of GIB.
RESULTS: EH at the final step of ER was performed in 52.6% (10/19) patients of Group 1 and 56.3% (9/16) patients of Group 2. The mean size of mucosal defects after ER was 21.2±14.9 mm and 25.3±18.1 mm respectively. All patients underwent SLE at the second day after the ER. In Group 1 EH was performed in 7 patients with stigmata, including 2 patients with vessel's size more than 1.5 mm. In Group 2 only one patient had exposed major vessels on the bottom of the postoperative defect after removal of a large villous duodenal tumor that required prophylactic placement of hemoclips. Only one 60-year-old female patient (5,3% from Group 1) had mild GIB on the second day after ESD for ulcerated tubulovillous adenoma of the stomach. It is remarkable that this complication occured a few hours after preventive endoclipping of all thrombosed vessels during SLE. The patient had a malignant course of hypertonic disease. In our opinion, an uncontrolled sharp increase in blood pressure was the main cause of postoperative bleeding. After succesfully perfomed EH the patient recovered on the background of intensified therapy for hypertention and doubled antisecretory therapy.
CONCLUSION: According to our preliminary data SLE with prophylactic clipping after ER for gastric and duodenal tumors has no significant impact on the frequency of postoperative GIB. SLE is feasible in selected patients with large postoperative mucosal defects after the wide excision of the tumor.

P1016 COMPARATIVE ASSESSMENT OF TOLERABILITY, DURATION AND COSTS BETWEEN THE 36-SOLID-STATE AND THE 24-WATER-PERFUSED HIGH RESOLUTION MANOMETRY FOR ESOPHAGEAL MOTILITY TESTING – DATA FROM A PROSPECTIVE, RANDOMIZED, DOUBLE BLIND, CROSSOVER STUDY

E. Savarino[1,*], R. Salvador[1], G. Capovilla[1], L. Nicoletti[1], G. Zaninotto[2], M. Costantini[1]
[1]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, Italy,* [2]*Imperial College, London, United Kingdom*

INTRODUCTION: High Resolution Manometry (HRM) is a new technique for intraluminal esophageal pressure measurement, performed with a multitude of closely spaced (<2cm) pressure sensors. Currently, two systems are most widely used in clinical practice: the 36-channel solid-state (SS) HRM and the 24-channel water perfused (WP) HRM. Comparative data regarding their ambulatory use are lacking.
AIMS & METHODS: We aimed to assess and compare the tolerability, procedure duration and costs between the 36-SS and the 24-WP system. These data have been collected conducting a prospective, randomized, double blind, crossover study aimed to measure and compare normal values of conventional and high-resolution manometry metrics as well as to assess the inter-rater and inter-device agreement for the diagnosis of esophageal motility disorders between the 36-SS (Given Imaging, Los Angeles, CA) and the 24-WP system (EB Neuro, Firenze, Italy). Twenty healthy volunteers [HVs; 11M/9F; median age 29 (IQR 26-33)] and 20 patients [11M/9F; 48 (43-55)] with esophageal symptoms (i.e. reflux symptoms, chest-pain or dysphagia) were enrolled. They underwent both procedures blinded and in random order. Tolerability was assessed by using a self-made questionnaire investigating the occurrence of symptoms, presence and location of discomfort and which procedure was better tolerated. System set-up time, procedure duration and analysis time were measured separately. Finally, costs related to their ambulatory use were provided by the Resources Management Office.
RESULTS: Details about tolerability are shown in the Table. Overall, HVs did not found any difference between the two systems, whereas the patients tolerated better the 36-SS HRM procedure [9 (45%) vs. 12 (60%), p = ns]. Significantly longer set-up (454sec vs. 222sec, p < 0.01) and plot analysis (601sec vs. 345sec, p < 0.01) time was required by the 24-WP system compared to the 36-SS system. No difference was observed between the 24-WP and 36-SS system in terms of tracing acquisition time (483sec vs. 552sec, p = 0.6). The single-procedure cost was 58.48 € for the 24-WP HRM and 79.18 € for the 36-SS HRM.

	HVs 24-WP HRM	HVs 36-SS HRM	Patients 24-WP HRM	Patients 36-SS HRM
Symptoms Occurrence, n (%)				
None	4 (20%)	3 (15%)	1 (5%)	14 (70%)
Pain	4 (20%)	3 (15%)	6 (30%)	2 (10%)
Heartburn	4 (20%)	5 (25%)	1 (5%)	0 (0%)
Nausea and Vomiting	1 (5%)	1 (5%)	4 (20%)	3 (15%)
Globus	10 (50%)	9 (45%)	9 (45%)	4 (20%)
Location of Discomfort, n (%)				
Nose/ Throat	16 (80%)	11 (55%)	16 (80%)	7 (35%)
Chest/Stomach	1 (5%)	0 (0%)	1 (5%)	0 (0%)

CONCLUSION: The 36-SS system was better tolerated by patients and required shorter set-up and analysis time. This may be explained by a heightened sensitivity of the patients to intraesophageal stimuli (i.e. water outflow). The procedure cost was substantially higher for the 36-SS system due to the higher price of the 36-SS catheter.

INTRODUCTION: The diagnosis of eosinophilic esophagitis (EoE) is established by symptoms of esophageal dysfunction not caused by GERD and with at least 15 eosinophils/high power field in biopsies from the esophageal mucosa.(1)
AIMS & METHODS: The aim of this study was to assess the correlation between the number of eosinophils and symptoms in untreated EoE-patients both by histopathological staining with haematoxylin-eosin (HE) and by immunohistochemical (IHC) technique against ''Eosinophil Major Basic Protein''. The biopsy slides were encoded, scanned and examined. At the peak value area the eosinophils were separately marked and counted (d = 0.52mm circle at x400). Symptoms and health-related quality of life (HRQL) were recorded using the Watson Dysphagia Scale (WDS), the European Organization for Research and Treatment of Cancer Quality of Life–Oesophageal Module 18 (EORTC QLQ-OES18) and the Short Form–36 (SF-36) questionnaires. Data on the presence of allergies and bolus impaction were reviewed from medical records.
RESULTS: EoE patients (n = 66) were consecutively included from Jan 2007 until May 2012. The mean age was 45 years (19-88) and 74% were males. Allergy occurred in 73% of the patients and 39% were diagnosed in connection with an incident of esophageal bolus impaction. More eosinophils were counted after IHC- than after HE- staining (p < 0.001). Age correlated weakly and negatively with the number of eosinophils in the IHC slides (R = -0.24 peak, R = -0.32 upper part). Bolus impaction was associated with higher numbers of eosinophils in the mucosa from the upper part of the esophagus (IHC p = 0.05 and HE p < 0.05). The response rate for WDS and SF-36 were 92% and for the EORTC QLQ-OES18 100%, however, the number of eosinophils did not correlate with any of the scores from these questionnaires.
CONCLUSION: The significantly higher eosinophil counts obtained after IHC as compared to HE-staining is uncontroversial.(2) So is the non-existing correlation between subjective symptoms and the numbers of eosinophils.(3) Still, higher eosinophil counts were found in biopsies obtained during the course of acute bolus impaction, which might be considered the ultimate grade of dysphagia. The weak negative correlation found between age and numbers of eosinophils should be carefully interpreted but might reflect the ageing immune system.(4) The significantly higher eosinophil numbers in the upper esophagus in patients with concomitant bolus impaction may motivate increased attention to this level regarding histopathology and motility in EoE.

P1019 IN VIVO HISTOPATHOLOGICAL ASSESSMENT OF THE MUSCULARIS PROPRIA IN ACHALASIA BY USING ENDOCYTOSCOPY

H. Sato[1,2,*], H. Inoue[1], H. ikeda[1], **C. Sato**[1], C. Phalanusitthepha[1], E.G. R. Santi[1], S.-E. Kudo[1]
[1]*Digestive Disease Center, Showa University, Northern Yokohama Hospital, Yokohama,* [2]*Department of gastroenterology, Niigata University, Niigata, Japan*

INTRODUCTION: Histopathology of muscularis propria (MP) is still unknown in patients with achalasia. Endocytoscopy (EC) was developed as ultra-high magnification endoscopy, and through the submucosal tunnel created during per-oral endoscopic myotomy (POEM), not only access but also subsequent consecutive assessment of the MP can be performed endoscopically.
AIMS & METHODS: In 7 achalasia patients (mean [±SD] age; 35±18.1 years, male:female; 4:3) who underwent POEM (myotomy length: 12±2.2 cm), subsequent EC examination was performed from mid esophagus to gastric side. EC images were taken and compared with histopathologic results (two biopsy from mid esophagus and lower esophageal sphincter) which was considered gold standard.
RESULTS: In all the cases, favorable EC images were taken, and spindle-shaped smooth muscle cells were clearly demonstrated. In our series, none of those showed particularly notable features such as atrophy or hypertrophy of smooth muscle cells. And the EC assessment was consistent with the results of biopsy. There were no complications encountered in all the procedures.
CONCLUSION: In clinical setting, real time assessment of the MP is feasible by using EC. It is expected that this technique will play an important role in unraveling the pathology of achalasia and other gastrointestinal functional diseases.

INTRODUCTION: POEM is a surgical procedure for esophageal myotomy similar to Heller myotomy, the frequency and the degree of postoperative reflux esophagitis are major outcomes that should be examined in the clinical setting. The purpose of this study was to examine the incidence and degree of reflux esophagitis after performing POEM, and to determine whether POEM causes reflux esophagitis.

AIMS & METHODS: AIMS: POEM has shown promise in overcoming limitations of current treatments for achalasia. This prospective study examined the effectiveness and risk of complications, especially reflux esophagitis, associated with POEM performed on achalasia patients. **METHODS:** Patients with achalasia were recruited from a single center where all POEM procedures were performed. The pre- and postoperative (3 months after POEM) assessments included Eckardt scores, manometry, endoscopy, and pH monitoring (Demeester score).
RESULTS: Forty patients (22 males; mean age, 46.2±16.1 years) underwent POEM between September 2011 and June 2013. A significant reduction was observed postoperatively in the lower esophageal sphincter pressure (from 39.0±16.5 mmHg to 18.6±11.0 mmHg [$P<0.05$]) and Eckardt scores (from 6.3±2.6 to 0.6±0.8 [$P<0.05$]). Four patients developed symptomatic gastroesophageal reflux disease (GERD; 3 patients, grade A; 1 patient, grade B). Twenty-seven patients were diagnosed with erosive esophagitis (19 patients, grade A; 6 patients, grade B; 2 patients, grade C). Both erosive esophagitis and GERD were well controlled with protein pump inhibitors intake without requiring surgery. Univariate logistics regression analysis identified postoperative duration of reflux (odds ratio [OR], 1.15; 95% confidence intervals [CI], 1.01-1.30) and Demeester score (OR, 1.04; 95% CI, 1.00-1.08) as predictors of development of reflux esophagitis (≥grade B). None of the POEM factors were found to be related to reflux esophagitis.
CONCLUSION: POEM is safe and effective in providing symptomatic relief for achalasia patients. Additionally, it is not associated with the development of erosive esophagitis. Periodic postoperative interviews and endoscopic examinations are helpful in evaluating reflux esophagitis.

INTRODUCTION: Oesophageal high resolution impedance manometry (HRiM) is an emerging tool used to assess oesophageal motility and function though it measures the efficiency of oesophageal motility and bolus transit.
AIMS & METHODS: The aim of this study is to assess the changes in HRM parameters and diagnosis as well as the bolus transit depending on the bolus type in patients with dysphagia. 46 patients with dysphagia referred for oesophageal function evaluation. All patients had upper endoscopy to exclude organic disease. Oesophageal HRiM was also performed on all (Manoscan, Given) administering ten liquid and ten viscous swallows in the supine position: The data were analyzed according to 2012 Chicago Classification criteria. Swallows were classified as having complete bolus transit or incomplete bolus transit according to criteria previously reported. Statistical analysis: Chi-Square or Fischer and T-test.
RESULTS: 18 male patients (39.1%), mean age 55.8 [39.9-71.5], mean BMI 25.9 [21.6-30.5]. HRiM parameters and diagnosis are expressed in the table. All patients had dysphagia, also associated with chest pain in 6 patients (13%) and heartburn in 4 (8.7%). 47.8 patients had pervious oesophageal treatment. There were significant differences in DCI between liquid and viscous swallows (2287.9 vs. 2718.1; $p=0.001$), and between complete bolus transit depending on the bolus type (21.7% liquid swallows vs. 13% viscous swallows; $p=0.002$).

HRiM parameters			
	Liquid	Viscous	p
IRP-4s (mmHg)	18.6 [16.2-21.1]	19.9 [16.9-22.8]	0.135
DCI (mmHg.cm.s)	2287.9 [1548.2-3027.6]	2718.1 [1897.5-3538.7]	0.001
VFC (cm/s)	7.0 [4.7-9.3]	9.1[2.8-15.5]	0.401
IBP (mmHg)	16.9 [14.9-19.7]	20.3 [15.3-25.1]	0.062
Complete bolus transit	10 (21.7%)	6 (13%)	0.002
HRiM diagnosis ($p=0.620$)			
Normal	13 (28.3%)	14 (30.4%)	
Oesophageal Motility Disorder	33 (71.7%)	32 (69,6%)	

CONCLUSION: There were some changes in HRiM parameters depending on the type of bolus consistency, but their involvement in final HRiM diagnosis was not relevant, although complete bolus transit was more frequent with liquid swallows. Therefore, viscous swallows are not discriminative enough compared to liquid swallows for the diagnosis of patients with dysphagia.

INTRODUCTION: Peroral endoscopic myotomy (POEM) is an endoscopic alternative to laparoscopic myotomy. This promising procedure is still considered experimental. Herein, we report single-center mid-term results of POEM in the Czech Republic.
AIMS & METHODS: Since 2012, a total of 41 POEM procedures have been performed in 40 patients (15 women, 25 men, mean age 45). All patients had a diagnosis of achalasia (n = 40) or Jackhammer esophagus (n = 1) based on endoscopic, manometric and radiologic examinations. A 3, 6, and 12 months follow-up was completed in 33, 24 and 12 patients. The primary outcome was treatment success defined as Eckhard score < 3. At three months, high resolution manometry and 24-hour pH metry monitoring were performed.
RESULTS: A. PROCEDURE: POEM was successfully completed in all patients. The median length of procedure was 80 minutes (range 43-145). The median myotomy length was 13 cm (8-15). In 17 patients (42%), capnoperitoneum had to be decompressed and 19 patients (47%) experienced a subcutaneous emphysema which resolved spontaneously. Fever was present on the first postoperative day in 6 patients (15%). We did not experience any serious intraoperative or postoperative complications and all patients were dismissed the 2nd or 3rd postoperative day. We observed the following minor complications: inadvertent mucosotomy 3x (treated with clips), respiratory instability during POEM 2x (decompression of capnoperitoneum was necessary), bleeding at the entry site 1x, difficult entry site closure 2x (necessary to use high resolution clips) and large subcutaneous emphysema 1x.
B. TREATMENT RESULTS: 3, 6 and 12 months after POEM, treatment success (Eckhard score < 3) was achieved in 31, 24 and 12 patients (94%, 100%, 100%), median score pre- vs. post-treatment was 7 vs. 0 at 3 and 6 months, and vs. 1 at 12 months; $p<0.001$. The median percentage of overall symptomatic improvement was 90%. Quality of live significantly improved (median score 107 before POEM vs. 130, 136 and 137 3, 6 and 12 months after POEM, $p<0.001$). Manometric parameters (IRP and LES pressure) normalized in a majority of patients.
Heartburn was present in 7 (21%), 4 (17%) and 2 (17%) patients 3, 6 and 12 months after POEM. Eight patients (20%) have been treated with proton pump inhibitors or antacids on demand. Three months after POEM, a mild reflux esophagitis (LA A) was diagnosed in 10 patients (30%) and a pathological gastro-esophageal reflux (DeMeester score >14) was detected in 16 (48%) patients.
CONCLUSION: POEM is a safe and effective treatment modality in patients with achalasia with excellent mid-term results which seems durable. There is significant (though almost asymptomatic) reflux postoperatively in 48% of patients in 3-months pH metry studies.

INTRODUCTION: Gastroesophageal reflux disease (GERD) is one of the most common gastrointestinal disorders in Western countries, affecting up to 20% of the general population, with relevant impact on quality of life and health care costs. Apart from the presence of more classic esophageal manifestations, GERD is increasingly associated with extra-esophageal syndromes such as dental erosions (DE). DE is defined as the loss of tooth structure in connection with environmental acidification in the oral cavity, without bacterial activity.
AIMS & METHODS: We aimed to evaluate the prevalence of GERD symptoms in patients with DE. We enrolled 119 patients, who presented at the Dentistry Unit to perform dental hygiene. During the visit, a distinct investigator completed a structured interview to the patients, including a careful medical history and current medications. All patients underwent an accurate evaluation for DE through a validated test: the Basic Erosive Wear Examination (BEWE). Moreover, the presence of behavioral risk factors for DE was evaluated (i.e., consumption of acidic foods and drinks). All patients completed a validated questionnaire (VAS and Likert scale) in order to assess the frequency and intensity of typical reflux symptoms (i.e., heartburn, regurgitation, non-cardiac chest pain -NCCP-) in patients with (cases) and without (controls) DE.
RESULTS: Male/female ratio was 0.54 (44/77). Mean age was 48.2±14.5 yrs. Twenty-three out of 199 patients (17.6%) showed DE clinical signs (BEWE > 1). Eleven out of 119 patients (9.2%) had risk factors for DE, of whom only three had DE. Reflux symptoms were more frequent in patients with DE (18/23; 78.3%) than in patients without DE (41/96; 42.7%) ($p=0.001$). In detail, regurgitation was reported in 14/23 (60.9%) ($p<0.001$), and NCCP in 13/23 (56.5%) ($p<0.001$). Heartburn showed a similar prevalence between patients with DE and controls but was more frequent (Likert scale; $p=0.001$) and more intense (VAS; $p=0.001$) in DE subgroup. Neither patients with DE or patients with positive reflux-symptom questionnaire had ever undertaken PPI therapy. No patients undertaking PPI therapy had DE.
CONCLUSION: Patients with DE showed more frequent and troublesome reflux symptoms than controls without DE. During dental hygiene, patients with DE should be allowed to complete a GERD questionnaire to better identify those with reflux symptoms.

INTRODUCTION: Gastroesophageal reflux disease (GERD) and atrial fibrillation (AF) are common diseases, but the relationship between these two diseases remains controversial. Previous studies suggest a potential association between GERD and AF. We aimed to investigate the association between GERD and AF.
AIMS & METHODS: This was a retrospective study created from chart review for patients who newly diagnosed by GERD or AF between January 1, 2011 and March 31, 2014. Patients were classified by two groups. The patients who diagnosed by newly GERD with presence of AF were classified by Group-1 (n = 129), the patients who diagnosed by newly AF with presence of GERD were classified by Group-2 (n = 134). We analyzed the association and risk factors between two groups.
RESULTS: The average age of two group were 69.3 ± 10.6 years / 73.5 ± 9.5 years (p = 0.001). The duration of diagnosis between GERD and AF were 40.1 ± 37.4 months / 44.5 ± 33.4 months (p = 0.32). In univariate and multivariate analysis, age, alcohol, underlying coronary artery disease, sustained arrhythmia, chronic obstructive pulmonary disease (COPD), hyperthyroidism, use of ACE inhibitor, B-blocker and warfarin were related to incidence of GERD in Group-1 ($p < 0.05$). COPD and proton pump inhibitor (PPI) were related to incidence of newly AF in Group-2 ($p < 0.01$). The presence of AF increased the relative risk (RR) of GERD (RR: 1.37, 95% confidence interval [CI]: 1.33-1.47), and the presence of GERD increased the risk of AF (RR: 1.12, 95% CI: 1.08-1.19).
CONCLUSION: GERD and AF were significantly associated with an increased risk of diagnosis of each other. The presence of AF increased the relative risk (RR) of GERD (RR: 1.37, 95% CI: 1.33-1.47), and the presence of GERD increased the risk of AF (RR: 1.12, 95% CI: 1.08-1.19). A large cohort study to assess the potential relationship between GERD and AF is needed.

INTRODUCTION: Patients with gastroesophageal reflux disease (GERD) have lower health-related quality of life (HRQL) than general population. Increasing frequency and severity of reflux symptom has negative impact on well-being. HRQL in patients with laryngopharyngeal reflux (LPR) is also significantly impaired. However, study comparing HRQL in GERD patients with and without LPR symptoms is rare.
AIMS & METHODS: The aim of the study was to compare HRQL, patient satisfaction, and disease burden in GERD patients with and without LPR symptoms. A national, random-sample, and face-to-face survey of 300 Koreans was conducted. The sampling frame was based on the previous national wide, population-based telephone survey, in terms of distribution of age, gender, occupation, and region of residence by quota sampling. Gastroesophageal reflux symptoms were assessed by the Rome III questionnaire, LPR symptoms by reflux symptom index (RSI), and the quality of life by EuroQol-5 dimension questionnaire (EQ-5D). Structured questionnaire on health service utilization, sickness-related absence, and patient satisfaction were also used.
RESULTS: Face to face interview was conducted from Jan to Mar 2013 in 300 subjects (141 male, 159 female, Mean age 43.5±12.6, GERD without LPR, n = 150, GERD with LPR, n = 150). Median RSI in patients with GERD and LPR was 19.5 (14-36). Mean EQ-5D index was lower in GERD patients with LPR than GERD patients without LPR (0.88 vs. 0.91, p = 0.002). GERD patients with LPR reported more problems in pain/discomfort (58.7% vs. 47.8%, p = 0.049), and anxiety/depression dimensions (39.3% vs. 22.0%, p = 0.001). Severity of LPR was related with HRQL when adjusted for age, gender, marital status, BMI, severity of GERD, household income and comorbidity. GERD patients with LPR have lower overall satisfaction (40.0% vs. 69.1%, p = 0.040). Satisfaction scores were lower in GERD patients with LPR: satisfaction with physician's concern (3.5 vs 3.9, p = 0.002), physician's professional knowledge (3.5 vs 3.9, p = 0.005), physician's explanation (3.5 vs 3.9, p = 0.003), medical cost (3.3 vs 3.7, p = 0.003), and treatment outcomes (3.1 vs 3.5, p = 0.005). There were no significant differences in the patterns of health service utilization between two groups. GERD patients with LPR reported longer sickness related absent hour per week (0.37±1.43 vs. 0.02±0.20, p = 0.016), and poorer work productivity score (3.08±2.28 vs. 2.08±1.72, p = 0.001).
CONCLUSION: GERD patients with LPR have lower HRQL than GERD patients without LPR, and the severity of LPR was related with decreased HRQL. GERD patients with LPR have lower satisfaction with physician, medical cost, and treatment outcomes. The economic burden seems to be higher in GERD patients with LPR in terms of increased loss of work and decreased productivity.

INTRODUCTION: The prevalence of gastro-oesophageal reflux disease (GORD) has been increasing worldwide over recent decades. Although the prevalence was considered to be lower in Asia, GORD has become more prevalent in Asia including Japan [1, 2]. A previous study demonstrated that gastric acid secretion in Japanese individuals increased in the era from the 1970s to 1990s [3]. That increased secretion is thought to be one of the important factors for the increase in rate of GORD. However, it remains to be elucidated whether that increasing trend has continued from the 1990s to the present.
AIMS & METHODS: The aim of this study was to evaluate whether gastric acid secretion has altered over the past 2 decades with and without the influence of *H. pylori* infection in non-elderly and elderly Japanese.
Seventy eight healthy Japanese subjects were enrolled, and divided into those aged between 20 and 25 (young group), around 50 (non-elderly group), and around 75 (elderly group) years old. Gastric acid secretion, concentrations of serum gastrin and pepsinogen I and II, and *H. pylori* infection were determined in each case, and the data were compared among the groups. Furthermore, those findings were compared with data obtained in the 1990s.
RESULTS: Basal acid output (BAO) and maximal acid output (MAO) gradually decreased with age even in *H. pylori*-negative subjects. In addition, those with *H. pylori* infection tended to show decreased gastric acid secretion as compared with those without infection, particularly in the elderly group. Consistently, serum gastrin concentration was significantly higher in the elderly as compared to non-elderly subjects. As for sex difference, MAO decreased gradually with age in males, while it remained unchanged with age in females. Interestingly, gastric acid secretion has not changed over the past 2 decades in Japanese individuals irrespective of the presence of *H. pylori* infection.
CONCLUSION: In contrast to the increased prevalence of GORD, gastric acid secretion has not increased over the past 2 decades in the Japanese as a whole. On the other hand, secretion has decreased with age in males but not in females, which may partly explain the female preponderance of GORD in the Japanese elderly.

INTRODUCTION: Gastroesophageal reflux disease (GERD) is a chronic disease which can cause troublesome symptoms. Asymptomatic erosive esophagitis (AEE) is a subgroup of patients with a lack in any symptom. The purpose of the study was to investigate the prevalence of AEE in a large population undergoing health checkups and to identify the predictive factors for the disease.
AIMS & METHODS: From March 2012 to August 2013, 2752 consecutive subjects who underwent upper gastrointestinal endoscopy during health checkup were enrolled. The severity of erosive esophagitis was evaluated according to the Los Angeles classification. A GERD subject was defined as any individual who has a diagnosis of endoscopic LA grade≥A or Barrett's esophagus or having troublesome symptoms as identified by Reflux Disease Questionnaire (RDQ) score. All participants were recorded with demographic characteristics, biochemical data, and evaluated with questionnaires including Pittsburgh Sleep Quality

Index (PSQI) score, Taiwanese Depression Questionnaire (TDQ) score, and State-Trait Anxiety Inventory (STAI) score. The independent predictive factors for asymptomatic erosive esophagitis were analyzed by the logistic regression method.
RESULTS: A total of 676 GERD subjects with erosive esophagitis (EE) were recruited for final analysis, and about 59.2% of subjects with EE had no reflux symptoms. In the univariate analysis, subjects with AEE have more female gender, older age, lower level of education, less alcohol and tea consumption, less depression, less anxiety, lower serum level of triglyceride, and lower prevalence of metabolic syndrome, compared with subjects with symptomatic EE. Multivariate analysis revealed that female sex (OR = 1.645, $p = 0.0146$) was a positive predictive factor for AEE, and higher level of education (OR: 0.564, $p = 0.044$), higher TDQ score (OR: 0.922, $p < 0.001$), and with the metabolic syndrome (OR: 0.625, $p = 0.0379$) were significant negative predictive factors for AEE.
CONCLUSION: Asymptomatic erosive esophagitis is common in subjects undergoing health checkup. Female sex, lower education level, less depression, and lower prevalence of metabolic syndrome are independent predictive factors for developing asymptomatic erosive esophagitis, compared with symptomatic erosive esophagitis.

P1028 IS PH IMPEDANCE MORE USEFUL THAN TRADITIONAL PH MONITORING FOR PATIENTS' MANAGEMENT IN CLINICAL PRACTICE? RESULTS OF A PROSPECTIVE STUDY

D. Pugliese[1,*], A. Mauro[1], D. Consonni[2], I. Bravi[1], A. Tenca[1], A. Elvevi[1], D. Conte[1], R. Penagini[1]
[1]*Gastroenterology and Endoscopy Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Department of Pathophysiology and Transplantation Università degli Studi di Milano,* [2]*Epidemiology Unit - Department of Preventive Medicine, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*
Contact E-mail Address: *delia.pugliese@unimi.it*

INTRODUCTION: Oesophageal pH tests are deemed to be useful in management of selected gastro-oesophageal reflux (GOR) disease patients. Development of pH impedance (pH-MII) tests has increased the diagnostic yield by documenting the role of weakly acidic refluxes. However to which extent results of pH-MII tests improve patients' management is largely unknown.
AIMS & METHODS: Aim of our study was to prospectively evaluate usefulness of pH MII monitoring in the patients' clinical management compared with traditional pH monitoring. One hundred and eighty four consecutive patients (72 men, median age 52, range 19-82 yrs) were enrolled for traditional pH or pH-MII monitoring. A telephone interview was done 3 and 12 months after the test. A standardized questionnaire was used in the visit before the test and in the telephone interviews, dealing with improvement ($\geq$ 50% reduction of symptom frequency) of the dominant symptom, patient's satisfaction with regards to the dominant symptom (1-10 visual analogue scale, satisfied if VAS $\geq$ 7) and treatment for GOR disease. Nineteen patients were lost at follow up at the 12 month interview. Indications of pH and pH-MII test were evaluated for appropriateness[1]. Mann-Whitney or Krusal-Wallis tests for comparison of quantitative variables and chi-square test for categorical variables were used.
RESULTS: Demographic and endoscopic variables, frequency of previous PPI use were similar in the two arms. Thirty-nine (42.4%) of the pH tests and 34 (37.0%) of the pH-MII tests were positive for GOR disease (pathological GOR and/or positive symptom association probability [SAP]); in the pH-MII arm 10 patients had an increased number of weakly acid refluxes and/or a positive SAP for weakly acid reflux whereas their acid reflux variables were normal/negative. See table for main outcome results. Outcomes were similar for tests with appropriate and those with inappropriate indication (p = NS) in both arms. After the test, as assessed at the 3 months interview, treatment for GOR disease (PPIs except in one pH-MII arm patient who underwent fundoplication) was undertaken in 87.2% of positive, 59.1% of indeterminate (i.e. normal GOR and no symptomatic episodes during the test), and 35.5% of negative tests in the pH arm, and in 97.1% of positive, 47.6% of indeterminate and 54.1% of negative tests in the pH-MII arm (p < 0.001 among groups in both arms).

	positive outcome*		satisfaction#	
	3 months	12 months	3 months	12 months
pH tests	53/92 (57.6%)	52/79 (65.8%)	47/92 (51.1%)	43/79 (54.4%)
pH-MII tests	58/92 (63.0%)	60/86 (69.8%)	45/92 (48.9%)	49/86 (57.0%)
p-value	0.621	0.234	0.768	0.225

CONCLUSION: Patients' outcome and satisfaction were similar in the two arms and independent of the appropriateness of test indication. Although PPI prescription was more frequent after a positive pH or pH MII monitoring, physicians often did not take into account a negative result. Our data cast doubts on the added value of pH MII monitoring for patients management in clinical practice.

INTRODUCTION: Patients affected by autoimmune atrophic chronic gastritis (AACG) often refer digestive symptoms and are prescribed proton pump inhibitors (PPIs). No data are available on the role of gastro-oesophageal reflux (GOR) in clinical presentation and on the appropriateness of anti-secretory drugs' prescription.
AIMS & METHODS: Aims of this prospective observational study were to investigate GOR, psychopathological profile and frequency of use/response to anti-secretory medications (PPIs and H_2 receptor antagonists [H_2RA]) in patients with AACG.
All patients affected by AACG with or without digestive symptoms and in regular follow-up at our hospital who were seen between January 2013 and December 2013 (n = 51) were asked to participate to this study. The study protocol included: (i) 24h intra-oesophageal and intra-gastric pH impedance monitoring (MII-pH) off-PPIs; median intragastric pH, number of acid and weakly acidic (WA) reflux as well as of Symptom Index (SI) and Symptom Association Probability (SAP) were calculated, (ii) a validated questionnaire evaluating psychopathological profile (SCL-90R) and (iii) a standardized clinical questionnaire including items on anti-secretory medications use/response.
RESULTS: Baseline characteristics. Thirty-one of the 51 patients agreed to be investigated, 4 men, median age 60, range 29-78 yrs. Twenty-two of them (71%) were symptomatic: n = 12 symptoms suggestive of GOR (i.e. heartburn, epigastric burning, regurgitation, non cardiac chest pain) and n = 10 dyspeptic symptoms. **MII-pH.** Median intragastric pH was 6.3 (IQR 5.8-6.8). None of the patients had acid reflux. Six patients had an increased number of WA reflux episodes (3 with GOR symptoms, 2 with dyspeptic symptoms and 1 asymptomatic according to our clinical questionnaire) and 4 additional patients had SI and/or SAP positive for WA reflux and GOR symptoms (n = 2) or epigastric pain (n = 2). **SCL-90R questionnaire.** Altered somatisation (defined as t-score $\geq$ 63) was present in 11/22 (50%) symptomatic patients and 3/9 (33%) asymptomatic patients (p = 0.40 by Chi-Square Test). Focusing on symptomatic patients, altered somatisation was similarly present in those with increased WA reflux or positive SI/SAP and in those without, n = 4/9 (44%) and n = 7/13 (54%), respectively. **Anti-secretory drugs** were prescribed in 13/22 (59%) symptomatic patients (PPIs in 12 and H_2RA in 1). A clinical benefit was reported by 8/13 patients, increased WAR being present in 2 of them and altered somatisation in 5.
CONCLUSION: In symptomatic patients with AACG: 1) acid reflux never occurred whereas increased WA reflux was not infrequent, 2) PPIs were often used, however their clinical benefit seemed to be more associated with altered somatizations than with objective variables suggesting GOR as cause of patients' symptoms and 3) MII-pH may be useful to diagnose GOR disease in a minority with severe symptoms who could benefit from anti-reflux surgery.

P1030 ESOPHAGOGASTRIC JUNCTION MORPHOLOGY MAY BE USEFUL TO PREDICT A POSITIVE IMPEDANCE-PH MONITORING IN PATIENTS WITH GERD

E. Savarino[1,*], C.de Cassan[1], F. Galeazzi[1], R. Salvador[1], E. Marabotto[2], M. Furnari[2], P. Zentilin[2], N.de Bortoli[3], S. Marchi[3], R. Bardini[1], G.C. Sturniolo[1], **V. Savarino**[2]
[1]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua,* [2]*Department of Internal Medicine, University of Genoa, Genoa,* [3]*Department of Internal Medicine, University of Pisa, Pisa, Italy*

INTRODUCTION: High-resolution manometry (HRM) provides a better representation of the esophagogastric junction (EGJ) making it possible to isolate the crural diaphragm (CD) contraction from expiratory lower esophageal sphincter (LES) pressure. According to the Chicago Classification (CC), three different EGJ morphologic subtypes can be detected based on the separation between the LES and the CD. Recently, these EGJ subtypes have been positively correlated with the objective evidence (i.e. endoscopy+ or pH-metry+) of gastro-esophageal reflux disease (GERD). To date, data on the correlation between EGJ subtypes and esophageal acid exposure as well as impedance-detected reflux episodes are lacking.
AIMS & METHODS: We aimed to correlate the different EGJ subtypes with impedance-pH findings in GERD patients. Consecutive patients with heartburn and/or regurgitation and a recent endoscopic assessment were enrolled. All

patients underwent a 36-Solid State HRM with a 5-min baseline recording to assess the EGJ and 10 single water swallows (5 mL) at 30-s intervals to evaluate the esophageal peristalsis and EGJ function. The tracings were analyzed based on the CC for motility disorders and each EGJ was classified as: Type I, no separation between the LES and the CD; Type II, minimal separation (>1 and <2 cm) between the LES and the CD; Type III, >2 cm separation between the LES and the CD. The patients also underwent impedance-pH testing off-therapy. We measured esophageal acid expsosure time (AET), total number of impedance-detected reflux episodes and symptom-reflux association using symptom association probability (SAP+ if $\geq$95%) and symptom index (SI+ if $\geq$50%).
RESULTS: We enrolled 53 [28M/25F; mean age 53 (21-76)] consecutive GERD patients. At upper endoscopy, 12 patients had erosive esophagitis, 2 had Barrett esophagus and 39 had no mucosal breaks. Based on CC, we identified 21 (40%) patients with Type I EGJ, 19 (36%) with Type II EGJ and 13 (24%) with Type III EGJ. Patients with Type III EGJ had an higher median number of reflux episodes [61 (12-305) vs. 38 (4-109) vs. 30 (6-98), respectively; $p<0.01$)], a greater mean AET [20.6 (4.4-43.4) vs. 14.1 (0.2-48.3) vs. 11.9 (0.1-54.3), respectively; $p<0.01$)] and had more frequently a positive symptom-reflux association [9 (69%) vs. 9 (47%) vs. 11 (52%), respectively; $p<0.05$)] compared to patients with Type II and Type I EGJ. Moreover, patients with Type II EGJ tended to have a higher median number of reflux episodes and mean AET compared to patients with Type I EGJ, but statistically significance was not reached ($p=0.06$).
CONCLUSION: With increasing separation between the LES and CD, from Type I to Type III EGJ, patients had a gradual and significant increase of reflux episodes and esophageal acid exposure. Thus, EGJ morphology may be useful to predict an abnormal impedance-pH testing in patients with GERD.

P1031 CLINICAL AND ENDOSCOPIC FEATURES OF GASTROESOPHAGEAL REFLUX DISEASE IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

E. Kostiakova[1,*]
[1]*endoscopy, Clinical Hospital 1, Smolensk, Russian Federation*
Contact E-mail Address: *katyalimova@yandex.ru*

INTRODUCTION: According to the literature data, up to 37 % of patients with chronic obstructive pulmonary disease (COPD) suffer from gastroesophageal reflux disease (GERD) [Hom C., et al., 2013], which is higher than in general population (10-20%) [Gadel A. A. et al., 2012]. However, despite the obvious relationship between these pathological conditions, investigators are still looking for risk factors associated with GERD development and progression in COPD patients.
AIMS & METHODS: Aim was to establish clinical, endoscopic and chromoendoscopic features of GERD in COPD patients in association with inhalation corticosteroid treatment. The study involved 75 patients with COPD, 50 of them received inhalation corticosteroid treatment and 25 received no inhalation corticosteroid treatment. The comparison group covered 65 patients without COPD. Esophagogastroduodenoscopy was performed with the endoscope Pentax 290. In esophagoscopy a dye congo red changing its color in acid medium from red into blue-black was injected through a spray-catheter at a maximal air insufflation in the lower third portion of the esophagus. This property of congo red can be used to diagnose acid gastroesophageal reflux. The affected area was calculated with the formula $2\pi rhK$ (r is a radius of esophagus abdominal part equal to 1 cm, h is a length of the affected area from Z-line in cm, K is a coefficient of staining fullness measured as 1, 3/4, 1/2, 1/4).
Statistical analysis was made with the software package Statistica 7.0 (StatSoft, USA) using nonparametric criteria. Statistical significance was considered at p value less than 0.05.
RESULTS: COPD patients complained of heartburn, acid regurgitation and dysphagia rarely in relation to the comparison group (14.7% and 35.4%, $\chi^2=8.13$; $p=0.004$). However, erosive esophagitis (66.7% and 9.2%, $\chi^2=36.6$; $p<0.001$), and well known risk factors for the development of GERD, such as cardioesophageal relaxation (65,6% and 7,8%; $\chi^2=43,43$, $p<0.001$) and hiatal hernia ($p=0.011$) were more frequently observed in patients with COPD. It is worth mentioning that Grade 2 of erosive esophagitis was detected only in patients receiving inhalation corticosteroid treatment (24% and 0%, $p=0.005$). Presence of esophagitis ($r=+0,85$; $p<0.001$) had a direct correlation with the congo red color changing in the main group. The affected area of esophagus in the main group was 6,38 cm^2 [3,14-8,38], in comparison group the size of the area was 2,36 cm^2 [1,57-3,14] ($p<0.001$)] and in COPD patients receiving inhalation corticosteroid treatment it was 6,38 cm^2 [2,36-9,42] (4.71 cm^2 [4,71-6,28] in COPD patients receiving no inhalation corticosteroid treatment, $p=0.041$). Esophagitis grade in COPD patients had a direct correlation with the extension of the affected area ($r=+0,75$, $p<0.001$).
CONCLUSION: In spite of the unmarked clinical picture GERD in a form of erosive esophagitis, induced by the acid gastroesophageal reflux, is more frequently seen in COPD patients. Grade 2 of erosive esophagitis is typical for patients receiving inhalation corticosteroid treatment. Extension of the affected esophageal area is a valid criterion for the quantitative assesment of the pathological acid gastroesophageal reflux in patients with COPD.

INTRODUCTION: Oesophageal intraluminal baseline impedance (BI) levels are determined by the conductivity of the oesophageal wall. Patients with non-erosive reflux disease (NERD) showed decreased distal oesophageal BI levels compared to healthy controls and this finding has been correlated to the presence of abnormal distal oesophageal acid exposure time (AET) in them. On the other hand, no differences have been found in the proximal esophagus probably due to the lower amount of acid reflux arriving at the most proximal sites. Systemic sclerosis (SSc) is a clinically heterogeneous and systemic disease characterized by deposition of collagen and other extracellular matrix proteins in the connective tissue of the skin and visceral organs, such as the gastrointestinal tract. This event could potentially affect the conductivity of the oesophageal wall and consequently BI levels, but data in this regard are lacking.
AIMS & METHODS: We aimed to prospectively investigate and compare BI levels between NERD and SSc patients. Consecutive patients with typical reflux symptoms (i.e. heartburn and/or regurgitation) and those with a defined diagnosis SSc underwent upper endoscopy in order to assess the presence of oesophageal mucosal lesions. Then, within 3 days from endoscopy, all endoscopy-negative patients underwent oesophageal manometry and impedance-pH testing off-therapy. During blinded and manual analysis of impedance-pH tracings, we evaluated esophageal AET, reflux episodes (acid/weakly acidic), symptom-reflux association using both symptom association probability (SAP+ if $\geq$95%) and symptom index (SI+ if $\geq$50%) and BI values at 3, 5 and 17cm above the LES, during the overnight rest, for at least 30 minutes after excluding swallows and reflux induced changes. NERD were diagnosed in case of abnormal AET and/or positive symptoms-reflux association.
RESULTS: Thirty patients with NERD and 30 with SSc were enrolled. Among SSc patients, 10/30 (33%) had an abnormal AET and 20/30 (67%) showed a normal. Among NERD patients, 14 (57%) had a pathological AET and 16/30 (53%) showed a normal acid exposure. In patients with SSc, median (25^{th}-75^{th}) BI impedance was 961.3 (734.3-1610.8) Ω at 3cm, 1114.9 (845.4 to 1512.7) Ω at 5 cm, and 2222.4 (1511.6 to 2734.3) Ω at the most proximal impedance recording site. All these BI values were lower than those observed in NERD patients, not only in the distal esophagus [at 3cm 1409.2 (1264.1 to 2118.6) Ω, $p=0.0065$; at 5 cm 1650.1 (1228.4 to 2266.4) Ω, $p=0.0054$], but also in the proximal esophagus [at 17cm 2678.7 (2183.0 to 3309.1) Ω, $p=0.0736$].
CONCLUSION: Despite the lower median AET and percentage of patients with abnormal AET, all BI values in SSc patients were lower than in NERD patients, suggesting that BI levels are related not only to oesophageal AET, but also to oesophageal tissue damage SSc-related. This finding is further corroborated by the differences observed at the proximal oesophagus. Thus, BI levels may be used as indirect markers of alteration of the oesophageal wall and, therefore, of oesophageal involvement in patients with SSc.

INTRODUCTION: Gastroesophageal reflux disease (GERD) adversely impacts on sleep, representing a major cause of disrupted sleep mainly due to reflux symptoms. This may lead to an impaired quality of life. Impedance and pH monitoring (MII-pH) is the gold standard technique for GERD diagnosis. During the sleep period, impedance values remain stable unless the occurrence of arousals.
AIMS & METHODS: We aimed to evaluate sleep disruptions in patients with heartburn and negative endoscopy by means of MII-pH. A group (33) of endoscopy negative patients with heartburn underwent MII-pH and were classified accordingly: 18 with non-erosive reflux disease (NERD) (i.e., pathological acid exposure time, AET); 15 with functional heartburn (FH) (i.e., normal AET and reflux number, negative symptom association). MII-pH tracings were reviewed manually using a 5-min window. During recumbent time, we identified sleep disruptions when at least 2 swallows were observed in a 5-min window. This data was evaluated in each group. We also calculated the overnight swallowing breaking sleep (OSBS) index (i.e., number of windows with swallows/total number of 5-min windows during the sleep period). All patients performed a validated questionnaire to assess the quality of sleep.
RESULTS: Male/female ratio was 7/11 in NERD and 3/12 in FH patients. Mean age was 51.3±12.4 in NERD and 49.3±9.7 in FH. The quality of a restful sleep was 64.3±8.3% in NERD and 67.3±7.8% in FH ($p=0.299$). Mean AET was higher in NERD (5.4±0.4) than in FH (0.4±0.4) ($p<0.05$). NERD group recorded higher total reflux number and acid reflux number ($p<0.05$). The total recumbent time was 541.4±64.7 min in NERD and 547.3±59.3 min in FH ($p=0.39$). During the sleep period, NERD patients recorded higher reflux number (9.8±8.7) than FH patients (0.6±0.9) ($p<0.05$). Moreover, the total

number of 5-min windows presenting at least 2 swallows was higher in NERD patients (49.7 ±6.4) compared to those with FH (27 ±5.3; $p<0.01$). The OSBS index was 46.2±4.0 in NERD and 25.3±5.5 in FH ($p=0.023$).

CONCLUSION: The manual analysis of the MII-pH tracings during the recumbent period might be useful to estimate sleep disruptions in patients with NERD, thus helping to identify those patients in whom GERD is perceived more severe and quality of life is much more impaired.

INTRODUCTION: During pathological assessment of esophageal biopsies several histological features characterizing the diagnosis of microscopic esophagitis [basal cell hyperplasia (BCH), papillary enlongation (PE), dilated intercellular spaces (DIS) and epithelial neutrofilic/eosinophilic infiltration (Neu/Eos)] can be assessed. Limited data are available about the single contribution of these histological abnormalities on the diagnosis of GERD and its related mucosal integrity in well-defined patients with reflux disease.

AIMS & METHODS: To determine whether these histological features contribute differently to the diagnosis GERD and to the impairment of mucosal integrity as expressed by baseline impedance (BI) levels. One hundred and four consecutive patients with typical reflux symptoms underwent upper endoscopy and multiple biopsies were taken at Z-line and 2 cm above it, in order to assess the presence and severity of BCH, PE, DIS and Neu/Eos [0 (absent), 1 (mild), and 2 (marked)]. Within 3 days from endoscopy, patients underwent impedance-pH testing off-therapy. During manual analysis of the impedance-pH tracings, we measured the esophageal acid expsosure time (AET) over the 24 hours and the total (acid + non-acid) number of impedance-detected reflux episodes. We evaluated BI values at 3 and 5cm above the LES, during the overnight rest, for at least 30 minutes after excluding swallows and reflux induced changes. Twenty healthy volunteers (HVs; 11F/9M; mean age 44) who underwent the same procedures were also enrolled as controls.

RESULTS: We included 85 patients with an endoscopic/impedance-pH diagnosis of GERD (45F/40M; mean age 46) who had esophageal mucosal breaks at upper endoscopy or an abnormal esophageal acid exposure or a normal esophageal acid exposure but a positive reflux-symptom association at impedance-pH testing. Among these patients, BI values at both 3 and 5 cm above the LES positively correlated with the esophageal AET ($r2=0.2033$, $P<0.001$ and $r2=0.1859$, $P<0.001$, respectively) and the number of impedance-detected reflux episodes ($r2=0.1373$, $P<0.001$ and $r2=0.1526$, $P<0.001$, respectively). Moreover, as shown in the Table, BCH and DIS were the lesions more significantly correlated with the endoscopic/impedance-pH diagnosis of GERD. No significant correlation was observed between BI values and impedance-pH parameters or histological lesions in HVs ($p=$ns).

	BCH	DIS	PE	Neu
BI at 3 cm	$r2=0.2150$; $P<0.001$	$r2=0.1357$; $p=0.001$	$r2=0.0526$; $p=0.035$	$r2=0.0516$; $p=0.036$
BI at 5 cm	$r2=0.2182$; $P<0.001$	$r2=0.1405$; $P<0.001$	$r2=0.0484$; $p=0.043$	$r2=0.0523$; $p=0.035$

CONCLUSION: BCH and DIS contribute more than PE and Eos/Neu to the endoscopic/impedance-pH diagnosis of GERD. Moreover, the same lesions seem to play a greater role than PE and Eos/Neu in determining mucosal integrity impairment as expressed by BI values in GERD patients. Overall, BCH and DIS can be considered the histological markers requiring more careful evaluation during pathologic assessment in order to help the diagnosis of GERD.

Contact E-mail Address: *nick.debortoli@gmail.com*

INTRODUCTION: Recent data indicate that low esophageal basal impedance may reflect impaired mucosal integrity and increased acid sensitivity.

AIMS & METHODS: We compared baseline impedance levels in patients with heartburn and pathophysiological characteristics related to functional heartburn (FH) divided into two groups on the basis of symptom relief after proton pump inhibitors (PPIs). Moreover, we aimed to compare these results with a group of patients affected by hypersensitive esophagus (HE) and with healthy volunteers (HVs).

Patients with heartburn and normal endoscopy underwent MII-pH testing off PPI therapy and those with negative symptom association an 8-week PPI (esomeprazole or pantoprazole 40 mg daily) therapy. Patients with >50% symptom improvement were classified as PPI response FH (FH+PPI) and those with <50% improvements as PPI non-response FH (FH-PPI). In addition we included patients with hypersensitive esophagus (HE) defined as normal endoscopy, normal acid exposure and positive symptom association and a group of healthy volunteers (HV). For each patient and HVs, we evaluated acid exposure time (AET), number of MII-detected reflux episodes, baseline impedance levels at channel 3, during the overnight rest, at three different times and PSPW index.

RESULTS: Data are summarized in the Table. Patients with FH+PPI showed a higher mean AET (1.4%±0.8 *vs* 0.5%±0.6, $p<0.05$), mean reflux number (30.4±8.7 *vs* 24±6.9, $p<0.05$), proximal reflux number (11.1±5.2 *vs* 8.2±3.6, $p<0.05$) and acid reflux number (17.9±6.1 *vs* 10.7±6.9, $p<0.05$) compared to FH-PPI. Patients with HE showed mean AET (1.8%±0.8) and total reflux number (34.4±8.2) similar to those recorded in FH+PPI ($p=$ns). Baseline impedance levels were lower in FH+PPIand in patients with HE then in FH-PPI and in HVs ($p<0.001$). No differences were found for PSPW index between FH+PPIand HE; in those groups PSPW index was lower than in FH-PPI and HV.

	HE (N = 30)	FH+PPI (N = 30)	FH-PPI (N = 30)	HV (N = 20)	P (FH+PPI vs HE)
AET tot (sd)	1.8±0.8#	1.4±0.8*	0.5±0.6	0.7±0.6	n.s
N° refluxes (sd)	34.4±8.2#	30.4±8.7*	24±6.9§	17.9±10.8	n.s
Baseline (sd)	2125.3±450.8#	2169.7±580.4*	3782.2±821.5	3427.8±42.7	n.s.
PSPW (sd)	55.9±4.6#	56.2±8.8*	71.1±6.1	76.1±13	n.s.
PPI Response	100%	100%	0%	N. A.	–

Table legend: (*) $p<0.05$ group FH+PPI versus FH-PPI; (§) $p<0.05$ group FH-PPI versus HV; (#) $p<0.05$ HE vs. FH-PPI vs HV

CONCLUSION: Patients with PPI responsive functional heartburn (FH+PPI) present similar MII-pH features as patients with HE. Esophageal baseline impedance measurements might allow to identify reflux patients who are not confirmed by MII-pH monitoring likely due the day-to-day variability or the limitations of the current reflux-symptom association indexes.

P1036 DISTAL AND PROXIMAL ESOPHAGEAL IMPEDANCE BASAL VALUES IN PATIENTS WITH NON-EROSIVE REFLUX DISEASE AND FUNCTIONAL HEARTBURN

N.de Bortoli[1,*], I. Martinucci[1], E. Savarino[2], R. Tutuian[3], S. Russo[1], L. Bertani[1], R. Franchi[1], M. Furnari[4], M. Bellini[1], V. Savarino[4], S. Marchi[1]

INTRODUCTION: Several studies have shown that proximal extent of reflux episodes plays an important role in gastro-esophageal reflux symptom perception. The relative hypersensitivity of the proximal esophagus is most evident in patients with non-erosive reflux disease (NERD). Recent studies demonstrated that low distal basal impedance values may reflect impaired mucosal integrity and increased acid sensitivity.

AIMS & METHODS: The aim was to compare distal and proximal basal impedance values in patients with NERD and functional heartburn (FH).

According to impedance and pH (MII-pH) monitoring off-therapy, we selected patients with NERD (i.e. pathological acid exposure time, AET) and FH (i.e. normal AET and reflux number; negative symptom association). FH patients did not show any symptom relief after acid suppression therapy. For each patient, we evaluated basal impedance values at the distal (3 cm) and proximal (17 cm) channel, during the overnight rest, at three different times: 1, 2, 3 am.

RESULTS: Male/female ratio was 23/23 in NERD and 13/33 in FH patients. Mean age was 52.3±13.2 in NERD and 49.2±11.3 in FH. Mean AET was higher in NERD (6.1%±3.8%) than in FH (0.6%±0.7%) ($p<0.05$). NERD group recorded higher total reflux number (67.8±18.2) than FH group (23.7±9.4) ($p<0.05$).

Basal impedance values were significantly ($p<0.05$) lower in NERD than in FH, both at the distal (1294.3±529.9 Ohm *vs* 3502.1±809.2 Ohm) and proximal (3480.7 ±1322.6 Ohm *vs* 4344.9±976.2 Ohm) channels. Distal basal values were significantly lower than proximal basal values, both in NERD and FH group ($p<0.05$). Moreover, in NERD group, 24/46 patients (52.2%) had an abnormal number of proximal refluxes. These NERD patients with pathological proximal refluxes did not show lower basal impedance values than NERD patients with normal number of proximal refluxes even if distal (1226.7±453 vs 1243.1±497.1; $p=0.5239$) or proximal channels (2670.8±1163.4 vs 2849.2±1434.2; $p=0.5046$) were compared.

CONCLUSION: Patients with NERD showed lower basal impedance values both at the distal and proximal esophagus. Consistently with the concept that low basal impedance may reflect impaired mucosal integrity, our results might be helpful to better investigate the pathophysiological role of proximal refluxes.

P1037 ARE WE ANY CLOSER TO A BLOOD-BASED TEST TO MONITOR DISEASE PROGRESSION IN THE BARRETT'S OESOPHAGUS MODEL?

H.N. Haboubi[1,*], B. Rees[2], C. Thornton[3], G. Johnson[2], G. Jenkins[1]
[1]*Cancer Biomarker Group,* [2]*DNA Damage Group,* [3]*Department of Immunology, Swansea University, Swansea, United Kingdom*
Contact E-mail Address: *h.n.y.haboubi@swansea.ac.uk*

INTRODUCTION: The increasing incidence of Barrett's Oesophagus (BO) and Oesophageal Adenocarcinoma (OA) has culminated in intensified efforts to better stratify patients at risk of progression. Endoscopic surveillance allows for such monitoring to take place but there still remains a potential for physical and psychological harm to patients undergoing regular surveillance, not to mention increased cost and resource allocation. Given the DNA damage induced by acid and bile reflux to the distal oesophagus as well as to blood cells circulating through this inflamed tissue, the application of novel blood-based toxicological approaches to the monitoring of patients with BO could offer a less invasive approach to current surveillance strategies.

The phosphatidylinositol glycan biosynthesis class A (Pig-A) gene is critical for glycophosphatidyl inositol (GPI) anchor synthesis. GPI-anchors tether specific epitopes to the cell surface membrane and are important in cellular responses to inflammation. Losses of gene function, as a result of a single mutational event within the Pig-A gene form a GPI-anchor negative phenotype, detectable using flow-cytometric methodology. Use of an adapted *ex-vivo* Pig-A gene mutation assay on whole blood, may have the potential to predict patients at a higher risk of progression through the dysplastic process as it is possible that circulating blood cells may acquire mutations whilst passing through the oesophageal mucosa.

AIMS & METHODS: Blood based cell lines were exposed to physiological carcinogens such as bile and the Pig-A mutant frequency measured.

Subsequent *ex-vivo* analysis of blood was undertaken in patients attending endoscopy with symptoms suggestive of GORD. Pig-A analysis of erythrocytes and leucocytes was performed and results correlated with histopathological analysis of oesophageal biopsies as well as a detailed lifestyle questionnaire. Finally, a challenge assay was undertaken whereby physiological doses of bile acids were used to treat enriched lymphocytes of patients with GORD, BO and OA and the change in mutational frequency measured.

RESULTS: *In-vitro* investigations confirmed the carcinogenicity of bile acids to blood based cell lines, with increased mutant frequencies detected through the Pig-A gene mutation assay ($p<0.05$).

Subsequent *ex-vivo* erythrocyte analysis demonstrated higher mutant frequencies in OA patients compared to both normal GORD patients and those with Barrett's ($p<0.01$) but there was no significant difference between BO and normal controls. Patient age, gender and length of Barrett's segment did not appear to have any influence on mutant-frequency, but smoking status suggests some effect.

CONCLUSION: The application of this simple, non-invasive blood-based mutation assay to patients with GORD suggests OA patients have higher mutational events than patients with Barrett's or normal oesophageal mucosa. Whilst it is not clear if Pig-A mutations in these patients are due to exposure to DNA damage inducing chemicals or an increased predisposition to mutation at a bone-marrow level, data from the challenge assay may allow for these questions to be answered. Furthermore, analysis of patients with dysplastic Barrett's will permit for this test to be better validated as a future biomarker for risk of progression.

INTRODUCTION: Recent studies showed that in patients with Barrett's esophagus (BE) the pooled estimate for annual esophageal adenocarcinoma (EAC) incidence varies between 0.12% and 0.14%. It is unclear whether dysplasia can regress over time but the difficulty in confirming low grade dysplasia presence seems to suggest it. The expression of costimulatory molecules CD80 and CD86 in the esophageal cancer tissue is significantly lower than in the mucosa of healthy patients. In inflammatory colonic carcinogenesis CD80 expression seem to trigger immune surveillance mechanisms in dysplasia. The aim of the study is to investigate the interplay between epithelium and CD8 T cells that characterizes the immune environment of inflammatory esophageal carcinogenesis.

AIMS & METHODS: Fresh esophageal biopsies were obtained from healthy subjects ($n=7$) and from patients with BE ($n=17$) eleven with previous history of dysplasia on BE and six with current dysplasia on BE, Biopsies were analysed by flow cytometry to quantify the expression of CD80 and HLA ABC on esophageal epithelial cells, whereas on CD8 infiltrating lymphocytes the activation marker CD38 and CD28 (CD80 receptor) were determined. Primary human cardia epithelial cells (CEC) were co-cultured with mesenteric nodal lymphocytes in the presence or not of anti-CD80 antibody and assessed by flow cytometry to quantify the frequency of activated cytotoxic lymphocytes. Non parametrical statistics was used.

RESULTS: CD80+ esophageal epithelial cells rate resulted higher in BE during inflammatory esophageal carcinogenesis compared to healthy subjects and to patients with BE and adenocarcinoma ($p=0.08$ and $p=0.03$, respectively). The mean intensity of CD28 was higher in patients with BE and previous history of dysplasia compared to those with BE and adenocarcinoma ($p=0.04$). In vitro, co-culture of mesenteric lymphocytes with CEC significantly increased CD8+CD38+ rate that returned to baseline if antiCD80 antibody was added ($p=0.06$).

CONCLUSION: In inflammation-driven esophageal carcinogenesis, there is evidence of an early active immune surveillance process mediated by CD80 overexpression on metaplastic esophageal epithelial cells. In vitro, CEC activated CD8+ T-cells through a CD80-dependent pathway confirming the role of this molecule in triggering immune surveillance mechanism in esophageal inflammatory carcinogenesis.

P1039 HOXA13 OVEREXPRESSION IN BARRETT'S ESOPHAGUS IS A POTENTIAL MEDIATOR OF ITS POSTERIOR PHENOTYPE

V. Janmaat[1,*], A. Verhaar[1], M. Bruno[1], M. Peppelenbosch[1], M. Spaander[1]

INTRODUCTION: Barrett's Esophagus (BE) is a metaplastic and precancerous condition. It is induced by bile and acid reflux and defined by the presence of intestinal-type tissue in the esophagus. The morphology of this tissue resembles a posterior phenotype, as observed in the colon. Identifying the cause of this positional misspecification can lead to a better understanding of BE pathophysiology. The mammalian *Hoxa* cluster encodes master regulators of embryonic anterior to posterior specification, making it a potential effector of positional misspecification. The 3' to 5' sequence of genes in the *Hoxa* cluster, corresponds to the sequence in which they act along the anterior to posterior axes of the body. Acquired deregulation of *HOXA* genes during adulthood can be linked to carcinogenesis and HOXA13 overexpression to poor survival in gastric cancer. However, *HOXA* cluster expression has never been thoroughly investigated in the gastrointestinal (GI) tract, nor in BE. Therefore, the aim of this study was to analyze the expression of *HOXA* genes along the gut, characterize HOXA expression in BE and investigate whether exposure of an esophageal cell line to acid induces *HOXA* gene overexpression.

AIMS & METHODS: Firstly, we collected biopsy specimens from nine places along the GI tract in patients who underwent double balloon enteroscopy for unexplained symptoms. Secondly, we collected biopsy specimens of BE and squamous epithelium from other patients. RT-qPCR was used to quantify the expression of *HOXA1, 2, 3, 4, 5, 6, 7, 9, 10, 11* and *13*. Thirdly, an immunohistochemical staining for HOXA13 was done on BE and squamous epithelium. Additionally, the esophageal cell line HET1A was exposed to an acidic environment, after which *HOXA13* levels were measured.

RESULTS: In this study *HOXA* cluster gene expression differed significantly along the GI tract. Expression of *HOXA* genes in the proximal part of the GI tract, from the esophagus to the proximal ileum, revealed a downward trend. Anterior genes had a higher expression compared to posterior genes. The expression of posterior genes *HOXA11* and *13* was low or absent. From the terminal ileum to the rectum, expression of *HOXA* genes revealed an upward trend. Notably, expression of *HOXA11* and *13* was only found in the colon. *HOXA13* showed the highest expression of all *HOXA* genes in the GI tract. Furthermore, in BE, *HOXA* genes revealed an upward trend of expression with a very high expression of *HOXA13*. Whereas the expression of *HOXA13*

in squamous epithelium was undetectable. These observations were confirmed on protein level for HOXA13. Furthermore, exposure of an esophageal cell line to acid led to overexpression of *HOXA13*.
CONCLUSION: Our data reveal position-dependent *HOXA* coding along the GI tract. This suggests a prominent role of this gene cluster in mediating locational genetic identity. The expression of *HOXA* cluster genes in BE resembles colonic *HOXA* cluster expression. This was confirmed on protein level for HOXA13. Additionally, exposure of an esophageal cell line to acid can induce *HOXA13* overexpression. The high overexpression of *HOXA13* found in BE, is a potential mediator of posterior phenotype in this disease and may play a role in neoplastic progression.

INTRODUCTION: Proton pump inhibitors (PPIs) are the most potent and widely used drugs for the treatment of Barretís oesophagus (BE) and have been suggested to decrease neoplastic progression. Recently, PPIs have been reported to disrupt tumour pH homeostasis and, in turn, cell viability, by the inhibition of vacuolar ATPase (H^+-VATPase), a proton pump overexpressed in the membrane of some tumour cells. This aspect has not been investigated in Barrett's carcinogenesis yet.
AIMS & METHODS: Aim: To investigate the expression of H^+-VATPase in the human oesophageal adenocarcinoma (EAC) sequence, to evaluate *in vitro* the effects of PPIs on proliferation, apoptosis and invasion of EAC cells and to further elucidate the mechanisms involved in these effects. **Methods:** H^+-VATPase expression was assessed by immunohistochemistry in 22 human biopsy samples of normal oesophagus, BE and EAC. The expression and location of H^+-VATPase was also assessed in cell lines by confocal laser scanning microscopy (Leica TCS SP2) and flow cytometry (ImageStreamX). Two different Barrett's-derived EAC cell lines were used: OE33 (ECACC) and SK-GT-4 (DSMZ); and one metastatic cell line, OACM5.1C (ECACC), obtained from a lymph node metastasis derived from a Barrett's adenocarcinoma. In addition, the effects of PPIs were tested in a non-dysplastic BE cell line, CP-A (ATCC). Esomeprazole (0, 1, 10, 50, 100, 200 μM) was added to the culture medium. Cell proliferation was assessed by ELISA (BrdU, colorimetric assay). Cell invasion was evaluated in a fluorometric assay. Apoptosis was determined by flow cytometry (FACSAria, BD) by staining the cells with Annexin V-FITC and propidium iodide (PI). Intracellular reactive oxygen species (ROS) levels were evaluated at different time points (1-6 hours) in a fluorometric assay using the ROS-sensitive probe DCFDA. Experiments were performed at least in triplicate. Statistical analysis was performed by student-t test.
RESULTS: H^+-VATPase expression was found to be increased in high grade dysplasia and adenocarcinoma samples compared to normal esophagus or non-dysplastic Barrett's samples. In addition, H^+-VATPase was shown both in the cytosol and plasma membrane in EAC cell lines. Treatment with esomeprazole (10-200μM) induced the apoptosis of cancer cells and reduced in a dose-dependent manner cell proliferation (50-200 μM). Conversely, addition of the PPI didn't affect apoptosis of Barrett cells whereas significantly decreased the proliferation rate at the highest dose (100-200 μM). Moreover, the highest dose of esomeprazole significantly diminished cell invasiveness in all three tumour cell lines. ROS seem to be involved in the antineoplastic effect of esomeprazole since the addition of esomeprazole was followed by a significant increase in ROS levels and the proapototic effect of the PPI was abrogated when tumoral cells were preincubated with the ROS scavenger N-acetylcysteine.
CONCLUSION: Esomeprazole exerts *in vitro* antineoplastic effects on esophageal adenocarcinoma cells, suggesting that the use of high doses of PPIs might be effective in the treatment of EAC. These effects seem to be dependent from ROS overproduction. Additional preclinical studies are required to further confirm these results

P1041 OESOPHAGEAL CRYOABLATION USING THE NEW CRYOBALLOON FOCAL ABLATION SYSTEM: DEEP TISSUE ABLATION WITH LITTLE OR NO LATE FIBROSIS IN ANIMAL AND HUMAN MODELS

D. Schölvinck[1,2,*], B. Weusten[1,2], G. Triadafilopoulos[3], T. Valli[4], S. Friedland[3]
[1]*Gastroenterology and Hepatology, St Antonius Hospital, Nieuwegein,* [2]*Gastroenterology and Hepatology, Academic Medical Center, Amsterdam, Netherlands,* [3]*Gastroenterology and Hepatology, Stanford University School of Medicine, Stanford, California,* [4]*VDx Veterinary Diagnostics, Davis, California, United States*

INTRODUCTION: Eradication of Barrett's oesophagus (BO) can be achieved by either mucosal heating (RFA, APC) or freezing. If the energy penetrates too deeply into the oesophageal wall, heating causes denaturation and destruction of extracellular architecture, resulting in fibrosis and stenosis. In contrast, cryotherapy affecting deeper oesophageal wall layers is believed to cause cell death while preserving the wall architecture, potentially enabling deeper ablation without causing fibrosis, stenosis, or perforation.
AIMS & METHODS: We evaluated the depth of tissue injury after cryotherapy using the newly developed Cryoballoon Focal Ablation System (CbFAS) - consisting of a balloon-based, through-the-scope catheter with a battery-powered handle containing a small disposable canister for delivering cryogenic fluid into the inflated balloon - in various therapeutic as well as supra-therapeutic doses. Ablations of several durations (ranging from 4 to 24 seconds) were performed in pigs (surviving 12 hours, or 2.5, 4 or 28 days) and in normal squamous mucosa of oesophageal cancer patients (directly prior to their scheduled oesophagectomy). All oesophagi were sent for blinded histopathological analysis. For all oesophageal wall layers (mucosa, submucosa, inner and outer muscularis propria, and serosa) histopathological parameters, such as inflammation, necrosis and fibrosis were scored by a injury grading system (scoring for presence/absence of layers, oedema, inflammation, necrosis and fibrosis) with a maximum score of 3 or 4 points per layer (max. total of 17 points). Primary outcomes were the short- and long-term effects of cryoablation on the oesophageal wall.
RESULTS: *Animals:* Forty ablations were performed in 8 pigs, all surviving the pre-determined period without any symptoms or complications. Nine ablations (2x 6 sec, 7x 8 sec) in one pig surviving 12 hours resulted in inflammation, cell necrosis and oedema throughout the entire oesophageal wall (median injury grading system score 11 [IQR 10-11.5]). Depth and severity of these ablation effects was even more severe after 2.5 and 4 days: median scores of 13 (IQR 13-13) in 8 ablations (4x 6 sec, 4x 8 sec) in one pig surviving 2.5 days and 14 (IQR 13-14) in 12 ablations (2x 4 sec, 8x 6 sec, 2x 8 sec) in 3 pigs surviving 4 days. Eleven ablations (3 ablations of 6 and 8 seconds, and 1 ablation of 10, 12, 16, 20, and 24 seconds each) were performed in three pigs surviving 28. Neither necrosis nor fibrosis remained present in these specimens (median score 1 [IQR 1-2]), not even after high ablation doses.
Human: Four cryoablations (6 seconds) on squamous epithelium directly prior to oesophagectomy in three humans showed moderate inflammation mainly limited to the submucosal layer with a median score of 5 (IQR 5-7.3).
CONCLUSION: In both humans and animals, CbFAS cryoablation penetrates deeply through the oesophageal wall resulting in severe early ablation injury. After four weeks, little injury and no fibrosis remain, even after high doses, suggesting that CbFAS cryoablation combines deep ablation with a favorable long-term safety and efficacy profile.

INTRODUCTION: Low-risk early esophageal adenocarcinoma (EAC) can safely be managed endoscopically. In case of high-risk early EAC (i.e. submucosal invasion >500 nanometers, poor differentiation and/or presence of lymphovascular invasion), esophagectomy with lymph node dissection is currently advocated given the relatively high rates of lymph node (LN) metastases. However, esophagectomy is associated with substantial morbidity and mortality and a reduced quality of life. Endoscopic *radical* local resection, followed by thoracolaparoscopic dissection of esophageal LNs without concomitant esophagectomy could be an alternative.
AIMS & METHODS: In this study, we aimed to evaluate the feasibility and safety of thoracolaparoscopic dissection of LNs involved in the drainage of the esophagus in human cadavers (1), living swine (2), and two pilot-cases (3).
(1) In human cadavers, thoracolaparoscopic dissection of LNs involved in drainage of the esophagus was performed. Thereafter, esophagectomy was performed and the esophagectomy specimens (ES) were analysed for any retained LNs. Outcome parameters included the number of dissected LNs, the number of retained LNs in the ES and technical success, which was defined as a ratio $\geq$ 0.9 between the number of dissected LNs during lymphadenectomy and the total (resected plus retained) number of LNs. (2) In swine, a thoracolaparoscopic LN dissection was performed. 28 days after the procedure, the swine were sacrificed and esophagectomy was performed. Outcome parameters included the presence of ischemia or stenosis in the ES (safety parameters), and other complications. (3) In the first human pilot-cases, thoracolaparoscopic LN dissection was performed, directly followed by esophagectomy with gastric tube reconstruction (same session). Outcome parameters included the number of dissected LNs during lymphadenectomy, the number of tumor-positive LNs, and the number of retained LNs in the ES.
RESULTS: (1) In 5 human cadavers, a median of 26 LNs (IQR 22-46) was dissected. In 2 ES, 1 retained LN was found. Technical success rate was 100%. (2) None of the 7 porcine ES showed signs of ischemia or stenosis. One swine died because of ventricular fibrillation during surgery; during follow-up no complications were observed in the remaining 7 swine. (3) In 2 patients with early EAC (T1bN0M0), 23 and 43 LNs were dissected, all without evidence of metastasis. In the ES, 2 and 1 retained paraesophageal LNs were found, proximal and distal, respectively.
CONCLUSION: In conclusion, thoracolaparoscopic dissection of LNs involved in the drainage of the esophagus is feasible. The porcine survival study suggests that esophageal vascularity is not severely compromised by this procedure.

INTRODUCTION: Endoscopic therapy has become an accepted treatment option for T1a esophageal carcinoma while for T1b cancers, surgery is still considered as a treatment of choice. Endoscopic resection (or dissection) allows precise histopathologic staging which is used to guide therapeutic decisions.
AIMS & METHODS: The aim of this prospective, single center study was to assess the long-term efficacy of endoscopic treatment for early esophageal carcinoma. The main outcome measurement was complete remission defined as an absence of any neoplasia (CR-neoplasia).
RESULTS: The study involved 47 consecutive patients (mean age 65, range 35-85; 41 males and 6 females) undergoing endoscopic treatment (42x endoscopic resection; 5x endoscopic submucosal dissection) for esophageal carcinoma. Forty patients (85%) were diagnosed with early adenocarcinoma (EAC) within Barrett's esophagus, the remaining 7 patients (15%) had early squamous neoplasia (ESC). In 22 patients (47%), ER/ESD was combined with radiofrequency ablation (RFA). The median follow-up was 24 months (range 3-70).
Thirty-one patients (66%) were diagnosed as T1a cancers with mucosal invasion. Among them, four patients were referred for surgery (three patients with multifocal cancer not allowing complete local remission, one patient in which RFA of remaining dysplastic mucosa was not technically feasible). In the remaining 27 patients the endoscopic treatment was considered as curative.
Sixteen patients (34%) were diagnosed as T1b cancers with submucosal invasion (13 patients with sm1 and three patients with sm2-3). Among them, 5 patients were referred for surgery (3 of them achieved a complete local remission after endotherapy, one patient is just waiting for surgery). The remaining 11 patients did not undergo surgical treatment (comorbidity, patient's preference, age etc.) and endoscopic treatment was considered as a definitive treatment.
In all 38 patients who underwent only endotherapy, a 100% local remission rate of neoplasia was achieved and no patients presented with lymph node metastases during the follow up.
CONCLUSION: Endoscopic therapy is effective in the treatment of T1a early esophageal cancer. It appears to be a good alternative to esophagectomy in patients with T1b cancers.

INTRODUCTION: Esophageal squamous-cell carcinomas (ESCC) have a high incidence of multiple ESCCs. Lugol-voiding lesions (LVLs) recognized by using iodine chromoendoscopy were reported to be precursors for multiple primary cancers in the esophagus associated with the "field cancerrization phenomenon". LVLs are highly associated with alcohol abuse.
AIMS & METHODS: The aims of this study were to assess the improvement of LVLs according to cessation or reduction of drinking habit after the initial endoscopic treatment of ESCCs. On 331 patients with newly diagnosed ESCC, endoscopic mucosal resection or endoscopic mucosal dissection were performed between September 2005 and May 2010. At initial diagnosis of ESCC, patients were examined by iodine chromoendoscopy and assessed the extent of LVLs according to the number of LVLs per endoscopic view. At study entry, drinking and smoking histories and dietary habits were recorded. All patients were instructed to abstain from smoking and drinking alcohol. After endoscopic treatment, all patients were prospectively followed up by iodine chromoendoscopy every six months with record of LVLs, drinking and smoking habit. Associations between improvement of LVLs and change of drinking habit are analyzed.
RESULTS: Of the 331 patients, 55 patients with no LVLs and 44 patients with no drinking habit at the initial treatment were excluded. Of the remaining 232 patients, 158 patients continuously ceased or reduced the drinking habit (Group A) and 74 patients continued drinking (Group B). Eighteen of 158 patients (11.4%) of Group A had shown improvement of LVLs, whereas two of 74 (2.7%) patients of Group B had shown improvement of LVLs ($p = 0.04$). Patients of Group A are significantly had higher cumulative improvement of LVLs than patients of Group B (log rank $p = 0.023$). Univariate and multivariate analysis including smoking habit and dietary habit show that only continuously cessation or reduction of drinking habit was a significant factor to improve the extent of LVLs (univariate analysis: HR = 4.6, CI 1.3-29.1, $p = 0.013$, multivariate analysis: HR = 8.6, CI 1.7-156.3, $p = 0.004$).
CONCLUSION: By the continuous cessation or reduction of drinking habit, LVLs were significantly improved. To prevent the metachronous multiple occurrences of ESCCs, continuous instruction to abstain from the drinking habit is needed.

INTRODUCTION: Recent studies confirmed the feasibility and the safety of minimally invasive esophagectomy for cancer. The purpose of this case-control study was to evaluate the impact of laparoscopic gastric tubulization during esophagectomy for cancer on postoperative inflammatory and nutritional status.
AIMS & METHODS: We retrospectively evaluated all consecutive patients undergoing laparoscopic gastric tubulization (LGT) during esophagectomy for cancer referred to our surgical unit between 2008 and 2013. A group of patients undergoing esophagectomy with open gastric tubulization (OGT) - matched for neoadjuvant therapy, pathological stage, gender and age – were enrolled as controls.
Demographic data, tumor features and post-operative course were compared. In particular, systemic inflammatory and nutritional status were monitored during the postoperative hospital stay. Quality of life was evaluated at one month after surgery using EORTC QLQ-C30 functional scales, EORTC OES-18 Eating scale and EORTC BR23 Body Image scale.
RESULTS: We enrolled 34 patients per group, with similar demographic and tumor characteristics and ASA score. Patients in LGT group had longer procedure ($p = 0.04$). Postoperative course was similar in term of complication rate and severity and of functional result. ICU length of stay was shorter patients in LGT group ($p = 0.002$). In the first postop day LGT patients had lower C-reactive protein (CRP) levels ($p = 0.001$) and white cell blood count ($p = 0.05$), and higher albumin serum level ($p = 0.001$). In this group, albumin remained higher also at third ($p = 0.06$) and seventh ($p = 0.008$) postop day, and CRP resulted lower at third post day ($p = 0.04$). No difference was observed in term of quality of life.
CONCLUSION: LGT during esophagectomy for cancer significantly improved the systemic inflammatory and catabolic response to surgical trauma, contributing to a shorter ICU length of stay. Quality of life and esophageal function were comparable between LGT and OGT patients.

P1046 RISK FACTORS OF INTRAOPERATIVE PERFORATION DURING ENDOSCOPIC SUBMUCOSAL DISSECTION OF SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA

M. Noguchi[1,*], T. Yano[1], T. Kato[1], T. Kadota[1], H. Morimoto[1], S. Osera[1], T. Odagaki[1], Y. Oono[1], H. Ikematsu[1], K. Kaneko[1]
[1]*Department of Gastroenterology, Endoscopy division, National Cancer Center Hospital East, Kashiwa, Japan*

INTRODUCTION: Perforation is the major complication during endoscopic submucosal dissection (ESD) for esophageal squamous cell carcinoma (ESCC), and the frequency is reported to be approximately 5%. However, there are few reports about the risk factors for intraoperative perforations and the subsequent clinical course.
AIMS & METHODS: A total of 147 patients with 157 ESCC lesions were treated by ESD in our hospital from April 2008 to October 2012. We divided the group into intraoperative perforation cases and nonperforation cases, and compared the characteristics and endoscopic findings of the 2 groups. We also retrospectively reviewed the clinical courses after the perforations. A dual knife or an insulation-tipped diathermic knife were used for the ESD procedures. In addition, 0.4% sodium hyaluronate diluted with normal saline solution including epinephrine (1:1) was used as the submucosal injection solution. "Intraoperative perforation" was defined as the detection of a perforation site during ESD, and the presence of mediastinal emphysema seen on computed tomography (CT) or radiograph.
RESULTS: Intraoperative perforation was recorded as having occurred in 9 lesions from 9 patients (5.7%). No significant differences were observed between the perforation group ($n = 9$) and the nonperforation group ($n = 148$) for age, lesion location, depth of invasion, or history of treatment for esophageal cancer. However, in the perforation group the lesion maximum dimension was larger (42.9 mm vs. 30.7 mm, $p = 0.015$) and the rate of 3/4th or larger circumference of mucosal deficiency after ESD was higher (78% vs 31%, $p = 0.007$). Furthermore, the procedure time was longer (183.8 minutes vs 102.5 minutes, $p < 0.001$), and the en bloc resection rate was lower (33.3% vs 93.9%, $p < 0.001$) in ESD for patients who developed perforation during the procedure. The left wall was the predominant site of perforation (67%), and 6 of 9 perforations were successfully closed by clips during the procedures. Two of 9 patients required drainage for

pleural effusions; however, all 9 patients recovered with conservative treatment without surgical intervention. The median fasting duration and hospital stay after the procedure were 6 days (5–22 days) and 12 days (7–41 days), respectively. Three of 9 patients underwent additional treatments including chemoradiotherapy or esophagectomy due to submucosal infiltrations. At the median follow up of 42 months after ESD, no case of local recurrence or metastasis was observed.
CONCLUSION: This study suggests that a larger maximum dimension and mucosal defects after ESD are risk factors for intraoperative perforation during ESD for ESCC.

INTRODUCTION: During the last three decades, the global incidence of oesophageal adenocarcinoma has increased more rapidly than most other cancers in certain populations. A concurrent reduction in the incidence of gastric cancer has been reported from some populations. We aimed to examine the geographical pattern of oesophageal adenocarcinoma versus non-cardia gastric cancer across the world where reliable cancer registry data were available.
AIMS & METHODS: Data were abstracted from "Cancer Incidence in Five Continents" Volume 10. Oesophageal and gastric cancers were selected based on ICD-10 codes C15 and C16, respectively. Oesophageal adenocarcinomas were classified according to histological groups based on ICD-O morphology codes. Out of 424 datasets from 290 cancer registries, 288 were selected as they reported >10 cases for oesophageal adenocarcinoma. We examined the association between the incidence of oesophageal adenocarcinoma and non-cardia gastric cancer. Spearman's test of correlation was used to explore the relationship between Age-Standardised Incidence Rates (ASR) of the two cancers and expressed as correlation coefficients (CC). Furthermore, all cardia cancer cases within a registry were assumed to be either oesophageal or non-cardia based upon the different gender ratios for oesophageal versus non-cardia gastric cancer on individual registries.
RESULTS: A total of 288 datasets covering 62 countries were included in the analyses. There was a statistically significant inverse correlation between oesophageal adenocarcinoma and gastric non-cardia cancer in males (CC = -0.685, p value < 0.001) and females (CC = -0.566, p value < 0.001). After dividing cardia cancer into two subtypes with potentially oesophageal or gastric origin and adding them to original oesophageal adenocarcinoma or gastric non-cardia groups, the correlation remained strong (CC = -0.688, p value < 0.001) in males and (CC = -0.656, p value < 0.001) in females. Oesophageal adenocarcinoma only showed a rise when the incidence of non-cardia gastric cancer fell below 9/100.000 person-years for males and 4.5/100.000 person-years for females.
CONCLUSION: This cross-sectional study is consistent with a common underlying factor predisposing to non-cardia gastric cancer and protecting from oesophageal adenocarcinoma, such as *H.pylori* atrophic gastritis. If this is the case, then the incidence of non-cardia gastric cancer would need to fall to substantially lower levels than currently seen in the Far East populations before any rise in oesophageal adenocarcinoma would be apparent.

INTRODUCTION: The prognosis of patients with recurrent disease after esophagectomy for esophageal cancer is generally poor.
AIMS & METHODS: The purpose of this study was to examine the prognostic factors in esophageal cancer patients with recurrence after esophagectomy and to determine the appropriate treatment strategy for such patients. **Patients:** Seventy-eight patients (33 %) developed recurrent disease among 237 patients with thoracic esophageal cancer who underwent R0 esophagectomy between 2001 and 2010.
RESULTS: Thirty-three (43%) patients had locoregional recurrence, 26 (33%) patients had recurrence in distant sites, and 19 (24%) had both recurrences. Recurrence occurred within one year in 45 patients (57%), within 2 years in 67 patients (85%), and within 3 years in all these 78 patients (100%). The overall 5-year survival rates after recurrence was 9%. Although there was no significant difference in survival between patients with only locoregional recurrence and those with only distant site recurrence (p = 0.3032), patients with recurrence in both locoregional and distant sites had poorer prognosis compared with only locoregional recurrence (p = 0.0003) or only distant site recurrence (p = 0.0050). Of 78 patients, 23 (30%) patients received chemoradiotherapy, 18 (23%) patients received chemotherapy, 8 (10%) patients received radiotherapy, 15 (19%) patients received surgery, and the remaining 14 (18%) patients received best supportive care alone. Surgery was performed in selected patients only when the lymph node did not invade the neighboring structures, and the distant lesion was detected as a single metastasis in a single organ. The 5-year survival rates after recurrence in patients who received anti-cancer treatment was 11%, and the patients with best supportive care survived less than one year (p = 0.0166). Furthermore, the 5-year survival rates for patients with surgery was 14% compared with 7% for patients without surgery (p = 0.0166). On univariate analysis, tumor location, depth of tumor invasion (pT), recurrent type, time to recurrence and treatment were found to be factors affecting the survival (p < 0.05). In multivariate analysis, the depth of tumor invasion (pT3T4 vs. pT1T2: hazard ratio 1.919; 95 % confidence interval 1.005–3.850; p = 0.0481), recurrent type (both vs. alone: hazard ratio 2.062; 95 % confidence interval 1.126–3.641; p = 0.0199) and treatment (best supportive care vs. anti-cancer treatment: hazard ratio 9.031; 95 % confidence interval 4.130–19.210; P < 0.00001) were independent prognostic factors.
CONCLUSION: The prognosis of patients with both locoregional and distant sites recurrence was poorer than those with each recurrence. The prognosis of patients who received anti-cancer treatment was better than that of the patients who received best supportive care alone. Surgery might be an option for selected patients.

P1049 ESOPHAGEAL CANCER DEVELOPMENT DURING THE COURSE OF *H. PYLORI*-INFECTED CHRONIC GASTRITIS

T. Yoshida[1,*], J. Kato[1], I. Inoue[1], M. Watanabe[1], S. Enomoto[1], S. Miyamoto[1], H. Deguchi[1], M. Iguchi[1], T. Maekita[1], H. Tamai[1], M. Ichinose[1]
[1]*The 2nd Department of Internal Medicine, Wakayama Medical University, Wakayama City, Japan*

INTRODUCTION: Esophageal squamous cell carcinoma (ESCC) is the most prevalent esophageal cancer worldwide. Although the etiology of ESCC remains unclear, recent studies have revealed that, because they presumably generate an anacidic intraluminar environment that favors bacterial overgrowth in the upper gastrointestinal tract (GI), which leads to an accumulation of carcinogens such as nitrosamines, *H. pylori* (HP) infection and atrophic gastritis are both important risk factors for ESCC. However, studies investigating this association, particularly follow-up studies, are limited, and thus the role of chronic HP infection in ESCC development remains controversial.
AIMS & METHODS: Therefore, we investigated ESCC development during the progression of HP-associated chronic gastritis in a study of 4655 male subjects. Healthy, middle-aged, male subjects (n = 4655; mean age, 49.5 ± 4.6 years) were screened annually for ESCC and gastric cancer (GC) for up to 16 years. Chronic atrophic gastritis (CAG) was diagnosed based on the following prostaglandin (PG)-test positive criteria: PG I ≤70 ng/ml and PG I/II ratio ≤3.0. Highly active gastritis was determined by serum levels of PG II ≥30 ng/ml or HP antibody titer ≥500 U/ml. The stages of HP-associated chronic gastritis were evaluated by serum levels of pepsinogen and HP antibody, and were categorized into 4 groups representing the progression of HP-associated chronic gastritis as follows: Group A (CAG-negative, HP-negative); Group B (CAG-negative, HP-positive); Group C (CAG-positive, HP-positive); and Group D (CAG-positive, HP-negative).
RESULTS: During the study period, 87 GCs developed (annual incidence rate: 0.16%). Cancer development increased in a stepwise manner from Groups A to D, reaching a peak annual incidence rate of 1.1%. In Group B subjects with mild atrophic gastritis (annual incidence rate: 0.14%), highly active gastritis assessed by serum tests showed an annual incidence rate of around 0.25%, which was comparable to that in Group C subjects (0.30%). Eight ESCCs developed during the same period (annual incidence rate: 0.015%). Both smoking and alcohol consumption elevated the risk of ESCC, but only smoking showed a marginal significance ($p = 0.08$). The annual cancer incidence rate in Group A was 0.008%, and neither HP infection nor CAG significantly increased the risk of cancer. Highly active gastritis in a mildly atrophic stomach tended to increase the risk of cancer ($p = 0.04$).
CONCLUSION: Unlike GC, the incidence of which increases with establishment of HP-associated gastritis and the progression of CAG, ESCC development appeared not to be affected by the stages of gastritis. However, the possibility that the activity of gastritis is somehow involved in esophageal carcinogenesis should be further investigated.

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been widespread treatment for superficial esophageal squamous cell carcinoma (ESCC), since en bloc resection can be performed even in large ESCC lesions of which could not be performed in conventional endoscopic resection. However, there are few reports regarding the long-term outcomes of ESD for ESCC.

AIMS & METHODS: The aim of this retrospective study was to clarify the long-term results of ESCC patients treated by ESD. Between January 2006 and October 2012, a total of 185 patients with 191 lesions underwent ESD in our institution. We analyzed the patients who met the following criteria: 1) histologically confirmed initial ESCC or metachronous ESCC after prior endoscopic resection; 2) depth of lesions suspected as limited to within SM1; 3) absence of lymph node or distant metastasis; 4) a follow up period of 1 year or longer from the ESD procedure; and Cumulative overall, and disease-specific survival rate were calculated by the Kaplan-Meier method along with the log-rank test.
RESULTS: A total of 171 patients with 177 lesions were evaluated in this study. The median age was 67 years ranging from 39 to 85 years, and men were predominant (86%). In addition, 77 of 171 patients (45%) had a history or concomitance of cancer in other organs. Of 177 lesions, 169 (95%) were initial ESCC, and the remaining 8 lesions were metachronous ESCC. In the location, upper, middle, and lower esophagus was in 12, 100, and 65 lesions, respectively, with the median tumor size of 28 mm (range: 7–70). The median operation time during ESD was 100 minutes, and the en bloc resection rate was 89%. While esophageal perforation complicated in 8 patients during the procedure, all recovered with conservative therapy. Esophageal strictures required endoscopic balloon dilation after ESD was found in 55 patients (31%). Additional therapy was recommended in 34 (20%) patients because of the histological diagnosis, such as positive vertical margins, invasion into the submucosal layer, or lymphatic infiltration. Of the 34 patients, 20 received additional chemoradiotherapy, 5 underwent surgery, and the remaining 9 were followed up without additional treatment because of poor physical condition. At the median follow up period of 36 months (range: 12–92 months) after ESD**,** The presence of local recurrence, metastatic recurrence, and metachronus ESCC were 1.1%(2/172), 2.8%(5/177) and 14.7% (26/177) respectively. The overall survival at 3 and 5 years was 95.5% and 93.5%, respectively. During the follow up period, 11 patients died from the following causes: 2 from esophageal cancer, 7 from other cancers, and 2 from benign diseases. Therefore, disease-specific survival at 3 years and 5 years was 99.2% and 97.1%, respectively.
CONCLUSION: The long-term outcomes of ESD for ESCC was excellent. However, during the follow up periods, physicians should pay attention to not only the possibile local and metastatic recurrence or metachronous ESCC, but also the occurrence of other organ cancers

INTRODUCTION: Local failure is a major problem after chemoradiotherapy (CRT) in patients with esophageal squamous cell carcinoma (ESCC), and salvage surgery for local failures associate with high complication and mortality rate. We have introduced photodynamic therapy (PDT) for local failures to develop a less invasive salvage treatment.
AIMS & METHODS: The aim of this study to clarify the long-term outcome and prognostic factors of salvage PDT. Between 1998 and 2008, 716 patients with ESCC were treated with definitive CRT in our institution. The indication criteria of PDT were as follows: 1) absence of lymph node and distant metastasis, 2) local failures limited within T2, 3) patients who could not tolerate or who refused surgery, 4) provision of written informed consent. PDT involved 2 mg/kg of porfimer sodium followed 48-72 hours later by excimer dye laser with a fluence of 75 J/cm2. We assessed overall survival (OS), progression free survival (PFS), and also prognostic factors. This study was approved by an institutional review board in our institution.
RESULTS: A total of 113 patients with local failure underwent salvage PDT. The characteristics before CRT were as follows; male/ female: 107/ 6, median age: 66 y-o (range: 50-84), T1/ 2/ 3/ 4: 18/ 18/ 60/ 17, N0/ N1: 54/ 59; and those of before PDT were as follows; T1/T2: 72/41; residue after CRT/recurrence after achieving CR with CRT: 64/49. Total 66 patients could achieved CR with PDT (CR rate: 58.4% (95% CI 49.3 – 67.5). Five patients developed esophageal perforation, and two of them died with bleeding due to esophago-aortic fistula after PDT, therefore treatment-related death rate was 1.7%. At the median follow up period of 61 months, the PFS rate and OS rate at 5 years from salvage PDT was 22.1% (95% CI 14.3–30.0) and 35.9% (95% CI: 26.7–45.1), respectively. N0 before CRT and period longer than six months between CRT and PDT were significantly associated with better survival.
CONCLUSION: PDT demonstrated a favorable outcome in an analysis of a large number of patients with local failure after definitive CRT for ESCC.

INTRODUCTION: Multimodality therapy has been established as an effective treatment for locally advanced esophageal cancer. However, esophageal cancer patients with distant organ metastasis have usually been treated to palliate symptoms without multimodality therapy, and the prognosis of these patients is extremely poor.
AIMS & METHODS: The aim of the study is to evaluate the role of multimodality therapy in esophageal cancer patients with organ metastasis. A prospectively maintained database identified 112 esophageal sqamous cell cancer patients with distant organ metastasis who were treated at our institution between 1989 and 2011.
RESULTS: The metastatic organ was the liver (n = 59), the lung (n = 47), bone (n = 16), and other (n = 10). Twenty patients had metastasis in two and more organs. Multimodality therapy was performed in 78 patients: 62 patients received chemoradiotherapy (CRT), and 17 underwent surgery with chemotherapy (CT) and/or radiation therapy (RT). Twenty patients received single-modality therapy; CT, RT, or surgery alone. The remaining 13 patients received best supportive care (BSC) alone. The median survival (MS) for the whole group was 5.6 months. The MS was 9 months for patients treated with multimodality therapy, 2.8 months for patients with single-modality therapy, and 2 months for patients with BSC alone ($P = 0.0001$, $P < 0.0001$). There was no difference in survival between single-modality therapy and BSC ($P = 0.1505$). By univariate analysis, an improved survival was associated with less advanced N stage (N0-1), the number of metastatic organ site (one organ), and type of therapy (multimodality therapy). Age, gender, performance status, location of tumor, T stage, and organ of metastasis did not affect survival. Multivariate analysis identified multimodality therapy to be the only independent factor for improved survival (hazards ratio, 0.317; 95% confidence interval, 0.207-0.495; $P < 0.0001$).
CONCLUSION: These results suggested that multimodality therapy could improve survival of the esophageal cancer patients with distant organ metastasis. A randomized study is necessary to confirm any definitive role for multimodality therapy in esophageal cancer patients with organ metastasis.

INTRODUCTION: The advantage of ESD is high R0 resection rate and low local recurrence rate. However, usefulness of ESD for big ESCC and long term prognosis after ESD for big ECCS is unknown.
AIMS & METHODS: The aim of this study is to clarify the usefulness of ESD for ECCS at least 50mm in diameter, and long term prognosis after ESD. Superficial ECCS at least 50mm in diameter treated by ESD were enrolled to this retrospective study. A total of 138 superficial ECCS at least 50mm in diameter were treated by ESD in 5 territorial hospitals from 2000 to 2013. Patient's characteristics were as follows; Male/Female is 118/20, respectively. Median age was 69 (42 – 88), An additional treatment (AT) such as esophagectomy, chemotherapy (CT), radiation (RT) and chemo radio therapy (CRT) was recommended for the patients who had T1b ESCC.
RESULTS: Result 1. En bloc resection rate was 99 % (137/138), and R0 resection rate was 88% (122/138). Horizontal and vertical margin was positive in 14 (10%) and 2 (1.4%), respectively. There weren't severe complication that needs surgical operation. Invasion depth T1a EP, LPM, MM, and T1bSM1 (200μm or less) and SM2 was 30/51/34/6/17, respectively. Result 2. Local recurrence rate was 1% (1/138). The patient had T1bSM2 ESSC, and refused an additional treatment. A local recurrence was diagnosed 51 months after ESD, and esophagectomy was performed. Result 3. Prognosis of T1a: No recurrence was found in T1aEP and LPM. Eight of 34 MM patients had lymph duct invasion. Four patients were treated by CRT, and two patients were alive without metastasis. Remaing two patients had lymph node metastasis (LNM) and treated by CRT again. One patient who was treated by RT was alive. The remaining 3 patients were followed up without AT, and LNM was found in one patient, and CRT was performed. One patient is alive without recurrence, and the other patient died of other disease. Twenty six patients who didn't have ductal invasion were followed up without AT. Two patients had LNM. One patient was treated by esophagectomy and alive. The other patient was treated by CRT and died of ESCC. Result 4. Prognosis of T1bSM1: One patient of 6 T1bSM1 had LNM, and treated by CRT. The patient is alive without recurrence for 60 months. The remaining 5 patients were followed up without AT, and one patient died of lymph node metastasis, and remaining 5 patients were alive without recurrence. Result 5. Prognosis of T1bSM2: Six of 18 patients had lymph duct or venous invasion. Five of these 6 patients were treated by CRT, and alive without recurrence. The remaining one patient was followed up without AT, and died of other disease 49 months after ESD. Three of 11 patients who didn't have ductal invasion were treated by CRT, and alive without recurrence. Eight patients were followed up without additional therapy. One patient had local recurrence 51 months after ESD, and was treated by esophagectomy. Remaining seven patients were alive without recurrence.
CONCLUSION: ESD is a safe and useful treatment for ECCS at least 50mm. The prognosis of T1aEP and LPM is excellent. And, prognosis of T1aMM, T1bSM1 or SM2 with an adequate AT was also excellent.
Disclosure of Interest: None declared

P1054 DISTRIBUTION OF LYMPH NODE METASTASES IN ESOPHAGEAL CARCINOMA: A SYSTEMATIC REVIEW

S.S. Gisbertz[1], **W. Borstlap**[1,*], S. Lagarde[1], M. I.van Berge Henegouwen[1]
[1]*Surgery, AMC, Amsterdam, Netherlands*
Contact E-mail Address: *s.s.gisbertz@amc.nl*

INTRODUCTION: Lymph node status is an important prognostic parameter in esophageal carcinoma and an independent predictor of survival. Distribution of metastatic lymph nodes may vary with tumor location, tumor histology, tumor invasion depth and neoadjuvant therapy. Surgical strategy depends on the distribution pattern of nodal metastases but consensus on the extent of lymphadenectomy differs worldwide. Aim of the present study was to evaluate the distribution of lymph node metastases in esophageal carcinoma specimens following transthoracic esophagectomy.
AIMS & METHODS: The Cochrane database of systematic reviews, the Cochrane central register of controlled trials, Embase and Medline databases were searched by two independent researchers using a combination of keywords relating to esophageal cancer, surgery, lymphadenectomy and lymph nodes. Studies were included if published from 1990 until July 1st 2013. Excluded were studies with 1-field lymphadenectomy, studies with neo-adjuvant therapy, studies describing only the sentinel node, animal studies and case reports. The primary end point was the distribution of lymph node metastases.
RESULTS: Out of 2406 articles, 8 studies, reporting on 5038 patients, fulfilled the eligibility criteria and were included. Seven studies described the distribution of nodal metastases in squamous cell carcinoma (4869 patients) and 2 studies in adenocarcinoma (169 patients; 1 study described both squamous cell and adenocarcinoma). All studies were retrospective analyses except for 1 prospective cohort trial on squamous cell carcinoma (1893 patients). The studies on squamous cell carcinoma discriminated between tumor location in the upper, middle and lower esophagus. All selected studies used a different classification system for lymph node stations and were therefore not comparable in a meta-analysis. For adenocarcinoma both studies found mediastinal and abdominal lymph node metastases, but in only 1 of 2 studies cervical metastatic lymph nodes were reported (10/32 patients; 27%). For squamous cell carcinoma all studies described cervical, mediastinal and abdominal lymph node metastases, independent of the location of the tumor, except for 1 trial with 9 patients, in which there were no abdominal lymph node metastases in upper esophageal squamous cell carcinoma and 1 trial with 41 patients in which there were no cervical lymph node metastases in lower esophageal squamous cell carcinoma.
CONCLUSION: Esophageal cancer frequently metastasizes to the neck, mediastinum and abdomen. However, few studies describe the distribution of lymph node metastases for esophageal adenocarcinoma. Additionally, there is no homogeneity concerning classification of lymph node stations, which makes interpretation of studies difficult and data hard to compare. This makes the choice for surgical strategy demanding, especially when considering the significant morbidity involved in esophageal surgery. A multicenter prospective study is needed to determine distribution of lymph node metastases in order to establish optimal surgical treatment for esophageal cancer patients.

Contact E-mail Address: *yasuaki-75@med.osaka-cu.ac.jp*

INTRODUCTION: Endoscopic submucosal dissection (ESD) to treat superficial esophageal cancer has become accepted owing to its high quality control for the disease. However, incidence of strictures caused by ESD for widespread lesions is high and sometimes leads to a low quality of life. Locoregional steroid injection was reported to be useful for prevention of such strictures formation (1). However, no prospective randomized comparative study about steroid has been observed.
AIMS & METHODS: We evaluated the prophylactic efficacy of locoregional steroid injection for stricture formation after ESD for superficial esophageal cancer using a propensity score matching analysis.
This is a retrospective study in single referral center. Between April 2006 and July 2013, a total of 357 patients with superficial esophageal cancer underwent ESD in our hospital. Four patients treated with metallic stent and 4 patients with lacking data were excluded. Consequently, 349 patients were enrolled in this study. We have used two fashions of locoregional steroid injection: one is an injection of 80 mg triamcinolone once just after ESD; second is an injection of 6.6 mg dexamethasone just after ESD and twice a week (1-6 times). Endoscopic evaluation of the stricture was performed after 4 and 8 weeks after the treatment. A propensity score matching analysis was performed to reduce the effects of selection bias of steroid injection and potential confounding factors. We compared the incidence of stricture formation by univariate analysis between patients with and without locoregional steroid injection before and after matching. In addition, multivariate analysis was used.
RESULTS: Of 349 patients, 42 patients underwent locoregional steroid injection (dexamethasone/triamcinolone, 23/19) after ESD and esophageal stricture formation occurred in 36 patients. Twenty-eight patients with or without steroid injection were matched after a propensity score matching. In univariate analysis, the incidence of stricture formation with steroid injection decreased to 10.7% (3/28) from 35.7% (10/28) as without steroid ($p = 0.035$). Multivariate analyses indicated that lcoregional steroid injection decreased the incidence of stricture formation (OR, 0.15; 95% CI, 0.03–0.73; $p = 0.02$). No serious adverse events such as delayed bleeding and perforation were encountered.
CONCLUSION: Locoregional steroid injection was efficient for preventing stricture formation after ESD for superficial esophageal cancer.

P1056 ROLE OF ENDOGENOUS AND EXOGENOUS HYDROGEN SULFIDE (H2S) IN GASTRIC PROTECTION AGAINST EXPERIMENTAL GASTRIC LESIONS

M. Magierowski[1,*], K. Jasnos[1], M. Wierdak[1], A. Ptak-Belowska[1], R. Pajdo[1], G. Krzysiek-Maczka[1], S. Kwiecien[1], T. Brzozowski[1]

INTRODUCTION: Hydrogen sulfide (H_2S) plays an important role in a number of physiological actions including vasodilatation, inhibition of oxidant stress, the anti-inflammatory activity and the inhibition of apoptosis. Three enzymes cystathionine γ-lyase (CSE), cystathionine β-synthetase (CBS) and 3-mercaptopyruvate sulfurtransferase (3-MST) are essentioal in the biosynthesis of H_2S by gastric epithelium. However, whether this gaseous molecule could be effective in protection against acid-dependent stress-induced lesions and whether the expression of CSE and CBS and the gastric mucosal biosynthesis of H_2S could affect the mucosal damage induced by stress in the presence or absence of exogenous H_2S, have been little elucidated.
AIMS & METHODS: We studied the effect of NaHS, a H_2S-donor and L-cysteine, a H_2S precursor against 3.5 h of water immersion restraint stress (WRS)-induced gastric lesions in rats with intact and capsaicin-denervated sensory nerves (large dose 125 mg/kg s.c for 3 days). Animals were pretreated i.g. 30 min before the oneset of WRS with A) NaHS (5 mg/kg); B) L-cysteine (10 mg/kg) with or without the combination with inhibitors of CSE activity, D,L-propargylglycine (PAG 15 - 80 mg/kg) and beta-cyano-L-alanine (BCA, 50 mg/kg). The number of gastric lesions was measured by planimetry, the gastric blood flow (GBF) by H_2-gas clearance technique and the gastric H_2S production resulting from CSE/CBS and 3-MST activity pathways and the gastric H_2S content were determined by modified methylene blue method and ELISA, respectively. In addition, the mucosal mRNAs expression of CSE, CBS, 3-MST, HIF1α and antioxidizing enzymes SOD and GPx were evaluated by RT-PCR.
RESULTS: Exposure to WRS caused mucosal hemorrhagic lesions accompanied by the fall in GBF, gastric H_2S content and an increase in H_2S production *via* CSE/CBS and 3-MST pathways and mRNA expression of CSE and CBS. NaHS (1-20 mg/kg) and L-cysteine (5-40 mg/kg) dose-dependently reduced WRS-induced gastric damage and significantly raised GBF and mucosal content of H_2S and these effects were completely lost in animals with capsaicin denervation. BCA and PAG which dose-dependently augmented the number of WRS lesions and decreased H_2S production and its tissue content, reversed the NaHS and L-cysteine-induced decrease in the WRS lesions and the accompanying increase in the GBF. Upregulation of mRNAs expression for HIF-1α mRNA, CSE and CBS in the gastric mucosa exposed to WRS was diminished by NaHS (5 mg/kg i.g.) and L-cysteine (10 mg/kg i.g.) and these effects were further enhanced in capsaicin-denervated rats treated with NaHS and L-cysteine. The increased expression of SOD and GPx mRNA was observed in NaHS- and L-cysteine-pretreated rats but not in those with capsaicin-denervation.
CONCLUSION: We conclude that: 1) an increase in H_2S production and the expression of CSE and CBS, two key enzymes in H_2S biosynthesis, could compensate for the stress-induced impairment of gastric mucosal defense; 2) an increase in endogenous production of H_2S in gastric mucosa contributes to the NaHS-induced protection against stress lesions, and 3) H_2S-induced gastroprotection and hyperemia against WRS-induced ulcerogenesis is mediated by vasoactive sensory neuropeptides such as CGRP and the activity of antioxidizing enzymes SOD and GPx.

P1057 CARBON MONOXIDE (CO) RELEASED FROM CORM-2 RELEASING CO ATTENUATES ASPIRIN-INDUCED GASTRIC LESIONS. INVOLVEMENT OF GASTRIC SECRETION, HEME OXYGENASE (HO-1) AND NITRIC OXIDE

K. Jasnos[1,*], R. Pajdo[1], S. Kwiecien[1], M. Magierowski[1], T. Brzozowski[1]
[1]*Department of Physiology, Jagiellonian University Medical College, Cracow, Poland*

INTRODUCTION: Previuos studies revealed that enzyme heme oxygenase (HO)-1 exerts an important protective action in acute and chronic inflammation of the gastrointestinal mucosa. Carbon monoxide (CO) synthesized due to activity of HO-1 has been shown to exert important physiological functions in the regulation of blood flow and motility but the contribution of this gaseous molecule to the mechanism of protection against nonsteroidal anti-inflammatory drugs (NSAID)-induced gastric mucosal damage has been little studied.

AIMS & METHODS: We determined the effect of tricarbonyl dichloro ruthenium(II) dimer (CORM-2), a CO releasing molecule, on gastric acid secretion in rats equipped with chronic gastric fistulas (GF) (series A) and gastric lesions induced by acidified aspirin (ASA) (series B). Rats were treated with CORM-2 (0.1-50 mg/kg i.g.) and received 30 min later ASA (125 mg/kg i.g.) without or with: 1) NO-synthase inhibitor L-NNA (20 mg/kg i.p.) without or with L-arginine (200 mg/kg i.g.), a substrate for NO-synthase activity, 2) ODQ (10 mg/kg i.g.), a guanylyl cyclase inhibitor, and 3) zinc protoporphyrin IX (ZnPPIX), an inhibitor of HO-1 activity. In addition, the effect of hemin, a HO-1 inducer which provides endogenous CO, and biliverdin, the product of heme catalysis, on ASA damage and the alterations in the GBF were also studied. The area of gastric lesions was measured by planimetry, the gastric blood flow (GBF) determined by H_2-gas clearance technique, plasma proinflammatory cytokines (IL-1β and TNF-α) were determined by ELISA and the mRNA and proteins for HO-1-, HO-2- and COX-1- and proinflammatry markers COX-2-, IL-1β-, and TNF-α were assessed by RT-PCR.

RESULTS: CORM-2 inhibited basal and histamine stimulated gastric acid secretion in rats with GF (series A) and dose-dependently attenuated ASA damage while increasing GBF; the dose inhibiting ASA damage by 50% (ED_{50}) being 5 mg/kg (series B). These protective and hyperemic effects of CORM-2 were significantly attenuated by L-NNA and restored when L-arginine but not D-arginine was co-administered with CORM-2. ODQ also significantly attenuated the gastroprotective and hyperemic effects of CORM-2. Pretreatment with hemin (5 mg/kg i.g.) significantly reduced ASA-induced gastric damage and significantly increased the GBF similarly as in case of CORM-2 while biliverdin was less effective. ZnPPIX which exacerbated ASA damage significantly atternuated the protection and the rise in GBF induced by CORM-2 (5 mg/kg i.g.). The increased mucosal expression of mRNA for HO-1, COX-2 mRNA, IL-1β and TNF-α and plasma levels of these cytokines were detected in rats exposed to ASA and these effects were significantly ameliorated by pretreatment with CORM-2.

CONCLUSION: We conclude that 1) CO released from CORM-2 exhibits gastroprotective activity against ASA-induced gastric lesions *via* mechanism involving an increase in the gastric microcirculation mediated by activation of HO-1/CO, NO-NOS and PG-COX systems and the inhibition of the expression and activity of proinflammatory markers COX-2, IL-1β and TNF-α, and 2) antisecretory activity of CORM-2 releasing CO can contribute to CO-induced protection against acid-dependent mucosal damage evoked by ASA.

Contact E-mail Address: *tonyaant@yandex.ru*

INTRODUCTION: Nonsteroidal anti-inflammatory drugs (NSAIDs) are commonly prescribed for a variety of inflammatory conditions. Among the most common side effects are NSAID-enteropathy/-gastropathy. It is known that in animal models NSAID-enteropathy is accompanied by shifts in numbers and types of intestinal bacteria. That's why probiotics (P) are thought as potential drugs for treatment and prevention of NSAID-enteropathy. The peculiarities of colonic microbiota and its correlation with the severity of gastric lesions in patients who used NSAIDs for more than 3 months haven't been studied before.

AIMS & METHODS: to study the peculiarities of colonic microbiota in *H. pylori*-negative patients who used NSAIDs more than 3 months with and without NSAIDs-gastropathy; to determine a correlation between the intensity of dysbiosis and age, severity of gastric mucous lesions (GML); and to optimize the treatment of NSAIDs-associated GML with the help of P. We observed 45 patients who were *H. pylori*-negative and used NSAIDs more than 3 months. The mean age was 64.1±6.1. For all of them gastroscopy, laboratory examination were performed. The fecal microflora has been analyzed by bacteriological culture methods. Patients with GML were divided into 2 equal groups. The first group (control) was treated with pantoprazole (20 mg 2 times daily) for 28 days. The second group (main) received combined therapy: pantoprazole (20 mg 2 times daily) for 4 weeks and P ''Symbiter acidophilic'' concentrated in dose 10 ml per day for 20 days. Over 1 month after the beginning of treatment we repeated all examinations which were done before. Normal distribution of studied parameter for each sampling was checked using Shapiro-Wilka's criteria. Average value (M) error and standard deviation (SD) were calculated to discover significant changes of investigated indices. Sampling comparison was performed using the paired Student's t-test.

RESULTS: Among 45 patients, who were examined, in 30 patients GML were observed, in 15 patients visible changes of GM were absent. Changes in colonic microbiota were observed in all patients who used NSAIDs for more than 3 monts. In 33.3% of them the level of Lactobacillus was less than 10^6. It was detected correlative conjunction between the severity of injuries and intensity of dysbiosis ($r = 0.67$, $p < 0.001$). The correlation between the intensity of dysbiosis and age of the patients is also observed ($r = 0.43$, $p < 0.003$). Over 1 month in the control group erosive lesions of GM were observed in 26.7%, in the main group erosive lesions after the treatment were absent ($p < 0.05$). In the main group the elevation of the level of haemoglobin, red blood cells were significantly more expressed. In the control group the intensity of dysbiosis was enhanced, in the main group dysbiosis was not registered.

CONCLUSION: The changes in the colonic microbial community structure correlate with the intensity of the GML and age of patients with NSAIDs-gastropathy. The inclusion of P in the general scheme of treatment of NSAIDs-gastropathy eliminates the detected dysbiosis and improves the indicators of complete blood count and what is important - it leads to the total healing of gastric mucous over 4 weeks from the beginning of treatment that allows us to recommend the inclusion of P in the general scheme of the treatment of NSAIDs-gastropathy.

Contact E-mail Address: *flaminia.purchiaroni@hotmail.it*

INTRODUCTION: Atrophic body gastritis (AG) is characterized by oxyntic glands and parietal cells destruction with loss of hydrochloric acid and intrinsic factor production. Vitamin B12 (vitB12) malabsorption may occur and lead to pernicious anemia (PA), the global burden of which is still unknown. AG and PA pathogenesis are linked to autoimmune mechanisms and to *Helicobacter pylori* (Hp) infection[1]. The role of single nucleotide polymorphisms (SNPs) in vitB12 malabsorption and PA is unknown.

AIMS & METHODS: To determine the frequency of SNPs potentially related to vitB12 absorption pathway in AG patients, with or without PA, compared to healthy controls.

83 AG caucasian patients were enrolled: 43 with PA (51% F, median age 59 years) and 40 without (85% F, median age 51 years). Controls included 173 caucasian subjects (73% F, median age 51 years). Genomic DNA from peripheral blood leukocytes was extracted. Fourteen SNPs potentially related to vitB12 absorption were analyzed by genotyping: TCN1 rs526934, TCN2 rs9606756, CUBN rs1801222, rs11254363, FUT2 rs492602, rs601338, rs602662, FUT6 rs3760776, GIF rs35211634, rs121434322, MUT rs9473555, rs1141321, MTHFR rs1801133, CLYBL rs41281112 [2,3]. Results are expressed as allele and genotype frequencies.

RESULTS: TCN2 (rs9606756) C/C genotype was significantly more frequent in all cases compared to controls: 3.6% vs 0%, χ^2 0.02. MUT (rs9473555) G allele was significantly less frequent in all cases compared to controls: 27% vs 72%, $\chi^2 < 0.0001$. The genotype and allele frequencies of remaining SNPs were similar in the two groups.

TCN2 (rs9606756) C/C and FUT6 (rs3760776) T/T genotypes were more prevalent in PA cases compared to controls: respectively, 4.6% vs 0%, χ^2 0.02; 9.3% vs 1.7%, χ^2 0.01. No difference was found in terms of allele frequency. GIF gene (rs121434322) T allele was not expressed in the examined population.

CONCLUSION: Compared to controls, AG patients, with and without PA, have a higher prevalence of TCN2 C/C genotype, which may be associated with altered plasma transcobalamin and thus with altered cellular vitB12 uptake. Among PA cases, FUT6 T/T genotype is more prevalent; this may alter FUT6 activity and individual susceptibility to Hp infection, a trigger of gastric autoimmunity. MUT G allele is more prevalent in controls and it has been linked to higher vitB12 levels, as it is expected in an healthy gastric body mucosa. This study shows that genetic polymorphisms related to vitB12 absorption pathway are associated to AG and PA; this suggests that specific SNPs in AG may lead to vitB12 malabsorption.

INTRODUCTION: Single nucleotide polymorphisms (SNPs) are associated with aspirin-induced peptic ulcer, but they are discrepant among races. There are few data on Koreans.

AIMS & METHODS: This study investigated the relationship of SNPs of COX-1, IL1B, TNF and IL-1RN genes on aspirin-induced peptic ulcer in Korean adults.

The subjects taking a low-dose aspirin of 100 mg for at least 4 weeks were enrolled in the study, and they underwent an upper GI endoscopy at Myongji Hospital. The subjects were divided into two groups: the control group that had no peptic ulcer in upper GI endoscopy, and the peptic ulcer group that had gastric or duodenal ulcer in upper GI endoscopy. The DNA was extracted from the subjects' whole blood, polymerase chain reaction was performed to detect SNP, and mutation analysis was performed.

RESULTS: A total of 48 patients consisting of 23 patients with peptic ulcer and 25 healthy controls were enrolled. In IL-1β -581C/T (rs1143627), the prevalence of CC, CT and TT alleles were 21.74%, 65.22%, and 13.04% in the peptic ulcer group, whereas 16%, 40%, and 44% in the control group, respectively. In IL1B-1061C/T (rs16944), the CC, CT and TT alleles were 13.04%, 65.22%, and 21.74% in peptic ulcer group, whereas 44%, 40%, and 16% in the control group, respectively. After adjustment for age and gender, the CT and CC allele of IL-1β -581C/T had an odds ratio of 4.625 (95% confidence interval: 1.054-20.303) for peptic ulcer. In IL-1β -1061C/T, the CT and TT allele had an odds ratio of 4.625 (95% confidence interval: 1.054-20.303) for peptic ulcer.
CONCLUSION: The C allele of IL-1β -581C/T and T allele of IL-1β -1061C/T had an increased risk of low-dose aspirin-induced peptic ulcer in Korean adults. It would be reasonable to screen patients for these SNPs before low-dose aspirin is prescribed, and to prevent peptic ulcer induced by low-dose aspirin.

P1061 LOCAL IMPLANTATION OF ADIPOSE-DERIVED MESENCHYMAL STEM CELLS (ADMSCS) ENHANCED HEALING OF GASTRIC ULCER VIA ACTIVATION OF ERK1/2-MAPK PATHWAY

L. Liu[1], P. Lam[1], E. Ng[2], **P.W. Chiu**[2,*]
[1]*THE CHINESE UNIVERSITY OF HONG KONG, Hong Kong, Hong Kong,* [2]*Department of Surgery, THE CHINESE UNIVERSITY OF HONG KONG, Hong Kong, Hong Kong*
Contact E-mail Address: *philipchiu@surgery.cuhk.edu.hk*

INTRODUCTION: Numerous studies confirmed the efficacy of ADMSCs in enhancing healing in injury to various organs including heart, liver, colon, brain and kidney. The aim of our study was to investigate the effect of ADMSCs in enhancing the healing of gastric ulcer and to explore the potential mechanisms for this effect.
AIMS & METHODS: Gastric ulcer model was successfully created in rats using 70% acetic acid. These ulcers were divided into three groups and received one of the following treatments: 1. Single dose of 1×10^7 ADMSCs directly transplanted to around ulcer by injection; 2. intragastric administration of pantoprazole; 3. Phosphate buffered saline alone (PBS). The healing of ulcer was assessed by the area measured at different time points after sacrifice of rat. Molecular mechanisms and potential signal pathway activated by ADMSCs were assessed using PCR-array. In addition, the therapeutic potentials of ADMSCs were also assessed when NSAIDs was simultaneously used.
RESULTS: The results showed that ADMSCs accelerated healing of peptic ulcer as evidence by the significant reduction in ulcer area at day 10 and 15 for ADMSC group compared to other two groups (ADMSCs vs. PBS group: $P<0.01$ for day 10 and $P<0.05$ for day 15). Histological assessment indicated that ADMSCs significantly increased re-epithelialization, angiogenesis and collagen deposition, meanwhile suppressing inflammatory reaction. ADMSCs group had more cell proliferation and angiogenesis compared with PBS group. Transplanted ADMSCs homed into the gastric ulcer and differentiated into endothelial and smooth muscle cells. The results of PCR-array indicated that genes for anti-inflammation, chemokines, growth factors and remodeling enzymes were significantly up-regulated in ADMSCs group. In addition, ADMSCs activated Erk1/2-MAPK signal pathway, which has been suggested as the most important pathway for the healing of peptic ulcer. Simultaneous use of indomethacin (a commonly used NSAIDs) greatly attenuated the therapeutic effect of ADMSCs as shown by reduced cell proliferation and angiogenesis, increased apoptosis and delayed ulcer healing at day 10.
CONCLUSION: Local injection of ADMSCs enhanced healing of gastric ulcer through activation of Erk1/2-MAPK signal pathway.

P1062 FEASIBILITY OF ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR EARLY GASTRIC CANCER IN ELDERLY PATIENTS

H. Noda[1,*], N. Ogasawara[1], K. Nagao[1], A. Shimozato[1], Y. Kondo[1], Y. Ito[1], K. Yanamoto[1], M. Sasaki[1], K. Kasugai[1]
[1]*Gastroenterology, Aichi Medical University School of Medicine, Nagakute, Japan*
Contact E-mail Address: *bisaipan@aichi-med-u.ac.jp*

INTRODUCTION: Endoscopic submucosal dissection (ESD) for early gastric cancer can achieve a higher rate of en bloc resection which allows more accurate pathological diagnosis, even for large lesions. If the correct indications are used, ESD can be a radical treatment with results comparable to open surgery. Therefore, ESD is thought to greatly improve the patient's quality of life (QOL). In Japan, life expectancy is approximately 80 years, and Japan has the longest life expectancy in the world for both men and women. In its increasingly aged society, a growing number of endoscopic treatments are performed on the elderly with age-associated comorbidities such as cardiovascular diseases. The proportion of people who regularly attend hospital for at least one chronic disease is nearly 70% among people who are 75–84 years of age, which is the highest rate compared to other age groups. Therefore, even esophagogastroduodenoscopy (EGD) itself can have risks for elderly patients, and further caution is particularly needed for those with comorbidities of heart or lung diseases. Elderly patients often have surgically operative risks due to complicated diseases, and the feasibility of ESD for such patients will improve the QOL. In the present study, we aimed to evaluate the efficacy and safety of ESD for early gastric cancers in elderly patients aged 75 years or older. The technical feasibility, the en bloc resection rate, and the complications of ESD in the treatment of early gastric cancers were compared with those of younger patients.
AIMS & METHODS: The subjects were selected from 213 consecutive patients with early gastric cancers for which ESD was performed between January 2006 and December 2013. They were divided into two group; 74 patients who were 75 years of age or older (elderly group) and 139 patients under 75 years old (non-elderly group). The following were used for analysis between the groups: pre- and postoperative performance status (PS) of subjects, prevalence rates of pre-existing comorbidities, characteristics of lesions, treatment outcomes, durations of hospitalization, operating times and incidence rates of complications.
RESULTS: In the elderly, there was one patient (1.4%) with PS of 3 before ESD. None of the non-elderly had a PS of 3 before or after the procedure. The PS increased in only one elderly patient (1.4%) after the ESD procedure. However, none of the non-elderly had the PS increase after the ESD procedure. There was no significant difference related with PS increase between the two groups. The ratio of patients with a pre-existing comorbidity was higher in the elderly than in the non-elderly. There were no differences between the two groups in the characteristics of the lesions, operating times, duration of hospitalization, or the incidence rates of complications such as perforation and post-ESD bleeding. The percentage of the patients taking anticoagulant drugs was significantly higher in the elderly. Of the patients on anticoagulant therapy, the duration of hospitalization tended to be longer in the elderly but no significant difference was found.
CONCLUSION: The present study shows feasibility of ESD for early gastric cancers in elderly patients. We conclude that ESD is useful in elderly patients because there is a similar risk as for the non-elderly regardless of PS or pre-existing comorbidity.

P1063 SUCCESSFUL TREATMENT OF MÉNÉTRIER'S DISEASE USING THE EGF-RECEPTOR-ANTIBODY CETUXIMAB

H.H. Nietsch[1,*]
[1]*Department of Gastroenterology, St. Elisabeth Medical Center, Halle (Saale), Germany*
Contact E-mail Address: *h.nietsch@krankenhaus-halle-saale.de*

INTRODUCTION: Ménétrier's disease (hypertrophic gastropathy) named after French physician Pierre E. Ménétrier; (1859–1935) is a rare, acquired, premalignant disease of the stomach characterized by enlarged gastric folds, excessive mucous production with resultant protein loss. The histology is characterized by massive foveolar hyperplasia. The glands are elongated with a corkscrew-like appearance and cystic dilation is common. There is no standard therapy as of yet. A few case series describe a dramatic response to the inhibition of the EGF-Receptor pathway (NEJM 2000; 343: 1697-1701).
AIMS & METHODS: We report the case of a 48-year old Caucasian male with a three year history of dyspepsia associated with lower extremity edema caused by hypoalbuminemia. Helicobacter serology was negative. The epigastric pain was only minimally responsive to PPI-treatment. An EGD was performed and showed large, tortuous gastric folds in the fundus and body of the stomach, with sparing of the antrum. Radial EUS at 10 mHz showed significant thickening of the gastric wall up to 9 mm caused by effacement of the first three wall layers. Five large biopsies using a hot snare were obtained. The histology did reveal the characteristic findings of Ménétrier's disease with extensive foveolar hyperplasia.
RESULTS: Given the persistent epigastric complaints and significant enteral protein loss leading to edema, we did recommend the off-label use of cetuximab, a monoclonal antibody against the EGF-receptor, according to the Vanderbilt University/Nashville/TN- study protocol. After informed consent and approval by the internal review board, four weekly infusions of cetuximab were administered ($400mg/m^2$ loading dose, followed by $250mg/m^2$). Prophylactic Pliazon® (Merck Serono) cream was applied in order to prevent drug-induced skin rash, which is a common side effect of anti-EGFR therapy. The patient only developed a mild erythematous rash without pruritus after the second infusion. The epigastric discomfort was relieved completely and the serum albumin level normalized after 6 weeks leading to resolution of the peripheral edema. EGD 8 weeks after completion of the anti-EGFR therapy showed normal gastric folds with only mild chronic gastritis on histology. The patient is currently without and GI symptoms 6 months after completion of therapy and will undergo annual EGDs for surveillance.
CONCLUSION: Anti-EGFR antibody therapy using cetuximab seems to be an effective treatment of symptomatic Ménétrier's disease and should be considered before more aggressive treatment options like gastrectomy are entertained.

Contact E-mail Address: *ikikuste@gmail.com*

INTRODUCTION: Patients with chronic atrophic gastritis (AG) or intestinal metaplasia (IM) should be considered to be at higher risk for gastric adenocarcinoma [1]. This study aimed to evaluate if the flexible spectral imaging color enhancement (FICE) endoscopic assessment of gastric mucosa could replace random biopsies to identify individuals with advance stages of gastric atrophy and/or intestinal metaplasia.

AIMS & METHODS: We included 191 consecutive patients (male 28%, average 62, range 50-87) from January 2013 to April 2014 aged over 50 undergoing FICE (gastroscope EG-590WR) endoscopy at Digestive diseases centre GASTRO. Targeted biopsies were obtained at the locations of visually suspected lesions. If no changes were determined by FICE, random biopsies were performed in antrum, incisura and corpus according to Sydney-Houston protocol. Histology assessment was performed according to the updated Sydney System. Both OLGA and OLGIM were used and individuals classified accordingly.
RESULTS: Table 1. FICE diagnostic accuracy for AG and IM.

	Sensitivity	Specificity	LR+	LR-
Atrophy (OLGA III/IV)	82.35	78.57	3.84	0.22
IM (OLGIM III/IV)	78.57	86.17	5.68	0.25
Atrophy (OLGA I/II)	46.88	78.57	2.19	0.68
IM (OLGIM I/II)	61.45	86.17	4.44	0.45

The overall prevalence of endoscopically and histologically diagnosed AG and IM cases were 48% and 93% (68% OLGA I), 39% and 50% (45% OLGIM I), respectively.
CONCLUSION: FICE endoscopy yielded favourable results in the endoscopic diagnosis of advance stages of gastric atrophy and/or intestinal metaplasia (OLGA/OLGIM III/IV) and this is very practical and easy way to use in a daily clinical practice for unselected patients.

P1065 RISK STRATIFICATION AND MANAGEMENT OF NON-CURATIVE RESECTION AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER

J.P. Han[1,*], S.J. Hong[1], H.J. Jung[1], Y.S. Myung[1], T.H. Lee[1], B.M. Ko[1], J.Y. Cho[1], J.S. Lee[1]
[1]*Digestive Disease Center, Department of Internal Medicine, Soon Chun Hyang University School of Medicine, Bucheon, Korea, Republic Of*
Contact E-mail Address: *rock5014@schmc.ac.kr*

INTRODUCTION: Non-curative resection after endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) can contribute to local recurrence or lymphatic and distant metastasis of the tumor. We stratified the risk of local recurrence in non-curative resection after ESD for EGC.
AIMS & METHODS: There were 892 EGC cases treated with ESD from 2001–2012; histology determined that 152 (17.0%) cases resulted in non-curative resection after ESD. These cases included positive cancer cells in the margin, lymphovascular invasion, or were beyond the expanded criteria of ESD from ESD specimens. The clinical outcomes and risk factors associated with local recurrence were analyzed retrospectively in non-curative resections after ESD.
RESULTS: Among 152 non-curative resections, 46 (30.3%) were interpreted as incomplete resection based on the margin and criteria fulfillment, 31 (20.4%) as complete resection based on margin and beyond the criteria, 41 (27.0%) as incomplete resection based on margin and beyond the criteria, and 34 (22.4%) as lymphovascular invasion regardless of complete resection. The patients with factors related to incomplete margin resection beyond the criteria (odds ratio [OR], 3.991; $P = 0.015$) or lymphovascular invasion (OR, 4.487; $P = 0.014$) showed a higher rate of local recurrence in non-curative resection. In those high-risk groups, endoscopic surveillance without additional treatment allowed significantly more local recurrence than those received additional treatment ($P = 0.029$).
CONCLUSION: Risk stratification for non-curative resection is important for EGC prognosis after ESD. Moreover, additional treatment for non-curative resection influences long-term outcomes, in a high-risk group that have incomplete resection of margin beyond the ESD criteria or lymphovascular invasion.

P1067 STUDY FOR CASES OF RECURRENCE AFTER ENDOSCOPIC RESECTION IN EARLY GASTRIC CANCER

S.K. Bae[1], **J.H. Kim**[1,*]
[1]*Internal medicine, Myongji hospital, Goyang-si, Korea, Republic Of*

INTRODUCTION: Endoscopic resection (ER) is widely accepted treatment for early gastric cancer (EGC), but little is known about recurrence after ER.
AIMS & METHODS: The aim of this study is to investigate cases of recurrence after ER for EGC.
We performed a retrospective review of medical records of 126 patients with EGC underwent ER.
RESULTS: The median follow up period was 26.7 months. During a follow up, a total of 10 patients (7.94%) developed recurrence in enrolled patients. According to univariate logistic regression analysis, piecemeal resection (odds ratio [OR] 7.067, 95% confidence interval [CI] 1.706-29.285, $P = 0.007$) and tumor-positive resection margin (OR 33.292, 95% CI 7.064-159.904, $P < 0.0001$) were significant risk factors for cancer recurrence after ER. However, there was no significant factor for recurrence in multivariate logistic regression analysis.
CONCLUSION: This study showed that piecemeal resection and tumor-positive resection margin were probable risk factors for recurrence after ER for EGC. Therefore, a study in a large number of patients and a longer period might show that piecemeal resection and tumor-positive resection margin are risk factors for recurrence.

P1068 VESSEL PLUS SURFACE CLASSIFICATION SYSTEM OF MAGNIFYING-NARROW BAND IMAGING FOR PREDICTING PRESENCE CANCEROUS LESION AND OTHER PROGNOSTIC HISTOLOGIC FACTORS IN GASTRIC EPITHELIAL NEOPLASMS: A RETROSPECTIVE SINGLE CENTER STUDY

J.H. Kim[1,*]
[1]*Gastroenterology, Busan Paik Hospital, Inje University College of Medicine, Busan, Korea, Busan, Korea, Republic Of*

INTRODUCTION: Although studies have addressed the predictive role of magnifying-narrow band imaging (MNBI) for gastric epithelial neoplasms, little is known of the relationship between MNBI indicators and histologic prognostic factors other than the presence of cancer.
AIMS & METHODS: We conducted this study to validate MNBI indicators for differential diagnosis of gastric neoplasms and as predictors for other prognostic histologic factors, using vessel plus surface classification system. The medical records of 171 consecutive gastric epithelial neoplasms which received MNBI before undergoing curative surgery or endoscopic treatment were retrospectively reviewed.
RESULTS: Irregular and absent microvascular pattern (MVP) ($p = 0.008$), absent microsurface pattern (MSP) ($p = 0.028$), presence of demarcation line (DL) ($p = 0.03$) and presence of irregular type white opaque substance (WOS) ($p = 0.015$), along with flat or depressed macroscopic morphology ($p < 0.001$), were significantly and independently correlated with presence of cancerous lesion. There was no significant difference in the AUC value prediction of cancer between MSP and MVP, while the AUC value of DL and WOS was lower than that of the MVP and MSP. Significant correlations were also evident between irregular or absent MVP, irregular WOS and submucosal cancer invasion. Absent MSP was independently correlated with presence of undifferentiated cancer and microscopic ulcer. Presence of irregular WOS was also significantly related with presence of LVI.
CONCLUSION: MNBI findings are valuable for predicting the presence of cancerous lesions, cancer differentiation, depth of cancer invasion, presence of microscopic ulcer and LVI.

INTRODUCTION: Recently, successful resection of the pyloric tumors by endoscopic submucosal dissection (ESD) using retroflexion in the duodenum has been reported. However, the detailed dissection method of the procedure was not well defined yet. We also had done the retroflexion ESD of dissecting retrogradely from the duodenum to the pyloric channel of duodenal part, after then antegradely from the antrum to the pyloric channel. But, we introduced a new retroflexion method of retrogradely dissecting mucosa from duodenum to transpyloric antrum as extensively as possible since February 2012. We studied the feasibility and effectiveness of the new retrograde prepyloric antral dissection using retroflexion ESD.
AIMS & METHODS: 61 patients with gastric neoplasm involving the pyloric channel underwent ESD from January 2007 to March 2013. In 27 patients, the conventional anterograde ESD were performed without using the endoscope retroflexed in the duodenum. The other 34 patients were procedured by the retroflexion method. Among that 34, the latest 16 patients underwent the new retrograde trans-pyloric antral dissection method. We retrospectively analyzed the procedure times, en bloc rates, complete resection rates and complications associated with each different techniques.
RESULTS: In retroflexion ESD group ($N = 34$), the rate of en bloc resection was 97%, and the rate of complete resection was 96%. The conventional group ($N = 27$) shows relatively 89% and 88%. There were statically significant differences between the 2 procedure methods ($p = 0.01$, $p = 0.02$). But, procedure times had no statically significant (45min vs 33 min, $p = 0.10$). In newly attempted retrograde trans-pyloric antral dissection method group, en bloc resection rate was 100%, and the rate of complete resection was 94%. The average time of procedure was 42min. Compared with the previously procedured retroflexion

ESD, the new technique had an advantages of saving procedure time (42min vs 48min, p = 0.035). but there was no statically significant differences at En-block resection and complete resection (100% vs 94%, p = 0.054 / 94% vs 83%, p = 0.059). Major procedure-related complications consisting of perforation and major bleeding were not encountered in all cases.
CONCLUSION: This new retrograde trans-pyloric antral dissection method for resecting tumors involving the pyloric channel tumor is feasible and effective therapeutic ESD method. So it could be the standard treatment method in such cases, based on the favorable outcomes.

INTRODUCTION: Perioperative chemotherapy (POC) is recommended for patients with advanced resectable gastric (GC) or esophagogastric junction (EGJ) carcinoma. However, its application in elderly patients could be limited due to comorbidities.
AIMS & METHODS: We intend to assess compliance, toxicity and survival in patients proposed to POC who are >70 years old. Among 418 patients with GC or EGJ carcinoma (February 2009 – June 2013), 148 were eligible for POC, of whom 54 were >70 years old (group 1) and 94 <70 years old (group 2). We evaluated clinical characteristics, Charlson comorbidity index (CCI), compliance and toxicity, resectability and survival. In our institution, patients who are >80 years old are excluded from POC. Statistics: chi2, t-Student, Kaplan Meier, Logrank (Stata 10).
RESULTS: Group 1: 54 patients (34 males, mean age 74 years, intestinal type adenocarcinoma 75.9%, diffuse carcinoma 24.1%. Mean CCI 7 (44 patients had >3 comorbidities). Out of 54 patients, 50 started pre-operative chemotherapy but 9 did not complete it (6 – treatment complications; 1 – disease progression; 1 – refusal; 1 – death). 45/50 (90%) patients were submitted to surgery (R0 – 35; R1 – 2; R2 – 1; unresectable disease – 1). Among 23 patients proposed to post-operative chemotherapy, 21 completed 3 cycles. Comparing both groups, 21/54 patients (39%) in group 1 completed POC vs 51/94 (54%) in group 2 (p = 0.1). In group 1, patients experienced more complications during pre-operative chemotherapy (major complications: 15/54 vs 11/94; p = 0.006), fewer patients were submitted to surgery (45/54 vs 94/94; p = 0.002) and started post-operative chemotherapy (22/54 vs 24/94; p = 0.036). However, recurrence and survival were not influenced by age (p = 0.8).
CONCLUSION: In patients with >70 years old, POC is associated with more risks. However, overall and disease free survival in this group is similar to the one observed in younger patients. Therefore, elderly patients should not be excluded from POC considering only their age.

INTRODUCTION: Perioperative chemotherapy (POC) is currently the gold-standard treatment of locally advanced gastric cancer, increasing in 10% the overall survival. Histopatological tumor regression (HTR) is an important objective parameter of response, being associated with a better outcome. However, in patients with limited response, surgery delay may compromise a curative treatment.
AIMS & METHODS: To evaluate in patients proposed to POC: 1) disease progression during POC; 2) HTR and its correlation with clinicopathological variables. 148 patients were proposed for POC and 2 for POC plus intraperitoneal chemotherapy. All surgical specimens were reviewed by two pathologists. HTR was defined by Becker's classification (Ia – no residual tumor; Ib – residual tumor: <10%; II – residual tumor: 10-50%); III – residual tumor: >50%) and correlated with clinicopathological variables and survival. Statistics: chi2, Kaplan-Meier, Logrank (Stata 10).
RESULTS: Among 150 patients, 143 were treated with POC (5 excluded due to disease progression). 135 of whom were submitted to surgery (no surgery: 1 – treatment complications; 4 – death due to chemotherapy; 2 – refusal; 1 – disease progression). Type of resection: R0 – 102; R1 – 5; R2 – 11; unresectable disease – 17. Therefore, disease progression was observed in 34 patients and complications / death in 5. HTR was evaluated in all patients submitted to resection: Ia = 11 (9.3%), Ib = 9 (7.6%), II = 30 (25.4%), III = 68 (57.6%). Besides early tumor staging (T = 1/2) (p = 0.008) no other variables (age, sex, differentiation degree, histologic subtype, tumor location) predicted HRT. All patients with palliative resections had partial (II) or minimal (III) HRT. Patients with Ia/Ib HTR showed less relapse rate (1/20 vs 26/87, p = 0.037) and better overall survival (88 vs 54%, p = 0.041).
CONCLUSION: We didńt find predictive variables of HRT and 39 patients (26%) could have been harmed due to delayed surgery. We admit that the benefit from POC is observed in a small group of patients. It is necessary to identify new markers of HTR which could help in the selection of patients who can really benefit from POC.

INTRODUCTION: Type 3 gastric neuroendocrine tumor (NET) is different from type 1 and type 2 gastric NET in view of management approach. The standard treatment of type 3 gastric NET is suggested as radical gastrectomy. Clinically endoscopic treatment has been tried. The aim of this study was to investigate clinicopathologic features of type 3 gastric NET according to the treatment modalities.
AIMS & METHODS: The Korean Society of Gastrointestinal Cancer has been conducting the Korean Gastroenteropancreatic Neuroendocrine Tumor Registry from 2012. This is a retrospective registry database of gastroenteropancreatic neuroendocrine tumor collected from 16 hospitals between 2002 and 2012. From the Registry, gastric NET patients with normal serum gastrin level (<100 pg/mL) were selected for analysis.
RESULTS: A total of 20 patients from 327 patients with gastric NET were classified as type 3 Gastric NET. The mean age was 55.5 ± 11.52 years. The mean tumor size was 1.08 ± 1.10 cm. According to the WHO 2010 classification, 14 (70%) patients had grade 1, and 5 (25%) patients had grade 2. Endoscopic treatment was performed in 13 (65%) patients, and surgery was performed in 6 (30%) patients. Endoscopic treatment group was younger than surgery group. T1 stage was more prevalent in endoscopic treatment group than in surgery group. After treatment, the median follow-up time was 10 months, during when there was no death related to NET, but there was one disease-progression in surgery group.
CONCLUSION: Clinically, Type 3 gastric NET has been frequently managed by endoscopy. However, proper evidence for endoscopic management should be further evaluated.

INTRODUCTION: Since endoscopic submucosal dissection (ESD) has been developed for en bloc resection of large superficial tumors, it is widely accepted as a reliable therapeutic procedure. This recent innovation allows safe treatment in elderly patients; however, there are only few reports of ESD in very elderly patients, aged 85 years old or above. This study aimed to assess the safety and feasibility of ESD in very elderly patients.
AIMS & METHODS: Between 2013 and 2014, patients with superficial gastrointestinal lesions at our institution were treated with ESD. A standard gastroscope (GIF-Q 260Z, Olympus) and a Dual knife (KD-650Q, Olympus) were used for ESD. All patients were treated under conscious sedation with midazolam (1-10mg). Patients were divided to an elderly group (60-84 years of age) and a very elderly group (85-92 years of age). For both groups, lesion sizes, procedure times, total amounts of midazolam, and ESD-related complications (hypotension, hypertension, hypoxia, arrhythmia, and bleeding) were analyzed.
RESULTS: From the database, we collected data on a total of 67 patients who underwent ESD for esophageal (5 cases), gastric (44 cases), and colorectal lesions (18 cases). In the elderly group, 49 patients were treated (35 males/ 14 females, 60- 84 years of age, mean age 78) and in the very elderly group, 19 patients were treated (4 males / 14 females, 85-92 years of age, mean age 87.9). All patients were successfully treated with ESD in both groups. The mean resected specimen size was 29.8 mm in the elderly group and 28.37 mm in the very elderly group (p = 0.8). ESD time was 79.5 minutes in the elderly group and 64.5 minutes in the very elderly group (p = 0.4). Midazolam doses of 6.7mg and 3.9 mg were administered (p < 0.01), and the complication rate was 12.0% and 57.9% (p < 0.01), in the same groups, respectively. Complications were 1 event of hypotension, 1 of hypertension, 4 of hypoxia, and 3 of bleeding in the elderly group, and 4 of hypotension, 1 of hypertension, 6 of hypoxia, and 0 of bleeding in the very elderly group. Based on the final pathological results, there were 2 cases on whom additional gastrectomy was performed, and 1 case of radiation in the

elderly group; and no additional therapy was performed in the very elderly group.
CONCLUSION: Our data suggests that ESD is safe and feasible in very elderly patients; however, such patients tended to be more sensitive to sedation. Our data also suggests that general anesthesia might not necessary for elderly and very elderly patients undergoing ESD, as long as there is intraoperative management. Further investigations to evaluate various other factors including past medical history, performance status, and anticoagulant medicine are necessary.

INTRODUCTION: Gastric cancer is one of the leading causes of cancer-related deaths worldwide. Progression of gastric cancer follows a several steps from gastritis to atrophy, intestinal metaplasia, dysplasia, and finally cancer.
AIMS & METHODS: To determine the prevalance of precancerous gastric cancer lesions and related common risk factors in our area.
A total of 688 Iranian chronic dyspeptic patients over the age of 40 years were enrolled. The exclusion criteria were pregnancy, history of gastric cancer and gastric surgery. A questionnaire including demographic and clinical data, smoking habits, alcohol use, NSAIDs and regular aspirin use was completed for all subjects. Upper endoscopy was done for all of participants and biopsies were taken according to biopsy protocol. The specimens were studied by two expert GI pathologists blindly.
RESULTS: The prevalence of intestinal methaplasia, gastric atrophy, and dysplasia were 19.8%, 12.8%, and 3.2%, respectively. The mean age of participants was 57.87±9.10. Positive *H.pylori* infection was 64.5%. Age and *H.pylori* infection had a significant association with pathological findings with OR = 3.10, P < 0.01, 95%CI: 1.91-4.72 and OR = 1.03, P < 0.01, 95%CI: 1.03-1.07 respectively. Male gender also had an association with gastric atrophy (OR = 1.57, 95% CI = 1.00-2.46).
CONCLUSION: According to high prevalence of precancerous lesions in patients with chronic dyspepsia over 40 years old, upper endoscopy and gastric mapping sampling for detection of these lesions is recommended in intermediate to high risk areas.

INTRODUCTION: Helicobacter pylori (*H.pylori*) is a gram-negative bacterium that colonizes the stomach of more than half of the world's population during their life span. *H.pylori* infection can cause peptic ulcer, chronic gastritis, mucosa-associated lymphoid tissue (MALT) lymphomas in 20 % of infected individuals. *H.pylori*-induced diseases can be associated with virulence factors of bacteria, host genetic factors and immune response. Virulence factors with potential value for specific pathologies are the cytotoxin associated gene A (cag A), vacuolating cytotoxin A (vacA), outer inflammatory protein A (oipA), the blood group antigen binding adhesin gene A (babA), and the putative neuraminyllactose-binding hemagglutinin homolog (hpaA). *H.pylori* infection induces T helper 1 (Th1) & T helper 17 (Th17) driven immune response in patients.
AIMS & METHODS: The aim of this study was to investigate the correlation of *H.pylori*- induced gastric pathologies with various H.pylor virulence factors and T cell response. Eighty consecutive *H.pylorii* positive endoscopy patients were included in the study. Mucosal biopsy samples were obtained from corpus and antrum parts of the stomach during endoscopy. All samples were tested for various *H.pylori* virulence factors using multiplex polymerase chain reaction (Multiplex-PCR) including cagA, vacA (s1,s2;m1,m2), hpaA, oipA, babA. Also, IFN-g (Th1) and IL-17 (Th17) mRNA expression levels of patients were measured using Quantitative RT-PCR.
RESULTS: Our study group consisted of 43 women and 37 men, mean age was 35 years (range 16-65 y). Twenty-three out of 80 *H.pylori* positive patients also had peptic ulcer. The majority of *H.pylori* strains are positive for hpaA (82% of ulcer, 75% of nonulcer patients) and vacA s1, m2 (52% of ulcer, 73% of nonulcer patients) but negative for oipA and babA. Also, the vast majority of the *H.pylori* strains isolated from nonulcer patients were cagA positive (61%). However, 56% of peptic ulcer patients carry cag A negative *H.pylori* strains. Eleven out of the 80 patients had intestinal metaplasia also (4 of 11 were peptic ulcer patients). All *H.pylori* strains isolated from ulcer and non-ulcer patients with intestinal metaplasia are positive for vacA s1/m2 genotype. All patients with the peptic ulcer and 71% of the nonulcer with intestinal metaplasia patients positive for hpa A. Also the *H.pylori* hpaA positive strains are negative for babA. Additionally, *H.pylori* infected patients are showing mainly a Th17 response (for ulcer 75%, for nonulcer 60 %) instead of Th1 response (for ulcer 25%, for nonulcer 40 %).
CONCLUSION: Overall our data suggests that patients infected with *H.pylori* strains positive for cagA, vacAs1m2, and HpaA are at higher risk for developing Th17- driven intestinal metaplasia.
Disclosure of Interest: None declared

P1076 THE RELATIONSHIP BETWEEN THE DENSITY OF HELICOBACTER PYLORI COLONIZATION AND THE DEGREE OF GASTRITIS SEVERITY

R. Meharich[1,*], M. Tahiri[1], S. Oussama[1], A. Bellabah[1], F. Haddad[1], W. Hliwa[1], W. Badre[1]
[1]*Gastroenterology, Ibn Rochd University Hospital, Casablanca, Morocco*

INTRODUCTION: Helicobacter pylori (*H. pylori*) is a major factor in determining the risk for development of gastric adenocarcinoma through the intermediate steps of atrophic gastritis and intestinal metaplasia. Because *H. pylori* infection is highly prevalent in asymptomatic populations and only a few people develop cancer, additional factors may influence the risk for development of cancer and preneoplastic lesions, once infection is established.
AIMS & METHODS: The aim of this study is to examine the relationship between the density of *H. pylori* colonization in gastric mucosa and the degree of severity of certain histologic parameters of gastritis, such as inflammation activity, atrophy and intestinal mataplasia.
Upper gastrointestinal endoscopy was performed in 410 *H. pylori* positive patients. Status and semiquantitative assessment of *H. pylori* was determined by histology. Gastric biopsies were examined under hematoxylin and eosin and Giemsa stains. Density of *H. pylori* colonization, activity of gastritis, gastric atrophy and intestinal metaplasia at different parts of stomach were graded according to Updated Sydney system.
RESULTS: There were 410 *H. pylori* positive patients (214 males and 196 females), whose age ranged from 18 to 90 years (mean age = 46 years).
The density of *H. pylori* was mild in 30.2%, moderate in 51.5%, and marked in 18.3% of cases.
The results of the study showed that along with the increase of density of *H. pylori* colonization there was a tendency of increasing the gastritis severity:

	Mild density of *H. pylori*	Moderate density of *H. pylori*	Marked density of *H. pylori*	p
Active gastritis	58.1%	70.1%	88%	**$p < 0.01$**
Gastric atrophy	26.6%	33.2%	42.7%	**$p < 0.01$**
Intestinal metaplasia	7.3%	10%	14.7%	$p < 0.1$

CONCLUSION: It can be concluded that a marked density of *H. pylori* colonization significantly increases the gastritis severity.

INTRODUCTION: To study efficacy of eradication therapy and inclusion of Enterojermin as prevention of intestine dysbiosis in the patients with gastroduodenal ulcer disease in association with the Helicobacter pylori.
AIMS & METHODS: In the investigation there were participated 64 patients with ulcer disease of duodenum associated with *H.pylori*. The patients were randomly divided into 2 groups by 32 patients in each group. Group 1 received three-component therapy in the complex with Enterojermin 1 bottle 3 times a day for 14 days. Diagnosis was verified by endoscopy findings. In order to study the state of microbiocenosis of the large intestine the microbiological examination of the feces was performed in the patients before and after treatment.
Group 2 received only three-component therapy with inclusion of IPP pantoprasol (Kontrolok) and 2 antibiotics during 14 days.
RESULTS: The standard three-component scheme of eradication on the basis of kontrolok and two antibiotics seem to be effective in relation to the scarring of the ulcer defect (96.6%), however, exactly in this group of patients to the end of treatment, by data of bacteriological feces cultivation there was noted dysbiosis of stage 3, while by the results of the same data in patients from group 2 who additionally received enterojermin the ulcer scarring was achieved in 97.2% of patients without changes of the state of microbiocenosis of the large intestine.
CONCLUSION: The results of investigations performed showed, that inclusion of the Enterojermin into the complex of eradication therapy of the duodenal ulcer associated with *H.pylori* resulted in attenuation of the undesirable actions of the used antibiotics which effected on the obligatory flora of the large intestine.

INTRODUCTION: Because *Helicobacter pylori* (*H.pylori)* can cause carcinogenesis of the stomach, we need sufficient information for deciding on an appropriate strategy of eradication. Many factors affect the efficacy of eradication including antimicrobial resistance (especially clarithromycin resistance) and *CYP2C19* polymorphism. This study was to survey the efficiency of gastric juice for detecting the clarithromycin resistance and CYP2C19 polymorphism.
AIMS & METHODS: The specimens of gastric juice were collected from all patients while receive gastroendoscopy. DNA was extracted from gastric juice and then *urease A* and *cag A* were amplified by polymerase chain reaction (PCR) for detecting the existence of *H.pylori*. By PCR-RFLP, the *23S rRNA* of *H.pylori* and *CYP2C19* genotypes of host were examined, respectively. During endoscopy examination, biopsy-based specimens were also collected for rapid urease test, culture and histology. The blood samples were also collected for analysis of *CYP2C19* genotypes. We compared the results of gastric juice tests with the results of traditional clinical tests.
RESULTS: Our results showed that the sensitivity(SEN), specificity(SPE), positive predictive value(PPV), negative predictive value(NPV) and accuracy(ACC) of gastric juice test to detect *H.pylori* infection were 92.1%(105/114), 92.9%(143/154), 90.5%(105/116), 94.1%(143/152) and 92.5%(248/268) respectively. The SEN, SPE, PPV and NPV to detect clarithromycin resistance were 97.3% (36/37), 91.5% (43/47), 90.0%(36/40) and 97.7%(43/44) respectively. By using PCR-RFLP, the consistency of human *CYP2C19* gene polymorphism from blood samples and gastric juice was as high as 94.9%(149/157).
CONCLUSION: The manipulated gastric juice is actually an effective diagnostic sample for evaluation of *H.pylori* existence, clarithromycin resistance, and host *CYP2C19* polymorphism.

P1079 HIGH RESOLUTION MELT CURVE ASSAY FOR THE DETECTION OF POINT MUTATIONS ASSOCIATED WITH CLARITHROMYCIN RESISTANCE IN HELICOBACTER PYLORI

T.T. Perets[1], E. Shporn[1], D. Hamouda[1], F. Valle[2], **R.M. Dickman**[3,*], Y. Niv[3]
[1]*Gastroenterology Laboratory, Rabin Medical Center - Beilinson Hospital, Petah Tikva, Israel,* [2]*Faculty of Engineering, Catholic University of Portugal, Rio de Mouro, Portugal,* [3]*Department of Gastroenterology, Rabin Medical Center - Beilinson Hospital, Petah Tikva, Israel*
Contact E-mail Address: *kaiser1974@gmail.com*

INTRODUCTION: Clarithromycin is used in the first line treatment of *Helicobacter pylori* (HP) infection and therefore, the prevalence of HP resistance to clarithromycin is increasing continuously. Clarithromycin resistance, the major cause of HP treatment failure, is attributed to three point mutations (PM): A2142C, A2142G and A2143G within the peptidyl-transferase region of the 23S rRNA gene.
AIMS & METHODS: To develop a fast and accurate method for the detection of the three mutations mentioned previously, from HP isolates. A total of 85 HP isolates, previously obtained from patients with general gastric discomfort, were analyzed using a high resolution melt (HRM) curve analysis. The isolates were compared to 4 reference plasmids that incorporate the three mutations and the wild type (WT) sequences.
RESULTS: There was a perfect correlation between the HRM results and the 85 positive isolates – all were positive using the HRM analysis. Of the 85 isolates, 18 had a WT sequence (21.2%), and 67 (78.8%) contained a 23S rRNA PM. Of the 67 isolates that include 23S rRNA PM, 18 had an A2142G PM sequence (26.8%), 22 had an A2142C PM sequence (32.8%) and 27 had an A2143G PM sequence (40.4%).
CONCLUSION: Our developed HRM assay has a perfect correspondence in its accuracy to other detection methods, including HP isolation. It serves as an option for detecting Clarithromycin resistance prior to administration of HP eradication therapy.

INTRODUCTION: The accuracy and repeatability of breath test in the diagnosis of *Helicobacter pylori* (HP) infection is debatable. Although it has been shown that storage for long periods does not affect the analysis results, no data are available, on the effect of repetitive testing.
AIMS & METHODS: To evaluate the repeatability of the analysis of the breath samples. A total of 202 breath samples were collected in duplicates, before and after administration of 75 mg urea-^{13}C dissolved in 50 ml of orange juice and the results were expressed as delta $^{13}CO_2$ ($d^{13}CO_2$). The cut-off value was 3.5 parts per thousand. Each sample was analyzed in a mass spectrometer 7 days after collection and in intervals of 7 days for the duration of additional 3 weeks. The precision calculation was based on the comparison of the $d^{13}CO_2$ obtained in the three consecutive weeks following the first run to the $d^{13}CO_2$ obtained in the first run. The samples were stored at room temperature.
RESULTS: In the second run, 200 out of the 202 (99%) samples were tested positive for HP and the precision of the $d^{13}CO_2$ was 98.6%. In the third run, 197 out of the 202 (97.52%) samples tested positive and the precision was 99.2%. In the fourth and final run 196 out of the 202 (97%) samples tested positive and the precision was 96.7%.
CONCLUSION: We conclude that short term storage of 1 month, does not affect sample stability and the results of HP diagnosis for up to three consecutive repeats.

INTRODUCTION: Antibiotic resistant strains of H pylori have been increasing worldwide, and it has been speculated that this may account for progressive decrease in eradication rates reported in the literature.
AIMS & METHODS: To assess the prevalence of resistant strains to metronidazole, clarithromycin, and levofloxacin in a cohort of treatment naïve patients undergoing EGDS for dyspeptic symptoms in Italy. 1065 *H.pylori* infected patients who had never been treated for H pylori (median age: 51 years; IQR: 39 and 62 years) underwent upper endoscopy and a biopsy sample was also obtained to perform culture and an *in vitro* antimicrobial susceptibility testing. According to EUCAST 2012 guidelines, susceptibility testing was performed by epsilometer test (Etest) and the following MIC breakpoints were used: resistance to clarithromycin (>0.5 microgram/ml); resistance to metronidazole (>8 microgram/ml), and resistance to levofloxacin (>1 microgram/ml).
RESULTS: Data on resistance were available for 1001 out of 1065 (93.9%) patients. Resistance to metronidazole was found in 38.3%; to clarithromycin in 32.7%; and to levofloxacin in 23.7% of the strains. Double resistance to clarithromycin + metronidazole was found in 10.4%; to clarithromycin + levofloxacin in 2.8%; and to metronidazole + levofloxacin in 5.6% whilst 10.4% of the strains were resistant to metronidazole + clarithromycin + levofloxacin. Female sex was found to be an independent factor of both metronidazole resistance (OR: 2.5, 95% CI = 1.9-3.3; p = 0.0001) and double resistance to metronidazole and clarithromycin (OR: 2.5, 95% CI = 1.5−4.0; p = 0.0001). Similarly, an association with single metronidazole and clarithromycin resistance was found among non-Italian patients (OR: 2.0, 95% CI = 1.4−3.0; p = 0.0001 and OR: 1.8, 95% CI = 1.2- 2.6, p = 0.003 respectively). Smoking, alcohol consumption, and BMI were not significant risk factors.

Resistance	%
ClaR (overall)	32.7
MetroR (overall)	38.3
LevoR (overall)	23.7
ClaR + MetroR	10.4
ClaR + LevoR	2.8
MetroR + LevoR	5.6
ClaR + MetroR + LevoR	10.4

CONCLUSION: 1. Single and multiple-drug resistant strains are widely prevalent in patients who have never been treated for H pylori. 2. First line therapies for H pylori need to account for these changes because failure rates for clarithromycin based therapy will increase further 3. Levofloxacin based triple therapies are unlikely to represent an alternative front-line therapy as the resistance rates are already quite high.

P1082 THE MEANING OF THE BORDERLINE RANGE OF THE 13C-UBT VALUE AFTER HELICOBACTER PYLORI ERADICATION

Y.H. Kwon[1,*], N. Kim[1], J.Y. Lee[1], Y.J. Choi[1], K.C. Yoon[1], J.J. Hwang[1], H.J. Lee[1], A.R. Lee[1], Y. Jung[1], H. Yoon[1], C.M. Shin[1], Y.S. Park[1], D.H. Lee[1]
[1]*Internal medicine, Seoul National University Bundang Hospital, Sungnam, Korea, Republic Of*

INTRODUCTION: The ^{13}C-urea breath test (^{13}C-UBT) (UBiTkit; Otsuka Pharmaceutical, Tokyo, Japan) is a reliable non-invasive method for diagnosing *Helicobacter pylori* (*H. pylori*) infection. However, in some range of ^{13}C-UBT value, the accuracy is doubtful after eradication of *H. pylori* infection.
AIMS & METHODS: In this study, we evaluated the diagnostic accuracy of the ^{13}C-UBT value ranging from 2.0‰ to 3.0‰ and affecting factors were evaluated. Among 820 patients who showed the result of the ^{13}C-UBT value from 2.0‰ to 3.0‰, one hundred seventy one patients were compared with the results of endoscopic biopsy-based methods (modified Giemsa study, CLOtest, and culture) from antrum as well as body for two years or more endoscopic surveillance. In addition, the possible affecting factors such as age, gender, underlying disease, history of gastrectomy, number of eradications, and histological atrophy and intestinal metaplasia were analyzed.
RESULTS: Of 91 and 80 patients who showed ^{13}C-UBT positive and negative results after *H. pylori* eradication, 38 patients (41.8%) and 2 patients (2.5%) were proved false positive and false negative results by biopsy-based methods evaluation, respectively. The sensitivity, specificity, false positive rate, and false negative rate of ^{13}C-UBT were 96.4%, 67.2%, 33.8%, and 3.6%. The positive predictive value and negative predictive value were 58.2% and 97.5%. The positive likelihood ratio and negative likelihood ratio is 2.85 and 0.05. In multivariate analysis (Table 1), moderate to severe intestinal metaplasia (OR = 1.953, 95%CI = 1.208-3.159, p = 0.006) and two or more trial of treatment for *H. pylori* (OR = 2.482, 95%CI = 1.109-5.555, p = 0.027) were significantly related false positive result of ^{13}C-UBT value after *H. pylori* eradication.
Table 1. The risk factors of false positive results for ^{13}C-Urea breath test

	Final UBT result		Univariate p-value	Multivariate p-value
	Positive	False positive		
Gender (Male:Female)	30(56.6%)/ 23(43.4%)	24(63.2%)/ 14(36.8%)	NS	
Age (≥ 60 years old)	23 (43.4%)	18 (47.4%)	NS	
Diabetes mellitus	6 (11.38%)	3 (7.9%)	NS	
Hypertension	11 (20.8%)	7 (18.4%)	NS	
History of gastrectomy	12 (22.6%)	8 (21.1%)	NS	
The number of eradication for *Helicobacter pylori* (Once / Two or more)	40(75.5%)/ 13(24.5%)	19(50.0%)/ 19(50%)	0.034	0.027
The degree of gastric mucosal atrophy (None to mild/moderate to severe)	49(92.4%)/ 4(7.5%)	31(81.6%)/ 7(18.4%)	NS	
The degree of gastric intestinal metaplasia (None to mild/moderate to severe)	44 (83.0%)/ 9(17.0%)	21(55.3%)/ 17(44.7%)	0.015	0.006

CONCLUSION: In the range of ^{13}C-UBT value from 2.5‰ to 3.0‰, false positive was found to be increased in this study. In this case endoscopic surveillance with biopsy based evaluation would be helpful to avoid unnecessary additional treatment for *H. pylori* infection.

INTRODUCTION: There have been a few reports suggesting that N-acetylcysteine (NAC) which is mucolytic and antioxidant could destroy biofilm formed by *Helicobacter pylori* (*H. pylori*). The aim of this study was to identify whether the addition of NAC on first-line sequential therapy for *H. pylori* infection could improve the eradication rate.
AIMS & METHODS: Ninety nine patients with *H. pylori* infection were randomly assigned to receive either sequential therapy with (study group, n = 49) or without (control group, n = 50) NAC. Sequential therapy consisted of rabeprazole 20mg and amoxicillin 1g for the first 5 days, followed by rabeprazole 20mg, clarithromycin 500mg and metronidazole 500mg for the remaining 5 days; all drugs are given twice daily. For study group, NAC 400mg b.i.d. was added for the first 5 days of sequential therapy. Four weeks after completing therapy, *H. pylori* eradication was evaluated by the ^{13}C-urea breath test, histology, or the rapid urease test. The eradication rate, drug compliance, and adverse event rates were compared between the two groups.
RESULTS: The eradication rates by intention-to-treat analysis were 58.0% (29/50) and 67.3% (33/49) in the control group and the study group, respectively ($P = 0.336$). The eradication rates by per-protocol analysis after excluding16.2% of patients who were lost to follow-up were 70.0% (28/40) and 80.5% (33/41) in the control group and the study group, respectively ($P = 0.274$). Compliance was very good in the both groups (control/study group: 95.2%/100%). The adverse event rates were 26.2% (11/42) and 26.8% (11/41) in the control group and the study group, respectively ($P = 0.947$).
CONCLUSION: The addition of NAC to first-line sequential therapy for *H. pylori* infection resulted in an approximately 10% increase in eradication rate. However, this feature did not reach statistical significance, indicating that larger trials are needed.

INTRODUCTION: The aim of this study was to evaluate the efficacy of a moxifloxacin-containing triple therapy as second-line treatment for *Helicobacter pylori* infection. We investigated the value of triple therapy with rabeprazole, moxifloxacin, and amoxicillin in second-line treatment and the impact of treatment of treatment duration on eradication success.
AIMS & METHODS: Between 2011 and 2013, one hundred and thirty-three patients who had failed first-line proton pump inhibitor-based triple therapy were randomized to oral rabeprazole (20 mg b.i.d.), axoxicillin (1000 mg b.i.d.), and moxifloxacin (400 mg q.d.) for either 7 (RAM-7 group, n = 52) or 14 days (RAM-14 group, n = 81). The eradication was compared by confirming of eradication rate. *H. pylori* status was evaluated by histologic finding, Campylobacter-like organism test and ^{13}C urea breath test. Antibiotic susceptibility test for *H. pylori* was not done in all cases.
RESULTS: The eradication rates by intention-to-treat analysis were 69.2% (36/52) and 81.4% (66/81) in the RAM-7 group and the RAM-14 group, respectively (p = 0.031). The eradication rates by per-protocol analysis after excluding 8.4% of patients who were lost to follow-up were 73.5% (36/49) and 90.4% (66/73) in the RAM-7 group and the RAM-14 group, respectively (p = 0.013). Compliance was very good in the both groups (RAM-7/RAM-14 group: 100%/100%). The adverse event rates were 26.5% (13/49) and 20.5% (15/73) in the RAM-7 group and the RAM-14 group, respectively (p = 0.441). There was no significant difference in the 1st-line treatment, previous ulcer history, smoking, alcohol, and endoscopic finding between RAM-7 and RAM-14 group.
CONCLUSION: Second-line *H.pylori* eradication therapy with rabeprazole, amoxicillin, and moxifloxacin is very effective and well tolerated. Fourteen days of treatment significantly showed lower adverse event rates (20.5% vs 26.5%) and higher eradication rates (90.4% vs 73.5%, p = 0.013) than seven days of treatment. Compliance was very good in both groups (100%).

INTRODUCTION: Triple therapy for *H. pylori* infection is discouraged when clarithromycin resistance rate is > 15-20%. Despite increasing antimicrobial resistance, triple therapy keeps on being the most prescribed eradication therapy, almost always on an empirical basis (this is, with unknown resistance rates). In this context, it remains unknown whether a non-bismuth quadruple concomitant therapy may be a preferable choice as empiric first-line eradication therapy.
AIMS & METHODS: To compare the effectiveness and safety of two optimized triple and concomitant quadruple therapies for *H. pylori* empiric treatment. Prospective multicenter study in 16 Spanish hospitals in which triple therapy was the first-line eradication regimen in clinical practice. In a first 3-month phase, patients received an optimized triple therapy, defined by esomeprazole (40 mg/12h), amoxicillin (1 g/12h) and clarithromycin (500 mg/12h) for 14 days. Over the second 3-month phase, patients received an optimized concomitant treatment, which consisted of an optimized triple therapy plus metronidazole (500 mg/12h) for 14 days.
RESULTS: 658 consecutive patients have been included so far (360 triple, 298 concomitant). Mean age 50 years, 58% females, 21% smokers, and 26% peptic ulcer. Intention-to-treat eradication rates were 82.6% (95%CI = 79-87%) and 91.2% (88-96%) for triple and concomitant therapy (p = 0.008). Respective per-protocol rates were 83% (79-88%) and 93.7% (89-96%) (p = 0.003). Compliance was 92% for both therapies. Adverse events (AEs) were reported in 54% of patients (triple 42% vs. concomitant 61%, p < 0.001). The most common AEs were metallic taste (46%), diarrhea (18%) and nausea (11%), with significant differences (p < 0.05) between therapies. Concomitant therapy achieved good eradication rates (> 90%) in a higher proportion of centers (64% vs. 35%) and triple therapy led to unacceptable cure rates (<80%) in a higher proportion of centers (41% vs. 14%).
CONCLUSION: On an empiric basis, an optimized non-bismuth quadruple therapy achieved significantly higher cure rates (>90%) when compared to an optimized triple therapy. Addition of metronidazole to an optimized triple therapy increased eradication rates by 10%, resulting in a higher rate of adverse events but withouth impairing compliance. An optimized triple therapy achieved unacceptable cure rates in 41% of participating centers, so concomitant therapy should be the choice for empiric eradication in clinical practice.

INTRODUCTION: Second-line bismuth-containing quadruple therapy is complex and frequently induces adverse effects. A triple rescue regimen containing levofloxacin is a potential alternative; however, resistance to quinolones is rapidly increasing.
AIMS & METHODS: AIM: To evaluate the efficacy and tolerability of a second-line triple regimen containing levofloxacin in patients whose *Helicobacter pylori* eradication treatment failed and to assess whether the efficacy of the regimen decreases with time.
METHODS: *Design:* Prospective multicenter study. *Patients*: Patients in whom treatment with a regimen comprising a proton pump inhibitor (PPI), clarithromycin, and amoxicillin had failed. *Intervention:* Levofloxacin (500 mg b.i.d.), amoxicillin (1 g b.i.d.), and PPI (standard dose b.i.d.) for 10 days. *Outcome*: Eradication was confirmed using the ^{13}C-urea-breath test 4-8 weeks after therapy. *Compliance/tolerance:* Compliance was determined through questioning and recovery of empty medication envelopes. Incidence of adverse effects was evaluated by means of a questionnaire.
RESULTS: The study sample comprised 1,400 consecutive patients (mean age 49 years, 49% males, 28% peptic ulcer and 72% with functional or non-investigated dyspepsia), of whom 96% took all medications correctly. Per-protocol and intention-to-treat eradication rates were 74.6% (95% CI, 72-77%) and 73.4% (71-76%). Efficacy (intention-to-treat) was 76% in the year 2006, 68% in 2007, 70% in 2008, 76% in 2009, 73% in 2010, 71% in 2011, 75% in 2012, and 76% in 2013. In the multivariate analysis, none of the studied variables (including diagnosis and year of treatment) were associated with success of eradication. Adverse effects were reported in 19% of patients, most commonly nausea, metallic taste, myalgia, abdominal pain, diarrhea and aphthous stomatitis. In 9 cases, the adverse effects were classified as "intense" (nausea, metallic taste and myalgia), but none of them was severe.
CONCLUSION: Ten-day levofloxacin-containing therapy is an encouraging second-line strategy, providing a safe and simple alternative to quadruple therapy in patients whose previous standard triple therapy has failed. The efficacy of this regimen remains stable with time.

INTRODUCTION: The resistance rates of *H. pylori* to clarithromycin, metronidazole and quinolone are known to be over 20% at the tertiary hospital in S. Korea.
AIMS & METHODS: The aim of this study was to evaluate the ultimate eradication rate of *H. pylori* after 1st, 2nd or 3rd line therapy and to compare the efficacy of each treatment regimen at the tertiary institute in Korea. 2,444 patients infected with *H. pylori* were prospectively treated with proton pump inhibitor (PPI)-based triple therapy for 7 days. In case of treatment failure or recurrence, moxifloxacin-based triple therapy (MNA) or bismuth-based quadruple therapy (QUAD) was randomly given. When the 2nd-line treatment failed or *H. pylori* recurred, the unused MNA or QUAD was used as a third-line treatment.
RESULTS: The intention-to-treat (ITT) and per-protocol (PP) rates of 'final' eradication up to 3rd line treatment were 69.1% and 92.1%, respectively. In detail, six-hundred eleven patients (25% of total population) were lost to follow up or refused further treatment at certain time during specific treatment plan. For the patients with 1st-line treatment failure (n = 415), the eradication rates (ITT/PP) with 2nd-line treatment were 49.9%/74.4%. There was no significant difference in the efficacy between MNA and QUAD as 2nd line treatment (p = 0.862/0.480, as ITT/PP, respectively). The 'final' eradication rates (ITT/PP) of recurred patients after the 1st line treatment (n = 63, mean interval from 1st line to recurrence: 26.9±19 mos) were 84.1%/94.1%.
CONCLUSION: The final PP eradication rate was relatively high, 92.1% at the tertiary hospital in Korea in spite of high antibiotic resistance rates. However, high rate of refusal of further treatment and follow-up loss made ITT eradication rate low. There should be strategy to raise the treatment adherence.

INTRODUCTION: *H. pylori* (Hp) infection affects almost 50% of the world population, and it is recognized as first grade risk factor for gastric cancer. Moreover, it is commonly considered a potential cause of dyspepsia and peptic ulcer. In European populations, without alarm signs, the test-and-treat strategy is usually preferred rather than other invasive investigations. Clarithromycin-containing triple therapy is considered the first line treatment. However, several warnings about the reduction of its efficacy has been published in the last years.
AIMS & METHODS: To assess the prevalence of active Hp infection in patients with dyspepsia and the eradication rate of the clarithromycin-based triple therapy.
We retrospectively evaluated the presence of active Hp infection in consecutive patients undergoing urea breath test (UBT) because of dyspepsia (i.e. epigastric pain, bloating, nausea, early satiety, post-prandial fullness, belching) without alarm signs and family history of gastric cancer. Patients were asked to stop proton pump inhibitors or antibiotics at least 15 days prior to testing. All the tests were performed directly at our Department, by specialized nurses, after an overnight fast, with the same kit (Sofar, Milano, Italy). Two basal breath samples and two breath samples 30 min after the ingestion of labelled urea diluted in acidic solution, were collected from every patients.
RESULTS: From July 2010 to July 2012, 3000 patients referred to our ambulatory (1881F/1119M; mean age 54, 6-92) because of dyspeptic symptoms. Prevalence of active H pylori infection was 32.1% (963). The prevalence per age-related decades was: 26%(<20yy), 33%(21-30), 34%(31-40; 41-50; 51-60), 33% (61-70), 32%(71-80; >80yy) [p = n.s.]. Prevalence was higher in women 33.7% (n = 634) than in men 29.4% (n = 329), but this tendency failed to reach statistical significance [p = 0.07]. No differences in terms of age were found between male and female Hp-positive patients (n.s). One hundred and forty-five patients (10.9%) were originally from South-America (111F/703M; mean age 41, 10-76) and younger than Italian patients [p < 0.001]. Higher UBT values were positively related with female sex (r2:0.01; p < 0.01). Only 789 (82%) positive patients returned after the first treatment attempt and 31%

(n = 244) had a second positive test, but no differences in terms of age, sex and ethnic group were found.
CONCLUSION: In our population, the prevalence of active *H. pylori* infection in patients with dyspepsia was similar to that reported by previous analysis in the general Italian population. Nevertheless, we found a dramatic low eradication rate achieved by using clarithromycin-containing triple therapy, thus confirming the worrisome reports of recent studies.

P1090 DIFFERENT ANTIBIOTIC SUSCEPTIBILITY BETWEEN ANTRUM AND CORPUS OF THE STOMACH, A POSSIBLE REASON FOR TREATMENT FAILURE OF HELICOBACTER PYLORI INFECTION

M. Selgrad[1,*], I. Tammer[2], C. Langner[1], J. Bornschein[1], J. Meissle[1], M. Varbanova[1], A. Kandulski[1], T. Wex[1], D. Schlüter[1], P. Malfertheiner[1]

Contact E-mail Address: *michael.selgrad@med.ovgu.de*

INTRODUCTION: *H. pylori* eradication rates with standard triple therapy show a constant decrease, mainly due to increasing antibiotic resistance. Antibiotic susceptibility guided therapy is recommended in patients receiving rescue therapy. So far, there are no reports whether only one biopsy from one anatomic site of the stomach is sufficient to detect antibiotic resistant *H. pylori* strains.
AIMS & METHODS: Aim: We assessed whether antibiotic resistance varies between the antrum and corpus of the stomach of patients that are either *H. pylori* therapy-naive or pre-treated.
Methods: *H. pylori* strains were isolated from antrum and corpus biopsies from 66 patients that underwent gastroscopy for different clinical indications. Susceptibility to commonly used antibiotics for *H. pylori* treatment was determined by Etest.
RESULTS: Primary, secondary and tertiary resistance to clarithromycin was 6.9%, 53.8% and 83.3%, retrospectively. Metronidazole and levofloxacin resistance also increased according to the number of previous treatments (17.2%, 69.2%, 83.3%; 13.8%, 23.1%, 33.3%). Tertiary resistance to rifabutin was detected in 12.5% of patients. Discordant antibiotic susceptibility between antrum and corpus isolates for different antibiotics was seen in 15.2% of the patients. DNA fingerprinting analysis revealed no substantial differences among DNA patterns between antrum and corpus isolates in the majority of patients suggesting an infection with a single *H. pylori* strain.
CONCLUSION: Different antibiotic susceptibility between antrum and corpus biopsies is a common phenomenon and a possible explanation for treatment failure. Resistant *H. pylori* strains may be missed if just one biopsy from one anatomic site of the stomach is taken for *H. pylori* susceptibility testing.

INTRODUCTION: To evaluate efficiency of using sequential *H. pylori* eradication therapy in patients with gastric and duodenal ulcer disease of Yekaterinburg.
AIMS & METHODS: 95 patients (55 male, 40 female, average age – 43 (16-74) years) with exacerbated gastric and duodenal peptic ulcer with severe and complicated clinical course: giant and multiple ulcers (42 patients), gastroenterorrhagia in near-term (2-3 weeks) anamnesis (48 patients), perforations (5 patients) are examined. Biopsy material of gastric and duodenal mucous tunic from standard and periulcerous areas is researched with electronic and light microscopy methods on machine «Morgagni 268». *H. pylori* diagnostic methods are histological, immunological methods, such as identification the quantity of anti - *H. pylori* IgG in blood serum, evaluation of *H. pylori* antigen in stool, detection DNA and pathogenic factors of *H.pylori* (CagA, VacA s1/s2) by PCR with fluorescent detection in real time. Intensity of gastritis is estimated by visual-analogy scale and system OLGA. Sequential therapy (pantoprazole, amoxycillin, clarithromycin, metronidazole) used in 75 patients (1 group), standard triple therapy (pantoprazole, amoxycillin, clarithromycin) – in 20 patients (2 group). All patients did not previously receive an eradication therapy. Control carried out in 2, 4, 8 weeks.
RESULTS: Ulcer cicatrization is attained in 70 (93%) of 1 group patients and 15 (75%) of 2nd group patients in 2 weeks. 100% ulcer cicatrization is attained in both groups in 4 weeks. Intensity of gastritis and efficiency of *H. pylori* eradication are estimated after 8 weeks. Before treatment the I grade of inflammation is discovered in 7 (9%) of 1 group patients, 1 (5%) of 2nd group patients, the II grade of inflammation – in 10 (13%) of 1 group, 3 (15%) of 2 group, III – 52 (69%) of 1 group, 13 (65%) of 2 group, IV – 6 (8%) of 1 group, 3 (15%) of 2 group. After treatment the I grade of inflammation is discovered in 45 (60%) of 1 group, 10 (50%) of 2 group, II – 29 (39%) of 1 group, 7 (35%) of 2 group, III – 1 (1%) of 1 group, 3 (15%) of 2 group, IV grade of inflammation aren't discovered at all ($p < 0,05$). Efficiency of *H. pylori* eradication in using sequential therapy is 96%, standard triple therapy – 87%.
CONCLUSION: Using sequential regimen of eradication of *H.pylori* infection in Russian patients with severe peptic ulcer disease demonstrated higher efficacy compared with standard triple therapy.

INTRODUCTION: With increased survival in cystic fibrosis (CF), gastrointestinal complications are becoming more prevalent. Small intestinal bacterial overgrowth (SIBO) has been discussed as a determinant of intestinal inflammation in CF patients before lung transplantation (LuTx). Data on intestinal inflammation in CF patients in the post-transplant setting are scarce.
AIMS & METHODS: Aim of this ongoing prospective study is to evaluate intestinal inflammation and its underlying mechanisms in CF patients after LuTx. So far, 23 adult CF patients after LuTx (all with pancreatic insufficiency, median age 34y, range 24-58y; 42% male) attending our outpatient clinic were evaluated for presence of intestinal symptoms. Intestinal inflammation was assessed by stool calprotectin (Bühlmann Co, Switzerland) and serum antisaccharomices cerevisiae antibodies (ASCA IgG, IgA, INOVA Co, San Diego,USA) measurement. Intestinal infection was excluded by stool cultures, celiac disease by negative EMA/TTG antibodies. Glucose-H2 breath test was performed to diagnose SIBO. 5 non-CF patients with solid organ transplantation were recruited as controls.
RESULTS: 10 of 23 (43%) patients presented with intestinal symptoms. Calprotectin was increased (cut off 100 μg/g stool) in 65% of patients (mean 186±82 μg/g). 83% of patients were positive for either serum IgG (65%, mean 49±23 U/ml) or IgA (61%, mean 35±17 U/ml) ASCA. In 53% of patients SIBO was diagnosed. Patients with SIBO had markedly increased fecal calprotectin levels (median 177±94 μg/g) compared with patients without SIBO (median 98±63 μg/g) ($p < 0,05$). Patients with intestinal symptoms had significant increase in IgG and IgA ASCA, but no difference in calprotectin was found in comparison to asymptomatic CF patients. No differences in serum IgG, IgA ASCA or stool calprotectin levels were observed between transplanted patients with or without CF.
CONCLUSION: Gastrointestinal symptoms and elevated markers of intestinal inflammation are common in CF patients after LuTx. SIBO may be a causative factor for increased calprotectin in these patients. Our data suggest that not only CF, but also other factors, such as immunosuppression, may contribute to the intestinal inflammation in transplant setting.

INTRODUCTION: Gender differences in the pathophysiological response to ischemia-reperfusion (IR) have particularly been recognized in cardiovascular and cerebral systems. However, it is unknown if sexual dimorphism exists in human intestinal IR, a frequent occurring and highly lethal disease. Recognition of such differences and elucidation of the underlying pathophysiological mechanisms could lead to more evidence-based medicine for females, and the development of novel therapeutic strategies to reduce IR-associated morbidity and mortality. Therefore, we aimed to investigate sex differences in human intestinal mucosal responses to IR.
AIMS & METHODS: Intestinal IR was studied using a human experimental model. In 16 patients (M8:F8) undergoing pancreaticoduodenectomy, an isolated part of jejunum was subjected to 45 minutes of ischemia (45I) followed by 30 (30R) or 120 minutes of reperfusion (120R). Intestinal tissue was collected at all time points to assess morphology (hematoxylin/eosin (HE)), neutrophil influx (myeloperoxidase (MPO)) and Paneth cell apoptosis (Lysozyme/M30 double staining). Endoplasmic reticulum (ER) stress was analyzed using an X-box binding protein-1 (XBP1) splicing assay and XBP1-spliced/XBP1-unspliced (XBP1s/XBP1u) ratios were calculated. QPCR techniques were used to determine inflammatory cytokine expression. Arteriovenous (V-A) concentration differences of intestinal fatty acid binding protein (I-FABP) were measured using an enzyme-linked immunosorbent assay (ELISA) to assess the level of enterocyte damage. Results were analyzed using Mann-Whitney U tests. Data are presented as mean±SEM. A P-value < 0.05 is considered statistically significant.
RESULTS: HE staining revealed more extensive small intestinal epithelial damage in male subjects compared to females. In line, I-FABP V-A concentrations differences were higher in males compared to females, both at 45I (233.9±73.3 ng/ml vs 55.5±18.3 ng/ml, $P < .05$) and at 45I30R (79.2±19.4 ng/ml vs 24.4±6.6 ng/ml, $P < .05$). Furthermore, male small intestine showed higher XBP1s/XBP1u ratios at 45I30R than female small intestine (4.3±0.8 vs 2.2±0.4, $P < .05$), indicating enhanced ER stress in males. As expected, this was associated with a higher number of apoptotic Paneth cells per crypt in male subjects compared to females at 45I (5.8±1.2 vs 1.7±0.4, $P < .05$) and 45I30R (18.3±2.9 vs 7.6±1.9, $P < .05$). Furthermore, males had a more pronounced influx of neutrophils per villus at 45I30R (6.9±1.2 vs 3.6±0.6, $P < .05$) and a higher relative

mRNA expression of inflammatory cytokines TNF-a and IL-10 after 45I120R, compared to females (2.6 fold and 6.4 fold respectively, P < .05).
CONCLUSION: The human female small intestine is better protected from IR-induced epithelial damage than the male small intestine, and correspondingly displayed notably less inflammatory responses. Unravelling the molecular mechanisms underlying this effect could lead to new therapeutic strategies for intestinal IR.

P1094 ENVIRONMENTAL ENTEROPATHY: IMAGING THE CELLULAR BASIS OF DISRUPTED BARRIER FUNCTION

P. Kelly[1,*], J. Louis-Auguste[1], T. Banda[2], R. Soko[2], E. Besa[2], R. Banda[2]
[1]*BLIZARD INSTITUTE, London, United Kingdom,* [2]*TROPGAN, Lusaka, Zambia*

INTRODUCTION: Environmental enteropathy (EE), originally termed tropical enteropathy, is very common in overcrowded living conditions in developing countries. It predisposes to growth failure in the young, and probably to poor performance of oral vaccines. By permitting microbial translocation it probably contributes to insidious systemic immune activation. In order to understand the impairment of barrier function in EE, we performed confocal laser endomicroscopy (CLE) in 57 healthy volunteers from a poor community in Lusaka, Zambia.
AIMS & METHODS: These asymptomatic volunteers were drawn from a community in which we have been conducting studies for 15 years. On day 1 a 3 hour lactulose: mannitol permeability and zinc absorption test was performed. On day 2 CLE of the duodenal mucosa was performed with diazepam/pethidine sedation and 5-10ml 2% intravenous fluorescein, and images collected for 10 minutes exactly (mean number of images analysed 135, SD57). Biopsies were subsequently taken to analyse villous morphology and markers of bacterial translocation and inflammation.
RESULTS: In the first 57 volunteers (40 female, 17 male) studied, a wide range of villous architectural patterns was observed from leaf-like to convolutions. Similarly, a wide range of barrier abnormalities was observed, with some volunteers showing severe fluorescein leakage within one minute of fluorescein injection. Epithelial breaks, particularly multicellular breaks (microerosions), were strongly correlated with the rate of fluorescein efflux (Spearman's rho 0.92; P < 0.0001). The number of plumes was almost as strongly correlated (rho = 0.69; p = 0.0004). Fluorescein leakage and epithelial barrier defects were not correlated with villous architectural change (rho = 0.01: p = 0.96), suggesting that villous remodelling and barrier defects are differentially determined. Fluorescein plumes were correlated with serum CD163, a marker of Kupffer cell activation, but only in HIV seropositive individuals (rho = 0.76; P,0.05).
CONCLUSION: CLE permits imaging of small intestinal epithelial barrier defects and suggests that cellular breaches are major routes of intestinal permeability but independent of villous architecture.

P1095 CELECOXIB MONOTHERAPY DEVELOPED FEWER SMALL INTESTINAL MUCOSAL BREAKS COMPARED TO LOXOPROFEN AND LANSOPRAZOLE CONCOMITANT TREATMENT: A DOUBLE-BLIND, RANDOMIZED, CONTROLLED TRIAL

S. Fujimori[1,*], R. Hanada[2], M. Hayashida[3], T. Sakurai[4], M. Keigo[1], I. Ikushima[2], C. Sakamoto[1]
[1]*Department of Gastroenterology, Graduate School of Medicine, Nippon Medical School,* [2]*Medical Co. LTA, Sumida Hospital,* [3]*3) The Third Department of Internal Medicine, Kyorin University School of Medicine,* [4]*Department of Gastroenterology and Hepatology, National Center for Global Health and Medicine, Tokyo, Japan*

INTRODUCTION: Two American studies report that COX-2 selective inhibitor celecoxib develops fewer small intestinal injuries than non-selective NSAIDs (1,2). Loxoprofen, which is a pro-drug for gastroprotection of non-selective NSAIDs, is the most frequently used in Japan for pain relief.
AIMS & METHODS: The purpose of the study was to compare celecoxib with loxoprofen for small intestinal protection, and to confirm celecoxib suppression of small intestinal mucosal injury compared with non-selective NSAIDs in Japanese people. 150 healthy volunteers between 40 to 70 years of age were enrolled. After medical check-up including physical, bloody, urinary examination, and fecal occult blood test, subjects were randomly assigned to either the CEL-group to receive celecoxib (200 mg daily) or the LOX-group to receive loxoprofen (180 mg daily) in addition to lansoprazole (15 mg daily). All drugs were pulverized to fill capsules and were prepared in the same manner as placebo capsules. After randomization, all subjects were first examined by baseline capsule endoscopy (baseline CE). After 14 days, subjects underwent post-treatment CE. Baseline and post-treatment CE were evaluated for small intestinal mucosal breaks, and the findings compared between the two groups. All capsule endoscopy data including baseline and post-treatment CE were evaluated blindly by 3 reviewers. Final evaluation of small intestinal mucosal breaks was made based upon the agreement of reviewers agreement before opening the key. This study was approved by the Ethics Committee at Nippon Medical School and Kyushu clinical pharmacology research clinic institutional review board, and all subjects provided written informed consent for enrollment (UMIN: 000007936). The study was funded by Pfizer Japan Inc.
RESULTS: Among 74 subjects (49±6 years of age, F/M: 36/38)in the CEL-group, five were excluded from analysis due to four incomplete CE examinations and one withdrawal from the study due to influenza. Among 76 subjects (49±7 years of age, F/M: 39/37)in the LOX-group, four were excluded from analysis due to three incomplete CE examinations and one withdrawal due to non-compliance for study protocol. Thus, 69 subjects in the CEL-group and 72 subjects in the LOX-group were compared. Small intestinal mucosal breaks were detected 0.2±1.1 at baseline and 0.3±1.0 at post-treatment in the CEL-group, and 0.4±1.8 at baseline and 6.8±21.5 at post-treatment in the LOX-group. Small intestinal mucosal breaks were much fewer in the CEL-group than in LOX-group (P < 0.0001). The percentage of subjects with at least one mucosal break at post-treatment was also lower in the CEL-group (10%) than in the LOX-group (49%) (P < 0.0001).
CONCLUSION: Celecoxib monotherapy developed fewer small intestinal mucosal breaks than loxoprofen and lansoprazole concomitant treatment in the Japanese population.

P1096 DIETARY WHEAT ALPHA-AMYLASE/TRYPSIN INHIBITORS (ATIS) EXACERBATE ALLERGIC AIRWAY INFLAMMATION

V.F. Zevallos[1,*], V. Raker[2], J. Maxeiner[3], M. Kahn[1], K. Steinbrink [2], D. Schuppan[1]
[1]*Institute of Translational Immunology,* [2]*Dermatology,* [3]*Asthma Core Facility, Research Centre Immunology (FZI), University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany*
Contact E-mail Address: *zevallos@uni-mainz.de*

INTRODUCTION: Wheat alpha-amylase/trypsin inhibitors (ATIs) are potent activators of innate immunity by engaging the toll like receptor 4 (TLR4)-MD2-CD14 complex in monocytes, macrophages and dendritic cells (Junker Y et al, J Exp Med 2012). ATIs, non-gluten proteins, that occur as contaminants even in "pure" gluten preparations are implicated in the pathogenesis of celiac disease (CD) and other autoimmune / inflammatory diseases.
AIMS & METHODS: We would like to investigate the effects of dietary ATIs on allergic airway inflammation. Therefore, female C57BL/6 mice on a gluten-free diet (GFD) were sensitised and challenge with ovalbulmine (OVA). Animals were divided in 5 groups: 1 continued with the GFD and mock-sensitised with PBS, 2: continued with the GFD and sensitised with OVA, 3: changed to a diet containing 25% gluten (containing amounts of ATIs equivalent to the human wheat based diet), 4: changed to a diet containing purified ATIs, and 5: changed to a diet containing 25% gluten de-enriched of ATIs. Furthermore, we evaluated the effect of ATIs, OVA or both during sensitisation and challenge.
We measured invasive lung function, bronchoalveolar lavage (BAL), IgG1 levels and proliferation of splenocytes and cytokine secretion after OVA stimulation. In addition, histological sections of lung were stained with Hematoxylin and Eosin (HE) *and* Periodic acid–Schiff (PAS) and scored according to the degree of cell infiltration and goblet cell hyperplasia.
RESULTS: Mice on a GFD sensitized with PBS did not develop airway hyperreactivity (AHR) after local provocation with OVA. Interestingly, mice on a GFD or on a diet containing 25% gluten de-enriched of ATIs and sensitized with OVA developed a reduced AHR compared to mice fed the pure ATIs rich diet or 25% gluten diet. Similar results were observed for IgG1 production, eosinophilic infiltration in BAL (HE) and mucus production (PAS) in the lung. We also observed that animals sensitised with OVA/ATIs and challenged with OVA, showed higher AHR compared to animals sensitised with OVA or ATIs alone.
CONCLUSION: We demonstrate that 1) dietary ATIs enhance allergic airway inflammation in OVA-challenged mice 2) sensitization with ATIs/OVA enhances further AHR in OVA-challenged mice 3) a gluten-free (ATI-free) diet appears to have a protective effect on allergic airway inflammation 4) Gluten depleted of ATIs has a reduced stimulatory effect compared with gluten containing ATIs or ATIs alone. Therefore, ATIs appear to be major and clinically relevant nutritional triggers of innate immunity in allergic airway inflammation and other autoimmune diseases.

P1097 MILD HISTOLOGICAL ABNORMALITIES IN NON-COELIAC GLUTEN SENSITIVITY DO NOT REPRESENT EARLY COELIAC DISEASE

I. Aziz[1,*], T. Key[2], J.G. Goodwin[2], D.S. Sanders[1]
[1]*Department of Gastroenterology,* [2]*Department of Histocompatability & Immunogenetics, Royal Hallamshire Hospital, Sheffield Teaching Hospitals, Sheffield, United Kingdom*

INTRODUCTION: Coeliac disease (CD) is defined by positive serology plus Marsh (M) grade 1-3 on duodenal biopsies; CD-M1 to CD-M3. In contrast, non-coeliac gluten sensitivity (NCGS) is defined by negative serology and duodenal biopsies that are normal, or show mild histological abnormalities, whilst on a gluten containing diet; NCGS-M0 to NCGS-M1.
AIMS & METHODS: As coeliac serology can be negative in those with mild histological abnormalities we aimed to determine whether NCGS-M1 actually represents early CD.

Baseline clinical characteristic, biochemical parameters and human leukocyte antigen (HLA) DQ2-DQ8 typing was compared between 100 NCGS-M0, 50 NCGS-M1 and 30 CD-M1 patients. Finally, serological and histological response to a repeat gluten challenge was assessed between HLA-DQ positive NCGS-M1 and CD-M1.
RESULTS: There was no statistical difference in age, sex, autoimmunity, family history of CD or baseline body mass index between the three groups. However, anaemia was significantly more prevalent in CD-M1 (20%) compared to NCGS-M1 (6.4%, p 0.05, OR 4.7, C. I 1.0-21.6) and NCGS-M0 (3%, p 0.009, OR 7.58, C. I 1.67-34.4).
Furthermore, HLA-DQ positivity was seen in 100% (n 30) of CD-M1 patients, in contrast to 70% NCGS-M1 (n 35, p 0.001) and 55% NCGS-M0 ($p < 0.001$).
26/30 CD-M1 patients and 30/35 HLA-DQ positive NCGS-M1 individuals agreed to undergo repeat gluten challenge. In CD-M1 there was a significant rise in coeliac serology (mean TTG value 124 U/ml before: 164 U/ml after, p 0.04) and histological deterioration on duodenal biopsies (35% M1, 15% M2, 50% M3, $p < 0.0001$). In contrast, all individuals with HLA-DQ positive NCGS-M1 maintained negative coeliac serology (mean TTG value 7 U/ml before; 8 U/ml after, p 0.12) and the majority improved their duodenal biopsies from M1 to M0 (23/30, 77%, $p < 0.0001$), with 7 cases persisting as NCGS-M1
CONCLUSION: NCGS-M1 individuals do not represent CD as demonstrated by i) negative HLA-DQ typing in 30% of cases or a ii) a lack of immune deterioration following repeat gluten challenge in those with HLA-DQ positivity. In cases with persisting NCGS-M1 duodenal immunohistochemical analysis may shed further light on the eventual diagnosis.

P1098 PREDICTORS FOR COELIAC DISEASE IN CASES OF LYMPHOCYTIC DUODENOSIS

I. Aziz[1,*], T. Key[2], J.G. Goodwin[2], D.S. Sanders[1]
[1]*Department of Gastroenterology,* [2]*Department of Histocompatability & Immunogenetics, Royal Hallamshire Hospital, Sheffield Teaching Hospitals, Sheffield, United Kingdom*

INTRODUCTION: Lymphocytic duodenosis (LD) is an early marker for coeliac disease (CD). However, the majority of cases are due to non-CD related conditions.
AIMS & METHODS: We aimed to identify the predictors of CD when presented with LD.
215 LD patients had undergone prospective and systematic evaluation for CD and other recognized associations.
The gold-standard diagnosis of CD was based upon the presence of HLA-DQ2 and/or DQ8, persistence or progression of LD following a gluten challenge, followed by a symptomatic improvement on a gluten-free diet.
Binary logistic regression models, adjusting for age and gender, were subsequently performed to compare presenting variables between CD and non-CD cases, and to determine their sensitivity, specificity, positive and negative predictive values (PPV and NPV).
RESULTS: CD was diagnosed in 48 cases (22%) and non-CD in 167 cases (78%). There was no statistical difference in demographics, clinical symptoms (i.e. diarrhea, weight loss, abdominal pain), anemia or hematinics between the CD and non-CD group.
Patients with CD, in comparison to non-CD, were significantly more likely to have a positive family history of CD (21% vs. 3.6%, OR 6.73; PPV 62.5%, NPV 81%, specificity 96.4%), positive HLA-DQ status (100% vs. 49.1%; PPV 36.4%, NPV 100%, specificity 50.9%), and presence of endomysial antibody [EMA] (48% vs. 0%; PPV 100%, NPV 87%, specificity 100%); all $p \leq 0.001$
A normal tissue transglutaminase antibody (TTG) level was seen in 29.2% CD and 83.2% non-CD cases (OR 0.084, $p < 0.001$; PPV 9.2%). There was no difference in the prevalence of TTG levels 1-2 x upper limit of normal (ULN) between the groups (29.2% CD vs. 14.4% non-CD; PPV 33-38%). However, TTG levels between 3-20 x ULN were significantly more prevalent in the CD group (33.3% vs. 2.4%; PPV 66.6%>89%), whilst a TTG > 20 x ULN was exclusive to CD (8.3%, $p < 0.001$, PPV 100%).
CONCLUSION: In the setting of LD, only the presence of a positive EMA or TTG > 20 x ULN at the outset can be used to make an immediate diagnosis of CD. Gastrointestinal symptoms, family history, anemia, or other celiac serology results do not reliably distinguish CD from non-CD without further investigations.

P1099 CHANGE IN AWARENESS OF GLUTEN-RELATED DISORDERS AMONGST CHEFS AND THE GENERAL PUBLIC IN THE UNITED KINGDOM: A 10 YEAR FOLLOW-ON STUDY

I. Aziz[1,*], M.A. Karajeh[1], J. Zilkha[1], E. Tubman[1], C. Fowles[1], D.S. Sanders[1]
[1]*Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield Teaching Hospitals, Sheffield, United Kingdom*

INTRODUCTION: For individuals with gluten-related disorders (GRD) eating out has traditionally been difficult, and socially impacting, due to concern over the lack of public awareness regarding GRD and a gluten-free diet (GFD). However, the recent rise in media coverage highlighting these conditions may have altered knowledge amongst the general public and chefs.
AIMS & METHODS: We assessed whether knowledge of GRD has altered amongst the general public and chefs.
A face-to-face questionnaire about coeliac disease (CD) and gluten sensitivity (GS) was performed on the general public and chefs based in Sheffield, United Kingdom. The assessment was first conducted in 2003 and repeated in 2013.
RESULTS: 513 public members in year 2003 (mean-age 49.2, 62% female) were compared to 575 public members in year 2013 (mean-age 37.8, 57% female). There was a significant rise in the awareness of GRD from the years 2003 to 2013; CD (44.2% to 74.4%, AOR 3.9 [C. I 3-5.19]) and GS (58.3% to 89%, AOR 7.1 [C. I 5-9.98]), p-value < 0.001.
322 chefs in year 2003 (mean age 37.6, 15% female) were compared to 265 chefs in year 2013 (mean age 27.1, 38% female). There was a significant rise in the awareness of GRD from the years 2003 to 2013; CD (17.1% to 78.1%, AOR 12.5 [C. I 7.9-19.6]) and GS (9.3% to 87.5%, AOR 65.7, C. I [35.4-122]), $p < 0.001$. Whereas in 2003 the public were significantly more aware of GRD than chefs, by 2013 this had reached similar prevalence in both groups. In addition, the correct recognition of the gluten-free symbol was 44% for the public and 40% for chefs (p 0.28). 41% of restaurants and 27% of takeaways sold gluten-free products (p 0.07).
CONCLUSION: There has been a dramatic rise in both the public and chefs awareness of GRD. This may ease the social phobia that individuals with GRD have traditionally been accustomed to.

P1100 UNSUSPECTED PREVALENCE OF CONDITIONS PREDISPOSING TO CELIAC DISEASE IN THE AMERINDIAN TOBA COMMUNITY OF ARGENTINA: A STUDY ON GLUTEN CONSUMPTION, GENETIC PREDISPOSITION AND AUTOIMMUNITY MARKERS

M.P. Temprano[1], H. Vazquez[1], E. Sugai [1], G. **I. Longarini**[1,1,*], E. Smecuol[1], S. Scachi[1], S. Niveloni[1], A.F. Costa[1], R. Mazure[1], D. Cisterna[1], R.de Miguel[1], A. Gonzalez[1], M.A. Bartellini[1], E. Mauriño[1], J.C. Bai[1]
[1]*Medicine, Hospital Udaondo, Buenos Aires, Argentina*
Contact E-mail Address: *hvazquez@intramed.net*

INTRODUCTION: The Toba indigenous ethnic community comprises more than 60,000 individuals living in very poor conditions in northeastern Argentina. The lower than average life expectancy in this population has been attributed, in part, to primary malnutrition, and very low socio-economic, sanitary and educational conditions. In recent years, they have experienced a change in dietary habits with wheat and wheat-products replacing ancestral alimentary practices mainly due to the governmental support. No studies have explored conditions predisposing to celiac disease (CD) in Amerindians.
AIMS & METHODS: Aims: 1- To estimate the consumption of gluten; 2- To explore the genetic background (HLA DQ2/ DQ8 haplotype); and 3- To determine the prevalence of CD autoimmunity in a population of members of the Toba community requesting medical attention by a multidisciplinary sanitary mission.
Methods: After written consent, individuals attending the mission underwent a detailed questionnaire by an expert nutritionist recalling the last 48-hs dietary intake. Gluten consumption was estimated by conventional formula. Clinical, biochemical and anthropometric parameters were collected. CD specific gene typing for the detection of HLA class II alleles was performed on DNA extracted from peripheral blood (DQ-CD Typing Plus. BioDiagene S. R. L.; Palermo; Italy). Serum samples were tested for IgA antibodies to tissue transglutamise (IgA tTG) and the deamidated gliadin peptides (DGP)/tTG Screen test. Those with positive results were tested for IgA endomysial (EmA) antibodies (INOVA Diagnostics Inc. San Diego, Ca).
RESULTS: One hundred and forty-three subjects (63% females) were enrolled. The median age of the study population was 30 yr (range: 3 to 72), and the mean body mass index was 27.1 kg/m^2 (SD: 6.7). The estimated mean gluten consumption was 47 g/day (range: 4 to 185), which resulted higher than that recommended by National Nutritional Guideline (18 g/day). Sixty out of 116 subjects (51.7%) had alleles associated with CD. Fifty-six cases (95%) had alleles codifying for HLA DQ8 and three for DQ2. Three and four subjects had serum concentrations above the cut-off of risk established by our group (>3 times the upper limit of normal) for tTG and DGP/tTG Screen antibodies, respectively. Three of these patients had concurrent positivity for both assays and EmA was positive in two of these patients who also presented the haplotype HLA DQ2 and DQ8.
CONCLUSION: Our study explores for the first time an Amerindian population previously unsuspected of having conditions predisposing to CD. The dietary analysis estimated a very high consumption of gluten due to the alimentary governmental support. The genetic background was dominated by alleles codifying for DQ8 antigen. We detected evidence of CD autoimmunity and, at least, two subject fulfilled serologic criteria of CD.

P1101 ADHERENCE TO DUODENAL BIOPSY GUIDELINES INCREASES THE DETECTION OF COELIAC DISEASE: A MULTICENTRE UK STUDY

P.D. Mooney[1], **M. Kurien**[1,*], M. Finegan[2], F. Khan[3], R. Keld[2], G. Naylor[3], D.S. Sanders[1]
[1]*Regional GI and Liver Unit, Royal Hallamshire Hospital, Sheffield,* [2]*Gastroenterology, Royal albert Edward Infirmary, Wigan,* [3]*Gastroenterology, Chesterfield Royal Infirmary, Chesterfield, United Kingdom*

INTRODUCTION: Coeliac disease (CD) is a common autoimmune condition affecting 1% of the adult population. However large numbers of patients remain undiagnosed which may have significant health consequences and so methods to increase detection should be sought. Guidelines suggest that at least 4 duodenal biopsies should be taken to rule out CD. A previous US study showed that biopsy guidelines were only followed in 35% of cases. The aim of the present study was to see whether guidelines were being followed in the UK and if adherence to the guidelines improved detection of CD.
AIMS & METHODS: Endoscopy and histology reports were retrospectively reviewed for all patients who had a duodenal biopsy in a 3 month period between November 2012 and January 2013 from 4 UK hospitals. Indications for biopsy, role of the endoscopist (physician, surgeon, nurse endoscopist), number of duodenal biopsies received by histopathology and the final diagnosis were recorded. The presence of villous atrophy was required for CD diagnosis. Patients were excluded if they had known CD.
The difference between a double and single bite biopsy technique was also assessed.
RESULTS: 1423 patients underwent duodenal biopsy for possible CD across the 4 sites in the study period. 97 (6.8%) of these were diagnosed with CD. Guidelines to take at least 4 biopsies were met in 40% of patients and the median number of duodenal biopsies taken for all patients was 3. CD was more likely to be diagnosed if guidelines were followed (10.1% vs 4.6%, $P<0.0001$). The median number of biopsies was greater in patients diagnosed with CD (4 vs 3) $P<0.0001$. Gastroenterologists and nurse endoscopists were more likely than surgeons to follow guidelines (41.8% vs 51.2% vs 18.2%, $P<0.0001$) and took a higher median number of biopsies (3 vs 4 vs 2, $P<0.0001$). As a result gastroenterologists and nurse endoscopists made a diagnosis of CD in more cases than surgeons (7.1% vs 6.7% vs 3.0%, P 0.1). All presenting characteristics (other than positive serology in which guidelines were followed in 65%) were associated with poor adherence to guidelines. 12.4% of newly diagnosed CD patients had at least 1 non-diagnostic gastroscopy in the 5 years prior to diagnosis. Changing biopsy technique to single bites resulted in improvement of median D2 biopsies from 3 to 4. (P 0.02).
CONCLUSION: We have shown that 12.4% of patients with CD had a previous gastroscopy 5 years prior to their diagnosis. Taking 4 duodenal biopsies results in increased detection of CD. We are the first investigators to demonstrate that there is variation in biopsy rates based on the speciality of the endoscopist and biopsy technique (single or double bite). Furthermore this variability has a direct relationship with the detection rate of CD. Education of all groups of clinicians in duodenal biopsy techniques may result in more patients receiving a prompt diagnosis of CD.

INTRODUCTION: Endoscopic markers of coeliac disease (CD) lack sensitivity; therefore many centers take routine duodenal biopsies or have a low threshold for biopsy, ensuring high detection rates. Newly available, point of care tests (POCT) provide rapid findings unlike conventional serological markers, potentially reducing the need for duodenal biopsies. This study evaluates a new POCT (Simtomax) which detects IgA and IgG deamidated gliadin peptide (DGP) with comparisons made to conventional serological markers and duodenal biopsies.
AIMS & METHODS: Patients referred from primary and secondary care for a gastroscopy to a specialist CD list were prospectively recruited between March 2013 to November 2013. Patients were excluded if they were on a gluten free diet at the time of the test or if they had previously been diagnosed with seronegative villous atrophy or coeliac disease. All patients had a duodenal biopsy as the gold standard for detecting coeliac disease. Concurrently serological testing for IgA tissue transglutaminase (TTG), endomysial antibody (EMA), total IgA immunoglobulin level and the DGP based rapid test was performed. Sensitivity, specificity, positive predictive and negative predictive values were calculated.
RESULTS: 354 patients met the inclusion criteria (45.8% male mean age 53.3 ±18.5). Of these, 52 (14.7% 11.2 – 18.9) had newly diagnosed CD and 302 were controls with a normal duodenal biopsy. The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for the POCT were 94%, 83%, 49% and 99% respectively. This compares with results for TTG of 92%, 88%, 57%, 99% and EMA of 88%, 97%, 85%, and 98% respectively.
CONCLUSION: This is the first study to prospectively demonstrate the value of a novel POCT for adult CD in endoscopy compared to the gold standard of histology. The sensitivity and specificity of the POCT is comparable to conventional serology. Simtomax could be used to appropriately identify patients requiring a duodenal biopsy within the endoscopic setting. This strategy may be cost effective by reducing the number of routine duodenal biopsies taken.

P1103 COMPARISON OF THREE COMMERCIALLY AVAILABLE POINT OF CARE TESTS FOR COELIAC DISEASE

P.D. Mooney[1], **M. Kurien**[1,*], S. Wong[1], D.S. Sanders[1]
[1]*Regional GI and Liver Unit, Royal Hallamshire Hospital, Sheffield, United Kingdom*

INTRODUCTION: Coeliac disease (CD) remains an underdiagnosed condition. A rapid finger prick based point of care test may increase uptake of serological testing in appropriate patient groups. There are 4 commercially available point of care tests (POCT) on the market in the UK: Biocard an IgA tissue tranglutaminase (tTG) test (BHR pharmaceuticals); Coeliac Quick Test (Biohit healthcare) which detects IgA, IgG and IgM tTG; Xeliac Test Pro (Personal Diagnostics) which detects IgA and IgG tTG; and Simtomax (Tillott's Pharma) which detects IgA and IgG de-amidated gliadin peptides (DGP). However there is a limited evidence base for these tests (Biocard 10 studies; Simtomax 2 studies; Coeliac Quick Test and Xeliac Test Pro have no published data) and frequently patients only have a duodenal biopsy if the POCT is positive leading to ascertainment bias. In our recent cohort the sensitivity of Biocard was disappointing at 70.1% when results were compared to histology in all patients [1]. For this reason we decided to compare 3 commercially available tests in an endoscopic setting.
AIMS & METHODS: Patients referred with a positive endomysial antibody (EMA) for duodenal biopsy to confirm CD were invited to take part. All patients had whole blood taken for repeat serum EMA, tTG and immunoglobulins. All patients were tested simultaneously with the 3 POCTs as per the manufacturers' instructions. All patients had quadrantic duodenal biopsies from the second part of the duodenum as well as a duodenal bulb biopsy. Demonstration of villous atrophy on duodenal biopsy was required to diagnose CD.
RESULTS: 47 patients (27 female, mean age 39.1) have been recruited. In 9 patients the EMA had normalised on repeat testing. None of these patients had villous atrophy on duodenal biopsy. 7 of these patients were referred with a weak EMA and had a negative tTG. Of the other 2, 1 patient referred with a positive EMA, had a tTG of 155 and subsequent gluten challenge revealed a positive EMA and villous atrophy.
Of the remaining 38 patients 30 new cases of coeliac disease were confirmed with the presence of villous atrophy, of the remaining 8 EMA positive patients 6 had Marsh 1 or 2 changes present with the remaining 2 patients having normal histology. Full sensitivity, specificity PPV and NPV for all of the tests compared to villous atrophy on duodenal biopsy are shown in the table below.

Test	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Serum tTG	97 (81-99)	41 (19-67)	74 (58-86)	88 (47-99)
Biocard	63 (44-79)	76 (50-92)	83 (60-94)	54 (33-74)
Coeliac Quick Test	80 (61-92)	59 (33-81)	77 (58-90)	63 (36-84)
Simtomax	93 (76 -99)	35 (15-61)	72 (55-84)	75 (36-96)

CONCLUSION: In this pilot data set Simtomax appears to be the most sensitive of the POCTs when compared to histology with similar results to serum tTG as screening test. Further work is required in larger cohorts and lower prevalence populations to confirm the utility of these tests in adult coeliac disease.

P1104 ASSESSING ADHERENCE TO GLUTEN FREE DIET IN COELIAC DISEASE: CAN WE AVOID DUODENAL BIOPSY?

P.D. Mooney[1], **M. Kurien**[1,*], S. Wong[1], D.S. Sanders[1]
[1]*Regional GI and Liver Unit, Royal Hallamshire Hospital, Sheffield, United Kingdom*
Contact E-mail Address: *peter.mooney@sth.nhs.uk*

INTRODUCTION: Up to 30% of patients with coeliac disease will have persistent symptoms despite the introduction of a gluten free diet. Assessment of adherence in coeliac disease can involve any combination of patient self-reporting adherence, dietetic assessment, serology and biopsy with histology. Histology is considered to be the 'gold standard' but this requires a repeat endoscopic examination with its associated risks and problems with tolerance. As a result surrogate markers of persistent gluten exposure and histological changes such as serology are frequently used but the relationship between serology and persistent histological changes is not linear. A structured interview with a dietician has been shown to be the most accurate method of assessing gluten exposure however this is time consuming and requires extra clinic visits. The aim of this study was to assess the usefulness of two novel options. Firstly a previously internally validated scoring system for assessing dietary adherence[1] (which has never been externally validated) and secondly a rapid de-amidated gliadin peptide based point of care test (POCT, Simtomax) for the prediction of persistent VA.
AIMS & METHODS: All patients with known coeliac disease and persistent symptoms coming to a specialist coeliac endoscopy list for the re-assessment of histology were invited to take part. All patients were tested for Endomysial

Antibody (EMA), tissue transglutaminase (tTG), immunoglobulins and the POCT. They were also asked to complete a questionnaire to calculate a 5 point score (0 – 4) with a high score representative of improved adherence to a gluten free diet. All patients underwent gastroscopy with at least 4 biopsies from the second part of the duodenum and 1 to 2 biopsies from the bulb.
RESULTS: 60 patients (78% female, mean age 51.4 range 16-79) were recruited between April 2013 and April 2014. 22 (36.7%) of these patients had persistent VA on duodenal biopsy. The POCT was the most sensitive marker with 73% of patients with VA having a positive test. EMA was the most specific surrogate marker at 84% although it was highly insensitive with only 36% of patients with VA having a positive EMA. No patients with completely normalised histology had a positive EMA. The adherence score could not be reliably used to predict villous atrophy with a sensitivity of only 32%.

Measure	Sensitivity	Specificity	PPV	NPV
Adherence Score	32%	82%	50%	67%
tTG	55%	76%	57%	74%
EMA	36%	84%	57%	70%
POCT	73%	66%	55%	81%

CONCLUSION: An accurate surrogate marker for villous atrophy could reduce the number of endoscopies required. In this cohort the POCT had the best sensitivity, detecting 16/22 (73%) cases of villous atrophy, however this is pilot data and further work is required. It maybe that additive methods for assessing adherence could achieve 100% sensitivity

INTRODUCTION: We recently showed that a diet rich in non-absorbable, fermentable residues in the short term increases intestinal gas production and induces digestive symptoms such as flatulence, bloating and abdominal distention. On the contrary, it has been shown that some prebiotics, which are also fermented by colonic bacteria, improve this type of symptoms. Hence, it is not clear whether fermentable residues from the diet have a beneficial or deletereous effect on digestive symptoms.
AIMS & METHODS: To demonstrate changes in metabolic activity of gut microbiota and colonic biomass induced by prebiotics. Healthy subjects (n = 20) were administered a prebiotic (Bimuno prebiotic powder, Clasado, London, UK; 2.8 mg/d) for three weeks; they also received a standardized diet during three days immediately before, at the beginning and at the end of the treatment. During these periods the following outcomes were measured: a) number of gas evacuations during daytime, by means of an event marker; b) volume of gas evacuated per anus during four hours after a test meal, by means of a rectal tube connected to a barostat that maintains a minimal resistance to flow across the collection line; and c) the volume of content in the undisturbed colon in the 24-h period after a bowel movement (n = 5), by means of magnetic resonance imaging of the abdomen using an original, previously validated analysis program.
RESULTS: Before treatment healthy subjects evacuated gas per anus 12.6 ± 0.9 times during daytime and evacuated 151 ± 15 mL of gas during four hours after the test meal. At the beginning of treatment, prebiotic administration significantly increased the number of anal gas evacuations (18.6 ± 1.8 times daily; $p < 0.001$) and the volume of gas evacuated after the test meal (235 ± 24.6mL; $p < 0.001$). Interestingly, by three weeks treatment, both the daily number of gas evacuations (11.2 ± 1.3), as well as the volume of gas evacuated after the test meal (161 ± 24) decreased and returned to pre-treatment levels. Prebiotic intake significantly increased the volume of content in the undisturbed colon (740 ± 73 vs 628 ± 62 pre-treatment; $p < 0.05$), and this increase in colonic biomass was maintained during the treatment period (792 ± 64 by three weeks; $p < 0.05$ vs pre-treatment).
CONCLUSION: Availability of substrates induces an adaptation of colonic microbiota ativity towards more efficient metabolic pathways.

INTRODUCTION: FODMAPs (fermentable oligo-, di-, monosaccharides and polyols) is a group of carbohydrates poorly absorbed in the small intestine – some will therefore serve as substrate for colonic fermentation. Studies show effect of FODMAP-restricted diet on symptoms of irritable bowel syndrome (IBS) – none have been conducted on patients with functional dyspepsia (FD). We aimed to see whether a 6-week diet low in FODMAPs would have an effect on symptoms (epigastric pain, postprandial fullness and nausea), quality of life (QoL) and gas produced during lactulose breath-test.
AIMS & METHODS: 11 FD patients according to the ROME III-criteria were included in the study (8F/3M, 32.4±12.2), instructed and followed up closely by a dietician during a 6-week diet. FD-symptoms (VAS 0-100) and QoL (SF-36) were collected at baseline, 3 and 6 weeks. FODMAP-intake (grams) was calculated at baseline and 6w using 4-day food records. Lactulose breath testing (n = 10) was performed at baseline and 6w to observe changes in gas production. Results were compared using t-tests, one-way ANOVA and correlation.
RESULTS: There was a significant reduction in FODMAP-intake (mean from 53.2g to 3.3g, $p < 0.001$). High compliance to the diet was reported (mean 90.4%) and it was somewhat challenging (mean 50.6%). Epigastric pain (median 54.1 to 0%, $p = 0.0002$), postprandial fullness (median 52 to 0%, $p < 0.001$) and nausea (mean 47.6 to 19.9%, $p < 0.05$) significantly reduced from baseline to 6w. SF-36 total score (mental health $p = 0.37$ and physical health $p = 0.07$). Hydrogen gas production (median 5558 to 2228ppm×min, $p = 0.0059$) significantly declined.
CONCLUSION: In this study, FODMAP-restricted diet significantly reduced FD-symptoms and hydrogen gas production in 6 weeks.

P1107 MALNUTRITION IN HOSPITALIZED IBD- A CALL FOR RECOGNITION AND TREATEMENT

I. Chermesh[1,*], T. Mashiach[2], Y. Chowers[1]
[1]gastroenterology, [2]Quality assurance unit, RAMBAM HEALTH CARE CAMPUS, Haifa, Israel

INTRODUCTION: Malnutrition is frequent in IBD patients. Protein-calorie malnutrition leads to fatigue, inability to carry on every-day life activities and make the patient prone to prolonged and complicated hospitalizations. Diagnosis of malnutrition relies upon integration of history taking, physical examination and laboratory results. Low Urea, Creatinine, CPK and lymphopenia are cornerstone laboratory findings of muscle wasting.
AIMS & METHODS: In this study, we set to check the frequency of recognition and treatment of malnutrition in hospitalized patients with IBD. Retrieval of data from electronic files of all hospitalized IBD patients 2012-2013. Screening criteria for risk of malnutrition included any two of the following: Weight loss > 5%; lymphopenia < 1000/mm^3; BUN≤5; Creatinine≤0.4; Uric acid≤2; CPK≤20
RESULTS: 134 patients, of whom 113 had complete data, 51% males, 73% with Crohn's disease; age 32.2 years+/-13.6. 55% lost > 5% weight; 58% diagnosed at risk for malnutrition, 53% of Crohn's and 73% of UC patients ($p < 0.05$). Length of stay (LOS) was 5.1 days and 8.1 days for well-nourished and malnourished patients ($p < 0.05$). On multivariate analysis, only nutritional state and hypoalbuminemia were independent factors for prolonged LOS. Only 15% of patients received the diagnosis of malnutrition, 38% were given nutritional therapy and 32% had recommendations to take nutritional therapy after discharge from the hospital.
CONCLUSION: Malnutrition is common in hospitalized patients with IBD and is associated with prolonged hospitalizationX1.5 times than patients who are well nourished. Assessment of patients at risk, recognition and treatment of malnutrition are suboptimal. Measures to optimize identification of patients at risk for malnutrition and provision of adequate treatment are needed.

P1108 HOW OFTEN DO WE RECOGNIZE MUSCLE WASTING AND MALNUTRITION IN HOSPITALIZED IBD PATIENTS

I. Chermesh[1,*], T. Mashiach[2]
[1]gastroenterology, [2]Quality assurance unit, RAMBAM HEALTH CARE CAMPUS, Haifa, Israel
***Contact E-mail Address:** i_chermesh@rambam.health.gov.il*

INTRODUCTION: Malnutrition and an inflammatory state can combine to contribute to muscle wasting in IBD patients. Since muscle wasting is directly related to frailty and quality of life it is of utmost importance to diagnose. Low Blood Urea Nitrogen (BUN), Uric Acid, Creatinine, and CPK are cornerstone laboratory findings of muscle wasting (MW). Weight loss characterizes protein-calorie malnutrition.
AIMS & METHODS: In this study, we set to check the frequency of recognition of muscle wasting and malnutrition in hospitalized IBD patients. Retrieval of data from electronic files of all hospitalized IBD patients 2011-4.2014. Screening

criteria for risk of MW and malnutrition included: Weight loss > 5%; BUN≤5; Creatinine≤0.4; Uric acid≤2; CPK≤20. Suspected MW was defined as a combination of two or more of the following low BUN, Creatinine, Uric acid or CPK. Malnutrition risk if one of the above and weight loss was present.
RESULTS: 169 patients, with active IBD, 54%% males, 73% with Crohn's disease; age 35 years+/-14. 38% lost > 5% weight; 11% had laboratory findings compatible with MW, 16% of patients with MW lost weight. Length of stay (LOS) was longer for patients with MW irrespective of WL or age (15.2+/-23 vs. 5.3+/-4 ($p<0.0001$). None of the patients were diagnosed with MW, only 15% of patients received the diagnosis of malnutrition
CONCLUSION: MW is prevalent in more than 10% of hospitalized IBD patients and is associated with prolonged hospitalization X3 times than patients. MW is a known factor associated clinical deterioration. The data herein presented, manifests lacking diagnosis and calls for measures to raise recognition of this important clinical manifestation.

P1109 INTRAGASTRIC PRESSURE DURING DIFFERENT NUTRIENT DRINK INFUSIONS

J.R. Biesiekierski[1,*], J. Tack[1]
[1]*KU Leuven, Leuven, Belgium*
Contact E-mail Address: *Jess. Biesiekierski@med.kuleuven.be*

INTRODUCTION: Recent intragastric pressure (IGP) measurements, used to assess gastric accommodation[1], have shown that intragastric nutrient infusion induces an initial drop in IGP, followed by a gradual recovery, with significant correlation to satiation and the volume required to induce maximal satiation. The type of nutrient(s) that drive(s) these IGP responses have not been identified.
AIMS & METHODS: The objectives were to assess the role of specific nutrients in inducing IGP response and their contribution to satiation. A manometry and infusion catheter were positioned in the proximal stomach of 15 healthy volunteers. After a stabilization period, one of three nutrient drinks (high lipid [10% lipid emulsion], high protein [whey protein isolate], or high carbohydrate [glucose]) were intragastrically infused at 60 mL/min, three days to one week apart in a single-blinded randomised order. There were no differences in caloric or osmotic load between the drinks. The experiment ended when subjects scored maximum satiation. IGP was presented as change from baseline (mean ± SEM). Satiation scores were measured before, during and after the infusion at 10-minute intervals using a 100 mm visual analogue scale. Results were compared using a repeated measures ANOVA.
RESULTS: 15 eligible volunteers (21-52 y, 7 men) were randomised. Volunteers scored maximal satiation after a higher volume of the carbohydrate drink infusion (1231 ± 126 mL) compared to the other nutrients (protein 1049 ± 99 mL, lipid 1006 ± 49 mL; $p=0.0027$). In all subjects and with each nutrient infusion, the IGP decreased initially to gradually recover thereafter. Maximum IGP decrease (termed nadir) was 7.6 ± 0.9 mmHg after 8.1 ± 1.3 min, 9.4 ± 1.0 mmHg after 10.1 ± 1.2 min, and 7.7 ± 0.6 mmHg after 8.7 ± 1.2 min for carbohydrate, protein and lipid respectively (nadir $p=0.1461$; time to nadir $p=0.4422$). Overall, the area above the IGP curve was greater for the lipid (114.7 ± 14.7 mmHg/min) compared to the carbohydrate and protein (94.6 ± 19.3 and 81.0 ± 9.5 mmHg/min, respectively) ($p=0.1020$). Post hoc analysis showed significant correlations between IGP and satiation score increase, with slightly greater satiation induced with the lipid (84 ± 3.5 mm; carbohydrate 78 ± 5.2 mm, protein 76 ± 6.3 mm; $p=0.1764$).
CONCLUSION: This study indicates all three macronutrients induce an IGP response in the healthy state. The findings offer opportunities to objectively identify whether these specific nutrients drive the impaired gastric accommodation seen in functional gastroduodenal patients (e.g., functional dyspepsia).

INTRODUCTION: Gluten free diet (GFD) is currently the only available therapy for patients with celiac disease (CD), the most common autoimmune enteropathy in Western Countries, occurring in genetically susceptible individuals and triggered by gluten ingestion. As gluten rich products are an important source of nutrients, it is not clear if GFD could have a negative effect on the nutritional status of CD patients and if GFD could expose to mycotoxins contained in gluten free flours.
AIMS & METHODS: Aim of the study was to estimate the nutrient intake and the dietary exposure to mycotoxins in treated CD *vs.* controls.
Sixty participants, thirty histologically proven CD and thirty sex-age matched, healthy control were enrolled. Total food and beverage consumption was assessed by means of a food record filled in every day for a total of 7 days. The nutrient intake was calculated using a Microsoft Access application linked to the food database of the European Institute of Oncology and integrated with the nutrient composition of sixty commercial GF (Gluten-Free) foods. Test for mycotoxins (fumonisin B1 and deoxynivalenol) biomarkers was carried out on 24 hour urine collection.
RESULTS: Compared to controls, CD patients on GFD consumed a lower percentage of energy as carbohydrates and a higher percentage of energy as fats (48 % *vs* 51% and 37 % *vs* 33%, respectively). Moreover, GFD has a higher intake of vitamin C, vitamin E and sodium than normal diet (142 mg *vs* 118; 18 mg *vs* 13 mg; 3340 mg *vs* 2959 mg respectively). Concerning mycotoxins exposure, preliminary results on urinary fumonisin B1 and deoxynivalenol excretion failed to evidence any differences between GFD and control diet.
CONCLUSION: Present data show a higher consumption of fruit and vegetables rich in micronutrients and an increased intake of fat and sodium (due to GF packaged product) in GFD.
Exposure to mycotoxins does not differ between CD patients and controls.
Disclosure of Interest: None declared

P1111 HYPERNATRAEMIA AND C REACTIVE PROTEIN ARE INDEPENDENTLY RELATED TO 1-,3-MONTH AND LONG TERM MORTALITY IN PATIENTS WHO UNDERWENT PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) FOR DYSPHAGIA - A SINGLE-CENTRE EXPERIENCE

A. Caponi[1], **G. Gibiino**[1,*], A. Lisotti[1], F. Azzaroli[1], F. Bazzoli[1], G. Mazzella[1], R. Muratori[1]
[1]*Medical and Surgical Sciences, University of Bologna, Bologna, Italy*
Contact E-mail Address: *giulia.gibiino@gmail.com*

INTRODUCTION: Percutaneous endoscopic gastrostomy (PEG) is performed to provide enteral nutrition to patients with swallowing disorders. Previous studies demonstrated that advanced age, low BMI, low serum albumin and high levels of C reactive protein (CRP) are related to worst clinical outcomes. The aim of our study was to evaluate predictive factors of morbidity and mortality in patients who underwent PEG placement.
AIMS & METHODS: Data from all consecutive patients undergoing PEG placement for oropharyngeal dysphagia between March 1999 and December 2013, were collected; in particular indication for PEG placement, comorbidities, concomitant medications and lab-tests were recorded.
All patients received antibiotic prophylaxis; anti-thrombotic drugs were discontinued when possible. Coagulation defects and serum potassium alterations were corrected. All procedures were performed under deep sedation administered by anaesthesiologists. Enteral feeding was started at least 24 hours after the procedure.
Patients were followed up and periprocedural (within 48h) major complications, 1- and 3-month mortality rates were recorded. Cox-proportional hazard regression and Kaplan-Meyer analyses were used to identify prognostic indicators of mortality; ROC curves were used to identify the best cut-off points.
RESULTS: 438 patients (178 Male; 77.4 ± 12.1 years) were included; causes of dysphagia were stroke (149), dementia (137), neurodegenerative disease (81), coma (40) and cancer (31); mean follow-up was 14.6 months. No periprocedural complications or death were observed; 1- and 3-month mortality rates were 4.0% and 8.1%, respectively. Gender (male), underlying neoplasia, presence of diabetes, low serum albumin, thrombocytopenia, hypernatraemia, increased CRP and leucocytosis were significantly related to mortality on univariate analysis.
Cox-regression identified serum sodium ≥ 150 mmol/L (OR 25.4; 95%CI 7.4-86.8; $P<0.0001$) as factor independently related to 1- month mortality and CRP >4,34 mg/dL (OR 5.3; 95%CI 1.8-15.9; $p=0.003$) to 3-month mortality. On Kaplan-Meyer analysis patients with CRP>4,34 mg/dL (HR 3.5; 95%CI 1.5-8.3) and Na ≥ 150 mmol/L (HR 4.3; 95%CI 1.1-17.6) presented a significantly increased risk of long term mortality.
The presence of an underlying neoplasia (as indication for PEG placement or comorbidity) is an independent risk factor for 1-, 3-month and long-term mortality (OR 3.69, 3.30 and 2.32, respectively). Finally, we observed that dementia was not associated with an increased risk of mortality (HR 1.21; 95%CI 0.75-1.96; $p=0.42$).
CONCLUSION: Significant hypernatraemia (≥ 150 mmol/L) and high levels of serum CRP (> 4,34 mg/dL) are independent predictors of short- and long-term mortality. Improvement in patients' selection criteria and pre-procedural management could lead to better outcomes after PEG placement. Our results suggest that serum hypernatraemia, reflecting an underlying modifiable dehydration status, has to be properly assessed and even corrected.

P1112 EFFICACY AND COMPLICATION OF ENTERAL FEEDING AFTER LIVER TRANSPLANTATION

J.H. Chun[1,*], J.Y. Ahn[1], H.Y. Jung[1], K.D. Choi[1], J.H. Lee[1], K.S. Choi[1], K.W. Jung[1], D.H. Kim[1], H.J. Song[1], G.H. Lee[1], J.H. Kim[1]
[1]*Department of Gastroenterology, Asan medical center, Seoul, Korea, Republic Of*
Contact E-mail Address: *joohyunchun@nate.com*

INTRODUCTION: Adequate nutrition support for patients undergoing major surgery has been shown to impact significantly on postoperative recovery. Data on the enteral feeding after liver transplantation (LT) are scarce.
AIMS & METHODS: We tried to know about the efficacy and complication of feeding tube which was inserted by fluoroscopic assistance, endoscopic assistance or transperitoneal jejunostomy in patients who were underwent LT. Between January 2008 and August 2013, 2058 cases of LT were performed at Asan Medical Center, Seoul, Korea and enteral feeding tube was inserted in 155(7.5%) patients after LT. Among 155 patients fluoroscopic placement was performed in 81 patients (52%), endoscopic placement in 49 patients (32%), and

transperitoneal jejunostomy in 25 patients (16%). We retrospectively analyzed the efficacy and complication of enteral feeding tube.
RESULTS: Median age was 55 years (interquartile range [IQR] 49-60years). Indication of enteral feeding were high risk of gastric aspiration (n = 90), gastric stasis (n = 27), pneumonia (n = 23), gastrointestinal bleeding (n = 12), and bowel rest (n = 3). Duration of enteral feeding was 14.5 days (IQR 8.0-30.7 days) in fluoroscopic placement, 20.0 days (IQR 8.0-40.0 days) in endoscopic placement, 37.5 days (IQR 18.2-86.2 days) in transperitoneal jejunostomy. Time to establishment of oral feeding was 13.0 days (IQR 6.2-25.7 days) in fluoroscopic placement, 24.0 days (IQR 10.5-43.5 days) in endoscopic placement, 37.0 days (IQR 17.0-64.2 days) in transperitoneal jejunostomy. After tube insertion, dislocation of tube and blockage of tube were found on 34 patients (22%) and 16 patients (25%). Most common enteral feeding related complications were diarrhea (n = 68, 44%).
CONCLUSION: Enteral feeding tube insertion to the patients who cannot maintain nasogastric tube or start oral intake for a long time is important for the nutritional support after LT. Each methods of tube insertion by fluoroscopy, endoscopy, or surgery show its own advantage and disadvantage. Proper selection of feeding methods according to the patient's condition can improve the prognosis of patients by better nutritional support after major surgery such as LT.

P1113 GLUCOSE HOMEOSTASIS IN CRITICALLY ILL PATIENTS IS NOT AFFECTED BY DIFFERENT ENTERAL NUTRITION FORMULAS

M. Wewalka[1,*], A. Drolz[1], M. Schmid[1], C. Zauner[1]
[1]*Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria*

INTRODUCTION: Hyperglycemia is common in critically ill patients and associated with increased mortality. It has been suggested that different nutrition formulas may beneficially influence glucose levels in surgical ICU patients. We investigated glucose homeostasis in response to different enteral nutrition formulas in medical critically ill patients.
AIMS & METHODS: A total of 60 patients were randomized to receive continuous fat-based (group A, n = 30) or glucose-based enteral nutrition (group B, n = 30) for seven days. Indirect calorimetry was performed to determine energy demand at baseline and repeated on days 3 and 7 to evaluate substrate oxidation. Glucose levels, insulin demand, insulin/glucose ratio, calorie and substrate intake per 24 hours, as well as nutrition related side effects were assessed for 7 days.
RESULTS: Patients presented with similar age (60±12 vs. 58±16 years, p = 0.657), Body Mass Index (26.2±5.2 vs. 27.5±4.4 kg/m^2, p = 0.294) and SAPS II score (58±14 vs. 63±13, p = 0.147). At baseline patients did not differ with regard to energy demand (1542±382 vs. 1485±384 kcal, p = 0.566) or fasting glucose levels (149±65 vs. 139±68 mg/dl, p = 0.571). Over the course of 7 days patients had similar glucose AUC (710±172 vs. 763±122, p = 0.193), similar average glucose concentrations per 24 hours (repeated measures ANOVA p = 0.655), similar overall insulin demand (187±165 vs. 186±125 IE, p = 0.991), and a similar insulin/glucose ratio (repeated measures ANOVA p = 0.962). Furthermore they received similar amounts of enteral nutrition per 24 hours and showed no difference in nutrition related side effects such as gastric reflux, vomiting, diarrhea, and hyperlipidemia.
CONCLUSION: Patients showed similar glucose homeostasis and insulin demand regardless of whether continuous enteral nutrition was fat-based or glucose-based. Special nutrition formulas do not seem to influence glucose homeostasis in the acute phase of illness in medical critically ill patients.

P1114 HEALTHCARE PROFESSIONALS' KNOWLEDGE ON THE INSERTION & BASIC CARE OF NASOGASTRIC FEEDING TUBES

M. Carter[1], **P. Eadala**[1,*], C. Planello[1]
[1]*Gastroenterology, Morriston Hospital, Swansea, United Kingdom*
Contact E-mail Address: *matthewphillip.carter@wales.nhs.uk*

INTRODUCTION: In the UK, thousands of nasogastric (NG) feeding tubes are inserted each day to administer enteral feeds and medication. The main risk associated with NG tubes is misplacement into the respiratory tract. Between 2005-2010, the National Patient Safety Agency (NPSA) reported 100 serious incidents relating to the misplacement of NG tubes, with 21 resulting deaths. Guidelines set by the NPSA aim to ensure that thorough checks are carried out to minimise patient risk.
AIMS & METHODS: The aim was to evaluate the knowledge of healthcare professionals on the basic principles behind inserting and caring for NG tubes. NPSA guidelines were analysed and a multiple choice questionnaire was created. Questions covered contraindications to NG tubes, basic safety checks to confirm correct placement (pH of aspirates and interpretation of chest x-rays) and basic care of NG tubes once sited. 120 questionnaires were distributed on one day to all available doctors and nurses in the ED, medical, surgical & intensive care wards in a South Wales hospital. Questionnaires were completed without time constraints and collected the same day. They were then marked against a prescored questionnaire.
RESULTS: 120 questionnaires were distributed. 73% were returned. 45% were completed by doctors & 55% by nurses. 38% were able to identify all contraindications to NG tube insertion. Participants were asked to estimate the length an NG tube should be inserted. A NEX (Nose-Ear-Xiphysternum) measurement should be taken prior to insertion. 32% of participants were able to identify the 3 correct anatomical landmarks. Questions regarding safety checks following insertion of an NG tube were answered well. 79% were able to identify the first line test (pH paper) that should be used to confirm correct placement. 82% were aware that chest x-ray is a second line test. Only 42% were aware of the correct pH which confirms correct NG placement. No participants were able to identify all situations requiring immediate re-confirmation of NG tube site. Worryingly, 16% did not identify that NG tube position should be reconfirmed before administering enteral medication/feeds. 14% were unaware that NG tube position should be reconfirmed after vomiting. 10% did not identify new signs of respiratory distress as a situation requiring reconfirmation of site. Participants trained to interpret chest x-rays were asked to identify chest x-ray features seen with a correctly sited NG tube. 29% correctly identified all features. The remaining participants did not identify one or more features that are essential to look for when checking NG placement on a chest x-ray. 56% did not identify bisecting the carina as a feature, and 15% did not select "clearly identifiable NG tube" as a required feature.
CONCLUSION: Amongst clinical staff there is poor knowledge on NG tubes. Many participants were unable to identify absolute contraindications and were unaware of the NEX measurement. Less than half the cohort were aware of the aspirate pH that confirms correct positioning. There was poor knowledge of situations requiring immediate re-confirmation of NG site and chest x-ray features confirming placement. These results highlight the need for improvement in training staff receive on NG tubes, to ensure that patent safety is not compromised.

P1115 FACTORS INFLUENCING MORTALITY FOLLOWING GASTROSTOMY INSERTION

M. Kurien[1,*], R. Andrews[1], M.E. McAlindon[1], D.S. Sanders[1]
[1]*Department of Gastroenterology, ROYAL HALLAMSHIRE HOSPITAL, Sheffield, United Kingdom*

INTRODUCTION: High mortality rates have previously been reported following gastrostomy insertion, particularly among certain patient groups (e.g. dementia). With the increasing use of prophylactic gastrostomy for head and neck cancer (HNC), our group aimed to examine survival in this cohort compared to other referral indications and assess risk factors.
AIMS & METHODS: Gastrostomy insertions were examined from two hospitals in Sheffield between 2004 - 2013. Data was prospectively collected from all referred patients including demographic data, biochemical parameters, referral indications and gastrostomy type. Statistical analysis was performed with Chi-squared or Fishers exact tests.
RESULTS: 1733 patients were included (1004 male, mean age = 65). 30 day and 1 year mortality was 9.66% and 44.98% respectively. Indications for gastrostomy included; HNC (n = 591), neurological disease (n = 429), dysphagic stroke (n = 393), dementia (n = 9) and other (n = 311). The lowest mortality was seen in patients with HNC (30 day mortality = 5.2%, 1 year mortality = 32.6%). In comparison, 30 day mortality in all other groups was significantly higher (8.47% in neurological diseases, 15.86% in dysphagic stroke, 33.3% in dementia and 11.25% in 'other' indication, p < 0.01). Mortality was also significantly higher at one year (p < 0.01). There was no significant difference in mortality when comparing radiologically inserted and percutaneous endoscopic gastrostomies. Higher mortality rates were seen in patients aged 60 years or above at 30 days (OR 2.439 (1.666 – 3.731) p < 0.0001) and also at 1 year (OR 3.140 (0.268 – 0.600) p < 0.0001). Albumin less than 30g/L was also associated with significantly higher 30 day (OR 4.486 (3.067 – 6.561) p < 0.0001) and 1 year mortality outcomes (OR 2.319 (1.830 to 2.939) p < 0.0001). In accordance with recent published data, our findings would support an elevated CRP (> 5mg/L) being a factor associated with 30 day mortality (OR 8.930 (1.199 to 66.51) p = 0.006).
CONCLUSION: Referral indication for gastrostomy significantly impacts 30 day and 1 year mortality outcomes, with lowest rates demonstrated in patients with HNC. Identification of factors associated with mortality as seen in this study could help improve patient selection and be of relevance in the decision making process for gastrostomy.

INTRODUCTION: Gastrostomy may be indicated in several situations usually when oral intake is not adequate. It can be done surgically or with endoscopy: percutaneous endoscopic gastrostomy (PEG). PEG placement allows adequate nutrition, in dysphagic patients of different etiologies.

AIMS & METHODS: The aim of this study was to characterize the patients in whom a PEG was placed and the complications associated with the procedure. Retrospective study of all patients in whom a PEG was placed between November 1993 until April 2014 in a referral center, based on data prospectively collected, including follow-up visits. All PEGs were performed using the pull-through technique by one experienced endoscopist.
RESULTS: 865 patients were included; 515 were male with a mean age of 63.28 years. The mean follow-up time was 19.21 months (0-158).
The most common indication for the procedure was motor dysphagia. Most patients were referred from neurology: 309 (35%), otorhinolaryngology: 227 (26%), and internal medicine: 94 (11%).
507 patients had neurologic disease and 292 had cancer. Of the neurologic diseases the most common were amyotrophic lateral sclerosis (216; 43%); stroke (87; 17%); dementia (58; 11%); Parkinson (32; 6%); traumatic brain injury (21; 4%) and cerebral palsy (17; 3%). The most common malignancies were pharyngeal-laryngeal (207; 71%); esophagic (40; 14%) and central nervous system (30; 10%. In 5 patients the procedure was not done because there was no gastric transillumination (4 had previous abdominal surgeries).
The most frequent complication in our series: Minor: inadvertent PEG tube removal (about 100, difficult to be exact), mucosal extrusion (150), significant peristomal leakage (20); Major: pneumoperitoneum with abdominal pain, leucocytosis and elevated C reactive protein (5), wound infection (4), buried bumper syndrome (4), small bowel perforation during PEG/PEJ placement (1), interposed bowel (3) and cardio-respiratory arrest (3), one during the procedure and the other 2 in the 48 h after the procedure. Only one patient needed surgical intervention.
There were three other procedure related deaths. One patient refused surgery after small bowel perforation during the procedure; other had peritonitis after inadvertent PEG tube removal and the other patient in the sequence of an abscess after buried bumper syndrome.
CONCLUSION: In our series PEG was quite a safe procedure that was more commonly used in patients with neurologic disease and cancer.

P1117 ARE DILATATIONS OF ESOPHAGEAL STRICTURES IN CHILDREN EFFECTIVE?

F. Benhassine[1,*], A. Yagoubi[1], **L. Benhassine**[1], M. Baghriche[1]
[1]*Hopital Bologhine, Algiers, Algeria*
Contact E-mail Address: *f_benhassine@yahoo.fr*

INTRODUCTION: Esophageal strictures in children are most of the time acquired and benign. Although they have multiple etiologies, they all respond to the same treatment: instrumental dilatations.
Our objective is to specify the etiology of esophageal strictures and to assess their response to dilatation treatment depending on the etiology.
AIMS & METHODS: The study covers all the cases of esophageal strictures treated in our pediatric digestive explorations unit, that benefited from dilatations between January 1996 and December 2011. Out of 1,022 cases of diagnosed esophageal strictures, 422 benefited from dilatations. The dilatations were performed using Savary-Gillard bougies in an outpatient setting, under heavy sedation, or general anesthesia for complex strictures. Three to four bougies are passed per session. The response to treatment is judged good when obtaining a quasi-normal oral feeding without food hangings.
RESULTS: 422 children, aged between 2 months and 15 years, benefited from repeated dilatations, performed at short intervals in the beginning, then at longer intervals depending on the results. The strictures were caustic (330 cases of which 16 presented an anastomotic stricture after oesophagoplasty), peptic (48 cases), and anastomotic (operated eosophagal atresia (25 cases), congenital (9 cases), thermal (2 cases), caustic plant ingestion (1 case), and unknown nature (9 cases)).
The response to the treatment, all causes combined, is good in 345 cases out of 422 (82%). The results are better for the peptic strictures (98%) compared to anastomotic (90%), caustic (79%) and congenital (78%) strictures.
The 422 patients required 2,711 dilatation sessions. The average number of sessions is higher in caustic strictures than in other etiologies: 8 sessions versus 4 respectively.
Complications consisted in 5 cases of perforation (4 caustic strictures and 1 congenital), 1 case of digestive bleeding and 1 case of septicemia that responded well to medical treatment.
CONCLUSION: Caustic esophageal strictures are the most frequent cause in our practice. Globally, the response to dilatations is relatively good but their future, on the long term, remains a subject of preoccupation and an endoscopic surveillance of these children in adulthood is necessary in order to detect a possible dysplasia.

P1118 THE CHARACTERISTIC OF GASTROESOPHAGEAL REFLUX IN CHILDREN WITH CYSTIC FIBROSIS

M. Dziekiewicz[1,*], A. Banaszkiewicz[1], A. Urzykowska[2], A. Lisowska[3], M. Rachel[4], J. Walkowiak[3], D. Sands[2], A. Radzikowski[1]
[1]*Department of Pediatric Gastroenterology and Nutrition, Medical University of Warsaw,* [2]*Department of Pediatrics, Institute of Mother and Child, Warsaw,* [3]*Department of Pediatric Gastroenterology and Metabolic Diseases, Poznań University of Medical Sciences, Poznań,* [4]*Allergology Outpatient Department, Provincial Hospital No 2, Rzeszow, Poland*

INTRODUCTION: Previously published studies have indicated that gastroesophageal reflux disease (GERD) is very common in patients with cystic fibrosis (CF), also in paediatric population. However, it hasn't been well characterized so far.
AIMS & METHODS: The aim of the study was to assess the frequency of GERD and characterize gastroesophageal reflux episodes (GER) in children with cystic fibrosis.
This was a multicenter, prospective study of children with cystic fibrosis older than 12 months of age. All children underwent 24 hour multichannel intraluminal pH-impedance (MII-pH) monitoring. The characteristic of GER was made with BioVIEW analysis software and manual revision made by single investigator.
RESULTS: 44 consecutive patients (22 boys, median age 10.65± 3.6, range 6.3-17.8) were enrolled into the study. GERD was diagnosed in 26/44 (59.1%) patients. A total of 1585 reflux episodes were detected by MII-pH. 1199 (75.6%) of them were acid, 382 (24.1%) – weakly acid and 4 (0.3%) weakly alkaline. 691 (43.6%) GER episodes reached the proximal oesophagus. In only 14/44 (31.7%) patients typical GERD symptoms were present.
CONCLUSION: It was the largest study characterising GERD in children with CF with a use of MII-pH performed so far. The frequency of GERD in children with CF is very high, similar to previously raised. Majority of GER episodes were acid, so proton pump inhibitors may be an effective therapeutic option in this population. Number of proximal GER was relatively high, which may increase the risk of aspiration. In children with cystic fibrosis GERD should be diagnosed regardless of presence of its typical symptoms.

INTRODUCTION: Esophageal stricture (ES) may arise in children from a number of etiologies, mainly as a primary anomaly, after esophageal surgery and as a result of chemical injury. Esophageal balloon or bougie dilation is a nonsurgical method for treatment of most esophageal strictures in children. Some strictures may be complex and require a divergent treatment approach.
AIMS & METHODS: The aim of this study was to determine the efficacy and safety of esophageal dilatations for symptomatic esophageal strictures in children.
A retrospective longitudinal study was carried out on children with ES who were submitted to esophageal dilatation in two pediatric hospitals in Rio de Janeiro over a median follow-up period of 6 years. The data collected were age, sex, type of ES, type of dilatation treatment, number of dilatations, intralesional injection of corticosteroid, use of rigid scope and dilatation with different accessories for endoscopes. All the procedures were under general anesthesia. The objective of each dilatation session was to break the stricture or to increase the esophageal diameter.
RESULTS: 63 patients were included in this study. Patients age ranges one month-old to 10 years-old and 54% were male. The most common stricture cause was postoperative (after esophageal atresia repair) in 46 patients (73%), followed by caustic stricture in 17% patients. A total of 453 bougie dilatations were carried out with the mean number of dilatations per patient being 7. Eighteen patients (29%) had complex strictures and require a special treatment. In 9 (14.3%) patients only the ERCP guide-wire pass the ES, 4 patients (6.3%) were treated with intralesional triamcinolone, 3 (4.8%) were first dilated with ERCP balloon, 2 (3.2%) require rigid esophagoscopy to the first dilatation, 2 were submitted to gastrostomy and retrograde positioning of the guide-wire, 2 were first dilated with biopsy forceps, 1 patient (1.6%) had been treated by electrocautery therapy and 1 with total esophageal occlusion were treated by anterograde-retrograde Rendez-vous approach. Dilatation was successful in 39 patients (62%), 13 patients (21%) are still being submitted to dilatation, 6 (9.5%) were referred to surgical treatment and 5 (8%) abandoned the treatment.
There were one (0.2%) anesthetic complication and 3 (0.6%) endoscopic perforations (2 treated clinically and 1 surgically).
CONCLUSION: Savary-Gilliard bougie dilatation is a safe and effective procedure in the management of the most ES in children. In ours series the most children (90%) had been treated endoscopically with low number of complications. Complex ES may require different treatment. The creativity of the endoscopist using different accessories for endoscopes allow many patients with complex stenosis to be treated in non surgical method.

P1120 PRIMITIVE PEPTIC ULCER DISEASE: A 5-YEAR RETROSPECTIVE STUDY IN A CHILDREN'S HOSPITAL FROM NORTH-EASTERN ROMANIA

S. Diaconescu[1,*], C. Olaru[1], G. Paduraru[1], G. Ciubotariu[1], M. Burlea[1], N. Gimiga[1]
[1]*Pediatrics, "Gr. T. Popa" University of Medicine and Pharmacy, Jassy, Romania*

INTRODUCTION: Primitive peptic ulcer disease is still frequent in children from middle income countries with a high incidence of *H. Pylori* infection and a large amount of population with impaired socioeconomic status.
AIMS & METHODS: To investigate the prevalence, clinical features and risk factors of primitive peptic ulcer disease (PUD) in a pediatric population from North-Eastern Romania. We examined retrospectively all endoscopy records from 2009-2013. Demographical, clinical, laboratory, endoscopical and therapeutic data were analysed.
RESULTS: We report an incidence of 6.09/100.000 individuals for primary PUD and a frequency of 4.61%. 49.36% of children were 14-16 years old (range: 7-18 years), male to female ratio was 1.46:1 and 77.41% of patients were living in urban areas. Clinical features included chronic abdominal pain (50.89%), followed by vomiting (34.18%) and upper digestive bleeding (11.39%). We found 65 douodenal ulcers (DU) and 9 gastric ulcers (GU). Family history was positive in 55.33 % of DU patients with group O and found type O blood in 55.56% of the patients. 71.42% were HP-related PUD; from these, 77.42 % were DU. Non HP-PUD was found in 28.58 % children We identify an improper diet (63.16%), smoking (57.39%), alcohol consumption (15, 78 %), psychological stress represented by school difficulties (27.27%), family conflicts (22.73%) and conflicts with entourage (13.64%) as additional risk factors for the disease. We noticed a significant correlation between a high number of family members ($r = 0.63$, $p = 0.002$), low socioeconomic status ($r = 0.87$, $p = 0.0003$) and *H.pylori* infection. We used standard triple therapy in 73.33% of the patients, bismuth-based quadruple therapy in 16.66 % children and sequential therapy in 10% of the cases. The global eradication rate was 66.66 % on all series of patients; we didn't have technical conditions to search antibiotic resistance of the bacteria but previous studies indicate a resistance to clarithromycin around 33 % in Romania.
CONCLUSION: In North-Eastern Romania, primitive PUD affects mainly teenagers from urban areas, originating from large families with a low socioeconomic status and a high incidence of *H.pylori* infection. DU were more frequent, associated with blood type O and family history; we also identified associated risk factors for the disease as diet, smoking, alcohol consumption and stress. Since we obtain a moderate eradication rate using the first line recommended therapies we considered this as an indirect proof of high clarithromycin resistance in romanian children due to the wide-spread practice of empirical antymicrobial therapy in our country.

INTRODUCTION: Recently, the prevalence of *Helicobacter pylori* infection in Japanese children has been reduced to 3-5%. The drug susceptibility is different depending on the country or region, so that it is necessary to consider the regional characteristics to eradicate *H. pylori*. We are inspired to re-evaluate the eradication therapy among Japanese chidlren by high eradication rate of sequential therapy in European children.
AIMS & METHODS: The present study aimed to evaluate the drug resistance rate and the eradication rate of *H. pylori* in the last 10 years in Japanese children. From April 2003 to March 2012, in Japanese three facilities, total 74 (mean age 12.3 ± 3.2, male 47.3%) children and adolescents under 18 years old, who had no history of eradication therapy in the past, were included in this study. *H. pylori* was cultured using biopsy specimens from gastric antrum and corpus then the drug susceptibility was evaluated. Patients were treated with susceptibility-based triple therapy and were examined the rate of eradication. Successfulness of eradication was evaluated by the 13C-urea breath test and/or stool antigen test at least 8 weeks later after the end of treatment.
RESULTS: *H.pylori* susceptibility test showed that 47.2% were resistance (MIC = >1) to clarithromycin (CAM), 30.1% (MIC = >16) to metronidazole (MNZ). Susceptibility of amoxicillin (AMPC) (MIC = >0.06) was 21.3 %, but MIC = >1 was only 2 strains. The MIC 50 of CAM during the first five-years of study period was 0.12 and resistance rate was 44.4%. On the other hand, in the last five-years period, MIC of CAM was 2.0 and resistance rate was 52.2%, so it was speculated to be in the increasing trend in CAM-resistant strain. The overall eradication rate was 89.4%(59/66) by intention-to-treat analysis (ITT) and 96.7% by per-protocol analysis (PP). The PPI, AMPC and CAM regimen was the first choice for CAM susceptible strain. The ITT and PP eradication rates were 91.7% (33/36) and 100% (33/33), respectively. The PPI, AMPC and MNZ regimen was the first choice for CAM resistant strain and the ITT and PP eradication rates were 91.3% (21/23) and 100% (21/21), respectively.
CONCLUSION: An antimicrobial susceptibility-guided triple eradication therapy for *H. pylori* is effective in Japanese children with very high, approximately 50%, CAM resistance rate and it was comparable to or greater than the previously described sequential therapy in western countries.

INTRODUCTION: In 2011, the European Society for Pediatric Gastroenterology, Hepatology, and Nutrition (ESPGHAN) has released its updated guidelines on celiac disease (CD) diagnosis.1 According to these new guidelines, symptomatic children with anti-transglutaminase (anti-tTG2) antibody levels ≥ 10 times upper limit normal (ULN) could avoid duodenal biopsies if the HLA test and serum anti-endomysial antibodies (EMA) are positive.1 So far, both symptomatic patients with anti-tTG2 titer <10 times ULN and those asymptomatic should undergo upper endoscopy with multiple duodenal biopsies to confirm a suspected CD.
AIMS & METHODS: The aim of this study was to assess the accuracy of serological tests in asymptomatic patients to diagnose CD. We retrospectively assessed 286 children and adolescents (mean age: 8.3 years; age range: 10 months-17 years) who had received a CD diagnosis based on elevated titer of anti-tTG2, EMA positivity, histology and HLA typing. All patients (95 boys, 191 girls) were positive for anti-tTG2 and EMA. Patients were distinguished between symptomatic and asymptomatic while histological lesions were graded according to the Marsh-Oberhuber (MO) criteria. Statistical evaluation was made with the Fisher exact test.
RESULTS: Among the 286 EMA positive biopsied children, 196 (68.53%) had anti-tTG2 titers ≥ 10 times ULN. Among them, a group of 156 (86.02 %) children also had symptoms suggestive of CD (namely "high-titer" symptomatic children); of these, 142 (91.02%) showed severe lesion degree (3a, 3b, 3c MO). On the contrary, 40 out of 196 (13.98%) children were asymptomatic (namely "high-titer" asymptomatic children); 37 (92.5%) of them showed severe lesion degree (3a,3b, 3c MO). No difference was found between "high-titer" symptomatic children and "high-titer" asymptomatic children with regards to histological damage (Fisher exact test $p = 1.000$).
CONCLUSION: Our results indicate that the absence of symptoms in children with anti-tTG2 titers >10 times ULN and positive EMA antibodies does not undermine a "biopsy-sparing" CD diagnosis. The "biopsy-sparing" protocol seems to be applicable to both symptomatic and asymptomatic patients with anti-tTG2 titer >10 times ULN, positive EMA and HLA-DQ2/DQ8.

P1123 SOCIOECONOMIC VARIATION IN THE INCIDENCE OF CHILDHOOD COELIAC DISEASE IN THE UNITED KINGDOM

F. Zingone[1,2,*], J. West[1], C. Crooks[1], K.M. Fleming[1], T.R. Card[1], C. Ciacci[2], L.J. Tata[1]
[1]*Division of Epidemiology and Public Health, University of Nottingham, Nottingham, United Kingdom,* [2]*Department of Medicine and Surgery, University of Salerno, Salerno, Italy*
Contact E-mail Address: *z.fabiana@hotmail.it*

INTRODUCTION: Socioeconomic status has been proposed as a potential risk factor for coeliac disease (CD), but the few studies that have investigated this possible association report conflicting results. We aimed to estimate the current diagnostic patterns among children in the United Kingdom (UK) and how they vary by socioeconomic status.
AIMS & METHODS: All children aged 0-18 years who were actively registered with a large population-based general practice database between 1993 and 2012 were identified. The incidence of CD was evaluated in each quintile of the Townsend Index of Deprivation, a measure of socioeconomic status, and stratified by age, sex, country of residence and calendar year.
RESULTS: Among 2.063,421 children we identified 1.247 coeliac disease diagnoses, corresponding to an overall CD incidence of 11.8 per 100.000 person-years, which was similar across the UK countries and higher in girls than in boys. We found a gradient of CD diagnosis across socioeconomic groups, with the rate of disease being 80% higher in children from the least socioeconomically deprived areas than in those belonging to the most deprived areas (Incident Rate Ratio (IRR) 1.80, 95% CI 1.45-2.22). This pattern held for both boys and girls and across all ages. Across all four countries of the UK, we found similar associations between CD incidence and socioeconomic status. Whilst CD incidence up to age 2 remained stable over the study period, diagnoses at older ages have doubled over the past 20 years.

Table 1. Incidence rates and Incidence rates ratios of Coeliac Disease across socioeconomic status
Table to abstract P1123

Socioeconomic deprivation (Quintile of Townsend Index)	Rate per 100.000 person-years (95% confidence interval)	Unadjusted Incidence Rate Ratios (95% confidence interval)
1 (least deprived)	14.1 (12.7-15.7)	1.80 (1.45-2.22)
2	14.5 (12.9-16.2)	1.85 (1.48-2.30)
3	10.8 (9.5-12.3)	1.37 (1.09-1.73)
4	10.4 (9.0-11.9)	1.32 (1.05-1.67)
5 (most deprived)	7.8 (6.5-9.4)	reference

CONCLUSION: Despite a doubling in childhood coeliac disease diagnoses over 20 years, children from the most socioeconomically deprived areas are half as likely to be diagnosed as those from less deprived areas. Awareness campaigns and implementation of national guidance may help to implement strategies for case-finding in all children and reduce this inequality. Moreover, future studies should explore the possible association between exposures to different specific risk factors and the risk of CD across socioeconomic groups.

P1124 NARROW BAND IMAGING (NBI) COMBINED WITH WATER IMMERSION TECHNIQUE (WIT): ANY DIAGNOSTIC YIELD FOR CELIAC DISEASE? A PEDIATRIC PROSPECTIVE STUDY

F. Valitutti[1,*], D. Iorfida[1], S. Oliva[1], I. Celletti[1], S. Leoni[1], S. Gatti[1], C.M. Trovato[1], M. Barbato[1], M. Montuori[1], C. Anania[1], A. Tiberti[2], G. Di Nardo[1], S. Cucchiara[1]
[1]*Department of Pediatrics,* [2]*Depertment of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome, Italy*

INTRODUCTION: Upper GI endoscopies are still required to diagnose the majority of children with celiac disease (CD), notwithstanding the recently updated ESPGHAN criteria.[1] The ''multiple-biopsy'' approach both in the duodenum and in the bulb has been suggested by several guidelines as the best strategy to confirm the diagnosis of CD; however, this approach increases the invasiveness of the endoscopic procedure itself and is fairly time-consuming
AIMS & METHODS: Our aim was to evaluate the diagnostic yield of a single biopsy guided by narrow-band imaging (NBI) combined with water immersion technique (WIT), in a prospective study of children with CD. We enrolled 43 children (12 males; mean age: 7.2 years; age range: 1.25-15.25 years) with suspected CD undergoing upper GI endoscopy to compare single ''NBI plus WIT''-guided biopsy versus the standard, duodenal and bulbar, ''multiple-biopsy'' approach (2 random biopsies in the bulb, 4 random biopsies in the 2nd-3rd duodenal portion). ''NBI-plus-WIT'' endoscopic severity was classified on a Likert scale as normal, altered with mild modifications (nodular mucosa, scalloping) or clearly altered (reduction and flattening of ''plicae''); inter-observer variability between two different physicians was also assessed with regards to endoscopic judgments. Histology was graded according to the Marsh-Oberhuber classification.
RESULTS: Diagnosis of CD was confirmed in 40 out of 43 children. ''NBI plus WIT'' approach correctly diagnosed 35 out of 40 celiac children, with a diagnostic sensitivity of 87.5 % (C. I.: 77.3-97.7); none among the studied patients showed an exclusive, ''NBI plus WIT''-detected histological damage. Clearly altered pattern at ''NBI plus WIT'' endoscopic visualization was significantly associated to villous atrophy both at ''NBI plus WIT''-guided biopsy and at multiple biopsy sampling (Spearman Rho 0.637 and 0.496). High anti-transglutaminase antibody titer ($\geq$10 times upper limit normal) was also associated to clearly altered pattern at ''NBI plus WIT'' endoscopic visualization. Concordance of ''NBI plus WIT'' endoscopic assessments was fairly high between two different operators (K: 0.884). After the passage through the pylorus of the endoscope, mean NBI plus WIT procedure time was 53.6 sec (DS: 12.7 sec), whereas mean time for multiple biopsy sampling was 218.2 sec (DS: 38.3 sec) ($p \leq 0.0001$).
CONCLUSION: Albeit time- and resource- saving, single ''NBI plus WIT''-guided biopsy is not as effective as the well established ''multiple-biopsy'' approach in confirming the diagnosis of CD. However, in presence of an altered ''NBI-plus-WIT'' pattern coupled to high anti-transglutaminase antibodies, a single ''NBI plus WIT''-driven biopsy might suffice to diagnose CD.
When no altered mucosal pattern is visible even at ''NBI plus WIT'', multiple bulbar and duodenal biopsies must be obtained to confirm diagnosis.

P1125 ANTI-TRANSGLUTAMINASE TITER, MARSH-OBERHUBER GRADING AND BONE MINERAL DENSITY IN CHILDREN WITH CELIAC DISEASE AT DIAGNOSIS

C.M. Trovato[1], I. Celletti[1], S. Gatti[1], S. Leoni[1], **F. Valitutti**[1,*], D. Iorfida[1], M. Montuori[1], C. Anania[1], M. Barbato[1], S. Cucchiara[1]
[1]*Department of Pediatrics, "SAPIENZA", UNIVERSITY OF ROME, Rome, Italy*
Contact E-mail Address: *chiaramaria.trovato@uniroma1.it*

INTRODUCTION: Metabolic bone disease remains a significant and common complication of celiac disease (CD). Several studies have demonstrated low bone mineral density (BMD) at the time of celiac disease diagnosis in both children and adults.[1] Low bone density in children and adolescents is defined as an areal BMD (aBMD) less than 2 SD below the age-adjusted mean value (Z-score < -2 SD).[2] The pathogenesis of bone loss in celiac disease has not been completely elucidated: two major causal factors are malabsorption and inflammation. Calcium and Vitamin D might be poorly absorbed substances in celiacs.1 Several studies demonstrated an increased RANKL/OPG ratio in vitro and an increased osteoclastogenesis in untreated celiac patients due to chronic release of pro-inflammatory cytokines.[3,4]
AIMS & METHODS: Aim of our study was to correlate Z-score value and anti-tissue transglutaminase type 2 (anti-tTG2) antibody titer and Z-score value and Marsh-Oberhuber grade (MO) in children with celiac disease at diagnosis. We enrolled 99 celiac patients (M 35; F 64; age-range: 4-15 years). All patients had positive test results for anti-tTG2 antibodies, histological lesions graded according to MO classification; all of them underwent lumbar DXA performed by Lunar Prodigy Advance (GE Healthcare, USA). Bone mineral density was estimated by Z-score. The linear correlation between the anti-tTg2 titer and Z-score value and between MO grade and Z-score was evaluated by the Pearson product-moment correlation coefficient (Pearson's *r*).
RESULTS: Anti-tTG2 antibody titers $\geq$10 times the upper limit of normal were found in 65 of 99 patients. 84 patients showed severe lesion degree (3c + 3b + 3a) in Marsh-Oberhuber classification, 3 patients showed MO2, 4 MO1, 4 no lesions and 4 didn't undergo conventional upper GI endoscopy (diagnosed according to the ''biopsy-sparing'' ESPGHAN 2012 criteria). Low BMD (Z-score ≤ -2DS) was found in 13 (13.13%) patients; 20 (20.20%) patients showed $-2 <$ Z-score < -1; 43 (43.43%) patients showed -1$\leq$ Z-score < 0 and Z score ≥ 0 was detected in 23 (23.23%) patients. No correlations were found between Z-score value and anti-tTG2 title (Pearson's r = -0.06) and between Z-score value and MO degree (Pearson's r = 0.07). Low bone mineral density does not correlate to the anti-tTG2 title and to Marsh-Oberhuber degree in a cohort of Italian children at CD diagnosis.
CONCLUSION: Our results indicate that there is no clear clinical predictor to identify children with low BMD and who should undergo DXA at the diagnosis. A follow up evaluation after few months of GFD might be more reasonable.

P1127 EFFICACY OF DEAMIDATED GLIADIN PEPTIDE-BASED POINT-OF-CARE TEST (SIMTOMAX®) FOR THE EARLY DIAGNOSIS OF COELIAC DISEASE IN PAEDIATRIC PATIENTS

I. Polanco[1], **T.K. Weber**[1,*], E.M. Ojinaga[1], M. Molina[1], J. Sarria[1]
[1]*Department of Pediatric Gastroenterology and Nutrition, Chidreńs University Hospital La Paz, Madrid, Spain*
Contact E-mail Address: *thabataweber@yahoo.com.br*

INTRODUCTION: Coeliac disease (CD) is currently under diagnosed. It is estimated that 90% of patients remain undiagnosed. Early diagnosis is essential to avoid complications.
AIMS & METHODS: The objective of the study is to assess the effectiveness of a rapid, minimally-invasive point-of-care test (POCT) that detects both IgA and IgG anti-DGP antibodies and total IgA (Simtomax®) in the early detection of coeliac disease in paediatric patients.
A prospective study was conducted in which children (£18a) under suspicion of CD (risk groups and/or symptomatic patients) were selected, including brothers of coeliac children under gastroscopy for other gastrointestinal conditions. Those with severe disease, gluten-free diet, gastrointestinal bleeding, coagulopathy and/or infections during the last month were excluded. All children were evaluated with Simtomax®. A further genetic HLA-DQ study was performed in patients under suspicion of CD. Results were compared against the detection of tissue transglutaminase antibodies ELISA IgA or IgG-tTG (EliATM Celikey®, cut-off 10U/ml) and/or EMA as well as results of duodenal biopsy (DB), used for CD diagnosis according to the current ESPGHAN criteria.
RESULTS: 100 children were studied; including 6 brothers of CD diagnosed patients. 18 children were under 2 years-old, and 14 were found CD positive (1 missed with Ttg). Prevalence of CD found in the present study was 47% (confidence interval of 95% (CI95%): 37.9 – 58.2%). The results of the rapid test

were highly concordant with the diagnosis established to CD: a sensitivity of 95.8% (CI95%: 85.7 – 99.4%), specificity of 98.1% (CI95%: 89.7 – 99.7%), positive predictive value of 97.9% (88.7 – 99.6%) and negative predictive value of 96.2% (87.0 – 99.4%). Positive and negative likelihood ratios were, respectively, 49.8 (CI95%: 72 – 347.5) and 0.04 (CI95%: 0.01 – 0.17). We found two false-negative patients and a false-positive (the latter with a coeliac brother).
CONCLUSION: Taking into account its high diagnostic accuracy in the pediatric population, this rapid test could be considered an effective tool for the early diagnosis of CD, especially in primary care High LR+ and low LR- imply Simtomax® is a suitable tool for ruling in and ruling out CD and results suggest that this POCT could potentially replace standard serology for CD diagnosis in children. Further studies should also cover potential cost savings with Simtomax.

P1128 UNVEILED. THE HIDDEN SHAPE OF NUMBERS. DATA MINING TECHNIQUES APPLIED TO HYDROGEN LACTOSE BREATH TEST

A. Rodriguez Herrera[1,*], Y. Hernández-Mendoza [2], J. Valverde Fernandez[1], C. Rubio-Escudero[3], I. Nepomuceno-Chamorro[4], B. Pontes-Balanza[4]
[1]*GASTROENTEROLOGY AND NUTRITION UNIT, INSTITUTO HISPALENSE DE PEDIATRIA, SEVILLE, Spain,* [2]*Networks and Computers, Universidad Ciego del Ávila, Ciego del Ávila, Cuba,* [3] *Computer Science and Languages,* [4]*Computer Science and Languages, Universidad de Sevilla, SEVILLE, Spain*

INTRODUCTION: Informatics applied to clinical data collection provide huge sets of data. Interpretation of these sets with classical descriptive techniques can miss relevant conclusions. Clustering is a method to discover hidden groups or patterns in big sets of data. No initial groups are provided but the clustering is allowed to form groups to maximize the similarity of the patients in each group.
AIMS & METHODS: Application of data mining techniques to identification of hidden patterns in data from hydrogen breath test with lactose. The goal was to identify non evident groups of patients than can potentially share common characteristics not easily evident. Secondarily, we conducted a classic descriptive study of our data set.
Mathematical review with use of clustering techniques of hydrogen breath test. Time range of 4 years, from June 2009 to June 2013. Cluster analysis as such is not an automatic task, but an iterative process of knowledge discovery or interactive multi-objective optimization that involves trial and failure. Measures were, taken at 0 minutes (baseline), 30, 60, 90, 120, 150, 180. Test with an increased level of 20 ppm over baseline were considered "positive".
RESULTS: Data sets from 2751 lactose hydrogen breath test were included. A set of 6 different typologies of data curves were identified:1. Straight line, non-ascending, linked to baseline minor than 20 ppm.2. Straight line, non-ascending, linked to baseline bigger than 20 ppm.3. Curved line, ascendant before 90 minutes.4. Curved line, ascending after 90 minutes.5. Curved line, with doubly ascendant, before and after 90 minutes.6. Curved line, ascendant only at 180 minutes 839 children (32.63 %) were "positive", when increase in 20 ppm was considered independently from the net value of baseline. Otherwise when"positive" is defined strictly as patient with baseline bigger 20 ppm result is similar, showing 32.61 % of children with positive test. 166 patients (6.5 %) had showed high vallues only at 180 minutes.
CONCLUSION:
Although data mining is being incorporated into clinical practice, there is currently no literature on the same test in hydrogen. Using clustering techniques, we have identified a total of 6 curves type in our patients undergoing the test. As 6.5% shows elevation at 180 minutes,test should be always extended up this duration in any case. Early interruption of test is an usual practice in some institutions. A future research option will be to link these 6 groups to different sets of symptoms or metabolic activity of gut flora. Data mining provide an identification of groups not decided in advance, providing less selection bias in clinical research.

INTRODUCTION: Several studies evaluate the efficacy of the Hydrogen (H_2) breath test as a non-invasive study with high sensitivity and specificity to diagnose lactose intolerance. Moreover, it has been reported that an increase in breath CH_4 excretion occurs in children with lactose intolerance. Several papers used different methods to evaluate CH_4 on expired air.
AIMS & METHODS: The aim of the study is to evaluate the importance of CH_4 measurements in the diagnosis of lactose intolerance using different cut-off.
We evaluated 133 children with symptoms suggestive of lactose intolerance. All patients underwent a Lactose H_2 and CH_4 Breath Test (LHMBT). Lactose was administered orally (dose of 2 mg/kg, max 50 mg) diluted in max 250 ml of water. The expired air was collected in specific syringes with a capacity of 20 ml. One breath sample was taken before the intake of lactose and breath samples were taken after the ingestion of lactose every 15 min for 3 hours. The expired H_2 and CH_4 was measured with a specific analyzer (Microlyzer DP; Quintron Instruments, Milwaukee, Wis.). The result was considered positive when a H_2 peak exceeded 20 part per milion (ppm) over the baseline value. Whilst, CH_4 was considered positive using three different cut-off, 20 ppm above the baseline (Method 1), 12 ppm above the baseline (Method 2) or 5 ppm above the baseline (Method 3). A clinician, blinded for the results of the breath test, registered the symptoms of the patients during the test. Statistical evaluation was considered statistically significant for a $p<0.05$).
RESULTS: Fifty-four patients (40.6%) out of 133 resulted positive with methods 1 and 2. Whilst, 63 patients (47.4%) out of 133 can be defined positive with method 3. The percentage of patients positive for hydrogen only (H_2+CH_4-) was 57.4% using method 1 and 33.3% using method 2. No patients showed H_2-CH_4+ values using these methods. Contrary, using method 3, 47/63 (74.6%) patients were positive for both the gases (H_2+CH_4+) and 9/63 (14.3%) children resulted H_2-CH_4+. The peak level of H_2 in H_2+CH_4+ patients was significantly higher than in H_2+CH_4- patients using method 1 and 2 ($P<0.0001$; $p<0.007$, respectively); but not using method 3 (P 0.09). Twenty-seven (50%) out of 54 symptoms was registered in positive patients using method 1 and 2 (p 0.0006); using method 3 we registered 28/63 symptoms in positive children (44.4%) (p 0.008). Sixteen/28 symptoms appeared at the same time of the maximum level of H_2 ($p< 0.001$), and in 13/28 symptoms appeared at the same time of the maximum level of CH_4 ($p< 0.001$). Patients positive only for methane did not respond to the free-lactose diet, showing different disease that explain the symptoms.
CONCLUSION: Our results show that CH_4 had no added value to a simple H_2 breathtest. Moreover, low cut-off of methane may reduce the specificity of the test.

Contact E-mail Address: *kmarakh@tut.by*

INTRODUCTION: Blood citrulline level is subject of several investigations but majority concern celiac disease. Can citrulline be a universal indicator of intestinal atrophy?
AIMS & METHODS: Inclusion criteria were: children with histological confirmed intestinal (duodenal) atrophy. Biopsy specimen was taken endoscopically before age 6 months. Endoscopy was provide on the EXERA III with an endoscope GIF - N180 «Olympus». Group A ($N=4$) have to be gluten independent enteropathy or congenital atrophy (presumably), with diarrhea and progressive malnutrition resistant to intensive treatment. Two cases of tufting enteropathy were detected prospectively. Age at time of biopsy sampling: median - 2.9 (10-90th percentile = 0.4-5, 6) months. Control group (B, $N=11$) were included children without symptom of diarrhea, with normal weight, height and head circumferential. Endoscopy wasn't done. Blood samples were taken 5.9 days (CI 95% = 4, 5 - 7, 4). Such age was chosen based on data that citrulline is a indicator of mass enterocytes and this group will have lowest citrulline level per life.
Serum level of citrulline, threonine and taurine was detected by standard validation method -high performance liquid chromatography (HPLC) by AGILENT 1100 chromatograph on the column Zorbax Eclipse C18 with the fluorimetric detector.
RESULTS: Significant difference in citrulline level between two groups atrophy/not atrophy was detected. Group A ($n=4$) median citrulline level 12.2 mmol/l (CI 95% = 6.1 - 12.9), group B 24.1 mmol/l (CI95% = 22.0-40.6), $p=0.002$ (Mann-Whitney U or Wilcoxon rank-sum for difference in median).
CONCLUSION: We can assume that the level of blood citrulline in infants can be used as a screening test to assess the risk of the small intestine mucosa atrophy. Endoscopy with biopsy sampling must be followed after low blood citrulline was detected. Further studies are required to clarify.

INTRODUCTION: Necrotizing enterocolitis (NEC) is an acute inflammatory necrosis of small bowel, being the most common neonatal gastrointestinal emergency, that mainly affects preterm low birth weight. NEC incidence is inversely proportional to gestational age (GA), only 10% of term infants develop this disease. Because the etiology and pathogenesis of NEC are still incompletely understood, therapeutic options, morbidity and mortality were not significantly improved in the last decade of time. NEC is a major cause of mortality (up to 25%) and morbidity including recurrent sepsis, dependence on parenteral nutrition, need for surgery and survival with short bowel syndrome. Taking into account the catastrophic development of this disease, it is necessary to focus research on prevention strategies and identify predictive risk factors for its occurrence.
AIMS & METHODS: To identify the risk factors for NEC in preterm infants with GA≤32 weeks in a third level maternity in Romania, using data registered in the National Registry of Respiratory Distress. **Methods:** We retrospectively studied 442 preterm infants ≤ 32 weeks of gestation, born in a third level maternity in Romania between 2010-2013. GA was between 23-32 weeks (with a medium of 29.60 ± 2.26, birth weight was between 480g-2350 g (1309.86 ± 369.44), gender: female 230 (52.0%); male 212(48.0%). Incidence of NEC was 2.7% (12 preterm infants with GA ≤ 32 weeks, stage II and III of disease). The risk factors were selected in four categories: maternal factors, fetal factors, therapeutic factors and factors related to newborns diseases. Statistical analysis of data was performed using Independent Samples T-test and Pearson Chi-Square correlation. p was calculated for confidence interval of 95% (statistical significance $p < 0.05$). To establish NEC predictors we used binominal logistic regression, the Wald model of regressive elimination**.** There were anlysed the characteristics that differentiates preterm babies who developed NEC of those who did not developed this condition.
RESULTS: The final model of regression indicates the fact that the higher risk in developing NEC have had those who presented: mother with ruptures membranes over 18 hours and nosocomial infections. Other most frequend factors implicated in the development of NEC, are, in order of frecvency: maternal-fetal infections, sepsis, maternal hipertension, corioamniotitis, persistent ductus arteriosus, ventilation in CPAP system, lack of antenatal corticotherapy, oxigenoteraphy. There was a statistically significant correlation between NEC and birth weight ($p = 0.003$), chorioamnionitis ($p = 0.02$), bronchopulmonary disease ($p = 0.02$), ruptures membranes over 18 hours ($p = 0.03$).
CONCLUSION: In this study the incidence of NEC was 2.7%, similar to that reported in the literature.
The variability depends on the diagnostic possibilities of each center. The most predictive factors for NEC in our study are: nosocomial infections, ruptures membranes over 18 hours and materno-fetal infections. The knowledge of risk factors for NEC can allow healthcare providers to assess and adjust care practices for preterm infants who presents a higher risk for NEC, based on empirical data.

Contact E-mail Address: *dickmanr1@gmail.com*

INTRODUCTION: Lactobacillus bulgaricus and Streptococcus thermophilus produce lactase enzyme. Probiotics may alleviate lactose intolerance by modifying the intestinal flora into one which contains lactase-producing bacteria.
AIMS & METHODS: To assess the efficacy of probiotics in improving lactose intolerance.
Patients were treated with a unique probiotic formulation (Bio-25, Ambrosia - SupHerb, Israel) for 6 months. All patients completed a demographic questionnaire as well as a visual analog scale (VAS) for the assessment of the intensity and frequency of bloating, flatulence, abdominal pain and change in bowel habits, at entry, every 8 weeks and at the end of treatment period. Measurement of hydrogen levels (parts per million - ppm) at each of these time points was also performed. Study end points were: Improvement in symptom intensity or frequency, and the decrease below cut off point of 20ppm of the breath test. The Wilcoxon signed-rank test was used to compare symptom intensity and severity before and after treatment.
RESULTS: The study group comprised eight symptomatic female patients with a positive lactose intolerance breath test. Mean age and mean body mass index (BMI) (kg/m^2) were: 36.4±18.6 years and 25.2, respectively. Treatment with probiotics was associated with a significant improvement in the reported intensity of bloating ($z = 2.55$, $p = 0.11$) and flatulence ($z = 2.21$, $p = 0.027$); frequency of bloating ($z = 2.06$, $p = 0.039$) and flatulence ($z = 2.04$, $p = 0.041$); abdominal pain ($z = 2.06$, $p = 0.039$), and constipation ($z = 2.07$, $p = 0.039$). Lactose breath test was successfully normalized in two (25%) patients.
CONCLUSION: Treatment with probiotics may lead to symptomatic improvement in patients with lactose intolerance. A larger study is warranted to confirm our findings.

P1133 IMPAIRED SECRETION OF SATIATION HORMONES IS ASSOCIATED WITH INSULIN RESISTANCE IN OBESE ADOLESCENTS

A.C. Meyer-Gerspach[1,*], S. Beglinger[2], S. Graf[2], U. Zumsteg[2], J. Drewe[1], J.-P. Gutzwiller[1], C. Beglinger[1]
[1]*University Hospital Basel,* [2]*University Children's Hospital, Basel, Switzerland*

INTRODUCTION: The role of gastrointestinal (GI) hormones in the pathophysiology of obesity is unclear, although they are involved in the regulation of satiation and glucose metabolism. The objectives of this study were i) to examine glucagon-like peptide 1 (GLP-1), amylin, ghrelin and glucagon responses to a test meal in obese adolescents and ii) to test which GI peptides are associated with insulin resistance.
AIMS & METHODS: A total of 16 obese (8 male and 8 female; mean age: 12.8 ± 0.6 yr; mean BMI 31.2 ± 1.0 kg/m^2) and 14 control (5 male and 9 female; mean age: 14.2 ± 0.4 yr; mean BMI 20.7 ± 0.6 kg/m^2) adolescents were included. Subjects were instructed to eat a test meal (490 kcal). Plasma samples were collected before and after meal ingestion for hormone and glucose analysis.
RESULTS: Obese adolescents were insulin resistant as expressed by the HOMA index and had significantly increased fasting glucagon and amylin levels compared to the control group ($P = 0.003$ and 0.044, respectively). In response to the test meal, the increase in GLP-1 levels was reduced in obese adolescents ($P < 0.001$). In contrast, amylin secretion was significantly increased in the obese population compared to the control group ($P < 0.005$).
Bivariate analysis for HOMA index and post-prandial GLP-1 levels showed a negative correlation ($R^2 = 0.343$, $P < 0.001$). Amylin post-prandial levels and amylin basal concentration demonstrated both a significant positive correlation (R^2 AUC = 0.42, R^2 basal = 0.46, both $P < 0.001$). Fasting glucagon showed a positive correlation to HOMA (R^2 0.46, $P < 0.001$).
CONCLUSION: We conclude that hyperglucagonemia, hyperamylinemia and reduced post-prandial GLP-1 secretion are important pathophysiological steps in the development of metabolic syndrome in adolescents.

P1134 USE OF THE PROBIOTIC LACTOBACILLUS REUTERI DSM 17938 IN THE PREVENTION OF ANTIBIOTIC-ASSOCIATED INFECTIONS IN HOSPITALIZED BULGARIAN CHILDREN: A RANDOMIZED, CONTROLLED TRIAL

M. Georgieva[1], R. Pancheva[2], **N. Rasheva**[3,*], N. Usheva[4], L. Ivanova[5], K. Koleva[3]
[1]*Pediatric gastroenterology,* [2]*Hygiene, Medical University of Varna,* [3]*Pediatric gastroenterology, UMBAL St. Marina,* [4]*Social medicine, Medical University of Varna,* [5]*Microbiology, UMBAL St. Marina, Varna, Bulgaria*

INTRODUCTION: Antibiotic-associated diarrhoea (AAD) occurs in up to 25% of all individuals receiving antibiotics. In hospitalized patients, AAD is related to significant increases in mortality, length of stay, and cost of medical care. Twenty-nine percent of hospitalized patients may develop diarrhoea after antibiotic use; therefore, identifying strategies to minimize antibiotic-associated diarrhoea could be of significant medical and economic advantage.
AIMS & METHODS: Objective:
To evaluate the effectiveness of *Lactobacillus reuteri* DSM 17938 for the prevention of antibiotic-associated diarrhoea and *Clostridium difficile*-related infections in hospitalized children in a Bulgarian hospital.
Study design:
Children ($n = 100$, aged 3 to 12 years) admitted to the hospital for acute infections were enrolled in a randomized, double- blind, placebo-controlled trial. They were assigned to receive either a probiotic supplement containing 1 x 10^8 CFU *Lactobacillus reuteri* DSM 17938 in the form of one chewable tablet once per day ($n = 49$) (BioGaia AB, Stockholm, Sweden) or placebo ($n = 48$). The probiotic or placebo was taken 2 hours after lunch each day, during the entire period of antibiotic treatment at the hospital and for additional 7 days.
RESULTS: Data from 97 children were included in the final analysis. The incidence of diarrhoea (defined as at least 3 loose or watery stools per day in a 48-hour period that occurred during or up to 21 days after cessation of antibiotic treatment) was unexpected low in both groups-L. reuteri ($n = 1$) versus placebo ($n = 1$): 2.04 vs 2.1 per 100 ($p > 0.05$, risk ratio 1.02, 95% CI 0.7-1.4). *L reuteri* DSM 17938 did not significantly affect the incidence or severity of AAD diarrhoea and *Clostridium difficile* infection. We found unusually high colonisation rate of non-symptomatic *C. difficile* measured by toxin-specific ELISA. There was no difference between the probiotic and placebo groups for any of the other secondary outcomes (i.e., incidence of mild diarrhoea, frequency of stool samples positive for *C. difficile* toxin A and B at the beginning and at the end of study period, frequencies of other gastrointestinal symptoms in the same study period) ($p < 0.05$). No adverse events were reported.
CONCLUSION: Due to the low incidence of antibiotic-associated diarrhoea in both groups, no conclusion can be made on the efficacy of *L. reuteri* DSM 17938 on AAD in hospitalized Bulgarian children. The probiotic did not affect the non-symptomatic high rate of *C. difficile* colonisation (33.3% in the placebo and 38.8% in the *L. reuteri* group at baseline) in this population. There was also no difference between groups regarding different gastrointestinal side-effects.

INTRODUCTION: Numerous studies have investigated the positive effect of physical activity in cancerous diseases regarding disease-free survival, presence of recidive tumours and lower risk of metastasis. In physiological and pathological conditions as well, circulating free DNA (cfDNA) level increases. During physical activity higher cfDNA was detected however the risk of malignancies decreased. Effect of cfDNA may depend on its origin.
AIMS & METHODS: Our aim was to study the influence of elevated cfDNA level on tumour progression using animal model. DNA was isolated by our standard method using Zymo DNA columns (DNA Clean & Concentrator™-500, Zymo Research). We had five groups with fifteen C57BL/6 mice in each. C38 non-necrotic colorectal adenocarcinoma tissue was implanted subcutaneously in every group at the same time. Group I got high concentration subcutaneous healthy C57BL/6 spleen-derived DNA (sdDNA), pretreatment started three weeks before tumour implantation and was continued until the end of the study. Group II got the same DNA treatment started at the date of tumour implantation. Treatment of group III started at the same time than in group II, but we used C38 tumour derived DNA (tdDNA). Group IV was used as a control group injected with PBS. Group V was subjected to five hours long physical activity five times per week in a rodent wheel started three weeks earlier than tumour implantation. On the 22nd day mice were slaughtered, peripheral blood, fresh frozen and paraffin embedded tumour tissue and colon samples was collected. Hematoxylin-eosin, cytokeratin, Ki-67, CD3 markers were used to investigate the cell proliferation, necrosis and T-cell invasion. RNA was isolated from tumour tissue (MagNA Pure 96 Cellular RNA LV Kit, Roche) and real-time PCR validation was performed of tumour growth and cell proliferation-related genes.
RESULTS: The size of the tumour in group V was 51%, in group I was 71% and in group II was 48% compared to control group IV. Investigation of implanted tumour tissue showed that proliferation increased in tdDNA treated group III and tumour tissue was less differentiated. CD3 expression was lower in group III than in control group IV, and group V showed strong positivity. The mucosa in colon samples of group III was destruated and showed IBD-like morphology. The number of lymphoid tissue plaques decreased as well. A group of genes showed expression alteration between group I and group V.
CONCLUSION: Plasma cfDNA level may regulate gene expression. The physical activity and DNA treatment has similar preventive effect. The ratio of tumour cell derived and healthy cells derived cfDNA in plasma may regulate immunitiy and tumour progression.

INTRODUCTION: In colorectal cancer carcinogenesis, serrated neoplasia pathway is characterized with BRAF mutation and aberrant DNA methylation. The aim of this study was to compare serrated polyps to conventional tubular adenoma in BRAF mutation and DNA methylation.
AIMS & METHODS: For DNA extraction, 146 paraffin embedded tissue samples including 47 tubular adenomas (TAs), 53 traditional serrated adenomas (TSAs), 17 sessile serrated adenoma/polyp (SSAs) and 29 hyperplastic polyps in proximal colon (HPs) were collected in Yonsei University Wonju College of Medicine. BRAF V600E mutation was identified through polymerase chain reaction and pyrosequencing assay, and methylation of LINE1, IGFBP7, hMLH1, and CD133 was evaluated through disulfite conversion, polymerase chain reaction, and pyrosequencing assay.
RESULTS: BRAF V600E mutation was found in 2.1% of TA, 47.2% of TSA, 41.2% of SSA, and 20.7% of HP. TSA and SSA had higher BRAF mutation than TA ($P<0.0001$). TSA had higher BRAF mutation than HP ($p=0.018$). IGFBP7 hypermethylation was found in 17% of TA, 37.7% of TSA, 88.2% of SSA, and 37.5% of HP. TSA and SSA had higher hypermethylation of IGFBP7 than TA ($p=0.021$ and $P<0.0001$, respectively). SSA had higher hypermethylation of IGFBP7 than HP ($p=0.002$). hMLH1 hypermethylation was found in 2.1% of TA, 5.7% of TSA, 0% of SSA, and 0% of HP. CD133 hypermethylation was found in 21.3% of TA, 9.4% of TSA, 35.3% of SSA, and 17.4 % of HP.
CONCLUSION: TSA and SSA had different expression of BRAF mutation and IGFBP7 hypermethylation from TA. HP in proximal colon had different expression of BRAF mutation from TSA, and IGFBP7 hypermethylation from SSA. These findings suggest that TSA and SSA have different genetic alterations from TA or HP.

INTRODUCTION: In case of tumorous and inflammatory conditions, the amount of self-DNA is elevated in the serum The methylation pattern of genomic DNA fragments may related to its organ and disease origin. Self-DNA sequences are recognized by TLR9 on human immune and other types of cells.
AIMS & METHODS:: We compared the immunostimulatory effect of DNA originated from normal and tumorous colonic tissue using isolated peripheral mononuclear cells (PBMCs) from healthy volunteers.
DNA was isolated from fresh-frozen colonic epithelium samples. PBMC was isolated from healthy volunteers by Ficoll-Paque (Sigma). After isolation the viability of PBMCs was determined by Trypane blue dying. PBMCs were incubated for 6 hours with 15-15 μg of self-DNA either of normal and tumorous origin. The expression level of the pro-inflammatory cytokine-related genes was measured by qPCR. Changes of PBMC-associated mRNA expression level of 84 genes were determined by qPCR-based Qiagen T and B cell activation arrays. After 24h incubation with DNA Affymetrix U133 2.0 whole-genome expression analysis was performed.
RESULTS: Incubation with normal DNA resulted in higher IL-2 mRNA expression of PBMCs (dCt of non-treated controls: 11.74 ± 0.1650; dCt of tumorous DNA-treated samples: 10.18, $\pm$ 0.1900; dCt of normal DNA-treated samples: 9.45 ± 0.2900). After incubation either with normal or tumorous DNA IL-6 mRNA expression increased (dCt of non-treated controls: 4.67 ± 0.2800 dCt of tumorous DNA-treated samples: 3.45, $\pm$ 0.1150 dCt of normal DNA-treated samples: 3.55 ± 0.1450).
Based on the results of whole-genome array (Affymetrix U133 2.0) analyses upon treatment with normal DNA overexpression of several matrix metalloproteinases (MT1E, MT1X, MT1G, MT1H, MT1M) and that of phosphatidic acid phosphatase (PPAP2B) were observed. Moreover, the fold changes of several other genes, like EEA1, IL1A, KCNJ2, NLRP3, THBD, OSM were also increased ($p \leq 0.05$). However, following tumorous-DNA treatment no expression changes of these genes were detected.
CONCLUSION: Overexpression of IL-2 on PBMCs induced by normal-DNA treatment may affect T cell maturation and differentiation along with T cell reactivity. IL-6 overexpression in cases of normal and tumorous DNA-treatments may indicate the activation of pro-inflammatory mechanisms leading finally to the overexpression of MMPs.

INTRODUCTION: We have reported that Toll-like receptor 9 (TLR9)-signaling pathway activiation by modified self-DNA depends on the structural characteristics of DNA sequences. However, no concrete data exists on how the characteristics of TLR9 activating self-DNA fragments influence the viability, proliferation, death, and differentiation of cancer cells, which all may have important immunobiologic consequences in inflammatory and tumorous colonic disorders.
AIMS & METHODS: To understand the biologic role of modified self-DNA bound to TLR9, we assayed its effect on cell viability, proliferation, death and differentiation in HT29 cells. HT29 cells were incubated separately with type-1 (normally methylated / non-fragmented), type-2 (normally methylated / fragmented), type-3 (hypermethylated / non-fragmented), or type-4 (hypermethylated / fragmented) self-DNAs for 24, 48 and 72 hours. Cell viability was examined by MTT-assay, cell proliferation by TUNEL method, cell proliferation by Ki-67 assay, while cell differentiation by pancytokeratin (CK) immunohistochemistry.
RESULTS: Treatments with type-1, -3 and -4 DNA sequences resulted in remarkable decrease of cell viability and proliferation, and increase of apoptosis after 72h. The effects of type-3 DNA incubation were the most significant. Type-2 DNA treatment resulted in a slight decrease of cell viability after 48h, but at 72h all parameter of cell kinetics were similar to that of control cells. Regarding cell differentiation, CK expression was only increased after type-3 DNA treatment.
CONCLUSION: Activation of TLR9-signaling pathways by modified self-DNA sequences may display significant effects on cell kinetic parameters like viability, proliferation or death, moreover may influence cell differentiation, which may have clinical importance in the future.

INTRODUCTION: Within tumorous and chronic inflammatory conditions self-DNA is released to the extracellular compartment. The Toll-like receptor 9 (TLR9)-mediated immunobiologic effects of self-DNA however are not fully clarified
AIMS & METHODS: Using HT29 carcimoma cells we compared the effects of self-DNA originated from normal and tumorous colonic tissue on the expressions of TLR9- and pro-inflammatory cytokine-related genes. DNA was isolated from fresh-frozen normal and tumorous colonic epithel tissues. HT29 cells were then incubated with DNA samples for 6 hours. After total RNA isolation Affymetrix U133 2.0 microarray analysis and qRT-PCR were performed regarding the genes of the TLR9 signaling pathway. CK20, E-cadherin and DNMT3A immunocytochemistries were also performed for cell differentiation analysis.
RESULTS: After treatment either with normal or tumorous DNA IL-1beta overexpression was observed (dCt in controls vs. tumorous DNA-treated vs. normal DNA-treated samples: 25.87 ± 0.1627 vs. 23.54 ± 0.2613 vs. 24.28 ± 0.2253, $p < 0.05$).
Based on the results of whole-genome expression analyses overexpressions of 3 types of metalloproteinase genes (MT1X, MT1F, MT1H), 3 of metastasis associated genes (TACSTD2, MACC, MALAT1), 1 differentation-associated gene (CEACAM), and 2 metabolism-associated genes (INSIG1, LIPG) were detected. Following incubation with tumorous DNA expressions of CK20, E-cadherin and DNMT3A proteins were increased.
CONCLUSION: Incubation with tumorous DNA binding to TLR9 may promote cancer cell invasion via increased activity of MMPs and other pro-metastatic proteins. Moreover, our results suggest a possible link between TLR9-signaling and DNMT3A regulation.

INTRODUCTION: Patients with celiac disease (CD) are defined as suffering from refractory celiac disease (RCD) when clinical and histological symptoms persist or recur, despite strict adherence to a gluten free diet (GFD). Intraepithelial T lymphocytes (IETLs) may show normal phenotype and are attributed to RCD type 1 (RCD-1). The IETLs that present an aberrant and even clonal phenotype are attributed to RCD type 2 (RCD-2). These IELs are associated a high risk for development of enteropathy associated T lymphocytes lymphoma (EATL). EATL is the main cause of death in these patients and has a 5 year survival of only 8%. Without detailed phenotyping of IELs, diagnosis of RCD could be missed.
AIMS & METHODS: To establish a diagnostic scheme, in Israel, for RCD diagnosis in CD patients with persistence of CD related symptoms and reported adherence to a GFD based on previously described diagnostic systems. RCD type was determined by performing flow cytometry analysis (FCA) and T-Cell receptor rearrangements PCR (TCR) on small duodenal biopsies, obtained from 11 distinct CD-GFD patients. In addition, Peripheral blood was also obtained and assessed from these patients and served as an internal control.
RESULTS: FCA exhibited RCD-1 phenotype in the duodenal biopsies of 10 patients – all IETLs were normal although abundant. Furthermore no IETLs clonality was demonstrated in these patients by TCR. RCD-2 phenotype was diagnosed in the biopsy of 1 patient who demonstrated a high presence of aberrant IETLs and distinct clonality observed by TCR. Peripheral blood samples, in both RCD-1 and RCD-2 patients, showed no presence of IETLs, nor clonality of T lymphocytes implying duodenal locality of the IETLs.
CONCLUSION: Characterization of IETLs as normal and aberrant by FCA, in CD patients with persistent symptoms despite adhering to a GFD is important for the diagnosis of RCD. Using FCA as an RCD diagnostic tool is as good as exploring IETLs clonality by TCR. Moreover, FCA is preferable and may be solely used for differentiating RCD patients at risk for EATL development. In these patients TCR serves as a complementary instrument for a complete diagnosis.

P1143 ACTIVATION OF TOLL-LIKE-RECEPTORS (TLR) ON ISOLATED KUPFFER CELLS (KC) AND SINUSOIDAL ENDOTHELIAL CELLS (SEC) OF THE LIVER: OPPOSING EFFECTS ON THE PRODUCTION OF THE VASOCONSTRICTOR THROMBOXANE B2

J. Schewe[1,*], L. Selzner[1], I. Liss[1], A.L. Gerbes[1], C.J. Steib[1]

INTRODUCTION: The role of TLR-dependent formed Thromboxane (TX) for portal hypertension in cirrhosis, we have already shown in previous work (including Steib CJ et al., Hepatology 2010). To develop risk stratification ratifications and targeted new therapeutic strategies for patients in the future, the aim of this study was to determine, which liver cells play a relevant role for TX-production and which TLR are involved in this process.
AIMS & METHODS: KC and SEC were isolated from mouse livers (male C57/Bl6) and stimulated over 24h with various TLR-agonists (Pam3CSK4 [TLR 1/2] 0.1g/ml; HKLM [TLR 2] $10e^8$ cells/ml; Poly (I:C) [TLR 3] 10ng/ml; LPS-EK [TLR 4] 10ng/ml; ST-FLA [TLR 5] 10ng/ml; FSL-1 [TLR 6/2] 1ng/ml; ssRNA40 [TLR 7] 0.25µg/ml; ODN1826 [TLR 9] 5µM; $n = 6$). Thromboxane B_2 (TXB_2) efflux before and after stimulation into the cell media was measured by ELISA (mean±SD, $*p < 0.05$).
RESULTS: In KC TXB_2-efflux increases differently (before stimulation vs. after stimulation in pg/ml; **TLR 1/2**:212±90 vs. 242±43; **TLR 2**:251±24 vs. 1271±255*; **TLR 3**:302±96 vs. 400±139; **TLR 4**:231±75 vs. 717±363*; **TLR 5**:254±46 vs. 640±250*; **TLR 6/2**:271±32 vs. 2291±1446*; **TLR 7**:213±91 vs. 296±206; **TLR 9**:229±34 vs. 704±232*), however in SEC after stimulation increasingly there is a decrease in TXB_2-secretion (**TLR 1/2**:544±187 vs. 42±27*; **TLR 2**:477±89 vs. 82±45*; **TLR 3**:408±204 vs. 107±62*; **TLR 4**:497±70 vs. 88±53*; **TLR 5**:238±150 vs. 284±306; **TLR 6/2**:301±191 vs. 100±53*; **TLR 7**:420±131 vs. 111±35*; **TLR 9**:324±207 vs. 84±55*).
CONCLUSION: The activation of TLR 2, 4, 5, 2/6, and 9 on isolated KC of healthy livers lead to a significant production of vasoconstrictive effective TXB_2, whereas the activation of SEC through TLR 1/2, 3, 4, 6, 7 and 9 led to a decrease of TXB_2 production. These findings are important to identify relevant early stage microbial products for the formation of TXB_2 in the future and to develop new targeted therapeutic strategies.

INTRODUCTION: Liver transplantation induces relative immune tolerance than the other organ transplantation. The mechanisms responsible for this phenomenon have been acknowledged as the liver resident tolerant immune cells that could be transferred to donor. In living donor liver transplantation, the effluent solution passing through the graft livers during perfusion before transplantation has been shown to be useful to characterize the leukocytes. Recent advances in multicolor flowcytometry enabled us to investigate the character of the leukocytes in detail. We analyzed the perfusate cells with multicolor flowcytometry, revealed the characteristics of the cells, and detected them after an early period post transplantation.
AIMS & METHODS: Liver perfusates were collected from 11 human liver grafts. During the backtable procedure, the grafts were perfused through the portal vein with 1-2L of Univeristy of Wisconsin solution under hydrostatic pressure, and the perfusate was collected from the vena cava. Mononuclear cells (P) were isolated within 12 hrs by density gradient centrifugation. Peripheral blood mononuclear cells (B) were drawn on the same day from peripheral vein. After isolation, cells were stained with cell surface antibodies collecting the population of B cell, CD4+ T cell, CD8+ T cell, NK cell, plasmacytoid dendritic cell (DC), myeloid DC, Programmed death (PD)-1 positive cells, CD45RA+ CCR7+ naïve T cells, CD45RA+ CCR7- effector T cells, CD45RA- CCR7-effector memory T cells, and CD45RA- CCR7+ central memory T cells, and CD4+ CD25+ CD127- regulatory T (Treg). To reveal the perfusate involvement in recipient after transplantation, we studied peripheral blood donor cell microchimerism in human leucocyte antigen (HLA) mismatched 17 patients.
RESULTS: Results: CD8+ T cells (P: 27.8%, B: 16.6%), CD14+ cells (P: 2.13%, B: 0.156%), NK (CD56+) cells (P: 82.9%, B: 66.8%), plasmacytoid DC (CD123+) (P:10.3%, B: 2.16%) and myeloid DC (CD11c+) (P: 6.38%, B: 0.926%) were increased and CD4+CD25+CD127low/- regulatory T cells (Treg) (P: 3.37%, B: 6.75%) was decreased in perfusate compared with peripheral blood. Furthermore, naïve subsets of T cells were lower, and effector memory subsets of T cells and PD-1 T cells were higher in perfusate lymphocyte than peripheral blood. The microchimerism was found in CD14+ cells (0.8%), CD8+ T cells (1.7%), CD4+ T cells (1.5%), B cells (0.95%) and NK (CD56+) cells (4.5%) as the perfusate pattern likely.
CONCLUSION: The perfusate contains CD4+T cells, CD8+ T cells, with higher exhaustion marker PD-1 and plasmacytoid DC, myeloid DC with lower activation marker CD86, probably not to react with many antigens flow into the liver via portal vein. This might explain one reason why liver transplantation exhibit more tolerant than other organ transplantation.

INTRODUCTION: Intestinal epithelium constitutes a physical and functional barrier which is essential for intestinal immunological activity. In fact, Toll-like receptors expressed in intestinal epithelium are responsible for microbiota recognition, and they also contribute to both intestinal homeostasis and inflammation. The balance between pro and anti-inflammatory cytokines seems to be crucial for homeostasis, and also for the development of inflammation. In this context, interleukin-10 (IL-10), a prototypical anti-inflammatory cytokine mainly produced by immune cells, has been shown to inhibit immune activation (1), and to be essential in tolerance to self (2) and mucosal antigens (3). In addition, deficient IL-10 expression seems to contribute to gut inflammation (4). Intestinal epithelium has been well documented as a rich source of proinflammatory cytokines, however little is known about the relation between intestinal epithelium and IL-10. Several studies have described IL-10 production mediated by TLR2 and TLR4 activation in immunological cells, however the role of TLRs expressed in intestinal epithelium in the modulation of molecular expression and release of IL-10 remains unknown.
AIMS & METHODS: The purpose of this work has been to assess the involvement of intestinal epithelium and TLR2 and TLR4 activation in the expression and release of IL-10. To carry out the study, we have used the human enterocyte-like cell line Caco-2 and intestine from WT, $TLR2^{-/-}$ and $TLR4^{-/-}$ mice. IL-10 release levels were measured by ELISA, and IL-10 mRNA and protein expression were analyzed by RT-qPCR and Western Blot respectively.
RESULTS: Caco-2 cells have shown to express and release IL-10. In addition activation of TLR2 or TLR4 in these cells showed to increase IL-10 mRNA and release. Surprisingly, IL-10 mRNA levels in $TLR2^{-/-}$ and $TLR4^{-/-}$ ileum and colon resulted increased, and IL-10 release levels were also augmented in $TLR4^{-/-}$ ileum whereas in $TLR2^{-/-}$ colon resulted decreased. TLR4 expression was increased in $TLR2^{-/-}$ ileum and reciprocally, TLR2 expression was augmented in $TLR4^{-/-}$ ileum, thus suggesting a cross talk between TLR2 and TLR4 which may maintain IL-10 release in the epithelium.
CONCLUSION: The present work shows that intestinal epithelial cells were able to synthesize and release IL-10, and that the activation of TLR2 or TLR4 stimulated IL-10 expression in these cells. In addition, IL-10 expression and release in mice intestine might be guaranteed by cross- regulation between TLR2 and TLR4. In summary, the results of the present work suggest that intestinal epithelial cells might contribute to the immune response by modulating IL-10 expression, and demonstrate cross-talk regulation of IL-10 expression between TLR2 and TLR4 in the intestine.

P1146 CLINICAL IMPACT OF THE SEQUENTIAL USE OF EUS ELASTOGRAPHY FOLLOWED BY CONTRAST-ENHANCED EUS IN PATIENTS WITH FOCAL PANCREATIC MASSES AND NEGATIVE EUS-GUIDED FNA

S. Iordache[1], M.-I. Costache[1], C.-T. Streba[2], **D.-I. Gheonea**[1,*], A. Saftoiu[1]
[1]*Research Center in Gastroenterology and Hepatology,* [2]*UNIVERSITY OF MEDICINE AND PHARMACY CRAIOVA, Craiova, Romania*
Contact E-mail Address: *sevastita@gmail.com*

INTRODUCTION: It is well known that EUS-guided FNA has a high sensitivity (over 85%) and specificity (100%) for diagnosis of pancreatic cancer. EUS elastography and contrast-enhanced EUS (CE-EUS) are useful methods for the assessment of patients with pancreatic masses, with high sensitivity and specificity reported in recent meta-analyses. In most of the cases, pancreatic adenocarcinoma is a hard (low strain), hypoenhanced (hypovascular) tumor.
AIMS & METHODS: The aim of the study is to establish an EUS based diagnostic algorithm in patients with pancreatic masses and negative cytopathology after EUS-FNA, based on previously published results and cut-offs of elastography and contrast-enhancement (CE-EUS).
We included in the study a subgroup of 50 consecutive patients with focal pancreatic masses who underwent an EUS examination with negative EUS-FNA for malignancy: 19 patients with pancreatic cancer and 31 patients with pseudotumoral chronic pancreatitis. Real-time elastography and contrast-enhancement during EUS were performed sequentially in all patients. The sensitivity, specificity and accuracy of these methods were calculated separately. Moreover, we established a clinical decision making algorithm based on real-time elastography (for characterization of tissue hardness), followed by contrast-enhanced EUS (for characterization of vascularity).
RESULTS: For the diagnosis of possible malignancy, the sensitivity, specificity and accuracy of EUS elastography were: 97.7%, 77.4% and 84% respectively, while CE-EUS has similar results: 89.5%, 80.7% and 84%, respectively. Subsequently, we selected the subgroup of 25 patients with soft/mixed appearance in elastography for sequential assessment using contrast-enhanced EUS. Thus, the sensitivity of CE-EUS in this set of patients was excellent (100%) while the specificity was 75%, with 76% accuracy. Overall, for the sequential evaluation with elastography, followed by contrast-enhanced EUS, there were no false negative results for possible malignancy, while the negative predictive value of this method was 100%.
CONCLUSION: The proposed algorithm of sequential use of real-time elastography, followed by contrast-enhanced EUS could be a good clinical tool to help select the patients with possible pancreatic adenocarcinoma in the setting of patients with negative EUS-FNA results.

INTRODUCTION: CE progresses inside the gastrointestinal tract only using intestinal motility and several approaches to actively guide the capsule have been proposed. Currently, the most promising solution seems to be the magnetic steering. Up to now the only system of CE magnetic steering available on the market is the Mirocam Navi CE. Aim: To evaluate the feasibility of exploring the gastric cavity and duodenal bulb using the guided CE Mirocam Navi system.
AIMS & METHODS: A small group of patients (18 pts, 9 females, mean age 65.5 yrs, range 52-81 yrs) undergoing CE was included in the study. The indications for CE included 13 pts with occult gastrointestinal bleeding (OGIB), 2 pts with suspected Crohn's disease, 2 pts with polyposis syndrome and 1 suspected ileal neoplasia. Patients with cardiac pacemakers or other implanted metallic devices were excluded. After the patient swallowed the capsule in a sitting position, the external controller was placed in the abdomen over the cardia in order to block the capsule and visualize the Z line. Then the aim of the study was to navigate the capsule through the stomach visualizing the gastric fundus, gastric body, and antrum. Each author moved the external controller and steered the capsule under direct vision through a real time view system. No specific movements were suggested and the attempts to visualize the gastric cavity lasted no more than 20 minutes. The authors reported if the gastric cavity visualization was satisfactory or not. Finally the authors tried to crawl the capsule through the pylorus using the external controller to visualize the duodenal bulb. Patients were asked to judge the tolerability of the procedure using a visual analogical scale (VAS) and any adverse event was registered.
RESULTS: A positive finding was observed in 11/18 of CE (diagnostic yield 61%). A complete visualization of the Z line, antrum, body, fundus and duodenal bulb was registered in 1/18 cases (5.5%), 18/18 cases (100%), in 12/18 (66.6%), 5/18 (27%) and in 6/18 (33%) of the cases, respectively. The crawl of the capsule into the bulb under external magnetic control was obtained successfully in 8/18 of the cases (44%). The mean score of the VAS scale was 9.3 cm (well tolerated). No adverse event was reported.
CONCLUSION: The Mirocam navi system is a promising method for controlled locomotion of CE; it is well tolerated and safe but the ability to control the movement in the upper gastro-intestinal tract is still unsatisfactory.

INTRODUCTION: Optical colonoscopy is currently the diagnostic gold standard for colic diseases, however it is also invasive, risky and embarrassing and minimally invasive diagnostic procedures are required. Market available video endoscopic capsules (VCE) explore the GI tract proceeding by means of visceral peristalsis and gravity. Higher diagnostic accuracy, more extensive clinical application and shorter times of investigation would be achieved by controlling the VCE locomotion. Some authors demonstrated that magnetic fields allow controlling the VCE movement. However the cylindrical shape, while may be suitable for the small intestine, esophagus and stomach, in the colon, due to its anatomical features, has intrinsic disadvantages as regard to VCE propulsion, surface friction and cleaning. Other limits of the previous solutions depend on the movement control precision, or in the use of a very cumbersome and expensive external instrumentation. The SUPCAM concept is based on the development of an innovative Active VCE (AVCE) whose design allows to safely and accurately guide it along the colonic lumen from the outside, using an innovative electromagnetic approach and an external compact assisted handle adapted to be transported and suitable for common outpatient setting. The SUPCAM EU Project is

aimed at developing a new generation of AVCE able to investigate the colon, ensuring a high level of navigation and diagnostic accuracy.
AIMS & METHODS: The aim of this study is to present a new mechanical configuration of a colon capsule and to demonstrate its precise locomotion in the colon from the anus to the cecum and vice versa through external magnetic fields generated by an external low-cost and assisted magnetic handle. An external electromagnetic handle and a capsule prototype were developed within the SUPCAM Project. Experimentally the prototype locomotion capabilities were assessed with motion control tests inside an insufflated human-sized plastic phantom colon.
RESULTS: A prototype of a double sphere colon capsule and external low-cost and assisted magnetic handle for magnetic fields generation and capsule propulsion have been fabricated. The prototype has been inserted transanally into the phantom colon. The endoscopist, moving manually the external handle, drove and accurately oriented the SUPCAM capsule within the phantom colon from the anus to the cecum and vice versa.
CONCLUSION: Our study demonstrated the development and test of a capsule prototype with a completely new double sphere mechanical configuration and an innovative electromagnetic approach. SUPCAM mechanical prototype allowed a precise, effective and safe propulsion and orientation in a phantom model through a low-cost, compact and easily manageable external assisted magnetic handle. In our opinion, SUPCAM endoscopy represents a highly innovative and disruptive solution for colon diseases diagnosis and screening. The further development of this innovative magnetically controlled AVCE, reducing clinical risk, improving tolerance, acceptability, territory availability and adherence to colorectal cancer screening programs, will provide significant benefits for patients and the whole healthcare system. Other studies are planned to test performance of more advanced SUPCAM prototypes in ex-vivo and in-vivo settings.

P1149 ACCURACY OF COLON CAPSULE FOR THE DETECTION OF COLONIC TUMORS

C. Carretero[1,*], C. Prieto[1], M. Muñoz-Navas[1]
[1]*Gastroenterology, University of Navarra Clinic, Pamplona, Spain*
Contact E-mail Address: *ccarretero@unav.es*

INTRODUCTION: Colon capsule has shown to be a safe and accurate procedure for the study of colonic pathology. Previous studies have been focused on the diagnostic yield of colonic polyps and, to date, there is scarce data regarding its ability to detect colon cancer. We describe our experience in this field.
AIMS & METHODS: From December 2007 to February 2014 we have performed 211 colon capsules. We describe our experience regarding colon cancer detection.
RESULTS: In our study population, there were 14 colon cancers (12 male, mean age 63 years old). All but one were detected by the capsule. The one not detected by the capsule was due to battery life, as it expired before reaching tumor location. The main reason for referral was colorectal cancer screening in 61.5% of cases, followed by rectal bleeding in 23.1%. Regarding tumor location, 3 tumors were located in the rectum, 3 in sigmoid, 4 in descending, 2 in transverse, 1 in ascending and 1 in cecum. 3/14 patients had a stenosing tumor, in those patients the capsule was retained although it did not cause any obstructive symptoms. In two of these three cases capsule excretion took place after chemotherapy treatment and in the other case we retrieved the capsule with a Roth Net.
Colon cleansing level was adequate in 92.3% of cases.
CONCLUSION: According to our experience, colon capsule is accurate also for colon cancer detection. Despite the theoretical risk of obstructive symptoms associated to stenosing tumors, we haven't found any obstructive complication.

INTRODUCTION: Attempts in employing a simple technique of capsule endoscopy for visualisation of the upper GI tract has, thus far, been experimental, cumbersome and potentially expensive. We describe the first human series for comprehensive visualisation of the upper GI tract using the simple Intromedic MiroCam-Navi system. Our aim was to demonstrate the manoeuvrability of this magnetic capsule and evaluate its ability to completely visualise and maintain views in the upper GI tract.
AIMS & METHODS: 26 volunteers observed a 12hr overnight fast. 30mins before the examination volunteers drank a preparation mixture of 20mg of maxalon syrup with simethicone and pronase. After capsule ingestion, volunteers were allowed sips of water during the procedure. The MiroCam-Navi magnet was placed at strategic points on the body surface and rotated to hold and manoeuvre the capsule. Control was assessed by moving and holding the capsule for 1 minute to visualise each of the following stations: lower oesophagus, cardia, fundus, body, incisura, antrum and pylorus and also traversing across the stomach and through the pylorus. Total procedure time was taken from the moment of ingestion of the capsule to either reaching the duodenum, or after attempting a maximum of 10mins to traverse the pylorus. All the procedures were performed on the same day in Seoul Konkuk University Hospital by 6 endoscopists (experts in capsule endoscopy). All volunteers subsequently underwent a standard upper GI endoscopy within 3 days.
RESULTS: Volunteers' median age was 38yrs (range 26-45), median BMI 24 (range 19-38), median volume of water consumed 800 mls (range 200mls-1500mls) and median procedure time 24 minutes (range 12-39 minutes). Table 1 shows the success of clear visualisation of landmarks

	Landmark Visualised	Landmark Not Visualised
GOJ	**92%** *(n = 24)*	**8%** *(n = 2)*
Cardia	**88%** *(n = 23)*	**12%** *(n = 3)*
Fundus	**96%** *(n = 25)*	**4%** *(n = 1)*
Body	**100%** *(n = 25)*	**0%** *(n = 0)*
Incisura	**96%** *(n = 25)*	**4%** *(n = 1)*
Antrum	**96%** *(n = 25)*	**4%** *(n = 1)*
Pylorus	**100%** *(n = 26)*	**0%** *(n = 0)*

The capsule could be held overall in 88% of designated stations for 1 minute. The capsule could be moved from the fundus to the antrum in all cases and traverse the pylorus in 50% (n = 13). Age ≥40 was associated with successful pyloric traversing (p = 0.04).
There was positive concordance for 8 out of 9 minor pathological findings with standard upper GI endoscopy. A small 4 mm submucosal lesion was missed by capsule endoscopy in the cardia of one volunteer where views were obscured.
CONCLUSION: This is the first convincing demonstration of the potential value of MACE in the upper GI tract. There is a high degree of visualisation and control, with some improvement required for optimising fundal views and traversing the pylorus.

P1151 NON-EXPOSED ENDOSCOPIC WALL-INVERSION SURGERY (NEWS) AS A NOVEL FULL-THICKNESS RESECTION TECHNIQUE FOR GASTRIC TUMOR

K. Niimi[1,2,*], S. Aikou[3], Y. Sakaguchi[2], S. Kodashima[2], N. Yamamichi[2], H. Yamashita[3], M. Fujishiro[2,4], Y. Seto[3], K. Koike[2]
[1]*Department of Center for Epidemiology and Preventive Medicine,* [2]*Department of Gastroenterology,* [3]*Department of Gastrointestinal Surgery,* [4]*Department of Endoscopy and Endoscopic Surgery, THE UNIVERSITY OF TOKYO, Tokyo, Japan*

INTRODUCTION: Non-exposed endoscopic wall-inversion surgery (NEWS) is a new advanced method of endoscopic full-thickness resection without transluminal communication, causing intra-abdominal contamination or possible tumor dissemination, applying endoscopic submucosal dissection (ESD) technique.
AIMS & METHODS: The aim of this study is to investigate the efficacy, safety and advantages of NEWS for gastric submucosal tumors (SMT). Between July 2011 and March 2014, 12 patients (5 females, 7 males; mean age 65.8 years, range 49-79 years) underwent NEWS for intragastric-type gastric SMT within 4cm in size at the University of Tokyo Hospital. After marking around a tumor on both the mucosal and serosal surfaces and submucosal injection of sodium hyaluronate, circumferential seromyotomy and sero-muscular suturing were made laparoscopically, followed by circumferential muco-submucosal incision endoscopically. The resected specimen was perorally retrieved. Clinical data and pathological features were analyzed.
RESULTS: The mean resected specimen and tumor size were 23.9 mm (range, 10-45 mm) and 35 mm (range, 25-50 mm), respectively. All lesions were successfully resected in an en-bloc fashion. The mean operation time was 229.5 minutes (range, 140-397 minutes), and the mean estimated blood loss was 41.7 g (range, 0-250 g). Patients started oral intake on mean postoperative day 2.1 (range, 2-3), and the mean length of postoperative hospital stay was 7.9 days (range, 6-13 days). Micro perforation occurred in the three cases due to technical inadequacy, which were treated successfully without open surgery. There were no severe complications, such as hemorrhage, anastomosis insufficiency, delayed gastric emptying or surgical site infection. Histopathological examination of the tumors showed GIST (n = 11) and schwannoma (n = 1).
CONCLUSION: NEWS enabled en bloc full-thickness resection effectively and safely with minimum possible margin without contamination and tumor dissemination into the peritoneal cavity. This treatment may be promising not only for gastric SMT but also for node-negative early gastric cancer difficult to resect by ESD.

P1152 MUCOSAL-INCISION ASSISTED BIOPSY FOR SUSPICIOUS GASTROINTESTINAL STROMAL TUMORS

J. Chung[1,*], Y. Seok[1]
[1]*Internal medicine, gastroenterology department, Sahmyook Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Tissue sampling is necessary for definitive diagnosis of GIST. Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) has been developed for tissue sampling of suspected GIST and is generally accepted to be a very useful for the diagnosis of this lesion, but the success rate for histology does not seem to be satisfactory (62%).
Recently Eikichi et al has published of retrospective review of mucosal incision assisted biopsy (MIAB) of suspected GISTs. So we performed prospective study of MIAB associated with suspicious GISTs.

AIMS & METHODS: To evaluate the diagnostic yield of the procedure, mucosal-incision assisted biopsy (MIAB), for the histological diagnosis of gastric gastrointestinal stromal tumor (GIST),and to know the complications of MIAB, we performed prospective study of the 14 patients with suspected gastric GIST who underwent MIAB in our hospitals.
RESULTS: Tissue samples obtained by MIAB were sufficient to make a histological diagnosis (diagnostic MIAB) in 12 out of the 14 patients (86%), where the lesions had intraluminal growth patterns. Histologic diagnosis were GIST (9, 64 %), Leiomyoma (2, 14 %) and inflammatory change (1.7 %). Locations were fundus (3, 21 %), cardia (3.21 %), body (5, 36%) and antrum (3, 21 %). Mean size 15.3 ± 0.8.
1patient had significant bleeding after MIAB but well controlled by endoscopic hemostasis.
CONCLUSION: Although it is generally accepted that EUS-FNA is the gold standard for obtaining biopsies for histological and cytological analysis of suspected gastric GIST, MIAB may be chosen as an alternative diagnostic modality only when the lesion has an intraluminal growth pattern. Further studies will be required to further assess MIAB, including randomized controlled trials to compare MIAB with EUS-FNA.

Contact E-mail Address: *miacucci@ucalgary.ca*

INTRODUCTION: In IBD sessile serrated adenomas/polyps (SSAs) are difficult to detect by standard white light colonoscopy. We aimed to determine the frequency of finding SSAs during surveillance colonoscopy in IBD and to define the characteristics and endoscopic findings of SSAs developed in a background of IBD.
AIMS & METHODS: Biopsies from a cohort of 87 patients (male 43, female 44, median age 53, range = 23-82 years), with long-standing (8 years or more median duration of the disease 13 years) colonic IBD (UC = 42, CD = 42, IC 3) undergoing surveillance colonoscopy were reviewed. The lesions of dysplasia (ALM or DALM), SSAs, adenoma-like polyps (ALPs), hyperplastic polyps (HPs), and inflammatory polyps (IPs) were identified. Detection procedures were as follows:- Twenty five were assessed by high definition colonoscopy, Thirty four by high definition –iscan virtual chromoendoscopy and 28 patient by high definition dye chromoendoscopy with methylene blue 0.1%.(Pentax EC-3490Fi; Pentax, Tokyo, Japan).
RESULTS: 14 SSAs were detected (16%). Two in the HD group (8%), seven in the HD-iScan virtual chromoendoscopy group (21%) and 5 in the HD dye chromoendoscoy with methylene blue (18%). These were predominantly in younger patients. The endoscopic characteristics of SSAs were: flat lesion predominantly localized in the right colon (11 in the cecum and ascending colon and 3 in the sigmoid colon), more than >5 mm in size, cloudy cover, Kudo pit pattern modified type IIO and irregular spiral vascular pattern. In comparison, 10 ALPs (11 %) were detected – 2 in HD group (8%), 3 in iScan-HD group (9%) and 5 in HD dye chromoendoscopy group (18%). Only 1 patient had a DALM lesion.
CONCLUSION: 16% of patients had sessile serrated adenomas detected at surveillance colonoscopy in longstanding IBD patients. This detection rate of SSAs was more than ALPs. SSAs can be detected more frequently by HD-iScan virtual chromoendoscopy and by dye chromoendoscopy than by HD endoscopy alone. Sessile serrated adenoma is a common finding at surveillance colonoscopy for IBD and may be missed if electronic virtual chromoendoscopy or dye chromoendoscopy are not used.

INTRODUCTION: Upregulated oxidative stress is recognized as important mechanism contributing to inflammation and fibrogenesis of the liver in non-alcoholic fatty liver disease (NAFLD). Leptin promotes oxidative stress and the fibrogenesis in the liver. Therefore, we aimed to evaluate the association between leptin levels, oxidative stress parameters and histopathological findings in NAFLD subjects.
AIMS & METHODS: Fifty-eight non-drinker patients with biopsy-proven diagnosis of NAFLD were studied (M/F: 31/ 27 mean age 47.4± 6.3 years). Histopathological examination was done using the system described by Brunt et al. For the determination of oxidative stress parameters malondialdehyde (MDA), and superoxide dismutase (SOD) activities were measured in serum and as well as in tissue specimens. Glutathione (GH) was measured in tissue homogenates. Nitric oxide (NO) and TNF-alpha receptor (TNF-sRp55) levels were measured in serum. Serum leptin levels were measured by radioimmunoassay. Statistical analysis was done using chi-squared test, Student's t-test, Mann-Whitney test, multivariate regression analysis and the area under receiver operating characteristic (ROC) curve. Comparison between the patients with non-alcoholic fatty liver (NAFL) and non-alcoholic steatohepatitis (NASH) were performed using Student's t test. Multivariate regression analysis and ROC curve were used to identify the independent predictors for NASH. All statistical analyses were performed using SPSS® statistical software program (Ver.10.0).
RESULTS: In bivariate analysis serum leptin levels didn't show any significant correlation with steatosis grade, necroinflammatory grade and stage. Serum leptin levels were neither significantly correlated with serum NO, SOD and MDA levels nor with tissue SOD, MDA and GH levels. The increases in TNF-sRp 55 levels correlated inversely with serum leptin levels (r = - 0.03, p = 0.04). Patients with NASH had significantly higher serum NO and tissue MDA and GH levels (p = 0.03, 0.04, 0.042, respectively). Using serum leptin levels the ROC curve for distinguishing between NASH and NAFL didn't show any respective sensitivity and specificity (AUROC = 0.48). In linear regression analysis serum NO ($\beta = 0.21$, p = 0.018), tissue MDA ($\beta = 0.06$, p = 0.01), and stage ($\beta = 2.6$, p = 0.01) were independently associated with increased leptin levels. In multivariate regression analysis increase of tissue MDA (OR:1.8; %95 CI:1.04-4.25, p = 0.04) and serum NO levels (OR:1.9; %95 CI:1.02-4.6, p = 0.04) were risk factors for NASH and increase of leptin activity had preventive effect against NASH (OR:0.052; %95 CI:0.004-0.72, p = 0.04).
CONCLUSION: Serum leptin levels did not show any significant correlations between oxidative stress parameters and overall histological severity. Patients with NASH had enhanced oxidative stress. In patients with NASH oxidative stress parameters and stage were independently associated with increased leptin levels with a preventive effect against NASH.
These data indicate that leptin may have preventive effect against oxidative stress and progression of hepatic injury in NAFLD.

P1155 ROLE OF LEPTIN AND INSULIN RESISTANCE IN THE DISEASE SEVERITY AND HEPATOCYTE APOPTOSIS IN NON-ALCOHOLIC FATTY LIVER DISEASE

B. Canbakan[1,*], H. Senturk[2], M. Tuncer[1], I. Hatemi[1], E. Köroğlu[1], K. Atay[1], A. Sonsuz[1], N. Kepil[3]
[1]*Gastroenterology, Istanbul University Cerrahpasa Medical Faculty,* [2]*Gastroenterology, Bezmialem University,* [3]*Pathology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey*

INTRODUCTION: Apoptosis and insulin resistance (IR) are major contributors in the pathogenesis and the disease severity of non-alcoholic fatty liver disease (NAFLD). Leptin plays a key role in insulin sensitivity. We aimed to evaluate whether serum leptin levels correlate with IR, apoptosis parameters and histopathological disease severity in NAFLD subjects with and without IR.
AIMS & METHODS: Sixty non-drinker patients with biopsy-proven diagnosis of NAFLD were studied (M/F:32/ 28; mean age 47.5±10.2 years). Thirty-six NAFLD patients with IR were compared with 24 subjects without IR. Insulin resistance index (HOMA IR) was calculated using the homeostasis model assessment method. Histopathological examination was done using the system described by Brunt et al. Serum leptin levels were measured by radioimmunoassay. For apoptotic activity immunohistochemistry was performed for caspase-3 and 8, transcription nuclear factor kB (NF-kB), and antiapoptotic Bcl-2 protein. Tumor necrosis factor receptor (TNF-sRp55) level was measured in serum. Statistical analysis was done using chi-squared test, Student's t-test, Mann-Whitney test, multivariate regression analysis and the area under receiver operating characteristic (ROC) curve. P-values < 0.05 were considered statistically significant. All statistical analyses were performed using SPSS® statistical software program (Ver.10.0).
RESULTS: HOMA-IR index correlated positively with the necroinflammatory grade, the stage, caspase-3 and 8 levels (p = 0.02, 0.002, 0.04, 0.021, respectively). The ROC curves revealed statistically significant discriminative power of HOMA-IR index for necroinflammatory grade,stage and non-alcoholic steatohepatitis (NASH) (AUROC = 0.7, 0.66, 0.65, respectively). Patients with IR had significantly higher steatosis grade, necroinflammatory grade, stage, caspase-3, caspase-8, TNF-sRp55, and serum leptin levels than those without IR.
In bivariate analysis serum leptin levels didn't show any significant correlation with fasting insulin, serum glucose, HOMA-IR index, steatosis grade, necroinflammatory grade and stage. Using serum leptin levels the ROC curve for distinguishing between NASH and simple steatosis didn't show any respective sensitivity and specificity (AUROC = 0.4). In linear regression analysis caspase-3 ($\beta = 0.11$, p = 0.002), caspase-8 ($\beta = 0.04$, p = 0.02), and stage ($\beta = 3.2$, p = 0.002) were independently associated with increased leptin levels In multivariate regression analysis caspase-3 (OR:2.2; %95 CI:1.06-5.26, p = 0.042) and caspase-8 levels (OR:2.3; %95 CI:1.06-5.72, p = 0.048) were risk factors for NASH and increase of leptin activity had preventive effect against NASH (OR:0.06; %95 CI:0.002-0.86, p = 0.043).
CONCLUSION: Insulin resistance in NAFLD is associated with enhanced hepatocyte apoptosis and histopathological disease severity. In patients with IR fibrosis severity and apoptosis parameters were independently associated with high leptin levels and increase of leptin activity showed preventive effect against NASH.
Our findings show that NAFLD patients with IR may have increased risk for disease progression and leptin has preventive effect against apoptosis and liver fibrosis.

P1156 LONG-TERM OBSERVATION OF WILSON DISEASE PATIENTS – EXPERIENCE OF A SINGLE CENTER

D. Gancheva[1,*], I. Kotzev[1], M. Kaneva[2], A. Kaprelyan[3], M. Grudkova[3]
[1]*Gastroenterology, Hepatology and Nutrition, University Hospital "St. Marina" - Varna,* [2]*Department of Statistics, University of Economics of Varna,* [3]*Department of Neurology, University Hospital "St. Marina" - Varna, Varna, Bulgaria*
Contact E-mail Address: *gancheva_vn@abv.bg*

INTRODUCTION: Wilson disease (WD) is an inherited copper metabolism disorder. If the patient remains undiagnosed and untreated, disease outcome may be fatal. Lifelong therapy provides normal WD patients' survival.
AIMS & METHODS: Aim: To evaluate the clinical course and long-term outcome of WD patients.
Material and methods: Sixty-five WD patients (22 females and 43 males) at a mean age of 37 years (range, 18-65 years) were analysed from January, 2003 to December, 2013. Survival analysis by Kaplan-Meier method and Logit model were used.
RESULTS: Twenty-eight patients (43.08%) were with liver disease alone, thirty-two (49.23%) - with hepatic and neurological presentation, three - with neurological features without any signs of a liver injury. There were two asymptomatic patients, too. The following hepatic forms were proved: steatosis (in 6.6%), hepatitis (in 41.7%), and cirrhosis (in 51.7% of the patients). There was a mean delay of diagnosis of 39 months. At the end of the study, 74.2% of cirrhotic patients were in Child A stage. Two patients developed acute liver failure after treatment discontinuation. We observed a hepatocellular carcinoma in one cirrhotic patient. Six patients with liver cirrhosis of Child C stage had fatal outcome during the observation. Three of them were with concurrent diseases – HBV and autoimmune cirrhosis. Kayser-Fleischer ring was detected in 35.4% of the patients being more common in those presenting with neurological symptoms. The cumulative survival rate of people with WD after first onset of symptoms was up to 76.38% at the end of 15th year, and that after diagnosis - 77.29%. It was estimated the impact of the lag in the diagnosis of WD on overall survival. At each year delay in the diagnosis the probability of death was increased by approximately 10%. There was a beneficial effect of D-penicillamine (D-p) treatment in almost all the patients. There were no complications during the pregnancies, with stable disease and normal birth.
CONCLUSION: Our observation showed a delayed diagnosis of WD. In most patients, the course of the disease was stable or even improved during the treatment. Mortality rate increased in the patients with cirrhosis. There was a favourable response after long-term treatment with D-p as first-line therapy in WD.

Contact E-mail Address: *k2dvorak@gmail.com*

INTRODUCTION: Non-alcoholic fatty liver disease (NAFLD) is a hepatic manifestation of metabolic syndrome. Risk of progression to cirrhosis is related to inflammatory reaction (NASH) and fibrosis. Despite all its limitations liver biopsy is still the gold standard in distinguishing NASH and staging of fibrosis, but non-invasive approaches are emerging.
AIMS & METHODS: The aim was to evaluate the usefulness of non-invasive laboratory parameters for detection of NASH and fibrosis in patients with NAFLD in routine clinical practice. Liver biopsy was performed in 56 patients with NAFLD (mean age 48.9 ± 15 years) and Kleiner score was used for histological staging and grading. Non-invasive parameters of fibrosis (hyaluronic acid, OELF, AST/ALT, BARD, APRI, NAFLD fibrosis score) and inflammation (M30 and M65 cytokeratin 18 fragments) were measured and calculated. The same parameters were applied to a group of other 56 patients not indicated to biopsy. 14 healthy individuals formed a control group.
RESULTS: NASH was bioptically diagnosed in 38 patients, simple steatosis in 18 patients. F0-F2 fibrosis was present in 39 patients; F3-F4 in 17 patients. Serum concentration of hyaluronic acid was significantly higher in patients with advanced fibrosis ($p = 0.01$), cut-off value 25 μg/l discriminated patients with F3-4 with 90% sensitivity and 84% specificity from those with F0-F2 (AUROC 0.94). AUROC for OELF score was 0.97; other parameters did not reach statistical significance. Serum concentrations of M30 a M65 in patients with NASH differed from subjects without NASH ($p = 0.01$). Examination of M65 discriminated patients with NASH with 80% sensitivity and 82% specificity (AUROC 0.89). Interestingly, when these non-invasive criteria were applied to a group of patients without biopsy, NASH would be diagnosed only in 15%, but the advanced fibrosis in 35% of them.
CONCLUSION: Non-invasive serum parameters in patients with NAFLD can differ with high accuracy those with steatohepatitis and advanced fibrosis. Among the patients not indicated for liver biopsy in the routine praxis a substantial part may have advanced fibrosis.
Supported by IGA MZ CR NT 12290/4, NT 11247/4 and SVV 260032-2014.

INTRODUCTION: Non-alcoholic fatty liver disease (NAFLD), a phenotype of metabolic syndrome in liver, is generally believed as a high-risk group in arteriosclerotic disease and type 2 diabetes. The progression of NAFLD is associated with oxidative stress; however, the proper treatment of NAFLD remains to be established. Recent studies have suggested that isoflavones have beneficial effects on metabolic syndrome-related disorders. Here we assessed the effects and mechanisms of isoflavones in Western diet (WD)-induced mice and NAFLD patients.
AIMS & METHODS: C57BL/6J mice were fed for 8 weeks on AIN93G (control) or WD (high in fat, cholesterol and sucrose) with or without 0.05% isoflavones (daidzein derivatives 50%, genistein derivatives 10%, and glycitein derivatives 40%). For human trial, nutrition survey was performed for 20 NAFLD patients and 20 healthy subjects. 25 mg of isoflavone aglycons were orally taken to 10 NAFLD patients for 28 days to evaluate blood tests and parameters related to oxidative stress.
RESULTS: The increases in ALT, blood glucose, liver fat accumulation and triglyceride in liver of WD-fed mice were improved by isoflavones treatment. The expression of hepatic genes related to steatosis, such as acetyl-coA carboxylase and peroxisome proliferator-activated receptor gamma, were also normalized by isoflavones. Further, isoflavones supplementation showed a tendency to improvement in the increases in oxidative stress (4-hydroxy-2-nonenal (HNE)-modified proteins) and glycation (methylglyoxal (MG)-modified proteins) in WD-fed mice. Nutrition survey showed that presumed oral intakes of daidzein and genistein in NAFLD patients were significantly lower compared to those in healthy subjects. Diet intervention trial indicated that isoflavones supplementation significantly reduced body weight and ALT as well as 7-ketocholesterol (7-KC) and hexanoyl-lysin (HEL)-modificed proteins in plasma.
CONCLUSION: Isoflavones supplementation attenuated liver function, and decreased oxidative stress or glycation in WD-fed mice and NAFLD patients. Further examinations are required due to low number of cases; however, isoflavones supplementation may be a treatment option for NAFLD.

P1159 NONINVASIVE DIAGNOSTIC OF NONALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

K. Aksentiychuk[1,*], E. Sklyarov[1], A. Bochar[1]
[1]*Therapy #1 and Medical Diagnostics, Lviv National Medical University by Danylo Galytskyi, Lviv, Ukraine*

INTRODUCTION: It is known that in 72% of patients with type 2 diabetes mellitus diagnosed NAFLD. Patients with NAFLD are usually asymptomatic, high values of liver enzyme tests being the most common finding. The definitive diagnosis of NAFLD is based of liver biopsies. Although liver biopsy is the current gold standart for diagnosis of NAFLD, it is not a practical screening tool given the cost, time-consuming nature and potential mortality of this procedure. However, more attention is attracted to early diagnosis NAFLD by using a special set of design formulas biochemical parameters, data Fibroscan or respiratory tests with 13C-methacethine (C13-MBT)
AIMS & METHODS: A comparative analysis of methods for diagnostics of clinical forms NAFLD using specially developed formulas 13C-methacethine breathe test (MBT), biochemical parameters.
The study involved 131 patients with type 2 diabetes mellitus (DM) (male 48, female 83, aged 43 to 82 years, mean age 60.94 ± 0.82 years). Control group, 106 patients without diabetes, men 47, women 59, aged 35 to 69 years (mean age 60.26 ± 1.27). Biochemical tests were performed: total bilirubin (TB), AST, ALT, AST / ALT, GGTP, lipidogram, carried ultrasonographic examination, the calculation formulas of Angulo, Forns, Fib-4, Apri. Defining the antitoxic function of the liver by 13C- MBT.
RESULTS: Total cholesterol (TC) ($p = 0.00127$), HDL ($p = 0.0001$), triglycerides ($p = 0.0001$), AST / ALT ($p = 0.09594$) were reliable indicators between the main and control groups. Among the patients of the main group were detected 91 patients with NAFLD, control -32. There were higher TB, AST, ALT and AST / ALT levels among patients with NAFLD, none of the indicators does not exceed the upper limit of normal. Formula Forns correlated with the clinical form NAFLD. Marked strong negative relationship between the Forns and ALT levels ($r = -0.944$) and TB ($r = -0.967$) with fibrosis, and TC ($r = -0.805$) and LDL ($r = -0.846$) with steatosis. 13C-MBT was conducted on 32 patients. In patients with steatosis and steatohepatitis, index MDT replied a moderate decrease liver (10-20%), marked reduction with fibrosis (< 10%). A strong negative correlation was noticed between LDL ($r = -0.878$) and TG ($r = -0.933$) and MBT in fibrosis.
CONCLUSION: In the resulting formula Forns over 4.25, 13C-MBT least 10%, lower levels of ALT but TB, and TC more than 2.6 mmol / L, triglycerides more than 2.6 mmol / l - high probability of fibrotisis. The result of the Forns least 4.25, 13C-MBT between 10-20% TC more 5.2 mmol / l and LDL more than 2.6 mmol / L indicates liver steatosis.

INTRODUCTION: Polycystic liver disease (PLD) is characterized by progressive hepatomegaly resulting from liver cysts and is associated with an impaired physical dimension of Health Related Quality of Life (HRQL). Somatostatin analogues reduce hepatomegaly in PLD.
AIMS & METHODS: We pooled data of two randomized placebo controlled trials (NCT00565097/NCT00426153) that evaluated HRQL with the short-form Health survey (SF-36) in 96 PLD patients treated 6-12 months with somatostatin analogues or placebo. SF-36 contains a summarizing physical component score (PCS) and was administered at baseline and end of treatment. We used multiple linear regression analysis with correction for trial (random effect) and baseline PCS (fixed effect) to delineate the effect of somatostatin analogues. As a secondary analysis, we determined the effect of severe hepatomegaly ($>75^{th}$ percentile), delta liver volume, underlying disease, gender, age and occurrence of adverse events on PCS change independent of treatment. Results are given as estimated mean score ± standard error. The PCS is standardized to the healthy population with a score of 50 points.
RESULTS: We included 87 patients (89% female, mean age 48 yrs) with a baseline PCS of 44.32 points and median liver volume of 4504 mL. PCS improved with somatostatin analogues, but remained unchanged with placebo (3.41 ± 1.29 vs. -0.71 ± 1.54, $p<0.05$). Severe hepatomegaly and adverse events significantly contributed to PCS decrease, while delta liver volume, gender, age and underlying diagnosis did not impact PCS.
CONCLUSION: Somatostatin analogues improve the physical dimension of HRQL in polycystic liver disease patients after 6-12 months of treatment. Besides treatment, severe hepatomegaly is independently associated with a decline in HRQL during follow up.

P1161 FEATURES OF UPPER GASTROINTESTINAL ABNORMALITIES IN NON-ALCOHOLIC STEATOHEPATITIS (NASH) PATIENTS

S. Yamamoto[1,*], M. Komori[1], M. Nishiyama[1], M. Fukuoka[1], S. Kudo[1], K. Maesaka[1], K. Shirai[1], S.-Y. Kimura[1], T. Okahara[1], Y. Okuda[1], M. Konoshita[1], M. Hirao[1], A. Hosui[1], H. Yoshihara[1]
[1]*Gastroenterology, Osaka Rosai Hospital, Sakai, Japan*
Contact E-mail Address: *shun0515suke@gmail.com*

INTRODUCTION: Non-alcoholic steatohepatitis (NASH), hepatic manifestation of metabolic syndrome has been considered the most common liver disease today. NASH patients are reported to have higher incidence of colon polyps, however, features of their upper gastrointestinal findings have not been reported.
AIMS & METHODS: The aim of this study is to clarify the upper gastrointestinal abnormalities of NASH patients by comparing with those of health check subjects.
This is a retrospective study. We diagnosed 94 patients as NASH in our hospital from March 1998 to July 2012. 1) Among them, 36 who underwent esophagogastroduodenoscopy (EGD) were enrolled in this study. 2) From 118 subjects who underwent health-check at our hospital from January 2012 to September 2012, 73 were selected as healthy control (group) excluding those with obesity (body mass index; BMI > 25), hepatic dysfunction, fatty liver, and diabetes, and 3) 14 obese subjects without hepatic dysfunction were selected as obesity group. Following findings in EGD were compared among 3 groups; esophageal hernia, reflux esophagitis, Barrett's esophagus, atrophic gastritis, superficial gastritis, erosive gastritis, gastric ulcer including scar, and gastric polyp.
RESULTS: Age, sex, and BMI of NASH/health/obesity groups were 65 ± 12/ 64 ± 14/ 65 ± 12 (mean ± SD); 22, 14/ 35, 38/ 10, 4 (male, female); 26.6 ± 3.8/ 21.6 ± 1.8/ 26.2 ± 1.0, respectively. Age was comparable among three groups. BMI of NASH and obesity group was significantly higher than that of healthy group ($p<0.0001$), while that of NASH and obesity was not different. Among NASH group, 6 (17%) were cirrhosis. Esophageal hernia and reflux esophagitis were significantly more observed in NASH group than in healthy group (77.8/50.7% and 50/26%, $p=0.01/0.01$), while prevalence of these findings were not different between healthy and obesity group. Prevalence of Barrett's esophagus, atrophic gastritis, superficial gastritis, gastric ulcer, and gastric polyp showed no significant difference among three groups. Prevalence of erosive gastritis in NASH patients was significantly higher than that in healthy group (44%, 16/36; 12%, 9/73; $p=0.0002$), while no significant difference of this finding was observed between NASH and obesity group. Only in NASH group, portal hypertensive gastropathy and esophageal varices were found in 2 cirrhotic patients.
CONCLUSION: NASH patients have higher risk of esophageal hernia and reflux esophagitis than healthy subjects.

INTRODUCTION: Studied the influence of the pathogenetic mechanisms of hyperhomocysteinemia on the formation and progression of nonalcoholic fatty liver disease (NAFLD) by inducing oxidative stress. It is shown knots in the degree of hyperhomocysteinemia depending on the stage of the disease.
AIMS & METHODS: Examine the degree of hyperhomocysteinemia (HHcy) in patients with non-alcoholic steatosis and steatohepatitis (NASH). Determine the correlation between homocysteine serum level and indicators of oxidative stress (nitric oxide (NO) and TBA-active metabolites in blood plasma). We observed 65 patients with NAFLD. The first group included 33 patients with hepatic steatosis. In the second group there were 32 patients with NASH.
RESULTS: HHcy were revealed in patients with disease severity: normal levels of homocysteine (Hcy) were reported in 6 patients (18.2%) in the first group (12.44 ± 1.6 μmol/L), while in the second group, only 2 patients (6, 2%) patients (12.96 ± 0.74 μmol/L). Mild degree HHcy was detected in 13 (39.4%) and 8 (25%) patients in the first (21.65 ± 3.93 μmol/L) and the second group (20.03 ± 3.24 μmol/L) respectively. HHcy moderate detected in 14 (42.4%) patients in the first group (42.19 ± 16.96 μmol/L) and 18 (56.3%) in the second (62.88 ± 22.24 μmol/L). Heavy HHcy occurred in 4 (12.5%) patients in the second group (113.22 ± 14.96 μmol/L), while the first group of patients had no evidence of violations. Significant correlation between the level of Hcy and NO: the first group - $r=0.79$; $p<0.05$; second group - $r=0.89$; $p<0.05$.
CONCLUSION: Our results show that the degree of HHcy increases with the severity of NAFLD. There are positive correlations between the Hcy and indicators of oxidative stress in patients with NAFLD.

Contact E-mail Address: *monasleman@hotmail.com*

INTRODUCTION: Recent research has shown that miRs are emerging as important regulators of cellular differentiation and undifferentiation. The miR-122 accounts for approximately 70% of all miRs in the liver, whereas other organs express much lower amounts of this miRs. And due to almost exclusive expression of miR-122 in the liver the presence of it in the serum is highly indicative of liver processes.
AIMS & METHODS: was to study the role of miR-122 as a prognostic new marker in patients with liver cirrhosis. MiR-122 that was detected by quantitative real-time reverse transcription (RT)-PCR technique. Eighty patients with liver cirrhosis were included in our study, we divided them into 4 equal groups according to the complications of liver cirrhosis (1-compensated cirrhotics, 2- ascites, 3-spontanious bacterial peritonitis SBP, and 4- hepatorenal syndrome HRS group) to evaluate if the serum level of miR-122 might be a suitable parameter for disease severity and prognosis in such patients.
RESULTS: miR-122 was statistically significantly higher in group 1 "compensated" compared to both groups 2 "ascites" and 3 "SBP" ($p=0.001$), while the difference was highly significant when compared to its level in group 4 ''HRS'' ($P<0.001$). Serum miR-122 levels were positively correlated with serum albumin, PC, and serum Na levels while it was negatively correlated with creatinine, urea, and INR. Also there was strong negative correlation between serum miR-122 level and MELD score ($p=0.001$), and very strong negative correlation between serum miR-122 level and Child score ($p<0.001$).
CONCLUSION: Lower serum miR-122 levels are associated with ascites, spontaneous bacterial peritonitis and hepatorenal syndrome. Therefore, serum miR-122 could be a new potential parameter for liver function and a prognostic parameter in patients with liver cirrhosis.

INTRODUCTION: Cirrhosis has been linked to high risk for infection and dysfunctional neutrophil granulocytes have been proposed to be one of the reasons for this ineffective immune response. However, contradictory reports have emerged regarding the nature and direction of their dysfunction, leaving the pathophysiological mechanism and underlying causes yet to be discovered.
AIMS & METHODS: Therefore we aimed to explore neutrophil granulocytes in cirrhosis as well as the role of aetiology, opsonisation, gut permeability and underlying diseases in neutrophil functionality.
Neutrophil function (oxidative burst, phagocytic and opsonisational capacity), gut permeability and hepatitis C virus infection (HCV) parameters of 98 liver cirrhosis patients of different aetiologies (56 alcoholic, 20 HCV, 22 other) and 72 controls (33 healthy, 39 HCV infected without cirrhosis) were analysed. Neutrophil function was assessed by flow cytometry, gut permeability by high performance liquid chromatography (differential sugar absorption) or ELISA (diamine oxidase, soluble cluster of differentiation 14) and HCV parameters by routine methods.
RESULTS: Compared to healthy control values, phagocytic capacity (Phagoindex, PI) is decreased in patients with HCV induced cirrhosis (0.7-fold), not significantly influenced in alcoholic cirrhosis (1.1-fold), and increased in cirrhosis of non-viral/non-alcoholic aetiologies (1.5-fold). In addition, the amount of neutrophils without measurable phagocytosis shows a significant increase in HCV induced cirrhosis but is not as prominent in alcoholic and other cirrhosis (5.0-, 1.9- and 1.2-fold, respectively). The progression from Child's A to B cirrhosis decreases PI approximately 30% regardless of the aetiology. Furthermore, alcoholic cirrhosis is accompanied by high amounts of primed neutrophils in the bloodstream, and HCV induced cirrhosis results in impaired production of reactive oxygen species after bacterial stimulation. However, opsonisation is sufficient in all cirrhosis groups and shows no differences compared to controls. Gut permeability is elevated in all aetiologies, most pronounced in alcoholic cirrhosis which shows a significant increase in every marker. High permeability is associated with neutrophil dysfunction but explains only partially the observed alterations. In HCV induced cirrhosis a part of the phagocytic dysfunction originates from HCV infection itself. Before the onset of cirrhosis and with normal gut permeability, HCV infected controls already display a 2.5-fold increase in neutrophils without phagocytosis and a slight non-significant decrease in PI, compared to healthy controls.
CONCLUSION: Aetiology, gut permeability and HCV infection impact strongly and diversely on neutrophil function in cirrhosis. Still, causal links between already published and well established explanations need to be explored.

P1165 INCREASING PREVALENCE OF MULTIDRUG-RESISTANT INFECTIONS IN PATIENTS WITH CIRRHOSIS

K. Klimova[1], **C. Padilla Suárez**[1,*], A. Matilla Pena[1], G. Clemente Ricote[1], R. Banares Canizares[1]
[1]*Gastroenterology and Hepatology, Hospital General Universitario Gregorio Maranon, Madrid, Spain*

INTRODUCTION: Bacterial infections are an important complication of liver cirrhosis. Moreover, they represent a common motive of its descompensation, hospitalization and health-care related costs. Recently, infections caused by gram-positive and multidrug-resistant bacteria have become more frequent, with a significant impact on patientś morbidity and mortality.
AIMS & METHODS: Aim: To asses the rate of infections caused by multidrug-resistant bacteria in hospitalized patients with liver cirrhosis. The most frequent infections (pneumonia, urinary tract infection, SBP, bacteriemia) were included. Methods: We evaluated 277 cirrhotic patients admitted to our center between Junuary 2012 and July 2013 due to a bacterial infection.
RESULTS: 340 infections were evaluated in 277 patients. Their mean age was 64.6 years (range 31 - 91). The etiology of the cirrhosis was: due to alcohol abuse (50%), hepatitis C infection (43.3%), hepatitis B infection (14%). 56 (20.2%) patients had hepatocellular carcinoma, 61 (22%) chronic renal insufficiency, 96 (34.7%) were diabetic and 127 (45.8%) were on beta blockers. The mean MELD on admission was of 14.6, and Child-Pugh score of 7.8 points.
The most frequent infections were UTI in 155 patients (56%), followed by SBP in 84 patients (30%), pneumonia (70%) and bacteriemia in 54 (19.5%). The infections were community-adquired in 104 patients (37%), health-care related in 120 (43%) and nosocomial in 83 (30%). We obtained microbiological isolation in 187 of the 277 patients, 73 of those had 2 or more different bacterial isolations, i.e. in total 290 isolations, 39.8% by gram positive bacteria and 60.2% gram negative bacteria, being *E. coli* the most frequent one. 42 (15%) of the bacteria were multidrug resistant, 32 BLEEs and 10 MRSA, and in 10 *Enterobacteriaceae*, Amp C betalactamase was identified. Risk factors for a multiresistant infection were: hospital admission and use of antibiotics during previous 90 days.
Global mortality rate during the episode was of 15.2 % (15 patients), with accumulated mortality of 30% during the following 6 months. In the univariate analysis, the factors associated to mortality were: acute renal insufficiency, microbiological isolation in control bacterial cultures, sepsis or septic shock, and diagnosis of pneumonia. The independent risk factors were: acute renal insufficiency (p: 0.022, OR 1.73 IC95: 1.15 – 2.58), and isolations in control cultures (p: 0.002, OR 1.98 IC95: 1.3 – 3.25).
As for the antibiotics, the third-generation cephalosporines remained the treatment of choice in 45.5% of patients, followed by carbapenems (23.8%). 54.5% of patients requiered the use of more than one antibiotic, mainly carbapenems or vancomycine.
CONCLUSION: In our group of cirrhotic patients with bacterial infections a relatively high rate of multidrug resistant infections were observed, especially as far as BGN are concerned. Treatment with broad-spectrum antibiotics is recommendable in high-risk group of patients.

INTRODUCTION: Indocyanine green (ICG) elimination is a test to evaluate hepatic function in patients with liver disease and to quantify liver perfusion. Conventional ICG clearance is dertermined by measuring the rate of elimination of the synthetic dye using several venous samples after its intravenous administration. With the new infrared-based transcutaneous pulse spectrophotometry (LIMON^{TM}) a plasma disappearance rate (PDR) and a calculated remaining concentration after 15 minutes (R15) are provided. Several studies have suggested that the LIMON^{TM} system is able to measure ICG-concentration accurately, however a direct comparison to conventional ICG clearance measurements in patients with liver cirrhosis has not been performed yet.
AIMS & METHODS: In a randomized controlled double-blind study to test the effect of Udenafil, a new phosphodiesterase-5-inhibitor, in patients with liver cirrhosis a conventional ICG clearance measurement as well as a determination by the LIMON^{TM} system was performed. Included patients had a proven compensated liver cirrhosis. After enrolment, two visits to evaluate hemodynamics and ICG kinetics before and after ingestion of a placebo or Udenafil were scheduled within 7 days. 0.3 mg/kg ICG were administered via an antecubital vein. Blood samples were drawn from the opposite cubital vein before and exactly 3, 6, 9, 12, 15, 18, 21, 30 and 40 minutes after ICG injection.
All samples were centrifuged immediately and stored at -80°C until analysis. Calculation of PDR and R15 were done by P. Thomann (Kineticon, Freiburg, Germany). In parallel, with transcutaneous spectrophotometry PDR and R15 were are measured with the LiMON^{TM}-device (PULSION Medical Systems AG, Munich, Germany). For this analysis, the results of the ICG determination via blood samples and LIMON before the drug ingestion on both study days are compared.
RESULTS: 20 patients with liver cirrhosis were included (4 female, age 54.9±10.8 years, Child-Score 6.7±1.3). One female patient stopped the study after Visit 1 because of side effects (dizziness, malaise) a few hours after application of ICG and 100mg Udenafll. 20 analyses were performed at Visit 1 and 19 analyses at Visit 2. In 2 patients a stable transcutaneous signal was not obtained at Visit 1 so the LIMON^{TM}-system failed. The plasma disappearance rate at Visit 1 was 9.82±5.68% for blood analyses and 10.34±5.54% for the LIMON device, respectively. The results for the R15 were 35.26±22.66% for blood analyses and 27.47±18.71% for the LIMON device. At Visit 2 the PDR results were 8.79±5.64% versus 10.37±6.58%, respectively. The results for R15 were 37.64±22.49% versus 29.20±21.34%, respectively. The correlation between the two methods was high (r for PDR Visit 1: 0.938, r for R15 Visit 1: 0.968; r for PDR Visit 2: 0.892, r for R15 Visit 2: 0.921).
CONCLUSION: This is the first analysis to compare conventional analysis of ICG clearance with a transcutaneous spectrophotometry in patients with compensated liver cirrhosis. ICG plasma disappearance rate and R15 estimated with the LIMON^{TM} device correspond well to conventional ICG clearance. With the LIMON^{TM} device the ICG kinetics can be obtained in an easy way within 5 minutes with only minor effort.

P1167 OSTEOPOROSIS IN PRIMARY BILIARY CIRRHOSIS: TWO BIPHOPHONATES COMPARED

G. Iafrancesco[1], **R. Filippetti**[2,*]
[1]*Ospedale S. Sebastiano M, Frascati (Roma),* [2]*Ospedale San camillo-Forlanini, Roma, Italy*
Contact E-mail Address: *prof_filippetti@yahoo.it*

INTRODUCTION: Osteoporosis characterized by loss of bone strength leading to fragility fractures is a common event in women who have Primay Biliary Cirrhosis (PBC). Although its pathogenesis is not well known it results mainly from low bone formation. At present the treatment of osteoporosis in patients with PBC mostly relies on oral biphosphonates,particularly in weekly 70 mg alendronate,but there are a concern because of poor compliance. The efficacy,adherence and safety of monthly 150 mg ibandronate were compared in a 2-year study in 20 postmenopausal women with osteoporosis and PBC.
AIMS & METHODS: Bone mineral density (BMD) of the lumbar spine and proximal femur by dual-energy x-ray-absorptiometry (DXA),liver function and bone markers were measured at entry and every 6 months at entry and every 6

months over 2 years. Adherence to therapy was assessed by the Moriski score. At enrollment the two groups were similar with respect to age,BMD,cholestasis,previous fractures and bone markers. Eighteen patients,nine in the alendronate group and nine in the ibandronate completed the study.
RESULTS: At 2 years both treatments resulted in a significant increase in BMD at the lumbar spine,the mean percentage change was 4.5% in alendronate and 5.7% in ibandronate group (p = not significant) BMD increased at the total hip by 2% and 1.2% respectively. Change in bone markers were similar in both groups and one patient with alendronate developed a new vertebral fracture. Adherence to the therapy was higher with ibandronate. Neither treatment impaired liver function or cholestasis. One patient in the alendronate group discontinued treatment because of gastrointestinal adverse effects such as dyspepsia,nausea and vomiting.
CONCLUSION: Both regimens,weakly alendronate and monthly ibandronate,improve bone mass and are comparable in safety for osteoporosis therapy in patients with PBC,although adherence is higher with the monthly regimen. Further larger studies are needed to assess fracture prevention.

P1168 HFE GENE C282Y AND H63D MUTATIONS ARE ASSOCIAED WITH LIVER CIRRHOSIS IN LITHUANIAN POPULATION

S. Juzenas[1,*], I. Valantiene[1,2], J. Kupcinskas[1,2], L. Kucinskas[1], J. Sumskiene[2], V. Petrenkiene[2], J. Venteriene[1], J. Kondrackiene[2], J. Skieceviciene[1], L. Kupcinskas[1,2]
[1]*Institute for Digestive Research,* [2]*Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Lithuania*

INTRODUCTION: Liver cirrhosis is an ultimate complication of different chronic liver disorders. Cirrhosis is commonly caused by alcohol use, viral hepatitis B and C and many other causes. The search for epidemiological, biological or genetic factors that could help to select patients at higher risk of developing cirrhosis is necessary. The literature data on impact of HFE-gene C282Y and H63D heterozygous mutations for liver cirrhosis risk in different populations and depending on cirrhosis etiology is controversial.
AIMS & METHODS: The aim of this study was to determine the association between the presence of HFE gene C282Y and H63D mutations and liver cirrhosis in Lithuanian population. A cohort of consecutive cirrhosis patients consisted of 209 individuals with different disease etiologies. The diagnosis of cirrhosis was confirmed by clinical features, liver biopsy and radiological imaging tests. Control group consisted of 1004 healthy blood donors. HFE gene mutations in cirrhotic patients and control group were detected using PCR-RFLP method. Statistical analysis were performed using statistical software for genetic association studies PLINK v2.050.
RESULTS: The presence of C282Y mutation was associated with higher risk of the liver cirrhosis when compared with controls (OR-2.07, p = 0.005). The carriage of C282Y/wt genotype increased the risk of liver cirrhosis compared with individuals having wt/wt genotype (OR-2.00, p = 0.012). A similar pattern was observed in a dominant model for C282Y mutation (wt/wt vs. C282Y/wt + C282Y/C282Y) which showed increased risk of developing liver cirrhosis (OR-2.07, p = 0.007). This link was even more evident in males as carriers of C282Y allele had increased risk of liver cirrhosis with an OR of 2.58 (p = 0.002). The presence of H63D mutation was not associated with cirrhosis risk in overall study population; however, after stratification into genders H63D allele was associated with higher risk of liver cirrhosis in males (OR – 1.5, p = 0.018), but not in females (OR – 0.84, p = 0.43).
CONCLUSION: HFE gene C282Y mutation is associated with liver cirrhosis irrespective of disease aetiology, while H63D mutation was linked with liver cirrhosis only in males. These genetic alterations might contribute to faster progression of chronic liver diseases of different aetiology to end stage in Lithuanian population.

P1169 AUTOLOGOUS BONE MARROW - DERIVED LIVER STEM CELLS REDUCE LIVER FIBROSIS AND IMPROVE LIVER FUNCTION IN CARBON – TETRACHLORIDE - TREATED HEPATIC CIRRHOTIC RAT

X. Guo[1,*], J. Chen[1]
[1]*General Hospital of Shenyang Military Area, Shenyang, China*
Contact E-mail Address: *guoxiaozhong1962@163.com*

INTRODUCTION: To determine the safety, feasibility and therapeutic effect of in vitro-expanded autologous bone marrow-derived liver stem cells (BMDLSC) transplantation in hepatic cirrhotic rats treated with carbon - tetrachloride.
AIMS & METHODS: Liver cirrhosis rat models were prepared and then divided randomly into three groups, 25 in each group. In rats, we analyzed the effect of different cells infusion in three experimental groups (group A, bone marrow cell infusion + CCl (4); group B, bone marrow - derived liver stem cell infusion + CCl (4); group C, bone marrow stem cell infusion + CCl (4)).
RESULTS: We observed significantly increased average serum albumin levels and higher expression of Differentiated liver cells, green fluorescent protein (GFP), matrix metalloproteinase 9 (MMP9), and proliferating cell nuclear antigen in the livers of group A. We observed MMP9/GFP double-positive cells in the cirrhotic livers. A significant decrease in the liver fibrosis areas was observed in group A. There were significant differences in ALT, ALB, TBIL and AFP in three groups, P < 0.05.
CONCLUSION: Infusion of bone-marrow-derived cultured liver stem cells improved liver function and liver fibrosis in rat with CCl4-induced cirrhosis.

P1170 THE RISK OF MALIGNANT TRANSFORMATION OF THE COLORECTAL POLYPS- PROSPECTIVE STUDY

A. Goldis[1,*], L. Daniela[1], I. Ratiu[1]
[1]*gastroenterology, V Babes Medical University, Timisoara, Romania*
Contact E-mail Address: *goldisadi@yahoo.com*

INTRODUCTION: Because colonic polyps are highly prevalent in the general population (especially with increasing age), they confer an important predisposition to colon cancer
AIMS & METHODS: We performed a prospective study including 659 patients, with amean age of 60.1 ± 11.5 years, in which a number of 928 polyps were resected. We have evaluated the correlation between the dimension of the polyps and the risk of malignant transformation on the ground of the grade of epithelial dysplasia revealed by the histopathological examination.
RESULTS: From the total number of the studied polyps, 324 were without dysplasia, 514 with mild/moderate dysplasia and 89 with high grade dysplasia/malignant polyps. The mean dimension of the polyps without dysplasia was significantly lower in comparison to the dimension of the polyps with high grade dysplasia/malignant polyps: 8.69 ± 0.5978 mm vs. 15.64 ± 1.626 mm, p < 0.0001 ES. There were no statistically significant diferencies between the mean dimension of the polyps without dysplasia vs. the dimension of the polyps with mild/moderate dysplasia: 8.69 ± 0.5978 mm vs. 8.85 ± 0.3489 mm (p > 0.05). The mean dimension of the polyps with mild/moderate dysplasia was significantly lower in comparison to the dimension of the polyps with high grade dysplasia/malignant polyps: 8.85 ± 0.3489 mm vs. 15.64 ± 1.626 mm, p < 0.0001 ES. According to the dimension, the studied polyps were subdivided into two groups: polyps < 15 mm, and polyps > 15mm, respectively. In the first group there were 803 polyps included, from which 286 (35.6%) without dysplasia, 460 (57.2%) with mild/moderate dysplasia and 57 (7%) with high grade dysplasia/malignant polyps. The second group was formed by 121 polyps, from which 38 (31.4%) without dysplasia, 54 (44.6%) with mild/moderate dysplasia and 29 (23.9%) with high grade dysplasia/malignant polyps. Comparing these two groups, we noticed that high grade dysplasia was found in a significantly higher number of polyps > 15mm in comparison with those < 15 mm, p < 0.0001 ES, OR 3.829 95% CI (2.185 to 6.709), RR 1.470 95% CI (1.186 to1.822).
CONCLUSION: Our results demonstrate the existence of a statistically significant correlation between the dimension of the polyps and the risk of malignant transformation, namely, the bigger the polyps are, the higher the risk of malignant transformation is. Polyps over 15 mm diameter hold a risk of malignant transformation 1.5 times higher than the smaller polyps.

INTRODUCTION: Spontaneous Bacterial Peritonitis (SBP) is the most frequent and life-threatening infection in patients with liver cirrhosis. It requires prompt recognition and treatment. Mortality is high for patients admitted with decompensation which is a growing problem due to the increasing prevalence of cirrhosis. Hence early detection of complications such as SBP is critical to improve outcome. EASL (European Association for the Study of the Liver) released Clinical Practise guidelines on management of SBP in 2010. We have compared our data on managing SBP and determine if this is compliant with guidelines and if there is uniformity within our DGH.
AIMS & METHODS: Our aim was to assess whether we are managing SBP in our DHG in accordance with EASL guidelines from 2010. We collected data retrospectively from October 2011 to November 2012. Then we collected data for 1 year following intervention from November 2012- November 2013. We requested our pathology lab to supply patient details of any ascitic fluid samples with a white cell count > 500/mm^3. We Investigated and recorded the following data:
1. Did patients receive an ascitic tap on admission
2. Was a Neutrophil count >250/mm^3 recorded
3. Was a WCC > 500/mm^3 recorded
4. Positive culture results documented
5. Was Antibiotics started before culture results
6. Was Intravenous albumin given
7. Evidence of Hepatorenal syndrome (HRS) documented
8. Was a Repeat ascitic tap performed
9. Prophylactic antibiotics

RESULTS:

Outcomes measured	Oct 11 – Oct 12 (n = 15)	Nov 2012 – Nov 2013 (n = 12)	Percentage improvement
Ascitic tap on admission	47%	50%	3%
Neutrophil count >250/mm^3 recorded	0%	0%	0%
Positive culture results documented	40%	17%	-23%
Antibiotics started before culture results	93%	100%	7%
Intravenous albumin given	27%	83%	56%
Hepatorenal Syndrome	53%	33%	20%
Repeat Ascitic Tap performed	17%	67%	50%
Prophylactic Antibiotics	33%	33%	0%
Mortality	60%	17%	43%

CONCLUSION: It was alarming to see the variation in management amongst doctors, especially gastroenterologists and hepatologists. Following education there has been improvement in outcomes which hopefully has a positive impact on morbidity and mortality. It is unclear why ascitic neutrophil count is not done in this trust and many other trusts.
This audit highlights the need to ensure that there is a standardised approach to the diagnosis and management of SBP. By adhering to guidelines it may help mortality and morbidity.

P1172 SYMPTOMATIC TREATMENT OF HEPATIC ENCEPHALOPATHY WITH CHOLINE ALPHOSCERATE

E.G. Manzhalii[1,*], O.M. Baka[2]
[1]*Internal medicine, Bogomolets of National Medical University,* [2]*Gastroenterology, Hospital for Scientists of the National Academy of Science, Kiev, Ukraine*
Contact E-mail Address: *elinam@ukr.net*

INTRODUCTION: The treatment of hepatic encephalopathy (HE) involves multiple drugs that may lead to recovery of consciousness and thinking but therapeutic options are often limited.
AIMS & METHODS: The aim of our work now was to assess the efficacy of *choline alphoscerate* for the treatment of HE in patients with liver cirrhosis. In this prospective study, we included 34 patients with liver cirrhosis and HE, stage I-II. The control group comprised 17 patients receiving standard treatment. Patients from the intervention group received *choline alphoscerate* (L-alpha-glyceryl phosphorylcholine, Gliatilin; 800 mg per day) for one month in addition to the basic treatment. HE was assessed by clinical symptoms, number connection test, and electroencephalography (EEG).
RESULTS: In the intervention group vs. controls the normalization of sleep and movement disturbance improved in 88% and 72% of the patients, respectively. In the control group only 53% of the patients improved in sleep patterns and 40% in motor coordination. Of note on the 10th day of treatment, patients in the intervention group started to perform in the number connection tests 27.2 ± 1.2s faster, whereas in the control group the improvement was significantly ($P < 0.05$) less (12.7 ± 1.4s). Patients on choline alphoscerate showed a marked clinical improvement correlating with EEG changes. Before treatment, a reduction of α-rhythm was detected in 82% of the patients; after treatment this proportion was only 41% ($P < 0.05$), indicating normalization of brain function in the majority of patients. In the control group 73% of patients showed abnormal EEG findings before and after treatment. The presence of θ-waves was observed in 45% of patients before and 24% after treatment with choline alphoscerate ($P < 0.05$); in the control group the corresponding frequencies were 54% and 47% ($P > 0.05$).
CONCLUSION: *Choline alphoscerate* eliminates pathological neurological symptoms in 78% patients with cirrhosis, whereas improvement is only detected in 38% of patients with HE on conventional therapy. The natural choline supplement has a favorable safety profile and should be studied further in randomised controlled trials.

P1173 DIFFERENT SCORING SYSTEMS IN PREDICTING SURVIVAL IN CHINESE PATIENTS WITH LIVER CIRRHOSIS UNDERGOING TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT

F. Zhang[1,*], Y. Zhuge[1], X. Zou[1]
[1]*Department of Gastroenterology, Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*
Contact E-mail Address: *fzdndx@126.com*

INTRODUCTION: Transjugular intrahepatic portosystemic shunt (TIPS) is an established minimal-invasive procedure to treat complications of portal hypertension, and several scoring systems have been used to help choose suitable patients. But the accuracy remains controversial.
AIMS & METHODS: To compare the performance of the Child-Turcotte-Pugh (CTP) classification system, Model for end-stage liver disease (MELD) score, Emory score, Bonn TIPS early mortality (BOTEM) score, and serum bilirubin and platelet count (SB/PLT model) in predicting survival in Chinese patients with liver cirrhosis undergoing Transjugular intrahepatic portosystemic shunt (TIPS). The clinical data of patients undergoing TIPS in our department were retrospectively analyzed to compare the 5 scoring systems based on survival after TIPS.
RESULTS: A cohort of 159 patients was involved. The survival curves showed statistical significance between classification B and C of CTP ($\chi2 = 9.451$, $p = 0.002$), between MELD < 10 and MELD ≥ 10 ($\chi2 = 10.099$, $p = 0.001$) and between low risk and moderate risk groups of Emory score ($\chi2 = 4.656$, $p = 0.031$), indicating a better discriminatory ability. By ROC curves and logistic regression model, MELD score and CTP system had a better power to predict 3-month, 12-month, and 24-month survival. MELD score and CTP classification system had smaller values of -2Ln(L), Akaike Information criterion (AIC), and Schwarz-Bayesian criterion (SBC), respectively.
CONCLUSION: MELD score and CTP classification system provide better prognostic stratification for a cohort of Chinese patients with advanced cirrhosis undergoing TIPS. However, MELD score is not significantly superior to CTP system.

P1174 IN MELD FIT A PREDICTIVE FACTOR FOR IN HOSPITAL MORTALITY IN CHIRROTICS PATIENTS WITH OESOPHAGEAL VARICEAL BLEEDING?

J. Silva[1,*], R. Cerqueira[1], M. Correia[1], C. Manso[1]
[1]*Centro Hospitalar entre Douro e Vouga, Santa Maria da Feira, Portugal*
Contact E-mail Address: *joanasilva67@hotmail.com*

INTRODUCTION: The model for end stage liver disease (MELD) score is very accurate for predicting mortality in patients with end stage liver disease. Since 2002, MELD is used for patient allocation on liver transplant waiting lists. Oesophageal variceal bleeding (OVB) is a high mortality rate complication in patients with cirrhosis. The aim of this study was to compare the prognostic value of MELD and MELD fit for in-hospital mortality (IHR) in cirrhotic patients with OVB.
AIMS & METHODS: The study cohort consisted of 135 patients [mean age 54.9 (±12.2), 73.3% male] consecutively admitted to our hospital with OVB. All the patients were submitted to upper endoscopy within 12h, and sclerotherapy or band ligation was performed in case of active bleeding. Octeotride or terlipressin therapy was started at admission and continued for 5 days. In order to calculate MELD and MELD fit scores, data of the laboratory results from blood samples taken within 6h from admission were used. The level of significance was set at $p < 0.05$.
RESULTS: The IHM was 17.0% (23 patients). On univariate analysis the predictive factors for IHM were **rebleeding** (OR = 17.3 (5.6-53.35), **p < 0.001), antibiotic prophylaxis** (OR = 5.05 (1.7-14.7), p = 0.001), **MELD score ^{3} 15** (OR = 5.7 (1.8-17.8), p = 0.001) **and MELD fit score ^{3} 14** (6.9 (1.9-24.6), p = 0.001). On multivariate analysis all remain independently associated to IMH. Applying a receiver operating characteristic (ROC) analysis after multivariate logistic models, the area under the curve (AUC) derived from the MELD and MELD fit scores were, respectively, 0.87 (95%CI: 0.79-0.95) and 0.88(0.8-0.95) for IHM.
CONCLUSION: In cirrhotic patients with OVB MELD score (best cut-off of 15) and MELD fit score (best cut-off of 14) identifies a group of patients with a higher risk of IHM.

P1175 EFFICACY OF ENDOSCOPIC BAND LIGATION AS PRIMARY PROPHYLAXIS OF BLEEDING FROM ESOPHAGEAL VARICES

J. Santos-Antunes[1,*], H. Cardoso[2], E. Rodrigues-Pinto[2], R. Morais[2], A. Albuquerque[2], F. Vilas-Boas[2], S. Rodrigues[2], A. Ribeiro[2], M. Marques[1], R. Gonçalves[2], S. Lopes[2], G. Macedo[1]
[1]*Gastroenterology,* [2]*Centro Hospitalar S. João, Porto, Porto, Portugal*

INTRODUCTION: Endoscopic band ligation is a very effective procedure for the treatment of esophageal varices. Its use is recommended for primary prophylaxis as an alternative to beta-blockers, for the treatment of acute hemorrhage or for secondary prophylaxis.
AIMS & METHODS: The aim of this study was to evaluate our experience regarding elastic band ligation for primary prophylaxis of variceal bleeding.
Analysis of patients undergoing variceal eradication program as primary prophylaxis of variceal hemorrhage, from January 2010 until February 2014.
RESULTS: From a total of 213 patients, 93 were treated for primary prophylaxis; 79% of those were male, with a mean age of 60±12 years, with a median follow- up of 11.4 months. The main cause of portal hypertension was alcoholic cirrhosis (54%), followed by HCV (20%) and HBV (6%) infection. Most patients had a Child-Pugh score of A (48%), with the remaining scoring B (28%) or C (24%). In 55% of the patients it was possible to eradicate varices, with a median number of 2 sessions and 12 rubber bands. The presence of hepatocellular carcinoma was related to the inability to eradicate varices (p = 0.001), and concomitant use of propranolol did not influence the efficacy of eradication (p = 0.937). The mortality rate in one year was 15%. Five patients had variceal bleeding (5%), which was significantly related to mortality at one year (p = 0.022). No patients had bled from the scar. Patients with Child C had greater difficulty in eradicating varices than those with Child A (38% vs 60%, p = 0.101), and higher mortality during follow-up (24% vs 4%, p = 0.036).
CONCLUSION: Endoscopic band ligation was effective in preventing variceal bleeding, with an overall success rate of 95%.
Disclosure of Interest: None declared

P1176 THE SAFETY AND EFFECTIVENESS OF SEDATION WITH MIDAZOLAM IN CIRRHOTIC PATIENTS UNDERGOING ENDOSCOPIC VARICEAL LIGATION

J.K. Lee[1,*]
[1]*Internal medicine, Dongguk University Ilsan Hospital, Goyang, Korea, Republic Of*

INTRODUCTION: Endoscopic variceal ligation (EVL) is the established treatment for acute esophageal variceal bleeding. Unlike other therapeutic endoscopic procedure, sedation is generally not used in a cirrhotic patient for fear of hepatic encephalopathy (HE). However, a successful procedure might not be guaranteed due to poor cooperation and/or delirious behavior. We study we evaluated safety and effectiveness of midazolam in cirrhotic patient undergoing EVL.
AIMS & METHODS: The medical records of 320 cirrhotic patients who underwent EVL between October 2003 and December 2012 were reviewed retrospectively. The main outcomes were treatment success and adverse drug reaction (ADR) that might be related with sedation. Also, risk factors for development of HE were pursued.
RESULTS: Midazolam was used in 151 patients and not in 161 and baseline characteristics were similar. The rates of treatment success were not differ in both groups (95.8% vs. 96.2%, p = 0.999). Although the incidence of ADR didn't differ (46.2% vs. 55.0%, p = 0.115), development of HE (6.6% and 0%, p = 0.001) and desaturation (23.2% vs. 7.7%, p = 0.001) were more common in the midazolam group. A patient from the midazolam group died due to uncontrolled bleeding. There were a total of 10 cases of HE. With logistic regression, ECOG score 2 turned out to be associated with ADR (OR = 2.69, 95% CI 1.68-4.29, p). However, age, body mass index, Child-Pugh classification and variceal grade were not related.
CONCLUSION: Because midazolam was associated with ADR including HE in a cirrhotic patient undergoing EVL, it should be used with extreme caution including appropriate intra- and post-procedural monitoring, especially when the ECOG score of a patient is not less than 2.

P1177 RESPONSE TO TERLIPRESSIN AND ALBUMIN IS ASSOCIATED WITH IMPROVED OUTCOME IN PATIENTS WITH CIRRHOSIS AND HEPATORENAL SYNDROME (HRS)

M. Nguyen-Tat[1,*], E. Götz[1], J. Ahrens[1], V. Sivanathan[1], J. Schattenberg[1], J. Rey[2], M.A. Wörns[1], P.R. Galle[1], J.U. Marquardt[1]
[1]*Department of Medicine I, University Medical Center Mainz, Mainz,*
[2]*Department of Medicine, St Mary's Hospital, Frankfurt, Germany*
Contact E-mail Address: *marc.nguyen-tat@unimedizin-mainz.de*

INTRODUCTION: Hepatorenal syndrome (HRS) is a severe but potentially reversible complication in patients with cirrhosis, left untreated it is associated with a very poor prognosis. Several randomized controlled trials (RCT) have proven that treatment with terlipressin and albumin improves renal function, however the effect on overall survival has not been well established.
AIMS & METHODS: Aim of the study was to gain further insight into the effect of terlipressin treatment in patients with HRS on renal function, overall survival and renal-replacement-free-survival.
All patients presenting with HRS and treated with terlipressin in our tertiary referral liver and transplantation center between April 2013 and March 2014 were included, and clinically relevant parameters such as response to therapy, overall survival and renal-replacement-free-survival were prospectively investigated.
RESULTS: Overall 57 patients were followed-up over a median of 65 days. Cirrhosis was in an advanced stage in the majority of patients (Child-Pugh C: 46; 81%). Median cumulative terlipressin dosage and treatment duration were 20 mg and 5 days. Complete or partial response to terlipressin with recovery from HRS was observed in 20 and 3 out of 57 patients (51%; 5%). Median overall survival was significantly better in patients with response to terlipressin than in patients with non-response (167 vs. 27 days; p < 0.0001), as well as median survival free of renal-replacement-therapy (82 vs. 4 days; p < 0.0001). In univariate analysis, non-response was associated with a high baseline serum-bilirubin-concentration.
CONCLUSION: Terlipressin in combination with albumine is effective in a majority of patients with HRS. Response to therapy is associated with improved survival.

P1178 NON INVASIVE ASSESSMENT OF LIVER FIBROSIS WITH SIMPLE BLOOD PARAMETERS, MYRIADS OF MARKERS. . .. WHAT TO MIX AND WHERE TO MATCH!

R.B. Thandassery[1,*], A.K. John[1], S.A. Mohiuddin[1], S.R. Al Kaabi[1]
[1]*Gastroenterology, Hamad General Hospital, Doha, Qatar*
Contact E-mail Address: *doc.ragesh@gmail.com*

INTRODUCTION: There are many simple scores (that require only routine blood parameters) for non-invasive assessment of liver fibrosis. But there are only limited data comparing these scoring systems.
AIMS & METHODS: Our aim was to compare simple scores for non-invasive assessment of liver fibrosis with liver biopsy in patients with chronic hepatitis C virus (HCV) infection and validate the recently proposed fibrosis cirrhosis index (FCI)[1].
In 193 chronic HCV patients who underwent liver biopsy, we compared the liver biopsy (Scheuer classification) fibrosis scores with AAR (AST/ALT ratio), APRI (AST/Platelet ratio), FIB-4, Fibrosis Index (FI) and FCI.
These scores are calculated as; AAR = [AST(IU/l)/ALT(IU/l)], APRI = [{AST(IU/l)/ AST(ULN)(IU/l)} × 100]/ platelet count (10^9/l), FIB-4 = [Age (Years) × AST (IU/l)]/ [Platelet count (× 109/l) × ALT (IU/l)1/2], FI = [8.0 - 0.01 × Platelet count (109/l) - Albumin (g/dl)], FCI = [Alkaline phosphatase (IU/ml) × Bilirubin (mg/dl)] / (Albumin × Platelet count)
RESULTS: The mean age of patients was 41.4±9.6 years (160 males), genotype-4 (144, 74.6%) was the commonest followed by genotype-1 (66, 34.2%).
Liver biopsy showed stage-0 fibrosis in 19 (9.8%), stage-1 in 77 (39.9%), stage-2 in 69 (35.8%), stage-3 in 25 (13%) and stage-4 in 3 (1.6%) patients. Compared with liver biopsy, AAR, APRI, FIB-4, FI and FCI showed correlation coefficient indices of 0.144, 0.409, 0.414, 0.558, and 0.54 respectively. The AUROCs for these indices for advanced fibrosis (F0-2 v/s F3.4) were; AAR (for cutoff > 1) 0.52, APRI (cutoff > 1.5) 0.83, FIB-4 (cutoff > 3.25) 0.79, FI (cutoff > 3.3) 0.92, and FCI (cutoff > 1.25) 0.92.
The sensitivity and positive predictive value for FI (80% and 84% respectively) and FCI (82% and 83% respectively) was significantly higher than other indices.
CONCLUSION: The fibrosis index (FI) and fibrosis-cirrhosis index (FCI) accurately predicted advanced fibrosis stage in chronic HCV infected patients; they seem more accurate than other frequently used serum indices.

P1179 RISK FACTORS AND OUTCOME IN ICU PATIENTS WITH END STAGE LIVER DISEASE

S. Mohamed[1,*], S. Soud[1]
[1]*Tropical medicine & Gastroenterology, Assiut University, Assiut, Egypt*

INTRODUCTION: Acute or chronic liver failure is associated with numerous complications which may occur in combination and patients may require intensive care unit (ICU) treatment. Therefore, it seems necessary to identify prognostic clinical parameters and risk factors at the time of ICU admission.
AIMS & METHODS: To estimate the frequency of mortality and cirrhosis morbidity among patients with end stage liver disease (ESLD) admitted to the ICU and to evaluate the relation between demographic, clinical and laboratory data (potential risk factors) of those patients and mortality.
120 patients with ESLD were enrolled [102 males (85%) and 18 females (15%)]. History taking,clinical examination,full investigations and classification of patients according to Child-Turcotte-Pugh (CTP) and MELD score were done.
RESULTS: Regarding clinical presentation, hepatic encephalopathy (HE) was found in 87.5%, jaundice in 60%, hematemesis in 41.7%, hepatorenal syndrome (HRS) in 35.8% and spontaneous bacterial peritonitis (SBP) in 20.8%. Mortality rate was 57.5%; the main causes of death were HRS (40.8%), HE (21.7), aspiration pneumonia (10%), septic shock (2.5%) and irreversible shock in only 1.7%. There was a significant relation between mortality and old age, CTP and MELD scores and a longer stay at the ICU. Increased white blood cell count, increased hemoglobin and decreased prothrombin concentration and raised creatinine were independent risk factors of mortality in ESLD patients in the ICU. Mortality rates were higher (86.2%) with 5-6 risk factors and (21.7%) with 1-2 risk factor(s).
CONCLUSION: The mortality rate in of ESLD patients admitted to the ICU was 57.5% and the most common cause of death was HRS. CTP, MELD score, HE, HRS and jaundice were significant predictors of mortality in ESLD patients. Mortality increased with increased number of risk factors. Creatinine level, white blood cell count, hemoglobin and prothrombin concentration were independent risk factors affecting the outcome of ESLD patients in the ICU.

P1180 SAFETY AND EFFICACY OF TOLVAPTAN FOR TREATMENT OF REFRACTORY ASCITES IN CIRRHOTIC PATIENTS

S. Kawazoe[1,*], S. Nakashita[2], W. Yoshioka[1], K. Tanaka[1], T. Akiyama[1], T. Kumagai[1], T. Otsuka[2], Y. Kawaguchi[1]
[1]*Hepatobiliary and Pancreatology, SAGA-KEN MEDICAL CENTRE KOSEIKAN,* [2]*Internal medicine, Saga medical school, Saga university, Saga, Japan*
Contact E-mail Address: *kawazoe-s@excite.co.jp*

INTRODUCTION: Since September 2013 in Japan, the vasopressin V_2 receptor antagonist tolvaptan (7.5 mg/day) has been approved for the treatment of cirrhotic patients with hepatic ascites and edema that do not respond to diuretics. Thirty-one patients with refractory ascites were given tolvaptan at two institutions.
AIMS & METHODS: We prospectively evaluated its safety and efficacy, and determined the predictive factors of a good response. From 14 September 2014 to 31 March 2015, among 31 (19 males, 12 females; 71 (range, 49–89) years) patients with refractory ascites treated with diuretics (furosemide 20–80 mg/day, spironolactone 0–100 mg/day), 29 patients were given tolvaptan at 7.5 mg/day and 2 patients were administered 3.75 mg/day. 15 patients were Child-Pugh class B and 16 were C in their hepatic function reserve. Underlying disease was constituted as follows, HCV was 24, HBV was 1, Alchohol was 4, NASH was 4. Correlations between pre-treatment data and decrease in body weight were determined using logistic regression analyses and scatter diagrams.
RESULTS: Pre-treatment parameters were: estimated glomerular filtration rate, 53.2 mL/min/1.73 m^2; serum osmolarity, 292.6 mOsm/L; albumin, 2.5 g/dL; serum sodium, 129.9 mEq/L; blood-urea-nitrogen, 34.9 mg/dL; hemoglobin, 10.1 g/dL. Twenty-two patients had a loss in body weight of 2 kg and were termed ''responders''. With regard to pre-treatment parameters, there were no

significant differences between responders and non-responders. There were no differences in the response rate for each Child–Pugh class. Responders had a higher rate of increase in urine volume in the first 24-h collection after tolvaptan administration than non-responders (183% *vs* 143%, p = 0.047). In six patients, the rate of change in urine osmolarity 24 h after tolvaptan administration was closely correlated with rate of change in body weight ($R^2 = 0.77$). Rupture of esophageal varices occurred in four patients in the observation period (three in G3 and one in G2). Hypernatremia (>150 mEq/L) was not experienced.
CONCLUSION: These data suggest that for cirrhotic patients with refractory ascites, tolvaptan is effective and safe. In the pre-treatment state, finding predictive parameters for responders is very difficult. However, 24 h after tolvaptan administration, the increasing urine rate and rate of change of urine osmolarity are useful guides to identify responders.

P1181 TREATMENTS OF ECTOPIC VARICES WITH PORTAL HYPERTENSION

T. Sato[1,*]
[1]*Gastroenterology, SAPPORO KOSEI GENERAL HOSPITAL, Sapporo, Japan*

INTRODUCTION: Ectopic varices that are not esophagogastric are located predominantly in the duodenum, jejunum, ileum, colon, rectum, or enterostomy stoma. Bleeding from ectopic varices, which is rare in patients with portal hypertension, is generally massive and life threatening.
AIMS & METHODS: From January 1994 to September 2013, we performed endoscopic treatments or interventional radiologic treatments for 1530 portal hypertensive patients with esophagogastric varices. In this study, we evaluated the clinicopathological features and treatments of ectopic varices.
RESULTS: Seventy-seven patients were hospitalized in our ward for treatments of ectopic varices. The underlying pathologies of portal hypertension included liver cirrhosis in 46 patients, cirrhosis associated with hepatocellular carcinoma in 12, primary biliary cirrhosis in 6, idiopathic portal hypertension in 7, extrahepatic portal vein obstruction in 5, and the other disease in 1. The location of the ectopic varices were rectal varices in 58, duodenal varices in 9, intestinal varices in 4, urinary bladder varices in 2, stomal varices in 1, colonic varices in 3. Seventy-three of 77 patients (94.8%) with ectopic varices had previously received emergency or prophylactic endoscopic injection sclerotherapy (EIS) for esophageal varices. In 47 of the 58 rectal variceal patients, EIS was performed with no complications. In 9 of the 58 patients, endoscopic band ligation (EBL) was performed, and 8 of whom experienced no operative complications after EBL. Percutaneous transhepatic obliteration (PTO) was successfully performed for the remaining 2 large rectal variceal patients. We successfully performed the treatments for 9 duodenal variceal patients (the bulbs in 1, the second portion in 6, and the third portion in 2); balloon occluded retrograde transvenous obliteration (B-RTO) in 4, EIS using Histoacryl in 3, EIS plus B-RTO in 1, PTO in 1. Four small intestinal variceal patients (3 jejunal varices, 1 ileal varices) had undergone B-RTO in 2, PTO in 1, endoscopic treatments in 1. B-RTO was successfully performed for ileal varices and jejunal varices. One jejunal variceal patient died 3 days after PTO because of poor general condition, and endoscopies revealed the recurrence of varices in the other jejunal variceal patient after endoscopic treatments. PTO was successfully performed for 2 urinary bladder variceal patients. Endoscopic treatments or interventional radiologic treatments were successfully performed for remaining ectopic varices.
CONCLUSION: Hemorrhage from ectopic varices should be kept in mind in patients with portal hypertension presenting with lower gastrointestinal bleeding.

P1182 CANDIDATES FOR CONSERVATIVE TREATMENT AMONG PATIENTS WITH PORTAL VENOUS GAS

C. Sakaguchi[1,*], R. Takenaka[1], Y. Baba[1], N. Okazaki[1], D. Kawai[1], K. Takemoto[1], H. Tsugeno[1], S. Fujiki[1]
[1]*Tsuyama Chuo Hospital, Tsuyama, Japan*
Contact E-mail Address: *chrskgc@yahoo.co.jp*

INTRODUCTION: Although hepatic portal venous gas (HPVG) is a sign of poor prognosis, there have been recent reports of cases treated conservatively. However, it remains difficult to determine whether emergency surgery is required. The aim of this study was to clarify the indications for conservative treatment in patients with HPVG.
AIMS & METHODS: Of 107.787 cases in which computed tomography (CT) was performed between April 2009 and September 2013 at our hospital, HPVG was detected in 117 patients. Seventy three patients were excluded because they presented with cardiovascular arrest. Therefore, a total of 44 patients were included in this study. The patients were divided into two groups, group A (n = 26), patients treated conservatively, and group B (n = 18), patients who required surgery or died within 30 hospital days. The factors associated with conservative treatment were analyzed using Fischer's exact test, Mann-Whitney U test and logistic regression analysis. The variables included age, gender, comorbidities (hypertension, diabetes mellitus, ischemic heart disease, cerebrovascular disease, liver cirrhosis, renal failure and malignancy), subjective symptoms (abdominal pain, constipation, vomiting and diarrhea), physical findings (systolic blood pressure, pulse rate, body temperature, abdominal tenderness and peritoneal irritation sign), laboratory findings, including blood gas analysis, and CT findings (pneumatosis intestinalis, ascites and location of HPVG). A receiver operating characteristic curve was used to determine the cut-off value.
RESULTS: The study subjects were 23 men and 21 women with a median age of 78.5 (range, 20 - 102). The major etiologies of HPVG in group A were ileus and enterocolitis. On the other hand, the etiologies in group B were mesenteric ischemia and emphysematous cholecystitis. Idiopathic HPVG was seen in 7 patients in group A and 1 in group B. In the univariate analysis, there were significant differences between the two groups related to body temperature and level of C-reactive protein (CRP), lactate dehydrogenase, aspartate aminotransferase, creatine kinase, lactate and base excess (BE). In the multivariate analysis, CRP and BE were identified as independent risk factors associated with poor prognosis. The cut-off values were 12 mg/dl for CRP and -4.0 mmol/l for BE. When CRP ≤12 mg/dl and BE ≥-4.0 mmol/l were used to identify candidates for conservative treatment, the sensitivity and specificity were 91% and 89%, respectively.
CONCLUSION: CRP and BE might be useful markers to determine the conservative treatment of patients with HPVG.

P1183 PORTAL VEIN THROMBOSIS IN THE SETTING OF LIVER TRANSPLANTATION

M. Hernández Conde[1], **E. Llop**[1,*], J.L. Calleja[1], J.de la Revilla[1], F. Pons[1], N. Fernández Puga[1], M. Trapero[1], J.L. Martínez[1], V. Cuervas-Mons[1], V. Sánchez Turrión[1]
[1]*Puerta de Hierro University Hospital, Madrid, Spain*

INTRODUCTION: The prevalence of portal vein thrombosis (PVT) in patients that have been undergone liver transplantation (LT) is 9.7%±4.5%. The factors associated with its presence and involvements in post-transplant prognosis are unknown. The aim of our study was to determine the prevalence, assess the factors that are associated with its presence as well as to clarify their association with the prognosis in patients with liver cirrhosis (LC) and LT.
AIMS & METHODS: From January 2005 to May 2013, laboratory, radiological and surgical data were retrospectively collected from patients with LC who had undergone LT in our center for the first time.
RESULTS: 165 patients who had (46.7%) or had not been diagnosed of hepatocellular carcinoma (HCC) were included, all of them without tumoral thrombosis. The mean age was 55 (SD9), male 73.3% and HVC 44.8%. Child-Pugh was (A/B/C:31.5/40.6/21.2%) and MELD 15 (SD6). Previous decompensations were: ascites 61.2%, hepatic encephalopathy 33.9%, variceal bleeding 26.1%, spontaneous bacterial peritonitis (SBP) 15.2%. The mean post-transaplant follow-up was 36 months (0-100).
TVP was diagnosed while LT in 16 (9.7%) patients. The TVP was previously diagnose with image tests in 4 patients (25%) (1(0.1% by Doppler ultrasound (DU) and 4(43.8%) by computed tomography(CT)). All patients had a DU in a mean time of 4 months prior the LT(0-10) and 7(43.8%) had a CT in a median time of 1 month before the LT(0-45).
TVP was significantly related to the presence of SBP (37.5 vs 13.1%;p = 0.01), high levels of creatinine (1.4(SD1.8) vs 1(SD0.6;p = 0.04), and low levels of albumin (3.1(SD0.9) vs 3.5(SD0.6);p = 0.03). MELD was higher in patients with TVP (16 (SD6) vs 14(SD5);p > 0.05). Surgery time was similar in both groups (6:05h vs 6:10h, p = 0.8), transfusion of blood products was higher in patients with TVP(plasma bags 15.5 vs 12.5, platelets pool 3 vs 4 and Red cells 7.5 vs 7.9), although the results were not statistically significant.
TVP was correlated with the mortality in the first 30 days (18.8 vs 8.4%;p > 0.05).
CONCLUSION: TVP is a common complication in patients with cirrhosis undergoing LT. Its presence is correlated with suffering from SBP, high levels of creatinine and low levels of albumin. The pre-transplant diagnosis rate is very low (25%) and its presence may have implications for short-term mortality.

P1184 COMPARISON OF PLATELETS FUNCTION USING MULTIPLATE® TEST IN CIRRHOTIC PATIENTS WITH AND WITHOUT PORTAL VEIN THROMBOSIS

M.Żorniak[1,*], P. Wosiewicz[1], M. Hartleb[1]
[1]*Department of Gastroenterology and Hepatology, Medical University of Silesia, Katowice, Poland*
Contact E-mail Address: *rzurio@interia.pl*

INTRODUCTION: Portal vein thrombosis (PVT) occurs significantly more often in cirrhotic patients, compared with total population. PVT diminishes survival in patients with cirrhosis, by increasing incidence of other complications such as bleeding from esophageal varices, loss of ascites responsiveness to diuretics or hepatic encephalopathy. Moreover, PVT complicates qualification for liver transplantation, in some cases preventing this procedure. Factors which influence development of PVT in cirrhosis as well as adaptive changes in coagulation system to this vascular complication are unclear.
AIMS & METHODS: Our study compares platelets function between cirrhotic patients with and without PVT.
Material and methods: 33 patients with liver cirrhosis were qualified for this study and PVT was diagnosed in 10 patients (spiral CT). Etiology of cirrhosis was: alcoholic (n = 18), HCV-infection (n = 6), HBV-infection (n = 4), autoimmune hepatitis (n = 3) and unknown (n = 2). The blood samples from all patients was collected for assessment of aggregation function using MultiPlate® system.
RESULTS: Cirrhotic patients with PVT had lower platelets aggregation activity related to stimulation with thrombin receptor activating-peptide (TRAPtest; 33.5±15.2 *vs* 59.8±22.9 U; $P < 0.05$), arachidonic acid (ASPItest; 25.1±13.4 *vs* 44.3±23 U; $P < 0.05$) and ADP (ADPtest; 21±12.5 *vs* 38.2±18.6 U; $P < 0.05$).
CONCLUSION: Our study showed decreased aggregation activity of platelets in cirrhotic patients with PVT that is probably an adaptive mechanism counteracting the expansion of thrombosis.

INTRODUCTION: The aim of this study was to investigate the relation between baseline characteristics including the serum lipid levels and the treatment outcome from telaprevir (TVR) in combination with pegylated-interferon (PEG-IFN) α2b and ribavirin (RBV).
AIMS & METHODS: This prospective study consisted of 218 treatment-experienced patients infected with HCV genotype 1. All received 12 weeks of TVR in combination with 24 weeks of PEG-IFNα2b and RBV.
RESULTS: The SVR rate was 83.0% (181 of 218) by intention-to-treat analysis. In multivariable logistic regression analysis of pretreatment predictors of SVR, low-density lipoprotein cholesterol (LDL-C) level (odds ratio [OR], 1.02, $p = 0.0036$), IL28B TT genotype (rs8099917) (OR, 3.21, $p = 0.0139$), and prior relapse (OR, 4.77, $p = 0.0006$) were extracted as independent predictors of SVR. Receiver operating characteristic analyses to determine the optimal threshold values of the baseline LDL-C level for predicting SVR showed that the area under the curve was relatively high (AUROC 0.78, $P < 0.0001$, cutoff value 95 mg/dL). IL28B TT genotype (OR, 6.89, $P < 0.0001$), prior relapse (OR, 2.33, $p = 0.0289$), and platelet count ($x10^9$/L) (OR, 1.01, $p = 0.0048$) were extracted as independently associated with LDL-C $\geq$ 95 mg/dL. For patients with prior partial/null responses, the SVR rates of the groups with LDL-C $\geq$ 95 mg/dL were significantly higher than those of the $<$ 95 mg/dL groups with any IL28B genotypes and pretreatment platelet count ($\geq$ 150 or $<$ 150x10^9/L).
CONCLUSION: The baseline LDL-C level had a strong impact on outcome from TVR-based triple therapy, especially for patients with prior partial/null responses, irrespective of IL28B genotypes and platelet count.

INTRODUCTION: Triple therapy of chronic hepatitis C G1 infection with the HCV protease inhibitor boceprevir is accompanied by hematological alterations such as anemia, leukopenia and thrombopenia. Data regarding the frequency and severity of these alterations caused by triple therapy in real-life are still scarce and were evaluated in the present analysis by comparison of two German real-life cohorts.
AIMS & METHODS: Data of treatment-naïve patients treated for G1 infection ($N = 1873$) with pegylated interferon (PegIFN) alfa-2b and ribavirin (RBV) in a large German observational study (Online-AWB) were compared with data of 153 treatment-naïve patients from the ongoing German NOVUS observational study who have started triple therapy with PegIFN/RBV together with boceprevir at least 8 months ago.
RESULTS: Hematologic alterations according to the WHO classification caused by dual or triple therapy are shown in the table. Patients undergoing triple therapy achieved a similar frequency of the most common hemoglobin (Hb) alterations grade 1 in contrast to significantly higher frequencies of grade 2 and grade 3 Hb alterations. Hb alterations during triple therapy were managed by RBV dose reductions in 51% while 2.5% received blood transfusions. Only one patient was treated with erythropoietin and one patient discontinued triple therapy because of anemia. Compared to dual therapy there was a higher frequency of alterations in leukocyte (grade 2 and grade 4) and platelet count (grade 1 and grade 3) in patients undergoing boceprevir triple therapy (table).

	Hematological alterations			
	Grade 1	**Grade 2**	**Grade 3**	**Grade 4**
Hb (g/dL)	**9.5- < 11.0** % (N)	**8.0 - <9.5** % (N)	**6.5 - <8.0** % (N)	**<6.5** % (N)
Online-AWB (N = 1873)	**33.5** (628)	**10.7** (200)	**0.8** (15)	**0.1** (1)
NOVUS (N = 153)	**39.9** (61)	**21.6** (33)	**3.9** (6)	**0.7** (1)
P	0.1115^	<.0001^	0.0035*	0.1454*
Leukocytes (10^3/μL)	**2.0 - <3.0** % (N)	**1.5 - <2.0** % (N)	**1.0 - <1.5** % (N)	**<1.0** % (N)
Online AWB (N = 1873)	**42.5** (795)	**13.8** (258)	**3.5** (66)	**0.1** (2)

P	0.5166^	0.0065^	0.2638^	0.0300*
Platelets (10^3/μl)	**70 - ≤ 100** % (N)	**50 - <70** % (N)	**25 - <50** % (N)	**<25** % (N)
Online AWB (N = 1873)	**17.0** (318)	**5.6** (105)	**3.4** (64)	**0.6** (12)
Novus (N = 153)	**26.3** (40)	**7.2** (11)	**8.6** (13)	**0.7** (1)
P	0.0037^	0.4053^	0.0015^	1.0000*

^ Chi-square test, * Fisher's exact test

CONCLUSION: Triple therapy with boceprevir results in a higher frequency of hematological alterations compared to dual therapy. Most alterations are mild to moderate. In German real-life Hb alterations are managed by RBV dose reductions without the use of erythropoietin and only few patient need blood transfusions.

INTRODUCTION: Different non-Invasive methods for assessing stage of hepatic fibrosis had emerged in the last decade. Most popular methods include transient elastography and serum biomarkers panels.
AIMS & METHODS: We aimed at studying the diagnostic performance of transient elastography and five biomarker panels (APRI, FIB-4, Forns' Index, Egy-Score and Hepa-Index) in detecting different stages of hepatic fibrosis in chronic hepatitis C Egyptian patients. Hundred treatment naïve chronic hepatitis C patients were enrolled. They were subjected to liver biopsy and histopathological scoring of fibrosis according to METAVIR scoring system, transient elastography (using FibroScan), APRI, FIB4, Forns' Index, Egy-Score and Hepa-Index. Calculations and cut off values for biomarkers panels were done according to their original publications.
RESULTS: Significant fibrosis ($\geq$ F2 METAVIR) was best detected by transient elastography followed by Forns' Index, Hepa-Index, Egy-Score, FIB-4, and APRI respectively (AUROC: 0.947, 0.806, 0.803, 0.776, 0.645 and 0.589 respectively). Advanced fibrosis ($\geq$F3 METAVIR) was best detected by transient elastography followed by Egy-Score, Forns' Index, FIB-4, Hepa-index and APRI respectively (AUROC: 0.976, 0.875, 0.851, 0.828, 0.783, and 0.754). Cirrhosis was best detected by transient elastography followed by Egy-Score, FIB-4, Forns' Index, APRI and Hepa-Index respectively (AUROC: 0.958, 0.874, 0.841, 0.827, 0.795 and 0.744).
CONCLUSION: Transient elastography had the best performance for non-invasive assessment of hepatic fibrosis in chronic hepatitis C Egyptian patients compared to the studied serum biomarkers.

INTRODUCTION: The achievement of early virologic response (EVR) during triple therapy of chronic HCV genotype 1 infection with BOC has been identified as predictor of high SVR rates of up to 90% and as predictor to shorten treatment to 24 weeks. The present interim analysis of the NOVUS observational study was aimed to investigate EVR during BOC triple therapy in German real-life and to identify factors associated with EVR.
AIMS & METHODS: From April 2012 until January 2014, 536 patients with G1 infection were recruited in the ongoing NOVUS study by 97 practices and hospitals in Germany. Patients were treated with pegylated interferons (PegIFN) and ribavirin (RBV) together with BOC for 24 to 44 weeks after a 4 weeks lead-in period with PegIFN/RBV. The present interim analysis was restricted to 203 untreated patients with documented HCV-RNA levels at treatment week 8.
RESULTS: The frequency of EVR was 73%. Achievement of EVR was significantly associated with age ≤50 years, baseline viral load ≤400.000 IU/mL, normal gamma-GT levels and ferritin levels ≤300 µg/L at baseline, but not with gender, ALT levels, glucose levels, platelet count or genotype 1 subtype (table). The significant differences above were confirmed by univariate logistic regression analysis. When a multivariate logistic regression model was used, viral load and gamma-GT levels at baseline were identified as independent predictors of EVR: baseline viral load (≤400.000 IU/mL vs >400.000 IU/mL): OR 2.99 (CI 1.13-7.93; p = 0.027); gamma-GT (normal vs elevated): OR 2.17 (CI 1.03-4.60; p = 0.042). In an expanded model that included virologic response at the end of the 4-week lead-in period a HCV-RNA decline $>1\log_{10}$ (vs $\leq 1\log_{10}$) was strongly predictive of an EVR: OR 6.63 (CI 2.88-15.26; p < 0.0001).

	EVR (N = 148) % (n/N)	**P***
Male/ Female	76.3 (87/114) / 68.5 (61/89)	0.2161
Age ≤50/ >50 years	78.6 (99/126) / 63.6 (49/77)	**0.0202**
Genotype 1a/1b	69.0 (49/71) / 70.7 (70/99)	0.8122
BVL: ≤/> 400.000/ IU/mL	88.9 (56/63) / 65.7 (92/140)	**0.0006**
GGT normal/ elevated	81.6 (84/103) / 60.7 (54/89)	**0.0013**
ALT normal/ elevated	78.4 (29/37) / 70.8 (114/161)	0.3539
Platelets ≤/> 150/nL	69.7 (23/33) / 71.9 (110/153)	0.7997
Glucose ≤/> 100 mg/dL	69.8 (67/96) / 71.9 (23/32)	0.8232
Ferritin ≤/> 300 µg/L	71.9 (46/64) / 47.6 (10/21)	**0.0419**

CONCLUSION: 73% of treatment-naïve patients with HCV G1 infection undergoing triple therapy with BOC in German real-life achieve an EVR. A low baseline viral load ≤400.000 IU/mL, normal gamma-GT values at baseline and a HCV-RNA decline $>1\log_{10}$ at the end of the 4-week lead-in period are independent predictors for an EVR.

INTRODUCTION: Since 2011, the "standard of care" treatment of Hepatitis C Virus genotype 1 is a combination of pegylated interferon, ribavirin and protease inhibitor: telaprevir or boceprevir.
AIMS & METHODS: The aim of this study was to evaluate its effectiveness and tolerance "in real life". Single center retrospective study of 100 unselected and consecutive patients whose antiviral treatment started between March 2011 and March 2013.
RESULTS: The median age was 53 years and 72% of the patients were men; 46% were F4 and 15% were F3. Status regarding previous treatment was: naive 30%, responder-relapser 28%, partial responder 17% and null responder 24%. After 2, 4, 8 and 12 weeks of treatment with protease inhibitor, Hepatitis C Virus RNA was undetectable in respectively 12%, 52%, 60% and 64% of the cases. The overall rate of sustained virological response at week 12 (intention to treat analysis) was 57%: 70% in the naive patients, 75% in responder-relapser, 41% in partial responder and 33% in null responder. During the therapy, the rate of serious adverse events was 41%. Four deaths occurred. Initial platelets count <100.000/mm3 and age ≥ 53 years were associated with a higher risk of occurrence of serious adverse events.
CONCLUSION: The rate of sustained virological response to tritherapy "in real life" is approximately 10% lower than those observed in phase III trials. Tolerance issues are limiting the use of protease inhibitor.

Contact E-mail Address: *rzykus@gmail.com*

INTRODUCTION: The role of non-invasive test to assess liver fibrosis is increasing and they are gradually introduced in clinical practice. FibroScan is dedicated tool for liver fibrosis evaluation. Aspartate aminotransferase to platelet ratio index (APRI) and FIB4 score are cheap and easy reproducable in daily praxis for liver fibrosis evaluation.
AIMS & METHODS: The aim of our study was to assess correlation between transient elastography (TE), aspartate aminotransferase to platelet ratio index (APRI), FIB4 score and histological stage of fibrosis (F). APRI index was assessed as (AST elevation/platelet count) x 100 and FIB4 index as age (yr) × AST (IU/L)/(platelet count (10(9)/L) × ALT^(1/2) (IU/L)). In this prospective study the correlations of TE, APRI and FIB4 score with fibrosis stage were assessed in 157 chronic HCV or HBV hepatitis patients. TE, APRI and FIB4 were measured at the same day before biopsy. Interquartile range/median <20% and success rate >60% were considered as good quality criteria during TE. Fibrosis was evaluated using METAVIR score. Pathologist was blinded to TE, APRI, FIB4 results. Cut-off values were established by ROC analysis.
RESULTS: We included 139 HCV, 16 HBV and 2 coinfected patients. Strong correlation of liver stiffness R - 0.76 (p < 0.01) and FIB4 R – 0.66 (p < 0.01), but moderate of APRI R – 0.59 (p < 0.01) with liver fibrosis stage were established. For histological F4 stage TE cut-off value 12.5kPa had sensitivity 0.90 and specificity 0.87; APRI cut-off value 1.4 had 0.87 and 0.82; FIB4 cut-off value 2.89 had 0.84 and 0.84 respetively. F≥3 10.7 kPa (0.89 and 0.88), 1.18 (0.80 and 0.76), 2.23(0.85 and 0.80); F≥2 8.5 kPa (0.79 and 0.77), 0.95 (0.74 and 0.72), 1.63 (0.80 and 0.75); F≥1 5.5 kPa (0.82 and 0.76), 0.54 (0.82 and 0.76), 0.98 (0.82 and 0.69). Summarized results are shown in the table below.

Fibrosis stage	TE in kPa (sensitivity/specificity)	APRI (sensitivity/specificity)	FIB4 (sensitivity/specificity)
4	12.5 (0.90/0.87)	1.4 (0.87/0.82)	2.89 (0.84/0.84)
>=3	10.7 (0.89/0.88)	1.18 (0.80/0.76)	2.23 (0.85/0.80)
>=2	8.5 (0.79/0.77)	0.95 (0.74/0.72)	1.63 (0.80/0.75)
>=1	5.5 (0.82/0.76)	0.54 (0.82/0.76)	0.98 (0.82/0.69)

CONCLUSION: Liver TE and FIB4 score are strongly while APRI moderately correlated with fibrosis and accurately predicts the stage of liver fibrosis in patients with chronic HBV and HCV hepatitis. More advanced stage of liver fibrosis are predicted more accurately. TE is more sensitive and specific than APRI or FIB4 for andvanced liver fibrosis and cirrhosis.

INTRODUCTION: Orthotopic liver transplantation (OLT) has been regarded as the best curative treatment for patients with end stage liver diseases including advanced liver cirrhosis and acute liver failure. It is also the alternative therapy for patients with early stage hepatocellular carcinoma (HCC). Because of the severe shortage of grafts from brain-death donors, and the importance of timely operation on recipients, living donor liver transplantation (LDLT) offers the unique opportunity of early transplantation with theoretically unlimited source of liver grafts. However, a liver graft from a living donor is frequently small-for-size for the recipient. Acute phase fatty graft injury after transplantation will exacerbate further when the graft is small-for-size. Such acute phase liver grafts injury will trigger a series of inflammatory cascades, which will mobilize the circulating immune cells leading to cancer invasiveness.

AIMS & METHODS: We aim to investigate the impact of acute-phase small-for-size graft injury on mobilization of circulating regulating B cells (Bregs) in HCC patients after liver transplantation and to explore the molecular mechanism.
There were 115 HCC recipients included in current study. The intragraft gene expression profile and Bregs infiltration of the grafts greater (Group 1) and less than 60% (Group 2) of standard liver weight (SLW) were detected by RT-PCR and immunostaining. Circulating Bregs ($CD19^{+}CD24^{hi}CD38^{hi}$) were also compared together with the clinical-pathological data including the incidence of tumor recurrence and metastasis. The direct roles of TLR4, CXCL10 and CXCR3 on circulating Bregs mobilization were investigated in TLR4-/-, CXCL10-/- and CXCR3-/- mice models, respectively. The association of intragraft Bregs infiltration and tumor invasiveness were also examined in a rat liver transplantation for liver cancer model. The role of Bregs on liver tumor growth and invasiveness were further studied in a series of in vitro and in vivo functional experiments with the application of in vivo imaging modalities and intravital confocal microscopy.
RESULTS: The patients were grouped into Group 1 ($>=60\%$ SLW, $n=37$) and Group 2 ($<60\%$ SLW, $n=78$). Much more patients in Group 2 developed tumor recurrence and lung metastasis [19/78(24.4%) vs 3/37(8%), $p=0.04$]. Level of circulating Bregs was significantly higher in Group 2 (Week1: 7.02 vs 1.31/10ˆ5PBMC, $p=0.03$; month3: 5.7 vs 1.3/10ˆ5PBMC, $p=0.03$). There was more intragraft Bregs infiltration in group 2 indicated by CD20/IL10 staining. Intragraft gene expression of TLR4, CXCL10 and CXCR3 were significantly higher in Group 2 at early phase after transplantation. In rat liver transplantation model, more Bregs infiltration at early phase after transplantation correlated with late phase invasive tumor growth. Levels of circulating Bregs were significantly lower in the mice model with major hepatectomy and hepatic I/R injury using TLR4-/-, CXCL10-/- and CXCR3-/- mice, respectively. Bregs also promoted liver cancer cell proliferation and migration in vitro, and tumor growth in vivo.
CONCLUSION: A significantly higher population of circulating Bregs, which are mobilized by small-for-size graft injury, may lead to a higher incidence of tumor recurrence and metastasis after LDLT. TLR4/CXCL10/CXCR3 signaling may play important roles on Bregs mobilization.

P1192 DE NOVO INFLAMMATORY BOWEL DISEASE AFTER ORTHOTOPIC LIVER TRANSPLANTATION FOR PRIMARY SCLEROSING CHOLANGITIS

L. Bajer[1,*], P. Drastich[1], P. Wohl[1], M. Benes[1], J. Spicak[1]
[1]*Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague, Czech Republic*
Contact E-mail Address: *lukasbajer1@gmail.com*

INTRODUCTION: For patients who develop end-stage primary sclerosing cholangitis (PSC), orthotopic liver transplantation (OLTx) is the only effective treatment currently available. PSC is commonly associated with inflammatory bowel disease (IBD), particularly with ulcerative colitis (UC) in 60-85% cases. De novo IBD after OLTx has been reported, the 10-year risk is estimated to be 14-30%. De novo inflammatory bowel disease activity and impact on the recurrent PSC and colorectal cancer (CRC) after OLTx is not yet fully clear.
AIMS & METHODS: A total of 944 liver transplants were performed in IKEM (Czech Republic) between 1995 and 2012. We analyzed 69 consecutive patients with PSC (50 men and 19 women) who survived more than 12 months and were regularly followed up in our center. IBD was confirmed in 49 (71%) patients pre-OLTx. Except 2 patients with Crohn's disease (CD) all other patients were suffering from UC. Colonoscopy was performed in all patients before OLTx and annually after OLTx. Patients were studied over median follow up period of 82 months (range 16-228) after OLTx.
RESULTS: The course of IBD was mild or in remission in 34/49 (69.4%) patients after OLTx. The remaining 15 patients (30.6%) were suffering from clinically active disease. De novo IBD was confirmed in 13 patients (UC 12, CD 1) after median of 3 years (1-8) after OLTx. Except 2 patients the course of IBD has been described as mild. Recurrent PSC (rPSC) was confirmed in total of 25 patients (36.2%). Risk of rPSC was higher in de novo IBD vs. pre-TX IBD group (9/13 vs. 17/49, $p< 0.05$). Low-grade dysplasia (LGD) of colonic mucosa was found in 3/49 (6.1%) patients in pre-TX IBD vs. 1/13 of de novo IBD patients. Advanced colorectal neoplasia was confirmed just in pre-TX IBD group, high-grade dysplasia (HGD) in 1 (2.0%) patient and colorectal cancer (CRC) was confirmed in 3 (6.1%) patients followed by colectomy.
CONCLUSION: The course of de novo IBD after OLTx is frequently mild but could have negative impact on recurrent PSC. Detection of dysplastic changes supports the usefulness of regular colonoscopic evaluations.

INTRODUCTION: The AMC-Bioartificial Liver (BAL) is a high-capacity bioreactor that facilitates the human liver progenitor cell line HepaRG in a non-woven polyester matrix, where cells in 3D configuration are directly oxygenated with 40% O2. The AMC-BAL is designed to bridge patients suffering from Acute Liver Failure (ALF) to transplantation or regeneration and has proven to be efficacious in prolonging survival in a rat model of total liver ischemia (1). A phase I clinical trial has been planned for 2015. During patient treatment, the cells in the BAL are exposed to human ALF plasma. It is therefore essential to investigate the performance of HepaRG cells in human plasma. We previously found that exposure to rat plasma reduced hepatic transcript levels and increased cell leakage in both monolayer (2D, 20% O2) and BAL cultures (2.3). The effect of healthy rat plasma was comparable to ALF-rat plasma. The effect of human plasma is, however, unknown.
AIMS & METHODS: The aim of the study was to assess human plasma cytotoxicity on HepaRG cells in monolayer and BAL culture, and to investigate the contribution of 3D arrangement and increased oxygenation to plasma tolerance. We compared monolayer cultures and static 3D cultures in non-woven polyester matrices under 20% (low-O2) and 40% O2 (high-O2), to BAL cultures.
At maximal differentiation, a baseline test was performed for ammonia elimination, urea synthesis, cell leakage, lactate elimination and transcript levels of the genes encoding hepatic nuclear factor 4a (HNF4a), enzymes involved in ammonia metabolism including urea cycle, and detoxification protein CYP3A4.
Cultures were exposed to 100% plasma +antibiotics (plasma group) or to standard culture medium (control group) for 16 hours, and subsequently tested again on the parameters mentioned above. The differences between baseline and post-exposure test were compared between groups.
RESULTS: After 16 hours of plasma exposure, in BAL cultures, HNF4a and urea cycle genes were decreased up to 50% compared to control, but CYP3A4 expression remained stable. No significant change in hepatic functionality or cell damage was observed.
In monolayers exposed to plasma under low-O2 all hepatic transcript levels and ammonia elimination were decreased by up to 95% compared to control.
In both the 3D configuration group and the high-O2 group, mRNA transcription of hepatic genes was less downregulated compared to the low-O2 monolayer group, up to 75% of the controls, but the cytotoxic effect remained stronger than in the BAL group.
CONCLUSION: Human plasma has a detrimental effect on HepaRG liver functionality and transcript levels, when cultured in 2D with 20% O2. However, BAL-cultured cells are significantly less susceptible to plasma toxicity compared to monolayer cultures, and both 3D configuration and increased oxygenation contribute to this resistance to plasma cytotoxicity. This suggests that the duration of effective BAL treatment may last at least up to 16 hours. These results should be confirmed with human ALF plasma.

INTRODUCTION: De novo hepatocellular carcinoma (HCC) in liver allografts is rare, with only 11 cases previously published in the last 14 yrs.
AIMS & METHODS: Our hospital has performed 1906 liver transplants (LT) from 1991 to 2012. 914 (47.9%) were due to hepatitis C virus (HCV). 67 (7.3%) of these were re-transplanted due to HCV recurrence and graft loss without evidence of HCC in the explant. Induction and baseline immunosuppression was based on calcineurin inhibitor (CNI) and all patients received metylprednisolone bolus as treatment of early acute cellular rejection. The median time to HCC was 13.5 yrs (range 8-19); the median age at diagnosis was 66 yrs (range 58-74). Three patients had chronic renal failure (one had a kidney transplant).
CONCLUSION: With improved survival of LT-patients and use of older allografts, an increase in the incidence of de novo malignancies may be expected. There are no screening guidelines in this patient population. We should be aware of the high-risk population of cirrhotic patients with HCV-allograft recurrence and CNI based IS.

Contact E-mail Address: *sofiacarvalhana@msn.com*

INTRODUCTION: Hypoxic hepatitis or acute ischemic hepatocellular injury represents 1% of Intensive Care Units (ICU) admissions. In most cases, it is underdiagnosed due to a reduced awareness of clinicians to its complex etiopathogenesis, and association with hypotension in only about 40 % of patients.
AIMS & METHODS: Aims: Evaluation of the causes and prognosis of acute liver failure (ALF) in an Intensive Care Unit with particular analysis of hypoxic etiology.
Methods: Retrospective analysis of the period between 1992-2013, all patients admitted to the Gastroenterology and Hepatology ICU with ALF; review of the etiology, progression and outcome (survival, liver transplantation and death).
RESULTS: 90 patients studied, mean age 42 years, 59% men. Etiology: viral - 35.6 % (HBV + HDV - 60.0%); toxic - 33.3% (Amanita phalloides - 30.0%); hypoxic - 16.6%; other - 11.1%; unknown - 3.3%. Causes of hypoxic ALF were: atrial fibrillation - 6; drepanocytosis/thalassemia - 2; cardiomyopathy - 2; epileptic seizure - 2; acute myocardial infarction - 1; cor pulmonale - 1; neuroleptic malignant syndrome - 1.
ALF mortality was 38.8 % (35 patients): viral 54.3%; toxic 34.3%; hypoxic 8.6%. 21 patients were referred for liver transplantation (23.3%) of which 17.7% were transplanted (16 patients). The majority of transplants were due to toxic ALF (69%) and none was performed due to hypoxic causes. Although 47 % of patients with hypoxic ALF have had inotropic support, there was a good clinical outcome.
CONCLUSION: Hypoxia is an etiology of ALF, which in our series represented one sixth of admissions for ALF. The prognosis is good if the diagnosis is made early on.

INTRODUCTION: The Cholangiocarcinoma (CC) is a tumour with limited therapeutic options. The natrium-iodide symporter (NIS) mediates the uptake of iodine by thyroid, representing a key component in the successful metabolic radiotherapy using iodine-131 (^{131}I) in the treatment of thyroid tumours. Recently it has been shown that the expression of NIS is increased in CC, opening the possibility of a new therapeutic approach for this type of tumour.
AIMS & METHODS: The aim of this study was to evaluate the therapeutic efficacy of ^{131}I in a human cell line of CC, the TFK1. Kinetic studies of influx and efflux were performed in order to determine the profile of uptake and retention of ^{131}I by the cell line. Subsequently, the cells were subjected to different doses of ^{131}I in order to evaluate and characterize the effects of metabolic radiotherapy. The effect on cell survival was evaluated by clonogenic assay using the crystal violet staining. Flow cytometry was used to assess the type of induced cell death, the effects on the expression of BAX, BCL2 and cytochrome c, changes on mitochondrial membrane potential, as well as the production of reactive oxygen species and anti-oxidant defenses. To determine the possible damages in the DNA it was also performed the comet assay. To assess the cellular expression of NIS, immunohistochemical methods were carried out using anti-NIS antibody.
RESULTS: Treatment with ^{131}I induced a decrease in cell viability dependent on the dose. The predominant type of cell death was apoptosis, and it was accompanied by a decrease in the BCL2 and increase in the BAX expressions. It also occurred release of cytochrome c and mitochondrial membrane depolarization. Irradiation with ^{131}I also induced breaks in DNA. Interestingly there were no differences in the production of intracellular peroxides, superoxide dismutase and reduced glutathione. The immunohistochemical study revealed a strong expression of NIS in this cell line, with a predominantly membrane localization.
CONCLUSION: The ^{131}I caused a decrease in the survival of the studied cell line (TFK1), inducing cell death by apoptosis, through the intrinsic pathway. The ^{131}I appears to be a promising option for the treatment of CC, considering the membrane expression of NIS and the type of induced cell death.

Contact E-mail Address: *dralince@gmail.com*

INTRODUCTION: Cholangiocarcinoma is generally detected late in the course of disease, and current diagnostic techniques often fail to differentiate benign from malignant disease. We analyzed the roles of serum and biliary MMP–9 and TIMP–1 concentrations in the diagnosis of cholangiocarcinoma.
AIMS & METHODS: The 113 patients (55 males, 58 females) included 33 diagnosed with cholangiocarcinoma (malignant group) and 80 diagnosed with choledocholithiasis (benign group). MMP–9 and TIMP–1 concentrations were analyzed in serum and bile and compared in the malignant and benign groups.
RESULTS: Biliary MMP–9 concentrations were significantly higher (576 ± 209 vs. 403 ± 140 ng/ml, $p<0.01$) and biliary TIMP–1 concentrations were significantly lower (22.4±4.9 vs. 29.4 ± 6.1 ng/ml, $p<0.01$) in the malignant than in the benign group. In contrast, serum MMP–9 and TIMP–1 concentrations were similar in the two groups. Receiver operating curve analysis revealed that the areas under the curve of bile MMP–9 and TIMP–1 were significantly higher than 0.5 ($p<0.001$). The sensitivity, specificity, positive and negative predictive values, positive and negative likelihood ratios and accuracy were 0.94, 0.32, 0.36, 0.93, 1.40, 0.19 and 0.5 for biliary MMP–9, respectively, and 0.97, 0.36, 0.39, 0.97, 1.5, 0.08 and 0.54 for biliary TIMP–1, respectively (Table I).

Table I. Concentrations of MMP–9 and TIMP–1
Table to abstract P1197

	Sensitivity	Specificity	PPV	NPV	PLR	NLR	Accuracy
Serum MMP–9 (cut-off: 325 ng/ml)	0.7273	0.3625	0.32	0.7631	1.1408	0.7523	0.4690
Bile MMP–9 (cut-off: 350 ng/ml)	0.9394	0.325	0.3647	0.9286	1.3917	0.1864	0.5044
Serum TIMP–1 (cut-off: 205 ng/ml)	0.9697	0.1375	0.3168	0.9167	1.1243	0.2204	0.3805
Bile TIMP–1 (cut-off: 31 ng/ml)	0.9697	0.3625	0.3855	0.9667	1.5211	0.0836	0.5398

CONCLUSION: Serum and biliary MMP–9 and TIMP–1 concentrations do not appear to be useful in the diagnosis of cholangiocarcinoma.

P1198 DEVELOPMENT OF A SWINE BENIGN BILIARY STRICTRURE MODEL USING ENDOBILIARY RADIOFREQUENCY ABLATION

D.H. Lee[1,*], S. Jeong[1], Y.W. Shin[1]
[1]*Internal Medicine, Inha University School of Medicine, Incheon, Korea, Republic Of*
Contact E-mail Address: *inos@inha.ac.kr*

INTRODUCTION: An established and reproducible animal model of benign biliary stricture (BBS) has been indispensable to develop new devices or methods for endoscopic treatment of biliary stricture.
AIMS & METHODS: We studied how to make a porcine BBS model using endobiliary radiofrequency ablation (RFA). Fourteen-month-old, female mini pigs (*Sus scrofa*), each approximately 30 kg, were used. Endoscopic retrograde cholangiography (ERC) was performed in 12 swine. The animals were allocated to three groups (100 W, 80 W, and 60 W) according to the electrical power level of RFA electrode. Endobiliary RFA was applied to the common bile duct for 60 seconds using by RFA probe which could be endoscopically inserted. ERC was repeated two and four weeks respectively after the RFA to identify BBS. After the strictures were identified, the animals were euthenized and bile duct samples were achieved to evaluate the pathologic findings.
RESULTS: BBS were verified in all animals. Cholangitis were detected on endoscopic findings of day 14 in all the animals of 3 groups, but not significant. Bile duct perforations occurred in 1 swine (n = 1, 100%) for 100 W group, and 1 swine (n = 7, 14.3%) for 80 W group. There was no major complication (n = 4, 0%) in 60 W group. All benign strictures were proven pathologically. The pathologic findings resembled BBS in human.
CONCLUSION: The application of endobiliary RFA with 60 W-electrical power resulted in a safe and reproducible swine model of BBS.

INTRODUCTION: Epidemiological data on cholangiocarcinoma in Greece is limited. Crete has a homogeneous population and environmental factors are uniform.
AIMS & METHODS: Patients with cholangiocarcinoma, resident on the island of Crete, diagnosed between 2002 and 2013 in the two reference centers, were studied. Periampullary tumors were excluded. Data were prospectively and retrospectively collected from the database of the 2 major hospitals of Crete. Crude incidence rates are presented. The statistical analysis was performed with the SPSS 19 software.
RESULTS: During the 12-year period a total of 89 patients (55.6% males, median age 74 years) were diagnosed with cholangiocarcinoma. 7 of them had cholangiocarcinoma of the intrahepatic ducts, 42 were hilar Klatskin tumors and 40 patients were diagnosed with extrahepatic ducts carcinoma. Diagnosis was radiologically established in 91% of the cases (40% MRCP, 28% CT, 20% ERCP, 3% PTC), while histological diagnosis was available in 8 (9%) patients. A steady incidence increase of cholangiocarcinoma, irrespective of location, was shown. The estimated incidence rate per three-year period progressively increased from 1.33 to 1.996 to 4.99 and 6.48 per 100.000 for the periods 2002-2004, 2005-2007, 2008-2010 and 2011-2013 respectively. Median survival time was 7 months [SE 1.76 95% CI 3.53-10.46]. Median survival times according to location were 3 months [SE 2.61] for intrahepatic, 6 months [SE 1.4] for Klatskin tumors and 11 months [SE 1.88] for bile duct carcinomas.
CONCLUSION: A steady incidence increase of cholangiocarcinoma cases in Crete during the time period 2002-2013 was shown. This is probably due to changing dietary habits since both the genetic background and other environmental factors in the island are more or less stable.

INTRODUCTION: The biliary tract cancer (include gallbladder, common bile duct (CDB) and Vateŕs ampulla) is the sixth cause of death for all cancer in Western countries with a global incidence rate of 2-6/100.000 habitants. Approximately 178.101 new cases of gallbladder carcinoma and 142.813 deaths were recorded in 2012. Although etiology and pathogenesis remain unclear, genetic alterations, environmental, and infection with enterohepatic *Helicobacter spp* such as *H. bilis*, *H. hepaticus*, or *H. cholecystus* have been suggested as risk factors.
AIMS & METHODS: The aim of this work was to study whether *H. bilis* or *H. hepaticus* are associated with bile duct cancer.
Multicenter, case-control study performed in 18 states of Mexico between May 2012-December 2013, included adults diagnosed with malignant stenosis of CBD and patients with benign pathology of the bile duct matched by sex, age (± 5 years) and place of residence. The diagnosis was made by endoscopic retrograde cholangiopancreatography (ERCP). All cases were confirmed by brush cytology-histopathology and clinical course. Epithelial cells were obtained by scraping the biliary ducts during ERCP and brushes were suspended in buffer solution and frozen at -80°C until tested. DNA was extracted from brushed cells using QIAamp DNA easy kit (Qiagen, Hilden, Germany) and quantified using PicroGreen kit (Life technologies, Carlsbad, CA). A PCR reaction to amplify a 207 bp fragment from the 16S rRNA gene specific for *H. bilis* and *H. hepaticus* was performed. Differences between groups were analyzed by chi square test, and odds ratio determined using Epidat 3.1 programme.
RESULTS: The study included 194 Mexican patients, 103 samples corresponded to extrahepatic bile duct cancer: 66 CBD, 11 gallbladder and 26 of Vateŕs ampulla. Mean age of cases was 61.81±13.95 years, 41 were men and 62 women. As controls, bile duct samples were obtained from 91 patients: 64 choledocholithiasis, 6 cholecystolithiasis, 3 biliary leaking, 14 benign stenosis, 2 normal biliary duct, 1 biliary post-surgical stenosis and one choledochal cyst.
H. bilis was positive in 44 (42.78%) of the patients with extrahepatic biliary cancer and in 19 (20.88%) of controls and difference was statistically significant (p = 0.002). Odds ratio for extrahepatic biliary cancer with H. bilis in comparison with gallstones or another benign pathology was 2.83 (95% CI 1.49-5.32). H hepaticus was detected in 17 (16.5%) cases, and 13 (14.28%) controls, a difference which was not significant (p = 0.82)
CONCLUSION: Our results suggest that *H. bilis*, but not *H. hepaticus* might be a risk factor to develop extrahepatic biliary cancer in Mexican population.

INTRODUCTION: Endoscopic sphincterotomy (EST) has been the optimal therapy for choledocholithiasis since it was introduced in 1974. And the cholecystectomy is generally recommended after EST in cases with gall bladder stone. But there are debates if the cholecystectomy is necessary for all of the patients, and lots of patients defer cholecystectomy for various reasons. We studied the natural courses of patients with gall bladder stone who deferred cholecystectomy after EST in our clinic.
AIMS & METHODS: There were 727 patients with gall bladder stone who received EST for CBD stone from 2004 to 2012 in Changwon Fatima Hospital. 605 patients received cholecystectomy soon after EST, and the other 122 patients who defered operation were analyzed retrospectively by chart review and phone calls. 43 patients were lost to follow up and 79 patients were finally enrolled.
RESULTS: The mean age was 72.88 years and the mean follow up duration was 39.73 months. 28 patients had biliary recurrence (35.4%) and 12(15.1%) patients

received emergent cholecystectomy later. All-cause death was occurred in 9(11.3%) patients. The mean interval to 1st biliary recurrence was 17.9(months) and the types of recurrence were mostly cholangitis (16 pts) followed by cholecystitis (15 pts) and uncomplicated biliary pain (3 pts). 34 patiens (43%) defered cholecystectomy for old age, 29 patients (36.7%) defered for personal reasons and 16 patients (20.2%) were high risk for operation. In 9 cases of death, cause of death was cancer in 4 patients and 3 patients were died of pneumonia. There were no biliary complication related death.
CONCLUSION: There was significant biliary recurrence who had gall bladder stone but defered cholecystectomy after receiving EST for CBD stone. Many patients defer operation because of old age and personal reasons. They should be warned enough about high incidence of biliary recurrence despite rare mortality of biliary complication.

P1202 PROTEOMIC ANALYSIS OF HUMAN BILE SAMPLES IDENTIFIES NOVEL MARKERS FOR CHOLANGIOCARCINOMA IN PATIENTS WITH, AS WELL AS WITHOUT, UNDERLYING PRIMARY SCLEROSING CHOLANGITIS

K.S. Jabbar[1,2,*], P. Hedenström[1], L. Eklund[1], G.C. Hansson[2], R. Sadik[1]

INTRODUCTION: Cholangiocarcinoma is a cancer form that is often detected late, resulting in poor prognosis. Its diagnosis is challenging, particularly in the context of primary sclerosing cholangitis (PSC). The aim of this study was to identify potential novel bile biomarkers for cholangiocarcinoma in patients with/without PSC.
AIMS & METHODS: Bile samples were prospectively collected from 21 patients referred for ERCP: 6 patients with a clinical diagnosis of cholangiocarcinoma (3 with and 3 without underlying PSC), 5 patients with PSC without suspicion of cholangiocarcinoma, and 10 patients with other benign bile duct diseases. Following delipidation, samples (60µl) were prepared by the filter aided sample preparation (FASP) method (modified), and digested by trypsin, before analysis by nano-LC MS/MS on a Q-Exactive instrument. Data were searched against the UniProt/Swissprot database using the Mascot software. At least one peptide at the 99% significance level with a score of 20 or above was required for protein identification.
RESULTS: The on-filter digestion approach, performed, to our knowledge, for the first time on bile, appeared to work well. Up to 758 individual protein identifications were possible from one sample, and the total time for preparation and analysis for all aspirates was less than a week. Interestingly, there was little resemblance between the PSC-associated and non-PSC -associated cholangiocarcinoma samples. Several markers for non-PSC-associated cholangiocarcinoma were identified, including EPS8L2 (3/3 non-PSC-cholangiocarcinomas, 0/18 others; $p = 0.0008$ [Fisher's Exact test]) and SLC9A3R1 ($p = 0.003$). Promising markers for PSC-associated cholangiocarcinoma are PDE4DIP (Myomegalin) (2/3 PSC-associated cholangiocarcinomas, 0/18 others; $p = 0.01$), and ITGA6 (Integrin alpha-6) ($p = 0.04$). Importantly, neither of the latter markers was found in PSC patients without suspicion of cholangiocarcinoma.
Furthermore, several differences between PSC ($n = 8$) and non-PSC ($n = 13$) samples were detected including the upregulation of S100P ($p = 0.03$) and down-regulation of EZR (Ezrin) ($p = 0.02$) in PSC samples. These two proteins are previously known to interact with each other, and S100P has been implicated in carcinogenesis, through the activation of ERK and NFκB signalling pathways.
CONCLUSION: A novel preparation method for proteomic analysis of human bile was evaluated, and proved to be simple, fast, and generate a high number of protein identifications. Several promising markers for PSC-associated and non-PSC-associated cholangiocarcinoma, were tentatively identified.

P1203 AUTOCRINE VEGF SIGNALING IN EXTRAHEPATIC BILE DUCT CANCER: CORRELATION WITH PATIENTS' PROGNOSIS AND TUMOR CELL PROLIFERATION

Y. Zhang[1,*], S. Peng[1], J. Li[1], M. Chen[1]
[1]*Division of Gastroenterology & Hepatology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

INTRODUCTION: Tumor cells express vascular endothelial factor (VEGF) that can activate VEGF receptors (VEGFRs) on or within tumor cells to promote growth in an angiogenesis-independent fashion, however, this autocrine VEGF pathway is not reported in extrahepatic bile duct cancer (EBDC) and the role of autocrine VEGF pathway in cholangiocyte pathophysiology and clinical significance is yet unknown.
AIMS & METHODS: Immunohistochemistry were used to characterize the expression of VEGF and phospho-VEGF receptors in EBDC patients. Using EBDC cell lines, we studied the mechanism of VEGF signaling on EBDC cell proliferation.
RESULTS: The number of VEGF-positive, pVEGFR1-positive and pVEGFR2-positive cases was 40 (55.5%), 26 (36.1%) and 24 (33.3 %), respectively. Comparison of clinicopathological characteristics and immunohistochemistry showed that the positive expression of pVEGFR1 and pVEGFR2 significantly correlated with the poorer survival. The positive expression of pVEFR1 was a significant independent poor prognostic factor in EBDC. The pVEGFR1 expression was positively correlated with cell proliferation marker pErk1/2 in EBDC tissues. In vitro, we showed that VEGF promoted phosphorylation of VEGFR1 and VEGFR2 in an autocrine fashion, which is pro-proliferative through a PLC-ERK pathway. Sorafenib treatment inhibited cell proliferation and reduced VEGF secretion by inactivating autocrine VEGF pathway.
CONCLUSION: In EBDC, the pVEGFR1 and pVEGFR2 expression are prognostic factors of the poorer survival. The activation of autocrine VEGF signaling promotes EBDC cell proliferation, supporting a role of autocrine VEGF signaling as potential therapeutic target for clinical treatment.

INTRODUCTION: Radiofrequency ablation (RFA) exerts heat energy on target tissue to induce localized necrosis. It has been used for local control of liver cancer. We recently developed RFA electrode and RF generator which can monitor total emitted amount of heat energy in real time for endobiliary application.
AIMS & METHODS: We evaluated histologically injury depth and whether perforation occurs or not in bile duct according to thermal energy amount after *in vivo* biliary RFA experiment of swine model. 14-month-old, female mini pigs (*Sus scrofa*) were used. After laparotomy and duodenal incision, guidewire was inserted into the common bile duct (CBD) through the major duodenal papilla. RFA electrode was passed over the guidewire, and placed in the distal CBD. Then RFA was applied to the CBD in different total energy amount of laser (50, 100, 150, 200, 300, and 1000 joule) with different target temperatures (80 and 90 °C). All mini pigs were sacrificed right after the procedure and bile duct samples were achieved to evaluate the pathologic findings.
RESULTS: Total eight mini pigs were verified for pathologic analysis. Mean value of injury depth of the bile ducts were 50 μm, 125 μm, and 150 μm in 50, 100, and 150 joule-group, respectively. Bile duct perforations were observed in all 3 swine at 200 joules or more with 90 °C of target temperature.
CONCLUSION: The application of *in vivo* endobiliary RFA under 150 joules of total heat energy with less than 80 °C of target temperature may result in unperforated, dose-dependent thermal injury of the bile duct.

INTRODUCTION: Hepatocellular carcinoma (HCC) is one of the most common malignancies, with an increasing incidence and is the third leading cause of cancer-related mortality in the world. Liver resection remains the curative therapy for BCLC stage A. For BCLC stage C, the efficacy of sorafenib has been demonstrated in clinical practice. However, certain patients could still benefit from liver resection than sorafenib, especially in Asian.
AIMS & METHODS: This study aims to evaluate and compare overall survival in HCC patients in BCLC stage C with macro vascular invasion treated with liver resection and sorafenib.
We retrospectively reviewed the medical records of 138 newly diagnosed hepatocellular carcinoma patients between 2005 and 2013 in BCLC stage C with macro vascular invasion and Child-Pugh class A were analyzed and compared at E-DA hospital, Taiwan.
RESULTS: Sixty-two patients (45%) were treated with surgical resection and 76 patients were treated with sorafenib (55%). The average age is 57.9 and 60.8 years old in the resection and sorafenib group, respectively. The rate of male is 78.8% and 82.6% in the resection and sorafenib group, respectively. The rate of HBV is 56.8% and 60.2% in the resection and sorafenib group, respectively. Median survival was 30.3 months (range 1.5-90.2 months) in resection group compared with 7.6 months (range 1.1-15.2 months) in the sorafenib group ($p < 0.001$). The 1-year survival rate is 67.8% and 15.6% in the resection group and sorafenib group, respectively.
CONCLUSION: Liver resection gets a better survival than sorafenib in HCC patients at BCLC stage C with macro vascular invasion and Child-Pugh class A.

INTRODUCTION: Hepatocellular carcinoma (HCC) is the sixth most common and the third cause of cancer-related death in the world. Due to its complex and heterogeneous nature, HCC could represent a real challenge for clinicians. The overall survival rate in West countries population is 63% at 1 year, 29% at 3 years and 33% at 1 year in untreated patients.
AIMS & METHODS: The aim of our study is to analyze the impact of a multidisciplinary approach on patients' survival, comparing survival of our centre with data published in literature. Since September 2008 to September 2013, medical records of 636 patients with primitive lesions of the liver (including benign tumors and dysplastic nodules) were collected in the archive of our centre's Multidisciplinary Group (HEPATOCATT) and were retrospectively reviewed. For the survival analysis we selected 463 HCC patients for whom an adequate follow-up was available. Therapeutic strategies for each patient have been decided after collegial discussion with different specialists according to the stage of disease, the liver damage and the patient's clinical state, also adopting BCLC international guidelines.
RESULTS: Data analysis showed an overall survival of 79% and 56% at 1 and 3 years respectively. 51% patients presented with early stage HCC (BCLC A), 27% with BCLC B, 17% with BCLC C and 5% with end stage HCC (BCLC D). The survival analysis according to BCLC stage showed a survival rate of 90% at 1 and 69% at 3 years for BCLC A, 78% at 1 and 52% at 3 years for BCLC B, 53% at 1 and 25% at 3 years for BCLC C, 59% at 1 and 31% at 3 years for BCLC D ($p<0.01$).
CONCLUSION: The current study shows that a patient-targeted and multidisciplinary management of patients with HCC allows similar or slightly better survival rates than data of literature. This was particularly evident for advanced stages. Furthermore, our study shows a better survival rate for BCLC D than for BCLC C stage, proving that a customized therapy of the underlying liver disease allows even patients with advanced HCC to access potentially curative treatments.

INTRODUCTION: Transcatheter arterial chemoembolization (TACE) is the conventional palliative treatment for HCC in the BCLC "intermediate" stage. Factors interfering with effectiveness include the neo-angiogenic reaction due to ischemia, with changes in circulating vascular endothelial growth factor (VEGF) and hypoxia-inducible factor (HIF) levels after TACE.
AIMS & METHODS: Our study sought significant differences in neo-angiogenesis before and after conventional TACE (C-TACE), compared to DC-Beads mediated TACE (DEB-TACE), measuring serum VEGF and HIF levels. VEGF and HIF levels (ELISA) were determined in the sera and plasma, respectively, of 129 consecutive HCC intermediate stage patients, before TACE (t0) and 4 weeks after (t1). C-TACE was administered to the first 86 patients and DEB-TACE to the next 43. Tumour vascularization was evaluated at t0 and response to treatment at t1, based on angiography and sCT scan (mRECIST criteria).
RESULTS: VEGF levels at t0 significantly correlated with lesion size (0.005) and number (0.004) in both C- and DEB-TACE. HIF levels at t0 significantly correlated with aetiology (0.02), in particular with HCV, and large size lesions (0.05) both overall and in patients undergoing DEB-TACE. VEGF showed a significant increase from t0 to t1 overall (0.002) and separately in C-TACE and DEB-TACE (0.02). The t0-t1 variation in HIF was not significant. The two markers showed opposite trends, with an increase in VEGF after treatment and a decrease in HIF (chi square 0.0001). An inverse significant correlation was observed between the two markers, with high VEGF at t0 corresponding with low HIF at t1 (0.03). VEGF t0 levels and tumour size were singled out in the Cox multivariate analysis as independent predictors of survival, with no significant results with respect to HIF. DEB-TACE and C-TACE effects in terms of mRECIST response to treatment did not differ, with similar severity of side effects and, finally, survival.
CONCLUSION: Our study confirms the evidence so far obtained for VEGF, that is confirmed as an independent predictor of survival, with higher levels identifying patients with worse prognosis. An unpredicted reduction after treatment of HIF was observed, in contrast with the few studies carried out so far, mostly oriental, which may suffer from small sample size and an ethnicity-related bias. The interesting correlation with viral aetiology, in particular with HCV, should be explored further, in order to search for possible viral and cellular molecular targets, involved in HIF-mediated carcinogenesis. The opposite behaviour of the two markers could be attributable to activation of alternative pathways, such as that involving VEGF, mediated by SP1 and PI3K/Akt, or it could depend on different transcription sites (VEGF being preponderantly produced in the pericancerous tissues and HIF in the tumour area). DEB-TACE and C-TACE seem equally effective as regards response to treatment, side effects and, most importantly, impact on survival.

INTRODUCTION: Hepatitis C infection is a major global public health problem. Egypt has the highest prevalence of HCV worldwide with 9% countrywide and up to 50% in certain rural areas **[1]** and the highest prevalence of HCV-4, which is responsible for almost 90% of infections and is considered a major cause of chronic hepatitis, liver cirrhosis, hepatocellular carcinoma ***[2]***. Hepatocellular carcinoma (HCC) is the fifth most common tumor and the third most common cause of cancer-related deaths worldwide [3]. There are few and controversial data available on the association between IL-28B SNPs and severity of liver fibrosis, presence of cirrhosis or developing HCC **[4].**
AIMS & METHODS: The current study aimed to investigate the association between rs12979860 SNP of IL-28B gene and HCC in Egyptian patients infected with HCV genotype 4. This hospital-based study included 150 patients with HCV infection that were classified into three groups: 50 patients with chronic hepatitis, 50 patients with cirrhosis, and 50 patients with hepatocellular carcinoma. The plasma Human interleukin 28B levels, liver enzymes activities and serum levels of total proteins, albumin, and α fetoprotein were measured, spiral computed triphasic scanning in focal hepatic lesion for documentation of HCC diagnosis (vascular flush with rapid washout). Also, Genotyping of IL-28B rs12979860 C/T allele Polymorphism was carried out using RFLP-PCR.
RESULTS: Fifty patients (33.3%) were CC homozygous genotype, whereas, the other 100 patients were either TT or CT. The genotype TT was more frequent in HCC group in comparison to chronic hepatitis group. In addition, T-carriers increase significantly in HCC group than chronic hepatitis group. Also, IL-28B and α-FP were significantly different in T-carriers than CC genotype, and in HCC patients in comparison to either chronic hepatitis or cirrhosis patients.
CONCLUSION: This study suggests that in IL-28B rs12979860 C/T polymorphism, the T allele appears to be more prevalent in patients with end stage liver disease (liver cirrhosis and HCC). Furthermore, chronic HCV infection with end stage liver disease may be associated with a reduced IL-28B production. Further research is needed to reveal the cause-effect of these polymorphisms on host protective immunity against HCV infection.

INTRODUCTION: In Japan, the population of patients with hepatocellular carcinoma (HCC) is aging, and the use of radiofrequency ablation (RFA) to treat elderly patients with HCC is increasing. However, there are few studies

that compare elderly and non-elderly patients regarding the efficacy of RFA. Therefore, we evaluated the efficacy of RFA for elderly patients with HCC.
AIMS & METHODS: Two hundred and nineteen patients with primary HCC (tumor size ≤ 30mm and tumor number ≤ 3) treated with RFA between 2004 to 2012 were analyzed. Elderly patients (age 75 or over) accounted for 33% (73 patients) of the patients. We analyzed patient characteristics, recurrence free survival (RFS), factors related to RFS and overall survival (OS).
RESULTS: The baseline characteristics of patients were comparable between two groups with the exception of gender (male, 49% vs. 69%, respectively, $p<0.01$), ALT (median, 39IU/L vs. 45IU/L, respectively, $p<0.01$) and the presence of diabetes mellitus (12% vs. 27%, respectively, $p=0.01$). The median RFS times were 29.7 months and 29.8 months in the elderly group and non-elderly group. The RFS rates at 1, 3, and 5 years were 80.7%, 31.8%, and 21.2% in the elderly group compared with 76.6%, 40.0% and 29.7% in the non-elderly group, respectively ($p=0.43$). The times to local recurrence (TTLR) were not significantly different between the two groups ($p=0.12$). In multivariate Cox analysis, AFP > 20ng/ml (HR:1.84, 95%CI:1.2-2.8, $p<0.01$) and multiple tumor (HR:1.74, 95%CI:1.2-2.6,$p=0.04$) were significantly associated with recurrence. The 5-year OS rates in the elderly group were 51%, and 72 % in the elderly and non-elderly groups ($p<0.01$), respectively. There were 67 and 123 patients positive for anti-hepatitis C antibodies in the elderly and non-elderly groups, respectively. In patients with HCV who received anti-viral therapy (3 elderly, 29 non-elderly), none of the elderly and seven of non-elderly patients sustained viral response. When we restricted the analysis to patients who didn't receive anti-viral therapy (64 elderly group, 94 non-elderly group), the 5-year OS rates were not significantly different (50% and 65%, $p=0.13$), respectively.
CONCLUSION: Results indicated that RFA is equally effective for treating elderly and non-elderly patients with HCC.

P1210 RADIOFREQUENCY ABLATION FOR THE TREATMENT OF COLORECTAL LIVER METASTASIS: A CLINICAL OUTCOME REPORT

S.J. C. Bellido[1,1,*], J.-A. V. Bisnar[1], J.G. Cervantes[1]
[1]*Institute of Digestive and Liver Diseases, St. Luke's Medical Center, Quezon City, Philippines*
Contact E-mail Address: *sarahbellido@gmail.com*

INTRODUCTION: The 5 year-survival rate of patients with Colorectal liver metastases (CRLM) without treatment is < 5%, with a median survival time of 8-10 months. Radiofrequencyablation (RFA) is one of the loco-regional therapies that may be used as an adjunct to chemotherapy in treating these patients, and improve survival.
AIMS & METHODS: Data from patients diagnosed with CRLM and treated with RFA from 2003 to 2012 were gathered and analyzed: age, sex, number of lesions, size of the largest lesion, the treatment regimen and the number of RFA sessions. The overall survival rate, median survival time and the prognostic factors that affect survival were determined using Kaplan-Meier and Cox regression analysis.
RESULTS: From the period of March 2003 up to June 2012, a total of 69 RFA sessions were performed in 42 patients. All of the patients included underwent chemotherapy together with RFA. Three also underwent percutaneous ethanol injection therapy, while 1 patient also underwent liver resection. Majority of the patients (71%) underwent only a single RFA session. Eight patients underwent RFA twice to three times, while another 4 patients required 4 to 5 sessions of RFA. The overall 3- and 5-year survival rates of patients with CRLM treated with RFA were both 20.6%. There seems to be no significant difference in survival between age groups (p = 0.660), gender groups (p = 0.815), number of lesions (p = 0.055), RFA treatment combinations (p = 0.777), and number of RFA sessions (p = 0.141). The size (p = 0.011), and the number (p = 0.017) of lesions are significant predictors of survival. Median survival time is 25 and 11 months for lesions < 5cm, and > 5cm, respectively. Patients have a median survival time of > 54, 14, and 12 months for solitary, 2-5, and > 5 lesions, respectively.
CONCLUSION: RFA in conjunction with chemotherapy improves the overall survival rate of patients to 20.6%, and the median survival time to 26 months.

INTRODUCTION: The Barcelona Clinic Liver Cancer Staging system (BCLC) is the most widely used system and has been reported to have good stratification ability in patients with hepatocellular carcinoma (HCC). Similarly, The Japan Integrated Staging (JIS) score also has been reported to effectively stratify patients with HCC. The aim of this study was to examine which staging systems can predict the survival of patients with HCC.
However, the JIS score could not estimate malignant grade of HCC. The aim of this study was to evaluate the performance of a new staging system: the biomarker combined JIS (bm-JIS) which includes three tumor markers: alpha-fetoprotein (AFP), Lens culinaris agglutinin-reactive AFP and des-gamma-carboxy prothrombin with the conventional JIS score.
AIMS & METHODS: A total of 11.531 HCC patients were included in this retrospective study. We compared their overall survival, the stratification ability and suitability as a prognostic model according to the BCLC staging system and the JIS score.
RESULTS: There were significant differences between the survival curves for all JIS scores ($p < 0.0001$) and all BCLC scores ($p < 0.0001$). The independent homogenizing ability and the stratification value of the JIS score and the bm-JIS score determined by the likelihood ratio test using the Cox proportional hazard regression model showed the bm-JIS score to have a higher value (chi2 = 717.348) than the JIS score (chi2 = 668.91).
CONCLUSION: The bm-JIS score showed superior stratification ability and thus was found to be a better predictor of the prognosis than the conventional JIS score, especially for the patients with good prognosis.

INTRODUCTION: At state of the art, patients with intermediate stage HCC (BCLC B) are suitable only of not curative treatment. Liver transplantation may potentially cure both the tumor and the underlying liver disease, but only patients with an early stage tumor disease (meeting Milan Criteria) could be evaluated for inclusion in the transplant list.
AIMS & METHODS: The aim of our study is to evaluate the efficacy of downstaging therapy in order to satisfy Milan criteria, in patients with intermediate stage of HCC (BCLC B) referred to our Center.
Since September 2010 to September 2013, among 463 HCC patients investigated at Multidisciplinary Group for the Treatment of Hepatocellular Carcinoma of our Center (HEPATOCATT), we retrospectively selected and reviewed medical records of patients younger than 65 years old, with intermediate-stage HCC (BCLC B) that underwent a downstaging treatment (liver resection, locoregional therapy, antiangiogenic drugs and/or combined treatments) and for whom an adequate follow-up was available. Tumor response was evaluated on 1-month follow-up multiphasic CT based on mRECIST criteria. CT scan was also performed on 3-month follow up to evaluate the persistence of the response.
RESULTS: We selected 20 patients with intermediate-stage HCC (BCLC B). In all patients more than one downstaging treatment have been performed (total of 41 treatments): 2 liver resections, 21 TACE, 10 PEI, 1 RFA, 7 combined treatments (5 TACE/RFA; 1 liver resection/antiangiogenic;1RFA/antiangiogenic).
On 1-month follow up CT scan, 14 out of 20 patients (70%) experienced an effective downstaging, satisfying Milan criteria. 3-months follow up CT scan showed a stability of disease in all patients. 9 out of 14 (64.3%) patients were listed for OLTx. Finally, 7/20 patients (35%) underwent liver transplantation.
CONCLUSION: Our results show that an effective downstaging strategy allows even patients with intermediate HCC (BCLC B) not suitable to liver transplantation, to access potentially curative treatments

INTRODUCTION: In patients with well-preserved hepatic function, hepatic resection (HR) is the most appropriate and effective treatment. In the last decade, local ablative therapies (mostly radiofrequency ablation -RFA) have obtained good results in term of efficacy. Whether ablation of HCC eligible

also for HR provides long-term disease control comparable to resection remains still in debate.
AIMS & METHODS: Aim. To compare the therapeutic outcome in terms of survival and recurrence of RFA and HR in the treatment of HCC lesions within Milan criteria treatable by both techniques.
Methods: Using inclusion and exclusion criteria, seventy-nine HCC patients treatable by both HR or RFA were included in this study. Thirty two patients were treated by HR and 47 by RFA. In the HR group, 22 lesions were located in the left lobe and 11 in the right lobe. In the RFA group 40 lesions were located in the right lobe and 7 lesions in the left lobe. Mean tumor size was 31.5 +/-7.55 mm in the RFA and 32.6 +/- 10 mm in the HR group. In the ARF group were included 41(88%) patients with Child Pugh A class and 6 (12%) patients were Child Pugh B class. In the HR group were included 30 (94%) patients with Child Pugh and 2 (6%) patients with Child Pugh B class. The outcome was considered in terms of overall survival (OS) and local recurrence rate. Survival curves were constructed with the Kaplan-Meier method and compared by using the log-rank test.
RESULTS: Even if in the first two years the RFA group presented a better OS, in the third year the survival rate was lower than HR (91%, 82%, and 35 % vs 81%, 65% and 57% at 1.2, and 3 years), respectively) ($p = 0.185$). The local recurrence was higher in the RFA group (38.2%) than in the HR group (3.1%)($p = 0.001$). There was one major complications in each group (death after surgical resection) and 1 case of haemoperitoneum after RFA.
CONCLUSION: RFA provides a better survival at 1 and 2 years than HR in patients with HCC within Milan criteria treatable by both treatments. The survival rate at 3 years is better for HR presumable due to the lower local reccurence rate.

INTRODUCTION: Patency of self-expandable metallic stents (SEMS) known to be better than plastic stents (PS) in palliating malignant biliary obstruction. However, data were scarce for the obstructive jaundice caused by hepatocellular carcinoma (HCC). This study aimed to compare SEMS and PS in palliating obstructive jaundice of unresectable HCC.
AIMS & METHODS: A total of 96 patients who undergone endoscopic retrograde biliary drainage (ERBD) for obstructive jaundice of unresectable HCC and deployed either SEMS or PS successfully were included in this retrospective analysis. Successful biliary drainage rate, complication rate, stent patency duration and patient survival were compared between SEMS and PS groups
RESULTS: Thirty-six patients were SEMS group and 60 patients were PS group. Successful biliary drainage rate was not significantly different between SEMS and PS (69.4% vs. 65.0%, $p = 0.655$). Complication rate was 16.7% in SEMS vs. 21.7% in PS ($p = 0.552$). The median patency duration was also not significantly different between SEMS group and PS (68 day vs. 60 day, $p = 0.396$). Median patient survival was longer in PS group than SEMS group (123 day vs. 48 day, $p = 0.005$). Use of PS, lower total bilirubin level, earlier TNM stage, successful biliary drainage, and following anticancer treatment was significantly related with longer patient survival in multivariate analysis.
CONCLUSION: SEMS was not superior to PS for palliating malignant biliary obstruction of HCC with regard to successful drainage, patency and complications and patient survival was longer in PS group. Considering the lower cost of PS, ERBD with PS could be a favorable option for malignant biliary obstruction caused by HCC.

P1215 SURGERY OR EUS-GUIDED CHOLEDOCHODUODENOSTOMY FOR DISTAL BILIARY CANCER PALLIATION AFTER FAILED ERCP

E.L. Artifon[1,*], J.F. Loureiro[1], P. Sakai[1]
[1]*university of sao paulo, sao paulo, Brazil*
Contact E-mail Address: *jarbasfaraco@gmail.com*

INTRODUCTION: Most patients with neoplasm in the biliopancreatic junction are diagnosed at an advanced stage. Endoscopic retrograde cholangiopancreatography (ERCP) is the method of choice for drainage of obstructed biliary tract. However, there is a failure rate of about 10%. In such cases, alternative techniques, such as, percutaneous transhepatic drainage and surgical drainage are applied.
AIMS & METHODS: To evaluate the technical and clinical success, quality of life and patient survival of biliary drainage by conventional surgery and endosonography-guided technique in patients with malignant neoplasm of the biliopancreatic junction.
From April 2010 to September 2013, 32 patients with malignant neoplasm of the biliopancreatic junction were studied. All patients included in this study had failed biliary drainage by ERCP. Three patients were excluded due to technical failure (failure in the construction of hepatico-jejuno anastomosis and formation of endosonography-guided choledochoduodenal fistula). Group I comprised of 15 patients who underwent Roux-en-Y hepaticojejunostomy (HJT) and gastrojejunal bypass. Group II consisted of 14 patients who underwent endosonography-guided choledochoduodenostomy (CDT). Clinical success was assessed by the decrease of more than 50% in total serum bilirubin in the first seven days after the procedure. Quality of life was assessed by SF-36 questionnaire and survival by Kaplan-Meier curve.
RESULTS: Technical success rate was 93.75% (15/16) in group I and 87.5% (14/16) in group II ($p = 0.598$). Clinical success occurred in 14 (93.33%) patients in group I and 10 (71.43%) patients in group II. There was no significant statistically difference ($p = 0.169$). The average quality of life score were statistically equal between the techniques during follow-up ($p > 0.05$ * Technical Moment). There were statistically significant mean changes during follow-up of functional capacity score, physical health, pain, social functioning, emotional and mental health aspects in both techniques ($p < 0.05$). The mental health score was, on average, statistically higher in group II (CDT) at all times ($p = 0.035$). The median survival time of patients in group I was 82.27 days and Group II patients was 82.36 days. Sixty percent of patients in group I died within 90 days after the surgical procedure. On the other hand, 42.9% of the patients who underwent CDT died in the same period. There was no statistically significant difference in survival time between the groups ($p = 0.389$).
CONCLUSION: Data relating to technical and clinical success, quality of life and survival were similar in both groups and there were no statistically significant differences.

P1216 APPROPRIATE THERAPEUTIC STRATEGY FOR BILIARY STENTING USING THREADED INSIDE STENTS BASED ON THE LOCATION OF THE MALIGNANT OBSTRUCTION

H. Hasegawa[1,*], O. Inatomi[1], Y. Morita[1], H. Ban[1], M. Shioya[1], S. Bamba[1], A. Andoh[1]
[1]*Division of Gastroenterology, SHIGA UNIVERSITY OF MEDICAL SCIENCE, Otsu, Japan*

INTRODUCTION: Although the use of endoscopic biliary stents in cases of malignant obstruction may be widespread, optimal endoscopic management remains controversial. We retrospectively evaluated the safety and efficacy of the placement of a threaded inside plastic stent above the sphincter of Oddi (threaded PS) and compared the results with those of other stent types with respect to the location of the obstruction.
AIMS & METHODS: Forty patients with malignant hilar obstructions (type I–IV; Bismuth classification) underwent endoscopic indwelling stent placements. These cases involved the use of threaded PS, conventional PS, and uncovered metallic stents (MS). To create a threaded PS, a nylon monofilament thread (size 3/0) was attached to a conventional PS (Flexima, Boston Scientific) using a puncher. The duration of patency and complications were retrospectively evaluated in each group. The patients with malignant hilar obstructions all underwent threaded PS placement as a salvage therapy after MS was obstructed due to tumour ingrowth. We compared the patency of MS and threaded PS in these cases. In cases with mid or lower bile duct obstruction, the duration of patency and any complications were retrospectively evaluated in the MS and threaded PS groups.
RESULTS: All procedures were successful in each group. The median duration of patency in the threaded PS group was significantly longer compared with the duration in the conventional PS group (126.3 vs 42.1 days, $P = 0.025$, Log-rank test) and was not significantly different compared with the MS group (126.3 vs 200.3 days, $P = 0.76$). The removal of threaded PS was simple because the attached thread was visible in the sphincter of Oddi except in one case. The stents did not migrate in any group. The median duration of the threaded PS patency was 123 days compared with that of the MS patency of 163 days ($P = 0.486$). In patients with mid or lower bile duct obstruction, the median duration of the threaded PS patency was significantly shorter compared with that of the MS patency ($P < 0.03$). In particular, the median patency of the threaded PS when there was no precedent endoscopic nasal bile drainage was significantly shorter (22 days).
CONCLUSION: The placement of threaded PS is safe and effective compared with conventional PS for the treatment of a malignant hilar obstruction; this procedure was not inferior to MS. In addition, the threaded PS patency was comparable with the MS patency even when used as a salvage therapy, suggesting that threaded PS may be useful not only for an initial therapy but also as a salvage therapy. On the other hand, the placement of threaded PS without a precedent ENBD was not superior to MS in cases with mid or lower bile duct obstruction. The type of stent should be decided in terms of both the location of the obstruction and the endoscopic therapeutic process.

INTRODUCTION: Endoscopic biliary drainage is one of the major palliative treatments for unresectable malignant hilar biliary obstruction. However, post-endoscopic retrograde cholangiopancreatography (ERCP) cholangitis could occur frequently due to inadequate drainage, especially after contrast injection into biliary tree.
AIMS & METHODS: The aim of this study was to investigate the effect of air cholangiography on post-ERCP complications for endoscopic bilateral stent-in-stent (SIS) placement of self-expandable metallic stents (SEMS). This study was included 42 patients with unresectable malignant hilar obstruction who underwent endoscopic bilateral SEMS placement using SIS technique. They were divided into the two groups, air ($n = 21$) or iodine contrast ($n = 21$)

cholangiography, respectively. We retrospectively compared comprehensive clinical and laboratory data in both groups.
RESULTS: There were no significant differences in age, gender, stent type, liver function tests, type of tumor origin, and Bismuth classification between the two groups. Technical success was achieved for all 42 patients and functional success rate was 95.2% (20/21) in each group. Post-ERCP complications were occurred in 5 (23.8%) of the patients in air group and 8 (38.1%) of the patients in iodine contrast group ($P=0.17$). The rate of cholangitis in air group was significantly lower than that in the iodine contrast group (4.8% vs. 33.3%, $P=0.045$). The difference of 30-day stent occlusion and 30-day mortality between the two groups was not significant ($P=1.000$ and $P=0.232$, respectively).
CONCLUSION: Air cholangiography is a safe and effective method to visualize intrahepatic bile duct with low incidence of post-ERCP cholangitis. In addition, it could be considered for endoscopic bilateral SIS placement of SEMS in patients with malignant hilar biliary obstruction.

P1218 THE USEFULNESS OF NARROW-BAND IMAGING SYSTEM IN DIAGNOSING AMPULLARY LESION

J.-S. Park[1,*], **D.-W. Seo**[1], T.J. Song[1], **D.H. Park**[1], S.S. Lee[1], S.K. Lee[1], M.-H. Kim[1]
[1]*Gastroenterology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of*
Contact E-mail Address: *Pjsinha@naver.com*

INTRODUCTION: The differentiation between ampullary tumors and benign ampullary lesions is challenging occasionally because endoscopic findings may be similar to each other. Narrow-band imaging system (NBI) can yield clear images of microvessel and surface structure, and it is widely used for the diagnosis of gastric or colonic cancer.
AIMS & METHODS: we evaluated the the usefulness of NBI for differentiating between the ampullary tumor and other benign diseases. 29 patients with 42 ampullary lesions were retrospectively analyzed between March 2010 and January 2011. Inclusion criteria were enlarged or protruded lesions that were suspected ampullary tumor during duodenoscopy. Abnormal NBI images were classified as follows: Irregular arrangement of villi; Irregular size of villi; Disappearance of ridged villi structure; Demarcation with normal villi; Abnormal microvasculature. The correlation between NBI images and histological findings was investigated.
RESULTS: In histological examination, there were 21 adenoma, 6 adenocarcinoma and 15 benign diseases. On NBI images, the abnormal findings according to our classification were: Irregular arrangement of villi (50%); Irregular size of villi (64%); Disappearance of ridged villi structure (40%); Demarcation with normal villi (55%); Abnormal microvasculature (67%). In multivariate analysis, irregular arrangement of villi (OR, 45.44; 95% CI, 2.87-604.34; $P<0.01$) and abnormal microvasculature (OR, 11.79; 95% CI, 2.24-235.67; $P<0.01$) were significant factors to identify ampullary tumor.
CONCLUSION: Our study suggested that Irregular arrangement of villi and Abnormal microvasculature on NBI image would be useful for detection of ampullary tumor.

P1219 THREE-MONTH SURVIVAL OF MALIGNANT OBSTRUCTIVE JAUNDICE PATIENTS: FACTORS AFFECTING MORTALITY

J. Kurniawan[1,*], I. Hasan[1], R.A. Gani[1], M. Simadibrata[2]
[1]*Division of Hepatology, Department of Internal Medicine,* [2]*Division of Gastroenterology, Department of Internal Medicine, Faculty of Medicine University of Indonesia/Dr. Cipto Mangunkusumo General National Hospital, Jakarta, Indonesia*
Contact E-mail Address: *juferdyk@gmail.com*

INTRODUCTION: Understanding any related factors affecting mortality in malignant obstructive jaundice patients will better guide to an approriate and optimal planning in making diagnostic approach and proper treatment for each aetiological and relating factors thus improving survival and patients' quality of life.
AIMS & METHODS: To obtain survival and mortality-related factors of malignant obstructive jaundice patients, retrospective cohort study was conducted with medical records of obstructive jaundice inpatients from January 2010 to December 2013 were reviewed. Suggested mortality-related factors include age, gender, sepsis, hypoalbumin, serum bilirubin level, serum CA 19-9 level, billiary drainage, non ampula vater carcinoma, and comorbid factors were analyzed. Overall survival and survival related mortality factors were measured, bivariat and multivariat analysis was done with Cox Proportional Hazards Regression Model to obtain Hazard Ratio (HR) of each prognostic factor. Prognostic score from each mortality-related factor was calculated based on the last regression model.
RESULTS: A total of 181 (106 male/75 female) patients were enrolled in this study, with patients aged 50 years or above was 57.5%. The cox proportional hazards model demonstrated that sepsis (HR 2.462; 95% CI 1.552 – 3.906), unsuccessful / no prior billiary drainage (HR 1.604; 95% CI 0.988 – 2.603), and Charlson comorbid score ≥ 4 (HR 2.476; 95% CI 1.562 – 3.923) were independent prognostic factors for mortality. Patients with significant prognostic factors had shorter survival than overall survival (median survival 14 days; 95% CI: 9.66 – 18.34 vs 26 days; 95% CI: 20.82 – 31.19, respectively) ($p=0.01$). Score ≥ 2 identified as the highest prognostic score threshold with sensitivity 68%, specificity 75%, and AUC on ROC curve 0.769.
CONCLUSION: Patients with significant prognostic factors had shorter survival than overall survival. Sepsis, unsuccessful / no prior billiary drainage, and Charlson comorbid score ≥ 4 were main prognostic factors with significant difference affecting mortality rate in malignant obstructive jaundice inpatients. Prognostic threshold ≥ 2 quite good to classify malignant obstructive jaundice inpatients into high risk mortality population. Mortality of patients with those significant prognostic factors can be predicted in 76.9%.

P1220 CLINICAL USEFULNESS OF BILE CYTOLOGY OBTAINED BY TRANSPAPILLARY CATHETERIZATION OF THE GALLBLADDER FOLLOWED BY RUBBING WITH A GUIDEWIRE FOR GALLBLADDER WALL THICKENING

K. Ito[1,*], S. Koshita[2], Y. Kanno[1], T. Ogawa[1], K. Masu[1], Y. Michikawa[1], Y. Iwashita[1], G. Kobayashi[1], Y. Noda[1]
[1]*Gastroenterology,* [2]*SENDAI CITY MEDICAL CENTER, Sendai, Japan*
Contact E-mail Address: *keiito@openhp.or.jp*

INTRODUCTION: Although gallbladder (GB) diseases have been increasingly detected with the widespread use of ultrasonography, MRI, and multi-detector-row CT, it is sometimes difficult to distinguish malignant GB diseases from benign ones.
AIMS & METHODS: The aim of this study was to evaluate the clinical usefulness of bile cytology obtained by endoscopic transpapillary catheterization of the gallbladder (ETCG) followed by rubbing with a guidewire for GB wall thickening. Between January 2008 and December 2013, 67 patients with GB wall thickening who underwent ETCG cytology were enrolled in this study. Fifty-five patients underwent surgical treatment. Pathological findings of the resected specimen revealed GB cancer in 20 patients and benign GB diseases in 35 (20, chronic cholecystitis; 11, adenomyomatosis; 2, xanthogranulomatous cholecystitis; 1, acute cholecystitis; 1, cholesterol polyp). Five patients were diagnosed as inoperable advanced GB cancer by CT findings such as liver/lymph node metastases. The remaining seven patients were diagnosed as benign GB diseases after a follow-up period of at least 12 months. The method of ETCG cytology was as follows. A 5 Fr catheter with side holes was inserted into the GB over a 0.025 or 0.032-inch hydrophilic guidewire. The first aspirated bile was discarded. Fresh exfoliated cells were obtained after washing by saline solution and rubbing the target lesion with a guidewire. Cytology was performed by HE stain with the cellblock method. A rating of Class IIIb or more was defined as malignancy. The sensitivity, specificity, and accuracy of ETCG cytology were evaluated.
RESULTS: Of the 25 patients with GB cancer, 16 were defined as having malignancy by ETCG cytology (6, Class V; 6, Class IV; 4, Class IIIb). The causes of false-negative results included insufficient material in 2 patient, inability to rub the lesion with a guidewire in 1, and indeterminate causes in 6. Of 42 patients without malignancy, one patient was found to be false positive by ETCG cytology (Class IIIb). Sensitivity, specificity, and accuracy of ETCG cytology were 64%, 98%, and 85%, respectively. No procedure-related complications such as cholecystitis and cystic duct perforation occurred.
CONCLUSION: Bile cytology obtained by ETCG is a feasible and safe method for differential diagnosis of GB wall thickening.

INTRODUCTION: Endoscopic papillectomy (EP) is performed in selected patients with ampullary neoplasm. Accurate preoperative tumor staging is indispensable for making management decisions.
AIMS & METHODS: The aim of this study was to elucidate the current status of endoscopic management for ampullary neoplasm. Eighty-three patients with ampullary neoplasm (male, 51; female, 32; mean age, 68; mean tumor size, 21 mm) who underwent transpapillary intraductal US (IDUS) of the bile duct (BD) were enrolled in this study. The indication for EP was determined based on the following findings by IDUS: (1) no tumor infiltration into the BD or the pancreatic duct (PD) and (2) adenoma or T1 cancer. In cases of T1 cancer, additional surgery was considered when the tumor had invaded the Oddi's muscle because of the risk of lymph node metastasis.
RESULTS: Based on the results of IDUS, EP was performed in 37 patients. Twenty-one had adenoma and 16 had adenocarcinoma (T1, 14; T2, 2). The other 46 patients, whose tumors were contraindicated for EP by IDUS, were treated by pylorus-preserving pancreatoduodenectomy (T1, 19; T2, 10; T3-4, 17). Of these 19 surgical cases of T1, 9 had a tumor invading the Oddi's muscle and 8 had a tumor spreading into the BD or PD. Theoretically, the remaining 2 patients could have been treated by EP based on the histopathological findings.
In the 37 patients who underwent EP, the accuracy of IDUS in T staging was 95% (35/37). Of the two patients with T2, one underwent additional surgical treatment, which revealed neither a residual tumor nor lymph node metastasis by histopathological evaluation of the resected specimen. The other refused surgical therapy and received chemotherapy without evidence of recurrence for 48 months. One patient with T1, whose tumor invaded the Oddi's muscle, died in an accident one month after EP. In one patient with T1 (tumor depth, Oddi's muscle) who refused additional surgical treatment, lung metastases were detected by chest CT 11 months after EP without local recurrence. In the remaining 12 patients with T1 (tumor depth, mucosa), neither local recurrence nor distant metastasis was observed. Of the 21 patients with adenoma, 4 successfully underwent argon plasma coagulation for a residual tumor. At follow-up (mean duration, 38 months; range, 1-108 months), no local recurrence was observed in the

remaining patients. The sensitivity, specificity, and accuracy of determining the indication for EP by IDUS was 89%, 96%, and 93%, respectively.
CONCLUSION: IDUS can provide useful information for determination of the indication for EP. Detailed histological evaluation of the resected specimen and long-term follow-up are mandatory after EP.

INTRODUCTION: The association between diabetes, smoking, obesity, and cholangiocarcinoma (CC) risk remain inconclusive. We evaluated the risk factors for both intrahepatic cholangiocarcinoma (ICC) and extrahepatic cholangiocarcinoma (ECC).
AIMS & METHODS: A case-control study in which cases were cholangiocarcinoma patients referred to Yokohama City University Hospital (YCUH) in Japan between 2009 and 2013 and controls were healthy individuals. Controls were randomly selected from an existing database of healthy individuals at YCUH. Data on family history, diabetes, smoking and drinking were collected by a retrospective review of the patients' records and health examination reports or by interview. The associations between potential factors and CC risk were determined.
RESULTS: A total of 111 patients (23 ICC; 88 ECC) and 547 age- and sex-matched controls were enrolled. Compared with controls, ICC patients had a higher prevalence of diabetes (34.8% vs 17.4%, $p = 0.04$). The adjusted odds ratio (OR) and 95% confidence intervals (CI) were 3.1 (95% CI: 1.08-9.19). ECC patients showed significant independent associations with diabetes (OR: 2.68; 95% CI: 1.36-5.29) and smoking (OR: 2.88; 95% CI: 1.57-5.30).
CONCLUSION: These findings strongly support the positive link between diabetes and the increased risk of ICC and ECC, and smoking were associated only with ECC.

INTRODUCTION: Differential diagnosis of bilio-pancreatic strictures includes cholangiocarcinoma and benign lesions. The nature of biliary tumors remains very difficult to diagnose due to the difficulty of getting adequate tissue samples and to the lack of histopathological evaluation. Confocal Laser Endomicroscopy (CLE) has been shown to considerably improve the characterization of those lesions as compared with standard modalities thanks to a sensitivity and an NPV higher than 90%. This substantial evolution has the potential to provide a more informed diagnosis and to impact patient management.
AIMS & METHODS: The aim of this study is to develop up-to-date evidence-based consensus statements for the diagnosis of biliary strictures.
Initial statements on the use of CLE for the characterization of indeterminate biliary strictures were developed by a single CLE expert based on the available clinical evidence. Those preliminary statements were edited and submitted by an external group of 16 GI physicians using a modified Delphi approach. After two rounds of votes based on relevant data, quality of the evidence and strength of recommendation, statements were validated if the threshold of agreement was higher than 75%.
RESULTS: Out of 9 proposed statements, 6 were validated and 3 rejected. CLE can be used to evaluate biliary strictures, and the probe can be delivered via a catheter or a cholangioscope. CLE is more accurate than ERCP with brush cytology and/or forceps biopsy in determining malignant or benign strictures, using established criteria. The accuracy of CLE in indeterminate biliary strictures may be decreased by prior presence of plastic stent.
The Negative Predictive Value (NPV) of CLE is very high. The use of CLE can assist clinical decision-making such as excluding malignancy. CLE should be cited as a valuable tool for an increased diagnostic yield in official guidelines. The «black bands» that can be seen in pCLE images have been shown to be collagen fibrils that predictably increase in pathologic tissue.
CONCLUSION: According to the panel of 16 physicians, given its very high accuracy, Confocal Laser Endomicroscopy has the potential to improve the current diagnostic algorithm of biliary strictures. At centers where expertise is available, Confocal Laser Endomicroscopy used during ERCP in the evaluation of biliary strictures should be considered as a standard practice complementary to conventional tissue sampling.

INTRODUCTION: Malignant biliary obstruction (MBO) is not a rare condition in advanced gastric cancer (AGC). However, the clinical outcome of this setting remains unclear. Moreover, the role of biliary drainage for this setting is not fully elucidated.
AIMS & METHODS: Between October 2004 and February 2014, 63 consecutive AGC patients (pts) with MBO who received biliary intervention were studied retrospectively.
RESULTS: Of 63 pts, 35 pts (%) had previous gastrectomy (B-1/B-2/RY reconstruction = 8/5/22). The primary tumor of differentiated adenocarcinoma in 23 pts (37%) and undifferentiated in 40 pts (63%), with liver metastases in 7 pts (11%) and ascite in 30 pts (48%). Portal vein stenosis and periportal collar sign were observed in 28 pts (44%) and 17 pts (27%), respectively. The causes of biliary obstruction were lymph node metastases in 8 pts, peritoneal metastases in 45 pts, and direct invasion in 10 pts, with the median lengths in biliary obstruction of 25 mm. Biliary drainage was performed via ERCP in 14 pts and PTBD in 49 pts, with technical and clinical success of 100% and 86% (ERCP/PTBD = 93%/84%), respectively. Periportal collar sign, emerged as a result of tumor infiltration to Glisson's capsule, was revealed as a risk factor for unsuccessful drainage (Odds ratio 9.2 (95% CI 1.5-78.0), $p = 0.02$). Nine complications were developed; 5 after ERCP (2 acute pancreatitis, 2 cholecystitis, and 1 cholangitis) and 4 after PTBD (1 stent migration, 1 pneumothorax, hemobilia in 1, and 1 pseudoaneurysm). After biliary intervention, 29 pts (46%) received systemic chemotherapy. Median survival after biliary intervention was 3.6 months. Clinical success of biliary drainage was prognostic of survival after intervention (4.9 vs. 1.1 months, $p < 0.01$).
CONCLUSION: Although the prognosis of AGC pts with MBO is poor, biliary interventions should not be considered as a contraindication because of its safety and efficay in selected pts.

P1225 THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY

R. Koyama[1,*], T. Tamura[1], Y. Koizumi[1], T. Imamura[1], K. Takeuchi[1]
[1]*gastroenterology, TORANOMON HOSPITAL, tokyo, Japan*

INTRODUCTION: Endoscopic retrograde cholangiopancreatography (ERCP) in patients with altered gastrointestinal (GI) anatomy remains a challenging procedure. However, the progression of techniques and devices like a Double-balloon enteroscopes (DBEs) enables us to perform ERCP on these patients. The aim of this study is to assess the efficacy and safety of therapeutic ERCP, especially biliary drainage for malignant biliary obstructions, in patients with surgically altered GI anatomy (patients with Billroth-I anastomosis were excluded).
AIMS & METHODS: 2239 consecutive ERCP procedures were performed at Toranomon Hospital during a 5- year period (2009 to 2013). In these, a total of 19 patients with altered GI anatomy underwent 33 ERCPs for malignant biliary obstruction. We retrospectively investigated: (1) the success rate of reaching either the papilla of vater or the bilioenteric anastomosis; (2) the success rate of cannulation to deeper parts of a biliary tract; (3) the rate of successful therapeutic ERCPs; (4) complications.
RESULTS: The mean age was 72.5 years, range 58 to 82 years; 68% were male and 32% were female. Bile duct cancer 45.5%(n = 15), pancreatic cancer 18.2%(n = 6), hepatocellular carcinoma 18.2%(n = 6), and lymph node metastasis from the recurrence of gastric cancer, or esophageal cancer 18.2%(n = 6) were major indications. 10 cases underwent Roux-en-Y anastomosis, 4 cases underwent Billroth-II anastomosis, 4 cases underwent biliojejunal anastomosis, and 8 cases underwent bilioduodenal anastomosis. A plastic stent and self-expanding metal stent (SEMS) were positioned for biliary drainage in 39.4% of the cases (13/33) and 33.3% (11/33), respectively. The results of the above investigations were: (1)87.9% (29/33), (2)84.8% (28/33), (3)84.8% (28/33), (4)3% (1/33): respiratory suppression. There were no cases of the therapeutic ERCPs being stopped by an accident during this procedure. Procedure-related mortality did not occur. There were no incidences of hemorrhage and/or perforation. The median duration of hospitalization was 21 days (2-82 days) and 44% of patients could be discharged within 2 weeks. The median duration of survival after therapeutic ERCPs was 80 days (16-601 days).
CONCLUSION: ERCP in patients with surgically altered GI anatomy remains a challenging procedure. But due to using DBE or PCF, the number of the successful therapeutic ERCPs is increasing in these patients. Successful therapeutic ERCP was achieved in 84.8%, a relatively high figure in this study. The median duration of survival time is short, only 80 days, because the most patients are at the end stage of their diseases. To improve the QOL of patients with malignant biliary obstructions, therapeutic ERCP should be performed positively, even if it's a case of altered GI anatomy, because it's relatively safe procedure, less invasive, and possible to discharge patients earlier.

P1226 CHARACTERIZATION OF CHOLANGIOCARCINOMAS: CLINICAL AND TOPOGRAPHIC FEATURES OF A GROWING ONCOLOGICAL REALITY

R. Coelho[1,*], M. Silva[1], E. Rodrigues-Pinto[1], S. Lopes[1], P. Pereira[1], H. Cardoso[1], F. Vilas-Boas[1], J. Santos-Antunes [1], J. Lopes[2], F. Carneiro[2], G. Macedo[1]
[1]*Gastrenterology Department,* [2]*Pathology Department, Centro Hospitalar São João, Oporto, Portugal*

INTRODUCTION: Cholangiocarcinomas account for 3% of the malignant gastrointestinal neoplasms. The incidence of intra-hepatic cholangiocarcinomas has increased for unknown reasons [1.2].
AIMS & METHODS: To determine the clinical and analytical characteristics, the diagnosis approach and the treatment options for patients with cholangiocarcinoma according to its location. Retrospective analysis of patients with diagnosis of cholangiocarcinoma in the last 5 years in a tertiary referral center.
RESULTS: 89 patients (55% male) were followed for a median of 23 weeks (P25-75: 8-80). There was a progressive increase in the number of cholangiocarcinoma diagnosis since the beginning of the cohort (14 new diagnoses in 2008-2009, 31 in 2010-2011 and 44 in 2012-2013). The mortality rate at 6 months was 40.5% and the median survival was 164 days (P25-75: 61-566). Most patients (53%) presented perihilar, 24% extrahepatic and 24% intrahepatic cholangiocarcinoma (ICC). The median age at diagnosis was 71 years, being lower in the ICC (68 vs 74, $p = 0.014$). The diagnosis was obtained using imaging methods in 73% of cases, the abdominal computed tomography was the most common method (45%). There was a statistically significant correlation between the diagnosis of ICC and the need of histological methods to make a diagnose ($p < 0.001$). Serum levels of G-GT, alkaline phophatase and total bilirrubin at diagnosis were lower in ICC ($p < 0.001$). In 36% of cases there was metastatic disease at diagnosis, being hepatic metastization the most common disease (12%). In 56% of cases palliative treatment was decided at diagnosis and in 54% of the patients underwent surgery. Hepatectomy was the most common intervention and was performed in 20% of the cases.
CONCLUSION: ICC presents with less cholestasis at diagnosis. It is more frequent the need for a histological diagnosis in this type of cholangiocarcinoma. An increase of the incidence of cholangiocarcinoma was verified in this cohort.

Contact E-mail Address: *rosacoelhoabrantes@hotmail.com*

INTRODUCTION: Most patients with cholagiocarcinoma present an unresectable disease at diagnosis with an extremely poor prognosis, an average five-year survival rate of 5 to 10 percent. Those, who undergo potentially curative resection, tumor-free margins can be obtained in only less than half of the patients [1-2].
AIMS & METHODS: To analyze the survival of patients with cholangicarcinoma according to clinical and therapeutic options. Retrospective study of patients with diagnosis of cholangiocarcinoma between 2008 and 2013 in a tertiary referral center. The Kaplan-Meier survival curves were used, alpha = 0.05.
RESULTS: We included 71 patients (39 male) with a median age of 71 years at diagnosis. The mortality rate during the follow-up period was 79% (37% at 3 months, 42% at 6 months and 51% at 12 months). The median survival was 44 weeks (P25-75: 8-90). A higher level of survival at 3, 6 and 12 months was associated with chemotherapy treatment ($p = 0.002$, $p = 0.001$, $p = 0.003$, respectively), lower levels of CA-19.9 ($p = 0.001$, $p = 0.009$, $p = 0.013$), surgical treatment ($p < 0.001$), TNM-R0 ($p = 0.006$, $p = 0.031$, $p = 0.039$) and no metastization at diagnosis ($p < 0.001$, $p = 0.006$, $p = 0.002$). Survival in the first trimester was associated with TNM-N0 ($p = 0.022$). Survival in the first year was associated with higher levels of albumin ($p = 0.032$), lower levels of alkaline phosphatase ($p = 0.020$), younger age ($p = 0.038$) and fewer days between the beginning of the symptoms until the diagnosis date ($p = 0.029$). The analysis of the Kaplan-Meier curves showed an association between survival, absence of metastization at diagnosis ($p < 0.001$), surgical treatment ($p < 0.001$) and chemotherapy treatment ($p = 0.009$). In terms of survival at 3, 6 and 12 months, the therapeutic surgery and the mestastization were associated independently in the logistic regression.
CONCLUSION: The factors that determine a greater survival are surgical treatment and chemotherapy. Absence of metastization at diagnosis seems to be related to a medium-term survival.

INTRODUCTION: The use of endoscopic snare papillectomy (ESP) for the treatment of duodenal major papillary neoplasm was increased. However, concerns about ESP included the risks of incomplete removal.
AIMS & METHODS: The aim of this study was to evaluate the clinical outcomes of ESP and the effectivity of argon plasma coagulation (APC) for the treatment of residual tissue.
Among the patients who received ESP for the treatment of duodenal major papillary neoplasm from November 2005 to march 2014, 33 patients were enrolled. These patients were followed for more than 3 months. We retrospectively reviewed the medical records of the patients.
RESULTS: Twenty eight patients had adenoma, 2 had adenocarcinoma, 1 had carcinoid tumor, 1 had paraganglioma and 1 had inflammation. Median follow-up periods was 12 months (range: 3-72 months). The overall rate of en bloc resection was 87.9% (29/33). Specimens with margin positivity after ESP were reported in 12 patients (9 lateral margin positivity, 3 lateral and vertical margin positivity). Among the 12 patients with margin positivity, 5 patients received additional treatment (4 APC, 1 hot biopsy and APC) and 7 patients with grossly no residual tissue were followed by close endoscopic surveillance with white light and/or narrow band imaging. Among all patients, local recurrence was detected in 4 patients (12.1%, 4/33). 3 cases (25%, 3/12) occurred in the patient with margin positivity and 1 case (4.8%, 1/21) occurred in the patient with margin negativity. Two patients with local recurrence were the patients who did not receive additional treatment of lateral margin positivity. There was no local recurrence in the patients who received APC for the treatment of residual tissue.
CONCLUSION: After ESP of duodenal major papillary neoplasm, additional treatment of margin positivity should be considered and close endoscopic surveillance should be performed. APC may be an effective method for the treatment of residual tissue.

INTRODUCTION: Mucoprotein plug formation within the pancreatic ducts is one of the early events of chronic pancreatitis (CP), but little is known about its pathogenesis. Recent evidence suggests impaired ion- and fluid secretion of pancreatic ductal epithelial cells (PDEC) in CP, which together with increased mucus secretion may alter mucus hydration and subsequently lead to plug formation.
AIMS & METHODS: We aimed to invesigate mucus secretion of PDEC in CP. Human and mouse pancreata were investigated. Human CP tissue samples were collected from surgically resected pancreata, whereas CP was induced by administration of 6x50μg/kg cerulein, 3 series/week for 4 weeks in mice. Morphometric analysis of mucus was carried out by CellF software. Total RNA was isolated from human and mouse tissue. The mRNA levels of different mucin subtypes were analysed by quantitative RT-PCR.
RESULTS: We found that mucus volume density (Vd_{muc}) of human PDEC was significantly higher in CP than in controls, in case of smaller ducts (ductal diameter $<100\mu m$: $1.21\pm0.13 nl/mm^2$ and $0.37\pm0.05 nl/mm^2$, respectively). Similarly, mouse PDEC showed significantly higher Vd_{muc} in CP than in controls, especially in ducts with smaller diameter (ductal diameter $<80\mu m$: $0.72\pm0.06 nl/mm^2$ vs. $0.005\pm0.0002 nl/mm^2$, ductal diameter $>80\mu m$: $0.075\pm0.020 nl/mm^2$ vs. $0.016\pm0.004 nl/mm^2$). Mucin gene expression analysis showed, that muc6 was ~1000-fold upregulated in mouse and 17-fold upregulated in human CP.
CONCLUSION: There is a substantial mucus hypersecretion in CP localized to the small ducts. Obstruction of the small ducts by mucus in CP may contribute to the pathogenesis of the disease. Supported by EPC Travel Fellowship.

INTRODUCTION: Alcohol consumption is the leading cause (70-90%) of chronic pancreatitis, which is known to be one of the major factors for pancreatic cancer pathogenesis. Pancreatic stellate cells (PSC) are known to play a key role in pathogenesis of chronic pancreatitis. It is known, that ethanol activates PSC

migration to pathological site of the pancreas. The effect of ethanol on PSC energy metabolism is unknown. The aim of our study is to investigate PSC growth change and energy metabolism under exposure to different alcohol concentrations.
AIMS & METHODS: Human PSC were extracted from pancreatic tissue obtained during pancreatic surgery. PSC were cultivated in Petri dishes in DMEM and F-12 media, containing 20% FBS with addition of Penicillin-Streptomycin. Immunofluorescence assay using beta-actin as primary antibody was performed for differentiation PSC from fibroblasts. Crystal violet test was performed using control cell group, 0.1%, 0.5% and 1% ethanol concentration. MTT assay was carried out to determine different alcohol concentration impact on the PSC viability. Oxygen consumption of PSC's was measured oxygraphically in cell media by using Oroboros-2K oxygraph (respiratory subtrates glutamate+malate).
RESULTS: Cultivated cells were beta-actin positive indicating presence of PSC, but not fibroblasts. Evaluating alcohol impact to the cell phenotype, we observed 0.5% alcohol induced cells were bigger compared to control. 0.1% and 1% ethanol concentration forced cell shrinking. MTT assay revealed that the best cell proliferation was achieved in PSC under pretreatment with 0.5% ethanol. Pretreatment of cells with 0.5% ethanol increased oxygen consumption by 34% as compared to control, i.e. activated energy metabolism, while low ethanol concentration (0.1%) had no effect. However, higher concentrations (1%) of ethanol decreased the pancreatic stellate cells respiration rate by 15% and 37% as compared to control and to 0.5% ethanol group, respectively. The 2.4-dinitrophenol uncoupled respiration rate was also found to be diminished (by 22%) after pretreatment with higher concentration (1%) of ethanol. Lower concentrations of ethanol (0.1-0.5%) had no effect on this parameter.
CONCLUSION: 0.5% ethanol concentration is the best PSC's promoter in the matter of growth and oxygen consumption, while other investigated concentrations seem to have opposite effect. Further studies are necessary to investigate the ways to reduce the activity of ethanol affected PSC's.

INTRODUCTION: Smoking represents an independent risk factor for the development of chronic pancreatitis, however, the pathomechanism remains unknown. Secretion of fluid and bicarbonate plays a crucial role in maintaining the integrity of the gland.
AIMS & METHODS: The aim of this study was to investigate the effects of cigarette smoke extract (CSE) on pancreatic ductal fluid secretion and on cystic fibrosis transmembrane conductance regulator (CFTR) Cl^- channel activity. Intra/interlobular pancreatic ducts were isolated from guinea pig pancreas. Basal and forskolin stimulated fluid secretion were measured by videomicroscopy, whereas, CFTR currents were detected by whole cell configuration of the patch clamp technique. CSE was prepared by smoking of 3 cigarettes into 40ml distilled water by a smoking machine and 10x (21μg/ml), 40x (5.25μg/ml) and 400x (0.5μg/ml) dilution of the extract were studied.
RESULTS: Administration of 5μM forskolin activated CFTR currents by 10-15-fold in magnitude. 15 min administration of 0.5, 5.25 and 21 μg/ml CSE inhibited the currents by 44%, 64.6% and 79.4%, respectively (n = 2-4). Concerning the fluid secretion, the basal volume of isolated intact pancreatic ducts in bicarbonate-free solution was considered to be 1.0. Administration of 25mM bicarbonate increased the relative luminal volume up to 1.57±0.02 (n = 7). Administration of 5 μM forskolin further increased the luminal volume to 1.87±0.1 (n = 16). Simultaneous administration of 21μg/ml CSE decreased fluid secretion by 24% (1.42±0.06; n = 12).
CONCLUSION: CSE inhibits pancreatic ductal fluid secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage.

INTRODUCTION: We have recently shown that chenodeoxycholate (CDC) in high concentration strongly inhibited ion transporters through the destruction of mitochondrial function in intact guinea pig pancreatic ducts. Since ursodeoxycholic acid (UDC) is known to protect the mitochondria against hydrophobic bile acids and have antiapoptotic effect, we investigated whether UDC is able to prevent the CDC-induced cell damage.
AIMS & METHODS: Intra-interlobular ducts were isolated from guinea pig pancreas. Ducts were then pretreated with UDC (0.1 mM and 0.5mM) for 5 h and 24 h and changes in intracellular Ca^{2+}concentration $[Ca^{2+}]_i$, ATP level $[ATP]_i$, pH $[pH]_i$, mitochondrial permeability transition pore (MPTP) opening were measured by microfluorometry. Mitochondrial transmembrane potential (MTP) was studied by confocal microscopy. Morphological changes of mitochondria were investigated by transmission electron microscopy. Expressions of bile acid transporters were studied by reverse transcriptase PCR (RT-PCR).
RESULTS: 5 h pretreatment with 0.1 or 0.5 mM UDC and 24 h pretreatment with 0.1 mM UDC did not significantly influence the effect of 1 mM CDC on duct cells. However, 24 h pretreatment with 0.5 mM UDC significantly reduced the rate of ATP depletion, mitochondrial injury, MPTP opening and the decrease of MTP induced by 1 mM CDC. In addition, 0.5 mM UDC prevented the inhibitory effect of CDC on the acid-base transporters, however, had no effect on the CDC-induced calcium signaling. mRNA expression of Slc10A1 and A2 was detected in the ducts by RT-PCR.
CONCLUSION: Our results indicate that protection of mitochondria with UDC administration may represent a novel option against bile acid-induced ductal injury.

INTRODUCTION: Liver and pancreas are supposed to have the common origin. There were publications by Rao et al. (1989) showing the possible appearance of hepatocyte-like cells in pancreas in copper-deficient diet model of pancreatic injury however the mechanisms of pancreatic regeneration in this model weren't described.
AIMS & METHODS: The aim of our work was to find out the possible sources of pancreatic tissue restoration in copper-deficient model of pancreatic injury. 24 white Wistar male rats (80-100 g weight) were maintained on copper-deficient diet (MP Biomedicals, USA) containing a relatively non-toxic copper-chelating agent, triethylenetetramine tetrahydrochloride (Tokyo Chemical Industry Co., Ltd, Japan) in final concentration of 0.6 % w/w and had unlimited access to water for 8 weeks, and then returned to normal rat chow for another 8 weeks (recovery phase). Control group animals were maintained on normal rat chow for the whole duration of experiment. Groups of 3 animals each were killed after 4, 6, and 8 weeks of copper-deficient diet and 4, 6, and 8 weeks after they returned to normal rat chow. Histological sections of pancreas were stained immunohistochemically using antibodies to insulin and glucagon.
RESULTS: After 4 weeks of copper-deficient diet we observed the signs of pancreatic acinar tissue injury, after 6 and 8 weeks of diet only few ducts and pancreatic islets were still present along with the almost total loss of acinar tissue. The same picture was observed 2 and 4 weeks after animals were returned to normal rat chow. Partial recovery of pancreatic acinar tissue was observed only at 6 and 8 weeks of recovery phase. In control group glucagon-positive cells were located predominantly on the periphery of pancreatic islets while insulin-positive cells occupied most central part of the islet. Staining with antibodies to glucagon after 2 and 4 weeks of copper-deficient diet revealed positive cells on the periphery of the islets; however there're some totally glucagon-positive islets as well as some separate glucagon-positive cells within the destroyed acinar tissue. Later on (6 and 8 weeks of copper-deficient diet and 2 and 4 weeks of recovery phase) few small totally glucagon-positive islets along with the larger islets with intense glucagon-positive staining on periphery and weaker staining in the central part of the islet were observed. Pancreatic acinar tissue seemed to be partially restored around the remaining/newly formed islets after 6 and 8 weeks of return to normal rat chow. Staining with antibodies to insulin was positive only in central parts of the islets at all terms of the experiment.
CONCLUSION: So we suppose that glucagon-positive progenitor cells can be probably the source of pancreatic islets and acinar cells restoration.

P1234 DIFFERENTIAL EFFECTS OF THE CENTRAL AND PERIPHERAL ADMINISTRATION OF OPIOIDS IN EXPERIMENTAL ACUTE PANCREATITIS IN RATS

B. Kui[1,*], Z. Balla[1], E.S. Kormányos[1], B. Iványi[2], T. Wittmann[1], P. Hegyi[1], A. Szabó[3], G. Horváth[4], T. Takács[1], Z.J. Rakonczay[1]

INTRODUCTION: Acute pancreatitis (AP) is often associated with severe pain, which causes discomfort and worsens the prognosis of the disease. Major analgetics (opioids) attenuate the pain associated with AP, but there are no experimental studies that investigated the effects and possible administration methods of analgesia on the severity of AP.
AIMS & METHODS: AP was induced by intraperitoneal (i.p.) administration of 3 g/kg L-ornithine in SPRD rats. Intrathecal (i.t.) catheter was implanted one

week before AP induction. 0.1-1 mg/kg i.p. or 0.01-0.03 mg/kg i.t. buprenorphine (or physiological saline) was administered one hour before AP induction. Control rats were injected i.p. or i.t. with physiological saline or buprenorphine one hour before the i.p. administration of physiological saline instead of L-ornithine. The animals were sacrificed after 24 hours. Laboratory (serum amylase activity, pancreatic dry/wet weight ratio) and histological (necrosis, oedema, inflammatory cell infiltration) parameters were measured.
RESULTS: I.p. and i.t. treatment with buprenorphine did not influence laboratory and histological parameters in the control group. In the AP groups, all of measured parameters were significantly elevated compared to control groups. Pretreatment of AP rats with i.p. administered buprenorphine significantly increased, whereas i.t. administration of the analgetic reduced all of the measured parameters compared to the AP groups pretreated with saline.
CONCLUSION: The different routes of opioid administration have varying effects on the pathogenesis of AP. Central administration of buprenorphine seems to have beneficial effects on the severity of experimental AP, however peripherally given opioids worsen the severity of the disease.

P1235 REVISION OF THE L-ARGININE-INDUCED EXPERIMENTAL PANCREATITIS MODEL IN MICE

E.S. Kormányos[1,*], B. Kui[1], Z. Balla[1], B. Iványi[2], T. Wittmann[1], P. Hegyi[1], T. Takács[1], Z. Rakonczay Jr[1]
[1]*First Department of Medicine,* [2]*Department of Pathology, University of Szeged, Szeged, Hungary*

INTRODUCTION: The pathogenesis of acute pancreatitis (AP) remains unknown and it has no adequate therapy. To investigate the pathomechanism, we rely on animal models such as L-arginine-induced AP, which is becoming increasingly popular. However, we found only mild inflammation in Balb/c and high mortality in FVB/n and C57BL/6 mouse strains with the originally published method (2x4 g/kg, 8% L-arginine).
AIMS & METHODS: We aimed to establish a basic amino acid-induced AP model with acceptable morbidity and mortality rate. AP was induced with different doses (2x4, 3x3, 4x2.5 g/kg) and concentrations (0-10%) of intraperitoneal L-arginine administration in Balb/c, FVB/n and C57BL/6 mice. Serum amylase-, pancreatic myeloperoxidase activity and oedema, necrosis, leukocyte infiltration were measured to determine AP severity. Our findings are represented as effectivity rate (ER = number of mice with AP/all treated mice).
RESULTS: In L-arginine treated groups, all parameters were significantly elevated compared to the control group. In all three strains, the injection with 3x3 or 4x2.5 g/kg L-arginine caused similar AP severity with lower mortality vs the 2x4 g/kg dose. In Balb/c mice, 10% L-arginine injection resulted in moderate morbidity and low mortality (ER = 90%). In FVB/n strain 5% L-arginine caused low mortality with severe AP (ER = 90%), while 10% L-arginine caused greater mortality (ER = 25%). C57BL/6 mice developed mild disease with low mortality due to 5% L-arginine (ER = 90%), however, disease severity and mortality were higher in case of 10% L-arginine administration (ER = 35%).
CONCLUSION: Mouse strains show different sensitivities to L-arginine and a fine borderline appears between effective and lethal doses and concentrations.

P1236 THE EFFECTS OF HMG-COA REDUCTASE INHIBITOR ON LIPOPOLYSACCHARIDE INDUCED ACTIVATION OF PANCREATIC STELLATE CELLS

H.S. Lee[1,*], **J.M. Lee**[1], J.J. Hyun[1], H.J. Kim[1], J.S. Kim[1], C.D. Kim[1]

INTRODUCTION: Pancreatic stellate cell (PSC) plays a crucial role in pancreatic fibrogenesis in chronic pancreatitis. Increased gut permeability has been described in acute and chronic pancreatitis with the effect of bacterial translocation across the mucosal barrier. Bacterial components such as lipopolysaccharide (LPS) may reach the bloodstream and pancreas. Islet cell dysfunction also develops during acute exacerbating stage and end stage of chronic pancreatitis. However little is known about the effect of LPS and hyperglycemia on PSC.
AIMS & METHODS: Aims: To investigate the effects of LPS and hyperglycemia on PSC activation and effects of simvastatin on LPS induced PSC activation.
Materials and Method: Primary cultures of rat PSCs were exposed to various concentrations of glucose and LPS with/without simvastatin. Quantification of proliferation was performed by Brd-U assay. PSC activation was assessed by expression of α-SMA and extracellular signal-regulated kinase (ERK) using Western blot.
RESULTS: Results: LPS induced activation and proliferation of PSC. However, glucose did not affect PSC proliferation. The proliferative effect of LPS on PSC was not affected by glucose concentration in culture media. Simvastatin inhibited LPS induced activation and proliferation of PSC. The proliferative effect of LPS was mediated by activation of Erk 1/2 pathway which was effectively inhibited by simvastatin.
CONCLUSION: Conclusion: This study shows that LPS is one of the activating factors toward PSC. Endotoxemia which is frequently encountered in the clinical settings of acute and chronic pancreatitis may act as a triggering factor for initiating and persisting pancreatic fibrosis. Simvastain could be a therapeutic agent for preventing pancreatic fibrosis.

P1237 THE ROLE OF HEAT SHOCK PROTEIN 70 IN PANCREATIC STELLATE CELLS

J.J. Hyun[1,*], J.M. Lee[1], H.J. Kim[1], J.S. Kim[1], H.S. Lee[1], C.D. Kim[1]

INTRODUCTION: The role of heat shock protein 70 (hsp70) in acinar cells (acute pancreatitis) and ductal cells (pancreatic cancer) has been extensively studied. However, the role of hsp70 in pancreatic stellate cell (PSC), an important cell responsible for desmoplastic reaction, is less well understood.
AIMS & METHODS: Aims: To investigate the role of hsp70 in PSC activation and proliferation.
Materials and Methods: PSCs were incubated at 42°C for 2hr and recovered at 37°C for 24hr in order to induce hsp70 expression. Cultured PSCs were treated with heat, PDGF, TGF-β, and LPS to measure α-SMA and hsp70 expression by Western blotting. Cell proliferation was measured by BrdU assay. Simvastatin and quercetin were used in order to inhibit PSC proliferation and hsp70 expression, respectively.
RESULTS: Overexpression of hsp70 did not affect cytokine induced α-SMA expression. Hsp70 expression was significantly increased with PDGF and to a moderate degree with LPS, but not with TGF-β. Similarly, PSC proliferation was also significantly increased by PDGF and to a lesser degree by LPS, but TGF-β did not induce PSC proliferation. Simvastatin suppressed hsp70 expression and PSC proliferation induced by heat or PDGF. Quercetin completely inhibited PDGF-induced hsp70 expression and cell proliferation and partly inhibited heat-induced effects. However, heat preconditioning which induces hsp70 expression had no additional effect on PDGF induced cell proliferation.
CONCLUSION: Hsp70 expression was closely related to cell proliferation in PSCs. Inhibition of hsp70 expression abolished or decreased the effect of PDGF and heat on cell proliferation. Therefore, modulation of hsp70 expression could be an effective therapeutic target for inhibition of pancreatic fibrosis.

INTRODUCTION: Chronic pancreatitis (CP) is a necroinflammatory process resulting in extensive fibrosis and loss of both exocrine and endocrine function. Granulocyte colony-stimulating factor (G-CSF), a hematopoietic stem cell mobilizer, has been shown an anti-fibrotic effect in liver partial through the enhancement of bone marrow (BM) cells into fibrotic liver[1]. In this study, we aim to test the effect of G-CSF on fibrosis in a mouse model of CP.
AIMS & METHODS: The BM from male green fluorescent protein transgenic C57Bl/6J mice was transplanted into irradiated female C57Bl/6J mice. CP was induced by consecutive caerulein injection (50ug/kg/day, two days a week) for 6 weeks. Mice were then treated with G-CSF (200ug/kg/day, 5 day a week) or normal saline for 1 week, and sacrificed at week 7 or week 9 after first caerulein injection. Pancreatic histology, collagen expression, myofibroblast and BM cells were evaluated to determine the effect of G-CSF in caerulein-induced CP.
RESULTS: The fibrosis was observed in the pancreatic tissues from mice with caerulein injection. The fibrosis was not induced by G-CSF alone. The degree of fibrosis and collagen were significantly decreased in the pancreas from mice with caerulein and G-CSF sacrificed at week 9, while there was no change observed at week 7. The number of myofibroblast in the pancreatic tissue was not changed between mice with or without G-CSF. However, the proportion of BM cells was significantly increased in the mice with G-CSF, suggesting a potential anti-fibrotic role of BM cells stimulated by G-CSF.
CONCLUSION: G-CSF administration contributes to the regression of pancreatic fibrosis at least partially through the enhanced migration of BM cells.

INTRODUCTION: The pathogenesis of acute pancreatitis (AP) is not well understood and the disease has no specific therapy. There is evidence that the L-kynurenic acid analogue SZR-72 has immune modulator roles in several inflammatory diseases. Therefore, we investigated its effects on experimental AP.
AIMS & METHODS: In the AP groups, male SPRD rats were injected intraperitoneally (i.p.) with 3 g/kg L-ornithine 1 hour after the administration of physiological saline (PS) or 30-300 mg/kg SZR-72 (n = 6-8). Control animals were injected i.p. with PS instead of L-ornithine and with 30-300 mg/kg SZR-72 or PS 1 hour afterwards (n = 6-8). Animals were sacrificed at 24 hours. Laboratory [serum amylase activity, pancreatic myeloperoxidase (MPO) activity, pancreatic dry/wet weight ratio (DW/WW)] and histological (necrosis, oedema, inflammatory cell infiltration) parameters were measured to evaluate disease severity.
RESULTS: The administration of 30-300 mg/kg SZR-72 did not influence serum amylase and pancreatic MPO activities, pancreatic DW/WW and histological parameters in the control groups. However, the injection of rats with L-ornithine significantly increased all parameters vs. the control groups. Pre-treatment of AP rats with 30 mg/kg SZR-72 did not have affect on disease severity. However, all measured laboratory and histological parameters were significantly reduced in AP animals in response to treatment with 300 mg/kg SZR-72.
CONCLUSION: Our experiments showed that SZR-72 has a dose-dependent effect on L-ornithine-induced AP. The administration of 300 mg/kg SZR-72 significantly ameliorated the severity of AP in rats. Further investigations are needed to determine the pathomechanism of SZR-72 action.

INTRODUCTION: The exact role and optimal timing for endoscopic retrograde cholangiopancreaticography (ERCP) for the management of acute biliary pancreatitis (ABP) remains a controversial topic.
AIMS & METHODS: The main aim of this study was to investigate any benefits early ERCP intervention may have in preventing the development of local and systemic complications due to ABP. Patients presenting to Türkiye Yüksek Ihtisas Teaching and Research Hospital (TYIH) between 1 January 2010 and 31 August 2011 with ABP, who underwent ERCP within 72 hours of the onset of symptoms were screened, and eligible patients were enrolled in the study. Patients were divided into 2 groups based on timing of ERCP (24 hour group: ERCP performed within 24 hours; 24-72 hour group: ERCP performed 24-72 hours after onset of symptoms), and comparisons between both groups were made in terms of patient characteristics, severity of pancreatitis, and local/systemic complications.
RESULTS: A total of 59 patients were included in the final analysis, for 32 of which ERCP was performed in the first 24 hours, while in the remaining 27 patients endoscopic intervention was undertaken 24-72 hours after the onset of symptoms. There was no difference between the 24 hour and 24-72 hour groups with regards to biliary stone detection rate (84.4% vs. 71.4% p = 0.196). However, impacted stones at the papilla were observed more frequently in the 24-hour group compared to the 24-72 hour group (50% vs. 11.1%; p = 0.006). Severity of pancreatitis, rate of pancreatitis-related complications, computed tomography severity index scores and durations of hospital stay were similar in both groups. The only deaths were observed in 2 (3.3%) patients in the 24-hour group.
Table 1. Comparison of disease severity between groups according to different scoring systems

	First 24 hours group n = 32 (%)	24-72 hours group n = 27 (%)	p-value
Ranson score			
≤2 – mild	25 (78.1)	22 (81.5)	0.750
3-5 – moderate	7 (21.9)	5 (18.5)	
mGPS			
≤2 – mild	25 (78.1)	21 (77.8)	0.974
>2 – severe	7 (21.9)	6 (22.2)	
CTSI*			
0-3	24 (92.3)	12 (85.7)	0.803
4-6	1 (3.8)	1 (7.1)	
7-10	1 (3.8)	1 (7.1)	
Organ failure**			
At least one organ	7 (21.9)	6 (22.2)	0.974
Hypotension	2 (6.3)	1 (3.7)	0.565
Acute renal failure	3 (9.4)	4 (14.8)	0.403
Respiratory failure	2 (6.3)	2 (7.4)	0.627
24-48. hour CRP, mg/L	59.95 (3.36-268	114.5 (6.26-271)	0.242
Length of hospital stay, days	5 (3-12)	7 (3-30)	0.122

MGPS, modified Glasgow prognostic score;CTSI, computerized tomography severity index; *calculated for 26 patients in the 24-hour group and for 14 patients in the 24-72 hour group, CRP, C-reactive protein,**based on Atlanta criteria
CONCLUSION: In our study, we could not demonstrate any added benefit of ERCP performed within 24 hours comparing with 24-72 hours of the onset of symptoms with regards to local and systemic complications of ABP. Undertaking early endoscopic intervention, however, increases the likelihood of detecting an impacted stone at the papilla, the delayed management of which may increase the risk for cholangitis. Early ERCP in patients with ABP is effective and safe, and may be recommended in the presence of cholangitis and persistent biliary obstruction.

INTRODUCTION: While factors like older age and greater severity of the initial disease cannot be influenced to reduce the readmission rate for pancreatitis, variables like alcohol-, tobacco- and substance abuse should be addressed in outpatient programs to reduce disease recurrence and readmission rate for pancreatitis.
To study positive and negative predictive factors for hospital readmissions of patients after in-hospital treatment for pancreatitis.
AIMS & METHODS: Data from patient records and reimbursement information of the years 2006 – 2011 were evaluated for 606 hospital admissions for pancreatitis (373 patients). 973 patient variables, 611 secondary diagnoses, and 295 different procedures (OPS) were assessed by bivariate and multivariate analysis.
RESULTS: The readmission rate of pancreatitis patients during the first 30 days after discharge was 15 %, over the entire study period 29 %. The best predictors for readmission were, when present during the initial episode, concomitant liver disease (OR 12.8; C31.5-111), a suspected tumor of the pancreas (OR 10; C31.1-92), alcohol- (OR 5.4; C32-13), tobacco- or substance-abuse or mental illness. Patients with pseudocyst formation or who had undergone contrast enhanced CT were also more frequently readmitted. Lower than average readmission rates were found when pancreatitis was treated in connection with decompensated diabetes or gallstone disease.
CONCLUSION: While factors like older age and greater severity of the initial disease cannot be influenced to reduce the readmission rate for pancreatitis, variables like alcohol-, tobacco- and substance abuse should be addressed in outpatient programs to reduce disease recurrence and readmission rate for pancreatitis.

INTRODUCTION: Early identification of patients at risk for severe acute pancreatitis (SAP) is an essential step to guide an intensive care and to improve outcomes.
AIMS & METHODS: Because the severity of acute pancreatitis (AP) was reclassified, we aimed to compare the prognostic value of various predictors including procalcitonin (PCT), C-reactive protein (CRP), CT severity index (CTSI), and complex scoring systems (BISAP, Ranson's, APACHE-II score) according to revised Atlanta classification. Between March 2010 and September 2013, 152 patients with AP were prospectively enrolled. CRP and PCT were obtained on admission, and various scoring systems including Ranson's, APACHE-II, BISAP and CTSI were calculated.
RESULTS: There were 152 patients with AP (mean age 51.3 ± 18.5, 63.2 % male), of which 45 patients (30%) was classified as moderately SAP and 17 patients (11%) SAP. In patients with moderately severe to SAP, PCT (on admission, > 0.5 ng/ml, AUC 0.61, CI 0.51-0.70), CRP 2d (24 hours after admission, > 10 mg/dl, AUC 0.64 CI 0.55-0.67) BISAP (score ≥3, AUC 0.60, CI 0.51∼0.70), Ranson's (score ≥3, AUC 0.65, CI 0.56∼0.76), APACHE-II (score ≥8, AUC 0.61, CI 0.52∼0.70), and CTSI (score ≥3, AUC 0.79, CI 0.72∼0.87) were significant predictors compared to mild AP. Multivariate analysis showed that CTSI (sensitivity 63%, specificity 84%, OR 11.5, CI 4.7-27.8, $p<0.01$), APACHE-II (sensitivity 32%, specificity 88%, OR 3.7, CI 1.2-11.6, $p=0.028$), and CRP 2d (sensitivity 39%, specificity 90%, OR 4.6, CI 1.6-13.6, $p<0.01$) were strongly related to moderately severe and SAP. In patients with SAP compared with mild to moderately SAP, PCT (AUC 0.79, CI 0.67-0.92), BISAP (AUC 0.66, CI 0.50∼0.82), Ranson's (AUC 0.76, CI 0.65∼0.88), and APACHE-II (AUC 0.72, CI 0.57∼0.86) were significant predictors. On multivariate analysis using them, PCT (sensitivity 75%, specificity 82%, OR 5.8, CI 1.4-24.2, $p=0.015$) was only strongly associated with SAP.
CONCLUSION: According to revised Atlanta classification, various biological and structural scoring system had different prognostic value for predicting severity of AP. In patients with SAP, the best efficiency in the early prediction would be achieved by the measurements of PCT. However, in case of moderately to severe AP, CTSI, APACHE-II and CRP 2d act as a valuable predictors for severity of them.

P1243 COMPLEX TREATMENT OF INTRAABDOMINAL HYPERTENSION IN PATIENTS WITH ACUTE PANCREATITIS

I. Kolosovich[1,*], V. Teplyi[1], A. Lutsiv[1], A. Kolosovych[1]
[1]*Surgery Department #2, O. Bohomolets National Medical University, Kyiv, Ukraine*
Contact E-mail Address: *kolosovich_igor@mail.ru*

INTRODUCTION: Abdominal compartment syndrome (ACS) is a serious problem in acute inflammatory diseases of the abdominal cavity. Causing severe changes in organs and tissues, this pathology is responsible for the up to 42% lethality (1). Acute pancreatitis (AP) occupies a special place among acute abdominal pathology. In case of wide-spread pancreatic and peripancreatic necrosis it can cause development of life-threatening complications, among which special subject of the interest is severe intra-abdominal hypertension (IAH)(2).
AIMS & METHODS: The purpose of this study was to use antiflatulents in complex treatment of IAH in patients with AP to prevent the development of ACS. We observed 35 patients with AP, in whom IAH of varying severity (according to classification of J. M. Burch et al.,1996) was identified at admission. Males were 21 (60%), females – 14 (40%). Age of the patients ranged from 24 to 58 years, averaging 38.6±1.2 years. We monitored intra-abdominal pressure (IAP) by measuring the bladder pressure (BP). First grade of IAH was detected in 12 patients (34.3%), second grade – in 18 (51.4%), third grade – in 5 (14.3%). With the help of ultrasonography liquid in omental bursa was found in all patients, in 13 of them – fluid in the abdominal cavity (enzymatic peritonitis). Complex conservative treatment of the 15 patients with AP (42.9%) corresponded to guidelines from the World Society of the ACS: insertion of nasogastric tube; prokinetic agents; intraabdominal catheter drainage (3 patients), epidural block; antisecretory and detoxification therapy and early enteral nutrition (Group 1). In 20 patients (57.1%) antiflatulent (50 Espumisan emulsion droplets in the probe for enteral feeding thrice daily) was added to diminish IAH (Group 2).
RESULTS: Complex conservative treatment in 60% of group 1 patients normalized bowel function (decreased bloating and flatulence, spontaneous defecation) during a week period. Monitoring of BP demonstrated significant decrease of IAP in 8 of them (53.3%): in 5 of the 7 patients (71.4%) with first grade IAH, 2 of 6 patients (33.3%) with II grade IAH and one of the two patients (50%) with IAH of III grade. Additional use of Espumisan emulsion allowed restoration of bowel function in similar terms in 90% of patients in group 2. In latter group normalization of IAP was achieved in 17 people (85%): in all 6 patients with first grade IAH, in 9 of 11 patients (81.8%) with second grade IAH and in 2 of 3 patients (66.7%) with third grade IAH ($p<0.05$). Conservative measures did not permit to normalize the IAP in 2 patients of every group whom then decompressive laparotomy was performed.
CONCLUSION: Complex conservative treatment of IAH including antiflatulents in patients with AP effectively normalizes bowel function, and thus decreases IAP in significantly more patients (85.0% versus 53.3% in the control group). The majority of patients could be avoided from the development of ACS.

P1244 RISK FACTORS FOR INFECTION AFTER ENDOSCOPIC ULTRASONOGRAPHY-GUIDED DRAINAGE OF SPECIFIC TYPES OF PANCREATIC AND PERI-PANCREATIC FLUID COLLECTIONS

J. Guo[1,*], S. Sun[1]
[1]*Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang, China*
Contact E-mail Address: *guojt@sj-hospital.org*

INTRODUCTION: Endoscopic ultrasonography (EUS)-guided drainage is a widely-used treatment modality for specific types of pancreatic and peri-pancreatic fluid collections (PFCs). The complication of infection have been reported. It is recommended that the infection rate should be assessed by measuring risk factors.
AIMS & METHODS: Aims: The objectives were to measure whether the risk of infection after endoscopic ultrasound guided drainage was associated with (1) patient-related factors and (2) procedure-related factors.
Methods: A total of 83 patients were eligible for inclusion in this study from September 2005 through November 2012. EUS-guided drainage was performed in all patients. The complication of infection was observed. The data on patient-related factors, and procedure-related factors were collected. Patient-related factors mainly included age, sex, etiology of PFCs, location of the cyst, cyst diameter, and so on. Procedure-related factors mainly included approach of EUS-guided drainage and stent diameter. Separate multivariate logistic regression models for all EUS-guided drainage were carried out.
RESULTS: Complete EUS-guided drainage was achieved in all patients (100%). A definitive diagnosis of infection after EUS-guided drainage was made in seven patients. All seven patients had a history of acute pancreatitis, and the cyst diameters were all > 15 cm. Three patients suffered from diabetes mellitus.
CONCLUSION: Acute pancreatitis and cyst diameter were the relevant independent risk factors for infection after EUS-guided drainage. Furthermore, cyst diameter was an independent risk factor for infection. Additional stent placement or using double flanged metal stents may be useful to avoid infection.

P1245 THE EFFECT OF ASPIRIN USE ON SEVERITY OF ACUTE PANCREATITIS IN HOSPITALIZED PATIENTS

N. Poowanawittayakom[1,*], M. Flicker[1]
[1]*Internal Medicine, Advocate Illinois Masonic Medical Center, Chicago, United States*
Contact E-mail Address: *nongnoochmd@gmail.com*

INTRODUCTION: Acute pancreatitis is a common gastrointestinal disease often seen in daily practice. Although the precise mechanism of pancreatitis is still not fully understood, it is believed that the inflammatory response via phospholipase A2, cyclogenase, and neutrophils plays a role. Aspirin is a commonly used NSAID, most notably prescribed for cardiovascular diseases such as stroke, myocardial infarction, and select groups of patients with atrial fibrillation. The aim of this study was to examine the effect of aspirin use on the severity of acute pancreatitis.
AIMS & METHODS: A total of 135 patients with the diagnosis of acute pancreatitis were included in this retrospective study. Relevant clinical data were collected. Patients were divided into two groups according to aspirin use or non-use and the severity of acute pancreatitis was compared. Severe pancreatitis was defined as a Ranson score at any time ≥ 3. Appropriate descriptive statistics

and statistical tests were performed. Statistical significance was defined as a p value < 0.05.
RESULTS: The cohort consisted of 58% (78 of 135) men with a mean (SD) age of 50 (18) years. Of the 135 patients, 4 (2.96%) had gallstone pancreatitis, 4 (2.96%) had alcoholic pancreatitis, and 127 (94.07%) had pancreatitis of unknown etiology. Median (interquartile range) Ranson score on admission and 48 hours afterwards were 2 (1.3) and 1 (0.2), respectively. On admission, there was no statistically significant difference in aspirin user group and non-aspirin user group between the mild-to-moderate acute pancreatitis group and the severe acute pancreatitis group (Table 1). Likewise, at 48 hours after admission, the percentage of patients with aspirin use was not statistically different ($p = 0.678$) between the two severity groups as shown on Table 2. Multivariable regression analysis showed that female gender was the only independent variable associated with a higher severity of pancreatitis ($p = 0.046$)
CONCLUSION: This pilot study demonstrates that aspirin use has no effect on decreasing the severity of acute pancreatitis. Female gender was associated with a higher severity of acute pancreatitis in the first 48 hours after admission. This association has never been identified in prior studies. Obesity, however, which has previously been found to be associated with a higher severity of pancreatitis was not identified as a predictor for the severity of acute pancreatitis in this study.

P1246 MEAN PLATELET VOLUME AND OTHER INFLAMMATORY MARKERS IN PATIENTS WITH ACUTE PANCREATITIS

Y. Okuturlar[1,*], A. Soylu[2], O. Harmankaya[1], S. Cakmak[2], H. Ozkan[1], B. Oztosun[1], I. Utku[1], S. Sayilan[2], U. Ure[1], B.A. Kumbasar[1]
[1]*Internal Medicine,* [2]*Gastroenterology, Bakirkoy Dr Sadi Konuk Research and Training Hospital, Istanbul, Turkey*

INTRODUCTION: Acute pancreatitis (AP) induced by different etiological factors is a pancreatic inflammation which is caused by the activation of pancreatic enzymes. The pancreas can usually heal itself without any local and systemic complications. No single laboratory markers are pathognomonic for AP. Mean platelet volume (MPV) has been investigated as an indicator of inflammation and related in several inflammatory diseases. In our study, we aimed to investigate the relationship between white blood cells (WBC) and C-reactive protein (CRP) which are the indicators of AP inflammation and MPV.
AIMS & METHODS: All the data from the 84 (male/female: 51/33) patients diagnosed by non-biliary acute pancreatitis (NBAP) were evaluated. The patients included in this study were diagnosed by clinically, laboratory methods (three times increase in amylase and lipase) and imaging. The symptoms of the patients at the first visit, the findings of the laboratory results and imaging were compared with the values at the time of discharge. The levels of MPV, WBC and CRP of the NBAP patients were compared with the control group (male/female: 53/47) at the first admission and discharge.
RESULTS: The mean age was 50.02 ± 17.69 years and 41.11 ± 10.46 years for NBAP and control group, respectively and there was no age and gender significant difference between groups ($p > 0.05$). WBC levels of the NBAP group at onset ($12.48 \pm 5.93/mm^3x10^3$) and remission ($7.54 \pm 2.4/mm^3x10^3$) were higher than the control group ($6.43 \pm 1.49/mm^3x10^3$) ($p = 0.0001$ for both groups). MPV levels of the NBAP group at onset (8.07 ± 1.07 fL) and remission (8.55 ± 1.05 fL) were lower than the control group (8.99 ± 0.94 fL) ($p = 0.0001$; $p = 0.003$). The mean CRP value was 10.46 ± 10.39 mg/dl at onset; however it dropped to the value of 3.48 ± 4.96 mg/dl at remission. CRP values of onset and remission were higher than the control group (0.47 ± 0.66 mg/dl) ($p = 0.0001$ in both groups) (Table 1). When the cut-off value of MPV was taken smaller than 8 fL in the ROC analysis, the sensitivity and specificity were found 54.7% and 86.8%, respectively (AUC: 0.74, $p < 0.001$).
CONCLUSION: In NBAP patients, the WBC and CRP values were higher at the initial phase of the disease than the healing phase. The MPV value was low at the first examination in which the inflammation was high; it was higher in the healing phase of the disease. In NBAP patients, the increase in MPV values during the healing phase shows that there is a decrease in the inflammation and the remission phase has started.

P1247 MARKED IMPROVEMENT IN PANCREATIC CANCER SURVIVAL – A SINGLE CENTER EXPERIENCE

A. Hann[1,*], W. Bohle[1], W. Zoller[1]
[1]*Department of Internal Medicine and Gastroenterology, Katharinenhospital, Stuttgart, Germany*
Contact E-mail Address: *a.hann@klinikum-stuttgart.de*

INTRODUCTION: Pancreatic cancer has a poor prognosis with a 5-year survival rate of less than 5%. Most patients are diagnosed in a locally advanced or metastatic state. Chemotherapy regiments have changed since the introduction of survival prolonging polychemotherapies like FOLFIRINOX (5-Fluoruracil, Oxaliplatin, Irinotecan and Leucovorin). In this retrospective study we analyzed the overall survival of patients diagnosed with locally advanced or metastatic pancreatic adenocarcinoma who were treated at our community-based hospital during the past ten years. We compared patients diagnosed with pancreatic cancer before (historical control) and after the introduction of FOLFIRINOX in 2011.
AIMS & METHODS: We retrospectively identified patients with pancreatic cancer who were treated at our hospital from 2011 to July 2013 by our cancer center registry. Patients treated in the years 2003 to 2010 (historical control) were identified using the diagnosis-related group C25 (malignant neoplasm of pancreas). Patients were included if pancreatic adenocarcinoma in a locally advanced or metastatic state was diagnosed and if at least one cycle of chemotherapy was given. Survival was assessed until February 2014.
RESULTS: 107 patients met the inclusion criteria. Of the 74 patients in the historical control group 62 patients received Gemicitabine, 6 Gemcitabine combined with Erlotinib, 5 Gemcitabine combined with Oxalipaltin and one 5-Fluoruracil as the first line chemotherapy. Of the 33 patients diagnosed between 2011 and July 2013, 15 patients received FOLFIRINOX, 17 Gemcitabine and one patient Oxaliplatin as the first line chemo therapy. 45 out of the 74 patients in the historical control group died and 29 were lost to follow-up. 12 out of the 33 patients in the group diagnosed from 2011 died, 10 were lost to follow-up and 11 were alive until February 2014. Mean of combined time of survival and lost to follow-up revealed 9.2 months (95% CI, 7.4 to 11.0) in the historical control group and 12.7 months (95% CI, 9.8 to 15.6) in the group diagnosed from 2011. Estimated mean survival using Kaplan-Meier was 14.2 months (95% CI, 10.4 to 17.9) in the historical control group and 20.1 months (95% CI, 16.1 to 24.1) in the group diagnosed from 2011. Comparison of the survival curves between the two groups using the log-rank test showed $p = 0.005$.
CONCLUSION: This retrospective study presents a marked improvement in survival of patients diagnosed with locally advanced or metastatic adenocarcinoma of the pancreas in a community-based hospital during the past three years. A possible contributing reason is the use of new polychemotherapies.

P1248 EXOCRINE PANCREATIC INSUFFICIENCY IN PATIENTS WITH PANCREATIC OR PERI-AMPULLARY CANCER: A SYSTEMATIC REVIEW

D.S. J. Tseng[1,*], H.C. van Santvoort[1], I.H. Borel Rinkes[1], I.Q. Molenaar[1]
[1]*Dept. of Surgery, University Medical Center Utrecht, Utrecht, Netherlands*

INTRODUCTION: Exocrine pancreatic insufficiency may occur due to loss of pancreatic parenchyma or obstruction of the pancreatic duct. This may occur in pancreatic or peri-ampullary cancer, both before and after resection. The prevalence and natural course of exocrine pancreatic insufficiency in these patients has not been thoroughly studied.
AIMS & METHODS: The aim of this study was to determine the prevalence of exocrine pancreatic insufficiency in patients with pancreatic or peri-ampullary cancer.
We systematically reviewed the literature published up to February 20th 2014, according to the PRISMA guidelines. We included studies reporting on exocrine pancreatic insufficiency in patients with pancreatic or peri-ampullary cancer. Studies reporting on exocrine pancreatic insufficiency due to other causes and focusing solely on a diagnostic test were excluded. Data on baseline characteristics, type of pancreatic resection, diagnostic test for exocrine pancreatic insufficiency and occurrence of exocrine pancreatic insufficiency were extracted. Prevalence of exocrine pancreatic insufficiency was calculated from these data.
RESULTS: After screening 3203 articles, 9 observational cohort (4 prospective, 5 retrospective) studies were included on a total of 664 patients. Of these patients 333 (50%) underwent pancreatoduodenectomy, 23 (3%) total pancreatectomy, 114 (17%) distal pancreatectomy and 194 (33%) no resection due to locally advanced pancreatic cancer. Median preoperative prevalence of exocrine pancreatic insufficiency was 44% (range 42-67%) before pancreatoduodenectomy; 20% (16-67%) before distal pancreatectomy; 63% before total pancreatectomy; and 50% in unresectable patients. The median prevalence of exocrine pancreatic insufficiency at least 6 months postoperative was 84% (36-100%) after pancreatoduodenectomy; 67-80% after distal pancreatectomy; and 100% after total pancreatectomy.
CONCLUSION: Exocrine pancreatic insufficiency is frequently seen in patients before resection for pancreatic or peri-ampullary cancer. The prevalence increases markedly following resection.

INTRODUCTION: In pancreatic cancer, abdominal dissemination is one of the most important determinants of prognosis. To date, there have been few studies on which surgical findings are relevant to abdominal dissemination, so we retrospectively analyzed patients who underwent surgery for pancreatic cancer.
AIMS & METHODS: We included 145 patients who underwent surgery for pancreatic cancer at our institution between January 2006 and October 2013 in this study. The patients were divided into 2 groups based on whether abdominal dissemination was found during surgery. Abdominal dissemination was defined as the existence of disseminated nodules on the peritoneum or the surface of the liver and confirmed pathologically. We analyzed the 2 groups with respect to patient characteristics, cancer stage, washing cytology results, tumor location [head of pancreas (Ph) / uncinate process of pancreas (UP) or body of pancreas (Pb) / tail of pancreas (Pt)], vascular invasion [portal vein or its branches (PV invasion), superior mesenteric artery, celiac artery, or their branches (arterial invasion)], and whether preoperative endoscopic ultrasonography-guided fine needle biopsy (EUS-FNA) was performed.

RESULTS: Fourteen patients had abdominal dissemination (dissemination group), and 131 patients did not (non-dissemination group). In patients' background, the number of diagnostic laparoscopic procedures was significantly higher in the dissemination group than in the non-dissemination group ($p<0.001$), and there were significant differences in the 2 groups in cancer stage ($p<0.001$). Univariate analysis revealed that the number of positive washing cytology results, tumor located in Pb/Pt, PV invasion, and arterial invasion were significantly higher in the dissemination group than in the non-dissemination group ($p<0.001$, $p=0.002$, $p=0.035$, and $p=0.012$, respectively). The number of EUS-FNA procedures was similar in the 2 groups ($p=0.208$). Multivariate analysis revealed that more patients in the dissemination group had positive washing cytology compared to the non-dissemination group ($p<0.001$), and more patients in the dissemination group tended to have arterial invasion compared to the non-dissemination group ($p=0.059$).
CONCLUSION: We observed a significant relationship between abdominal dissemination and positive washing cytology. Arterial invasion may also be relevant to abdominal dissemination in pancreatic cancer.

P1250 SERUM CA 19-9 AS SCREENING TEST FOR PANCREATIC CANCER IN NEW ONSET DIABETIC PATIENTS

J.S. Kim[1,*], J.W. Choe[1], **H.J. Kim**[1], M.K. Joo[1], J.-J. Park[1], Y.-T. Bak[1]
[1]*Korea University Guro Hospital, Internal Medicine, Seoul, Korea, Republic Of*
Contact E-mail Address: *hjkimmd@korea.ac.kr*

INTRODUCTION: Patients with diabetes newly detected within 2 years have higher risk of pancreatic cancer than general population. The need of screening is suggested and CA19-9 is the only available biomarker for pancreatic cancer, however it is unknown in these patient.
AIMS & METHODS: The aim of this study was to evaluate the usefulness of CA 19-9 as a screening test for pancreatic cancer in the new onset diabetes patients. We retrospectively reviewed medical records of 9.584 patients with new onset (< 2yrs) diabetes from January 2004 to January 2013. Independent t-test, Kai square test, and ROC curve analysis were used to identify clinical features and usefulness of CA 19-9 as a screening test in diabetic patients.
RESULTS: Total 1465 patients were analyzed (male; female = 877;588, mean age was 62.1 yrs). Total 40 cases of pancreatic cancer (2.7%) were occurred but 1.425 patients did not show pancreatic cancer. Their mean age was 58.2 and 62.3 respectively ($p=0.019$). 279 patients were CA 19-9 high group and 1186 patients were low group. There was no significant difference in basal characteristics between two groups. In high group, 9.7% (27/279) developed pancreatic cancer and only 1% (13/1186) in low group. Compared with low group, a significant risk of pancreatic cancer was observed in CA19-9 high group ($p<0.001$). Pancreatic cancer patients with new onset diabetes showed higher CA 19-9 level than non-cancer patients (1744 vs. 33U/mL, $P<0.01$). When setting CA 19-9 cut off value as 37.05U/mL, sensitivity was 67.5% and specificity was 83.1%.
CONCLUSION: CA 19-9 is suggested as a screening test for pancreatic cancer in newly diagnosed diabetic patient.

INTRODUCTION: Pancreatic cancer is a leading cause of death in Europe with more than 100 000 deaths in 2012. Surgery remains the only curative option. Whereas extended surgery with venous resection have been demonstrated to be safe and may contribute to improvement of patient survival, arterial resection remains a controversy because of a high related morbidity.
AIMS & METHODS: Retrospective review of prospectively collected data on 18 patients who had pancreatectomy for malignant tumor with arterial resection between October 2008 and september 2013 at our institution. The main end point was postoperative outcome and secondarily the need for new interventional procedure.
RESULTS: The most common type of resection was total pancreatectomy (TP) in 10 cases, followed by pancreaticoduodenectomy (PD) in 8 cases and distal pancreatectomy in 2 cases. There were 15 arterial resection: 3 celiac trunk, 6 superior mesenteric and 9 hepatic artery. In 10 cases, resections were planned. Unplanned arterial resection was done in 8 cases, 3 because of intraoperative arterial injury and 5 because of tumour adhesions discovered intraoperatively. 2 patients had grade $\geq$ IIIb post operative complications including 1 pancreatic fistula. 4 patients required an interventional procedure, 3 were interventional radiology and 1 had surgery. Hospital and 30 day mortality was 0%. Mortality at 90 days occurred in one patient. Fifteen patient had pancreatic duct adenocarcinoma (pT3 = 14, pT2 = 1; R1 = 7), and 3 patients had neuroendocrine carcinoma (pT3N+ = 2, pT1N+ = 1; R1 = 0). In case of adenocarcinoma (n = 15), overall survival and disease free survival was respectively 24 months [2.6-63.5] and 14.3 months [2.6-61.2]. 10 patients had distant metastasis, 2 aptients had local recurrence.
CONCLUSION: In selected patients and after eventually neoadjuvant chemotherapy, pancreatectomy with arterial resection is associated to low morbidity. Overall survival and disease free survival are acceptable. In case of arterial resection, surgery is more radical with high rate of R0 and low rate of local recurrence.

P1252 ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION OF SOLID PANCREATIC MASSES: IMPACT ON MANAGEMENT STRATEGY

L.C. Lourenço[1,*], A. Oliveira[1], C.G. Rodrigues[1], D. Horta[1], J. Reis[1], J.M. Pontes[1], J.R. Deus[1]
[1]*Serviço de Gastrenterologia, Hospital Prof. Dr. Fernando Fonseca, Amadora, Portugal*
Contact E-mail Address: *luisclourenco@gmail.com*

INTRODUCTION: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is a safe and accurate technique for diagnosing pancreatic cancer. However, few studies investigated its impact for management of these patients.
AIMS & METHODS: AIM: To investigate the diagnostic yield and the impact of EUS-FNA in the management of solid pancreatic masses. METHODS: All patients who underwent EUS-FNA for a solid pancreatic mass between June 1st 2011 and December 31st 2013 were included. Aspirates were placed onto glass slides for cytological examination and microbiopsies were fixed for histology. The impact on clinical management was analysed prospectively according to different endpoints, such as its impact on indications for chemotherapy, surgery or appropriate follow-up modality.
RESULTS: Forty-five patients were included; two procedures were considered failures. A final diagnosis was obtained in 43 patients. The sensitivity, specificity and accuracy of combined cytology and histology for the diagnosis of malignant or potentially-malignant tumours were 89.2%, 100% and 90.7%, respectively. The sensitivity and accuracy of cytology alone were significantly higher than those of histology alone ($p<0.05$). There were no complications related to the procedure. By intention-to-diagnose analysis, EUS-FNA directly influenced the management strategy in 33 of 45 patients (77%).
CONCLUSION: In patients with pancreatic mass and suspected malignancy, EUS-FNA provides an accurate diagnosis in approximately 90% of cases. EUS-FNA can directly influence the management in three-fourths of patients.

P1253 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION FOR PANCREATIC SOLID LESIONS – CYTOLOGICAL PREPARATIONS VERSUS CELL BLOCK SECTIONS

L. Elvas[1,*], D. Brito[1], R. Carvalho[1], M. Areia[1], S. Alves[1], S. Saraiva[1], J.M. Pontes[1], A.T. Cadime[1]
[1]*Gastroenterology, Portuguese Institute of Oncology of Coimbra, Coimbra, Portugal*

INTRODUCTION: Endoscopic ultrasound (EUS) enables imaging of the pancreas with high resolution; however, it is not enough to distinguish between benign and malignant lesions. EUS-guided fine-needle aspiration (EUS-FNA) allows obtaining a tissue sample from pancreatic lesions for cytological or histological diagnosis.
AIMS & METHODS: The aim was to evaluate the diagnostic accuracy of EUS-FNA for solid pancreatic lesions, comparing the cytological preparations and cell block sections. We performed a retrospective study of EUS-FNA procedures for pancreatic solid lesions performed between January 2006 and December 2013. The diagnosis was established with cytology alone, cell block alone or both. Final diagnosis was based on clinical and imaging follow-up and/or surgical pathology.
RESULTS: Eighty-six EUS-FNA were performed in 84 patients (46 men; mean age 63 $\pm$ 11 years), using a 22-gauge needle. Median number of needle passes per procedure was 3. More than half of the lesions (56%) were located in the pancreatic head and median lesion size was 30mm [11-103]. Tissue samples were collected for both cytological preparations and cell block sections in 75 procedures (87%). Sensitivity, specificity and accuracy were 84%, 62% and 80%, respectively, for cytology alone, and 81%, 100% and 83% for cell blocks alone. EUS-FNA results that relied on both techniques had 90% sensitivity, 83% specificity and 89% accuracy.
Cytology revealed 5 malignancies not diagnosed on cell blocks, while cell blocks revealed 7 malignancies not diagnosed by cytology. There were 3 procedure-related minor complications (3.5%) but there was no mortality associated with the technique.
CONCLUSION: Our study revealed that EUS-FNA is a safe procedure with a high diagnostic accuracy for pancreatic solid lesions. Combination of cytological

preparations and cell block sections improved EUS-FNA accuracy, showing that collecting tissue samples for both techniques should be tried in every procedure.

P1254 FEEDING PATIENTS WITH GASTRIC OUTLET OBSTRUCTION UNDERGOING PANCREATODUODENECTOMY: ROUTINE TUBE FEEDING VERSUS EARLY ORAL FEEDING

A. Gerritsen[1,2], **R.A. Wennink**[1,*], I.Q. Molenaar[1], I.H. Borel Rinkes[1], D.J. Gouma[2], O.R. Busch[2], M.G. Besselink[2]
[1]*Department of Surgery, University Medical Center Utrecht, Utrecht,* [2]*Department of Surgery, Academic Medical Center, Amsterdam, Netherlands*
Contact E-mail Address: *rooswennink@gmail.com*

INTRODUCTION: Early oral feeding is nowadays considered the optimal routine feeding strategy after pancreatoduodenectomy (PD). However, 33-45% of patients develop delayed gastric emptying (DGE) after PD, usually requiring nutritional support. It is suggested that patients with preoperative symptoms of gastric outlet obstruction (GOO) have such a high risk of developing DGE that GOO represents one of the few remaining indications for routine postoperative tube feeding.
AIMS & METHODS: The aim of this study was to determine the association between preoperative GOO and postoperative DGE. We also compared routine postoperative tube feeding with early oral feeding in patients with GOO undergoing PD.
A multicentre retrospective cohort study was performed in all consecutive patients undergoing PD in two tertiary referral centres between 2010 and 2013. GOO was defined as two or more of the following preoperative symptoms: nausea, vomiting, loss of appetite, dysphagia, or postprandial complaints (abdominal pain, early satiation, or bloating). Patients with GOO were categorized into two groups based on the applied feeding strategy: routine postoperative tube feeding or protocolized early oral feeding (with on-demand tube feeding). Primary outcome was the time to resumption of an adequate oral intake.
RESULTS: Of 421 patients undergoing PD, 61 (15%) suffered from preoperative symptoms of GOO. DGE developed in 26 of 61 (42%) patients with GOO versus 113 of 360 (31%) patients without GOO ($p = 0.08$). Of 61 patients with GOO, 15 patients (25%) received routine tube feeding and 46 (75%) early oral feeding. Time to resumption of adequate oral intake (11 (4-69) vs.14 (7-11) days, $p = 0.80$), incidence of DGE (40% vs. 43%, $p = 0.81$) and length of hospital stay (17 (7-67) versus 14 (4-46) days, $p = 0.19$) did not differ between the two feeding strategies. Of the patients receiving early oral feeding, 24 of 46 (52%) patients with GOO ultimately needed postoperative tube placement as compared to 112 of 297 patients (37%) without GOO ($p = 0.06$).
CONCLUSION: In this retrospective study, the risk of DGE and need for postoperative tube placement tended to be slightly increased in patients with GOO, but outcomes were comparable between routine tube feeding and early oral feeding. Since almost half of patients with GOO tolerate early oral feeding, routine tube feeding may not be indicated in these patients.

P1255 IRREVERSIBLE ELECTROPORATION IN LOCALLY ADVANCED PANCREATIC CANCER: A SYSTEMATIC REVIEW

S. Rombouts[1,*], S. Fegrachi[1], H. V. Santvoort[1], M. Besselink[2], R. V. Hillegersberg[1], Q. Molenaar[1]
[1]*SURGERY, University Medical Center Utrecht, UTRECHT,* [2]*Surgery, Academic Medical Center Amsterdam, Amsterdam, Netherlands*
Contact E-mail Address: *S. J. E. Rombouts@umcutrecht.nl*

INTRODUCTION: Ablative techniques are being explored as a new treatment option for locally advanced pancreatic cancer (LAPC). Unlike radiofrequency ablation, irreversible electroporation (IRE) is a non-thermal ablation technology and might preserve vascular and ductal structures.
AIMS & METHODS: The aim of this study was to evaluate the safety and potential benefits of IRE in patients with LAPC.
A systematic search was performed in PubMed, Embase and Cochrane Library for English articles published until March 2014 and subsequently reviewed according to PRISMA guidelines. Included were clinical studies reporting on outcomes of IRE in LAPC. Exclusion criteria were: 1) studies that did not report morbidity and mortality; 2) case reports; 3) conference abstracts. Baseline characteristics as well as study characteristics were extracted. Outcomes expressed as morbidity, mortality and overall survival were extracted from the articles.
RESULTS: After screening 143 studies, 4 clinical studies were included. These studies involving 176 patients, reported overall morbidity of 21-59%, IRE-related morbidity of 7-18.8%, and mortality of 0-3%. The IRE-related complications consisted of pancreatic fistula, portal vein thrombosis, duodenal leak and acute pancreatitis with reported rates of up to 3.7%, 7.4%, 7.4% and 7.1% respectively. Only one clinical study ($n = 139$) reported median survival of 20.2 months.
CONCLUSION: IRE for LAPC seems feasible and safe based on clinical studies. However, the number of complications does not seem improved in comparison with RFA, except for pancreatic fistula. A large prospective, preferably randomized study should establish whether morbidity, overall survival and quality of life are improved by IRE as compared to alternative established treatments.

INTRODUCTION: Routine placement of intraabdominal drains has been challenged for distinct abdominal surgical procedures. Studies for abdominal drains after pancreatic resections are inconsistent. The aim of this meta-analysis was to investigate morbidity and mortality of patients with and without abdominal drains after pancreatic resections.
AIMS & METHODS: According to the PRISMA guidelines, a literature search of medical data bases was performed for eligible studies reporting on patients with any kind of pancreatic resection, and comparing a group with abdominal drainage to a group without abdominal drainage. The quality of studies was assessed according to MINORS and STROBE criteria. Morbidity, mortality, and the length of hospital stay were compared by random effects models.
RESULTS: Overall, eight studies with 2.773 patients were included in this meta-analysis. Patients without intraabdominal drainage had a significant reduced rate of any kind of complications ($p < 0.001$). However, no significant differences were detected when separated into minor complications, major complications, pancreatic fistulas, intraabdominal abscesses, need for radiological interventions, need for re-operations, postoperative mortality, and length of in-hospital stay. Study heterogeneity made the results difficult to interpret.
CONCLUSION: The meta-analysis of the current literature does not allow explicit recommendations for or against the routine placement of intraabdominal drains after pancreatic resections. At least, omitting drains seems not to increase the rate of complications and should be considered for unproblematic pancreatic resections. Systematic review registration number CRD42014007497. No funding.

INTRODUCTION: Gastroenteropancreatic neuroendocrine tumors (GEP NET) with hepatic metastases (HM) have a poorer prognosis in comparison with localized GEP NET.
AIMS & METHODS: Primary endpoints of the study are overall survival from the diagnosis of liver metastases (OS), progression-free survival (PFS) and treatment effectiveness. Among 186 consecutive patients with diagnosed GEP NET from 1995 to 2012, 74 had HM. Prognostic factors and survival times of GEP NET with HM with different treatments were calculated using Kaplan-Meier method and regression analysis.
RESULTS: Median OS (range) was 96 (3-201) months. Prognostic factors for OS were grading, presence of extrahepatic disease (EHD) and treatment ($p < 0.0001$). Ten patients (14%) achieved complete remission, 18 (24%) partial remission, 18 (24%) stable disease, and 28 (38%) progression of disease. Among responsive patients median PFS was 84 (4-180) months. Prognostic factors for PFS were grading and presence of EHD ($p < 0.001$). Five- and 10-year survival rate were 86% and 71% for radical surgery (RS), 82% and 58% for palliative surgery (PS) with radioreceptor therapy (RT), 58% and 37% for PS and medical treatment (MT), and 23% and 8% for MT alone.
CONCLUSION: Overall survival of GEP NET with HM resulted high, as described from other authors. Interestingly, we found that OS and PFS of patients treated with RS are similar to those of patients treated with PS and RT. Main prognostic factors for GEP NETs with HM are grading and EHD.

INTRODUCTION: The identification of environmental risk factors for sporadic pancreatic neuroendocrine tumors (PNETs) may suggest mechanisms of pathogenesis and allow the identification of groups at high risk of disease.
AIMS & METHODS: The aim of this systematic review was to assess if diabetes, smoking, alcohol and/or a family history of cancer are risk factors for sporadic PNETs. MEDLINE and abstracts from the ENETS and NANETS were searched for studies published until October 2013. Eligible studies were selected according to the PRISMA statement.
RESULTS: Four studies were included (study accrual period 2000-10) in a meta-analysis, involving 518 (range, 160-196) cases and 1805 (range, 233-924) controls. All studies were case-control studies and described regional cohorts. The pooled and adjusted OR was 3.512 (95% CI 2.188-5.638; $p \leq 0.001$) with a history of diabetes, 1.401 (95% CI 1.082-1.814; $p = 0.011$) with a history of ever smoking, 1.371 (95% CI 0.986-1.906; $p = 0.061$) with a history of heavy smoking, 1.397 (95% CI 1.075-1.816; $p = 0.013$) with a history of ever alcohol consumption, 3.206 (95% CI 2.038-5.043; $p \leq 0.001$) with a history of heavy alcohol consumption, and 2.160 (95% CI 1.639-2.847; $p \leq 0.001$) with a first degree family history of cancer. There was some heterogeneity in the results that was most apparent with regard to the risk of heavy smoking and heavy drinking.
CONCLUSION: Diabetes, smoking, alcohol and first degree family history of cancer are associated with an increased risk of developing sporadic PNET. There is a need for larger international case-control studies with homogenous study populations to draw definitive conclusions with regard to heavy smoking and heavy drinking and other potential risk factors for sporadic PNETs.

INTRODUCTION: Pancreatic neuroendocrine tumors (PNETs) are diagnosed by multidetector computed tomography (MDCT) with increasing frequency: the roles of EUS-FNA and PET/CT in the diagnostic algorithm of these lesions has not been established yet.
AIMS & METHODS: We aimed to investigate the role of EUS-FNA and PET/CT in the evaluation of pancreatic lesions suspected to be PNETs, on the basis of MDCT. We retrieved from our institution databases all patients, who underwent both EUS-FNA and PET from Jan 2007 to Mar 2014, for diagnosis and staging of pancreatic lesions identified by MDCT. Only patients having a MDCT suspected for PNET, were considered in the analysis. We compared 1) the accuracies of EUS-FNA and PET in confirming the diagnosis of PNET and 2) the detection rates of MDCT and PET for suspected secondary lesions. The reference standard for the diagnosis of PNET was histology or cytology (confirmed by at least 6 month follow-up - mean 30 months).
RESULTS: 34 patients were identified (lesions diameter: 27 mm;8-98). The final diagnoses were: PNET ($n = 31$; $G1 = 20$; $G2 = 10$; $G3 = 1$); duct cells pancreatic carcinoma (1) and clear cell carcinoma metastases (2).
Table 1 shows results of the methods, according to the diagnosis:

	True positive	True negative	False positive	False negative
EUS-FNA	28	3	0	3
EUS-FNA (overall)	30	3	0	1
MDCT	31	0	3	0
PET/CT	27	0	3	4

In patients with clear cell metastases PET/CT showed a high tracer uptake, while only a faint uptake was found in the patient with duct cell carcinoma. EUS-FNA results were inconclusive in 3 patients; in 2 of them the diagnosis of PNET was confirmed by performing EUS-FNA again. In 5 patients with PNET, EUS and/or PET/TC identified additionally primary lesions. MDCT did not show any pathological lymph node, neither distant site metastases in 26 patients affected by PNET; PET identified a suspected secondary metastasis in one of these patients, but at a retrospective review of the MDCT findings the lesion was confirmed as visible, but missed during initial evaluation. MDCT diagnosed secondary lesions in 2 patients and these diagnoses were confirmed by PET/CT. In the other 3 patient the results of MDCT were doubtful; in all of them PET/CT identified secondary lesions, but these findings were later found to be false positive diagnoses in 2/3.
CONCLUSION: Although the majority of PNET identified by MDCT resulted positive using PET/CT, EUS-FNA remains necessary to confirm suspected PNET. In patients affected by PNET, in whom MDCT suggests the presence of secondary lesions, PET/CT may be useful providing additional clinical information. On the other hand, the probability of diagnosing secondary lesions by PET/CT in patients, without secondary lesions at MDCT is low.

INTRODUCTION: Endoscopic ultrasound is used for precise preoperative evaluation of pancreatic neuroendocrine neoplasm. Endoscopic ultrasound-guided fine-needle aspiration provides safe, highly accurate cytologic confirmation. However, in contrast to adenocarcinomas, the degree of nuclear pleomorphism and architectural pattern do not correlate well with prognosis. It is desirable to find biomarkers that detect the malignant potential without morphological cytological changes. DNA methylation is important in transcriptional regulation, chromatin remodeling and genomic stability. DNA hypomethylation and regional DNA hypermethylation are commonly observed in various tumours, including pancreatic cancer, even in precancerous states, which lack obvious cytological atypia.
We investigated epigenetic alterations and clinicopathologic features of pancreatic neuroendocrine neoplasms using immunohistochemistry.
AIMS & METHODS: A case-control study of 38 patients with pancreatic endocrine neoplasm who underwent pancreatic resection and one case obtained from autopsy. The observation period was 3 to 192 months. We analysed correlations between clinicopathologic factors and immunohistochemical stains of DNMT1. DNMT1 was detected in nuclei of lymphocytes (positive control) and tumour cells. To discriminate definitely positive cases from cases, if more than 5% of cells in a sample exhibited nuclear staining the sample was considered to show immunoreactivity. Correlations between the incidence of DNMT1 immunoreactivity and recurrence were analysed using a chi-square test. A p-value < 0.05 was considered significant.
RESULTS: There were nine males and 30 females, including 23 cases of non-functioning neoplasms, nine of insulinoma, three of serotonin-producing neoplasms, two of gastrinomas, one of ACTH-producing neoplasm, one of VIP-producing neoplasm, and two of microadenomas. Multiple endocrine neoplasia type 1, invasive ductal adenocarcinoma of the pancreas, and gastric cancer were seen in each case. Tumour size was 10–44 mm. From 2010 WHO classifications, 76% of tumours were G1, 20% were G2, and 4% were G3. From 2000 classifications, 30 patients had well-differentiated endocrine neoplasms and nine had well-differentiated endocrine carcinomas. One patient died from liver metastasis 9 years after surgery. Six patients were alive with liver metastasis and had undergone chemotherapy. In one case, liver metastasis occurred 15 years after surgical resection. The remaining 17 cases were alive without recurrence. DNMT1 protein overexpression was significantly associated with liver metastasis ($p < 0.0006$). There was one case with metastasis 15 years after surgery and DNMT1 tested positive in the resected primary specimen.
CONCLUSION: Increased DNMT1 expression correlated to the metastatic potential of pancreatic endocrine neoplasm.

INTRODUCTION: Upper Gastrointestinal bleed (UGI Bleed) is very common cause for presentation to the emergency department often leading to unnecessary admission and prolonged length of stay, whilst awaiting in-patient endoscopy

AIMS & METHODS: To validate GBS in our population and to determine if those with GBS up to two can be managed with outpatient OGD
This was a prospective single-centre observational study of patients presented to our centre between December 2012 to June 2013. We recruited those with a working diagnosis of upper gastrointestinal bleeding (UGIB) including those who were discharged from the emergency department (ED) for outpatient OGD. Patients younger than 18 years of age and those who did not give consent were excluded. Data collections include patients' demographics, GBS, hospital admissions, OGD findings (normal or abnormal). Analyses were performed to determine the correlation between GBS and OGD findings (using the Forrest Classification) emphasizing on those with GBS score up to two
RESULTS: Seventy out of 93 patients who presented during the recruitment period had an OGD performed. The mean age of patients was 62.6 years and 53 patients were males (57.0%). The mean GBS was 6.2. Forty-six patients had a normal OGD and their mean GBS was 3.5.
11 had Forrest Classification III, 3 had Forrest IIc, 1 had Forrest IIb, 2 had Forrest IIa, 4 had Forrest Ib and 3 had Forrest 1a. 14 patients were re-admitted within four weeks but none for UGIB. There is a statistically significant correlation between the GBS and Forrest Classification in our cohort ($r = 0.431$, p-value < 0.001). Four patients with variceal bleed were included in the abnormal OGD group as well. Thirty four patients have GBS of 0 to 2 ('0' = 15, '1' = 12, '2' = 7) and all have normal OGD findings.
Ten of the twenty three not having OGD, had GBS score of zero, Three had score 1 and Two had GBS score 2. Patients with score zero and one were discharged from the emergency department for follow OGD but they never returned back to the endoscopy or represented to the hospital within 4 weeks with any symptoms of upper GI bleed. Three of the patients were very unwell with other co morbidities and they had GBS score of more than 8; in that case looking after physicians decided not to go for the OGD. Five of the patients had GBS score of more than 6 but their OGD record was not available in the notes as they may have endoscopy in the operation theater under surgical team.
CONCLUSION: Our study validates the GBS as per previous studies and suggests that we can push the score up to two at which it is safe to discharge and offer out-patient endoscopy.

INTRODUCTION: Peroral endoscopic myotomy (POEM) achieved myotomy for treatment of achalasia through submucosal tunnel. The determination of extent of myotomy depends on preoperative high resolution manometry and endoscopic measurement. Endoscopic observation of the inner circular muscles showed a difference in appearance between the tight lower esophageal sphincter (LES) and normal muscle fibres. This study aimed to determine the criteria for observation through probe based confocal endomicroscopy (pCLE) in determining the pathological extent of LES during POEM.
AIMS & METHODS: This is a prospective clinical trial on the use of probe based confocal endomicroscopy to determine the extent of pathological LES. Prospective patients who underwent POEM for treatment of achalasia were recruited. After development of the submucosal tunnel from 15cm above gastroesophageal junction (GEJ) to 5cm below, the pCLE was applied to observe for changes at 2cm intervals from 10cm above to 5cm below GEJ. The criteria for changes during confocal endomicroscopy in pathological LES included – 1. Non-distinct vasculature; 2. No visible normal muscular fibres; 3. Increased cellularity; 4. Presence of thick dark bands. The patients received intravenous fluorescin 2 minutes before the observation. The pCLE was performed using a catheter type confocal probe (Cellvizio MKT) with a diameter of 2.0mm. All the procedures were video recorded for reassessment.
RESULTS: Four patients who underwent POEM for treatment of Achalasia received pCLE for determination of the extent of pathological LES. The mean operative time for POEM was 94.1 mins, and the mean duration for confocal observation at 8 different levels was 10.4 minutes. All the features employed for distinction between pathological LES and normal inner circular muscles were observed for all patients with Achalasia after development of submucosal tunnel. The corresponding length of abnormal pCLE findings was generally longer than that reported in preoperative manometry.

	Patient 1	Patient 2	Patient 3	Patient 4
Age / gender	75/M	M/78	F/76	F/62
Abnormal pCLE	40 – 45cm	39 – 42cm	38 – 45cm	37 – 45cm
Preop Abnormal LES	44 – 47 cm	40 – 42cm	41 – 44cm	42 – 46cm
Preop LES pressure	60 – 70 mmHg	8 – 12mmHg	26 – 32mmHg	30 – 40 mmHg
IRP4s	48.6mmHg	-	21.6mmHg	17.8mmHg

CONCLUSION: In this preliminary study, we were able to establish preliminary criteria to differentiate between pathological LES and normal inner circular muscle fibres during POEM. These changes shall serve as guidance to determine the extent of myotomy during POEM.

P1264 ENDOSCOPIC MUCOSAL RESECTION OF SPORADIC DUODENAL POLYPS IS ASSOCIATED WITH A HIGH RISK OF COMPLICATIONS

P. Martens[1,*], I. Demedts[1], S.Van Gool[2], H. Willekens[1], R. Bisschops[1]

INTRODUCTION: Endoscopic mucosal resection (EMR) is an established technique for the treatment of early neoplastic lesions in the colon, esophagus and the stomach. Sporadic duodenal adenomas (SDA) are a rare finding on endoscopy. Little data is available about the safety and efficacy of EMR for SDA in larger case series.
AIMS & METHODS: The aim of this study is to report our experience with regard to the safety and efficacy of duodenal EMR for SDA.
Methods: Prospectively collected data of fifty nine patients (31 men, 28 female, mean age 61) referred for duodenal EMR to our center between 2006 and 2013, were analyzed. Only duodenal polyps were included in the study. Data regarding polyp size, location, endoscopic morphology, EMR technique, procedure time, complications, pathology result and periodical follow up were recorded. All patients underwent day after endoscopy to detect and treat delayed bleeding.
RESULTS: Seventy-one duodenal EMRs were performed in fifty nine patients during the study period. The median polyp size was 15mm (range 7-40 mm). The success rate of complete endoscopic removal after a single EMR was 83%. Complete remission was achieved with 2 and 3 EMRs in 9 and 3 patients respectively. Complications occurred in 26% of the procedures. We encountered 10 cases of early bleeding (<4 hours after EMR) and 10 cases of delayed bleeding (>4 hours after EMR) with need of additional hemostatic measures, transfusion or radiological intervention and admission to intensive care. In one patient a small perforation could be managed conservatively with clips. No patients were referred for rescue surgery. Except for 2 neuro-endocrine tumors, all lesions were adenomas with low grade dysplasia in 82% and high grade dysplasia in 18%. Long term histological follow up (median: 18 months, range 12-50 months) was available in 30 patients, complete histologic remission was achieved in 25 patients (83%). Five patients revealed histologic arguments of residual adenomatous tissue, all showing low grade dysplasia. No tumor related deaths were reported.
CONCLUSION: This study is one of the largest available series confirming the efficacy of EMR for SDA. Duodenal EMR is efficient *(83%)* in achieving long term complete histological remission. However morbidity (26%) seems higher for duodenal EMR as compared to EMR in other location within the gastrointestinal tract and in comparison to other smaller series. Our systematic approach of day after follow-up endoscopy could contribute to the higher morbidity rate with detection of late bleeding.

P1265 ENDOSCOPIC RESECTION OF DUODENAL ADENOMAS-COMPARISON OF SAFETY AND EFFICACY BETWEEN SPORADIC ADENOMAS AND ADENOMAS IN FAP

P. Mundre[1,*], B. Rembacken[1], A. Rehman[1], L. smith[1]
[1]*Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds, United Kingdom*
Contact E-mail Address: *bj.rembacken@ntlworld.com*

INTRODUCTION: Although there is a low risk of malignant conversion of duodenal polyps in FAP, EMR is often considered. However, few studies have looked at the safety and efficacy of EMR. We compared the outcome of duodenal EMR's in patients with FAP vs sporadic adenomas. To our knowledge, this is the largest series of duodenal EMRs that is published so far (1)
AIMS & METHODS: We looked at Clinical records of all patients who underwent endoscopic resections for duodenal adenomas at Leeds in a 10 year period.
RESULTS: A total of 49 sporadic adenomas were resected (in 51 patients) and 44 FAP related (in 22 patients). Most lesions appeared either sessile (43) or flat elevated (48). The average size of the FAP related polyps was 16.9mm vs. 20.7mm in sporadic lesions. Most were removed by standard EMR ($n = 82$) rather than the strip biopsy technique ($n = 9$). Two procedures failed and no follow-up data was available after the resection of 2 sporadic polyps.
The final histology of the lesions were; TA+LGD (76), TA+HGD (13), adenocarcinoma (2) and 2 polyps were not retrieved. In 11 lesions, there was a change in the histological grade after resection.
There were 4 perforations (4.3%), 3 were managed surgically. 12 patients (13%) were readmitted with significant late GI bleeding and 8 patients required endoscopic therapy and transfusion.
There was no significant difference in the success rates in the two groups (19/44 vs 32/49) p value 0.94). However, the resection of polyps ≥2cm were significantly more likely to be associated with a complication (7/59 vs. 8/19 $p = 0.02$). There was no difference in the risk of complications with the polyp location, ASA status, Spigelman score or patient age.
Amongst the FAP polyps, polyps > 20 mm were significantly more likely to have local recurrence (3/6 vs 3/31 p value 0.04). There was no difference in the chances of success of the resection with the growth pattern, the location of the polyp or the Spigelman score.
CONCLUSION: Duodenal EMR is hazardous, particularly when lesions 2cm or larger are resected. However, there was no significant difference in the hazards or success rates between the two groups. Most FAP patients had further neoplasia

on follow up, but this is due to the fact that many of the adenomas were not resected /treated in the first sitting.

P1266 WHAT IS THE OPTIMAL TIME TO DO ENDOSCOPY IN ACUTE CAUSTIC INGESTION?

R. kochhar[1,*], P.K. Siddapa[1], U. Dutta[1], S.K. Sinha[1]
[1]*Gastroenterology, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India*
Contact E-mail Address: *dr_kochhar@hotmail.com*

INTRODUCTION: Early (<24 h) upper GI endoscopy (UGIE) is used to prognosticate mucosal injury after caustic ingestion.

AIMS & METHODS: To evaluate the usefulness of day 5 UGIE over day 1 UGIE in prediction of cicatrisation and other outcomes after acute caustic ingestion.

Consecutive adult patients of caustic ingestion seen by us between 2009-2013 were subjected to upper GI endoscopy after informed consent within 24 hours and on fifth day of caustic ingestion. Upper GI mucosal changes were graded using Zargar's classification. Patients with changes of grade ≤IIa were classified as mild and those with ≥IIb were classified as severe. Patients were regularly followed up for development of complications. Management of cicatrisation included endoscopic dilatation followed by surgery if the former failed. Comparison was made between day 1 and 5 endoscopy changes for development of cicatrisation and complications.

RESULTS: A total of 63 patients had presented to us within 24 h of caustic ingestion of who 51(mean age 32±13.3yrs, 31 males) had day 1 and day 5 UGIE. Acid intake was seen in 43(84.3%), alkali in 6(11.8%) and unknown substance in 2(3.9%). The cause of caustic intake was suicidal in 24(47.1%), accidental in 20(39.2%) and unknown in 7(13.7%). Esophageal stricture developed in 12(23.5%) and antro-pyloric stricture developed in 18(35.3%) patients. 1(2%) patient died, emergency surgery was done in 1(2%) patient and definitive surgery for cicatrisation was done in 7(13.7%) patients. 42 (82.3%) patients recovered on conservative management requiring only dilatation in those with cicatrisation. Endoscopic grading on day 1 significantly overestimated severity of mucosal changes compared to day 5 grading **(table.1)**. Endoscopic grading on day 1 overestimated esophageal injury severity by 23.5% compared to day 5 grading. Endoscopic grading on day 1 overestimated gastric injury severity by 29.4% compared to day 5 grding. Day 5 endoscopic grading of esophageal injury correlated with stricture formation ($p = 0.019$) better than day 1 endoscopic grading ($p = 0.287$). For gastric injury both day 1($p = 0.005$) and day 5 ($p = 0.000$) endoscopic grading correlated with gastric cicatrisation. Day 5 endoscopic grading correlated better with need for surgery and recovery as compared to day 1 endoscopic grading ($p < 0.05$).

Table 1: Endoscopic grading on day 1 and day 5

	Mild changes grade ≤IIa	Severe changes grade ≥IIb	Day 1 vs day 5 (significance)
Esophagus day1(n = 51)	**19(37.3%)**	**32(62.7%)**	
Esophagus day5(n = 51)	**31(60.8%)**	**20(39.2%)**	**p = 0.008**
Stomach day 1(n = 51)	**11(21.6%)**	**40(78.4%)**	
Stomach day5(n = 49)	**25(51%)**	**24(49%)**	**p = 0.006**

CONCLUSION: Endoscopic assessment on day 1 significantly overestimates the grade of injury. Endoscopic grading of injury on day 5 is a better predictor of esophageal and gastric cicatrisation and need for surgery. We suggest that relook endoscopy on day 5 should be done in all patients of caustic ingestion.

P1267 A RANDOMIZED CONTROLLED TRIAL OF WHITE LIGHT ENDOSCOPY VERSUS BLUE LASER IMAGING ENDOSCOPY FOR THE DETECTION OF FOCAL GASTRIC LESIONS; A PRELIMINARY REPORT

R. Pittayanon[1,2,*], R. Rerknimitr[1]
[1]*Medicine, Chulalongkorn University,* [2]*Medicine, King Chulalongkorn Memorial Hospital, Bangkok, Thailand*
Contact E-mail Address: *rapat125@gmail.com*

INTRODUCTION: White light endoscopy (WLE) may miss subtle mucosal changes of stomach. Blue laser imaging (BLI) (Fujifilm Co., Japan) is a novel bright illumination with high definition resolution diagnostic tool that may improve mucosal surface contrast and facilitate visualization of mucosal details.

AIMS & METHODS: To evaluate the detection rate of focal gastric lesions between WLE and BLI system. From November 2013 to March 2014, 110 patients were recruited (55 in each). Inclusion criteria: 1) aged > 50 years undergoing UGI endoscopy with indications; for instant, chronic dyspepsia, unexplained weight loss, iron deficiency anemia, etc. Exclusion criteria: 1) presence of active gastrointestinal bleeding; 2) presence of coagulopathy; 3) past history of partial gastrectomy. Patients were randomized to either WLE or BLI. The presences of focal gastric lesions, the morphology based on the Paris classification and real-time diagnosis were recorded. All lesions were biopsied for histological confirmation. The difference in the detection rate of focal lesion was analysed.

RESULTS: There was no significant difference in mean age (64 vs. 66 years) and gender distribution (41% vs. 50% male) between patients undergoing WLE and BLI. WLE and BLI could detect gastric polyp, erosion, ulcer, intestinal metaplasia (IM) and advanced gastric cancer (**Table 1**). BLI provided a trend of better focal gastric lesions detection when compared to WLE (52% vs. 41%, $p = 0.082$). All IM lesions were detected only by BLI, whereas WLE did not detect any IM. These five cases of IM were classificed as 0_IIa at 80% and 0_IIb at 20%. However, no early gastric cancer was detected in this study.

Table 1

	Gastric polyp	Gastric erosion	Ulcer	Intestinal Metaplasia (IM)	Advanced gastric cancer	Total
WLE	7	9	4	0	2	22
BLI	6	8	9	5	1	29

CONCLUSION: WLE and BLI are both potentially a promising tool for detection of subtle focal gastric lesions. However, BLI may have more advantage than WLE on detecting IM lesion. Additional cases should be recruited to determine the usefulness of BLI.

P1268 PUSH-METHOD PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) FOR HEAD AND NECK (H&N) CANCER PATIENTS; OUR EXPERIENCE AT A LARGE GASTROENTEROLOGY UNIT

R. Sinha[1,*], H. Taha[1], D. Oliver[1]
[1]*Endoscopy Unit, South Tees NHS Foundation Trust, Middlesbrough, United Kingdom*
Contact E-mail Address: *rohits78@gmail.com*

INTRODUCTION: Nutritional support via gastrostomy is advocated in H&N cancer patients undergoing chemo-radiotherapy treatment.

These may be inserted either endoscopically (PEG) or radiologically (RIG; Radiologically Inserted gastrostomy). PEGs may be performed using a pull or push (Seldinger) method. BSG guidelines 2010[1] specify that push-PEG technique should be preferred where cure is the intention of treatment for H&N cancer to avoid risk of tumour seeding[2]. We have adopted this method and describe our experience at a large gastroenterology centre of using push-PEGs for this purpose.

AIMS & METHODS: The aim of this study was to audit safety and success rates of push-inserted PEGs for H&N cancer patients. We retrospectively audited case-records of all patients receiving push-inserted PEG procedures between January 2012 to December 2013

RESULTS: Push-PEGs were successfully placed in 95% (53/56) patients. Mean age was 57.2 years; male:female ratio 36:17. Preprocedure antibiotics were used in 98% (52/53) patients. 84% (46/55) received a combination of midazolam (mean dose 2.8mg) and fentanyl (mean dose 52.5mcg); rest 16% received single sedative (midazolam). Discomfort scores[3] were recorded as 65% (33/51) comfortable during the procedure and 35% had mild discomfort. 30-day mortality was 3.8% (2/52). Major complications occurred in 2 patients (3.8%): misplaced suture in the peritoneal cavity requiring laparotomy retrieval; suture-tension induced gastric perforation 3 days post-procedure in an obese patient. No gastrostomy site metastases were observed. Minor complications occurred in 2 patients (3.8%); balloon rupture resulting in dislodged PEG and skin hematoma after day1 post-procedure. Our complication rates were lower than published 4.8%[4]. Three patients required RIG, having failed intubation due to stricturing disease.

CONCLUSION: Push method PEG is safe, useful and a viable alternative to RIG with high success rate in H&N cancer patients. RIG or surgically placed gastrostomies should be reserved as second-line approach. We aim to provide push-PEG for all H&N cancer by 2015 by education and training,compared to 62.2% (56/90). We reflect that obesity leading to suture-tension may be a risk factor for major complication.

P1269 EFFICACY AND SAFETY OF ENDOSCOPIC MUCOSAL RESECTION OF NONAMPULLARY DUODENAL POLYPS

R. Combes[1,*], Y. Duny[2], P. Bauret[1]
[1]*Hepato-gastroenterology Department, CHU Montpellier,* [2]*INSERM, Montpellier, France*
Contact E-mail Address: *roman.combes@hotmail.fr*

INTRODUCTION: Endoscopic mucosal resection (EMR) of nonampullary duodenal (NAD) polyps is an alternative to surgical treatment. The literature is quite poor about this subject and series often includes small sized populations.

AIMS & METHODS: This study aimed to evaluate efficacy and safety of EMR for NAD polyps. This is a retrospective cohort analysis of all consecutive patients referred between 2002 and 2013 for management of NAD polyps at a tertiary-care center by a single practitioner.
RESULTS: Between 2002 and 2013, 61 NAD polyps have been resected in 53 patients (22 females, 31 males). The mean age was 64.5 years (34.5-91.5). The mean polyp size was 23.4 +/- 14.1mm of wich 8.2% (n = 5) <10mm, 50.8% (n = 31) between 10 and 20mm and 41% (n = 25) >20mm.
Of 53 patients who underwent attempted endoscopic resection, complete resection was achieved in 52 cases (98.1%), during a single session in 48 patients (90.4%) and with double or triple sessions in 5 patients (9.6%). En bloc resection was performed for 36 polyps (59%) and piece meal resection for 25 polyps (41%). 37 of resected areas were closed by endoclips (60.7%) but closure failed or was incomplete in 8 cases (21.6%).
Histological findings revealed 50 adenomas (15 tubulars and 35 tubulovillous or villous with high degree of dysplasia in 5 (10%) of them), 11 non adenomatous lesions (5 Brunner's gland hyperplasias, 1 Brunner's gland hamartoma, 1 gangliocytic paraganglioma, 1 lipoma, 1 neuroendocrine tumor, 1 inflammatory fibroïd polyp and 1 ectopic pancreas).
Complications occured in 11 patients (20.8%): 8 haemorrhages (15.1%) of which a lethal one, with surgery needed in 2 cases, and 3 perforations (5.7%). In multivariate analysis, the only predictive factor of complication was the failure of resected area closure by clip (OR = 7.2; IC 95 [1.3-39.6]).
5 recurrences (17.2%) have been observed among 29 patients diagnosed with adenoma who benefitted from a follow-up (mean follow-up: 23.4 months). All recurrences were successfuully treated by EMR.
CONCLUSION: EMR of NAD polyps is an effective therapy but with significant morbi-mortality rate. However, in most of cases, complications have been successfully treated by medical or endoscopic therapies. Long term endoscopic follow-up is needed in adenomas with a recurrence rate of 17.2%.

INTRODUCTION: It is very difficult to establish an accurate diagnosis for upper GI submucosal tumours. Biopsy during endoscopy cannot go deep enough. EUS is unable to give a tissue diagnosis. The risks of surgical resection are higher than the benefits as the lesion may very well be benign. As a result most of these patients keep having endoscopic surveillance as 'possible' GISTs.
AIMS & METHODS: A retrospective cohort study of patients undergoing ESD for upper GI submucosal tumours. They were all referred to us as possible GISTs that were found to be growing in size on surveillance. ESD was carried out in all these cases. As these lesions are mostly bulky, gravity and patient positioning were utilized as traction during ESD to achieve deroofing and enucleation of these tumours. Any complications were recorded. Endoscopic follow up was performed to assess for incomplete resection or recurrence.
RESULTS: 21 submucosal lesions were resected by ESD between 2007 and 2013. 7 were oesophageal, 10 gastric and 4 duodenal. Sizes ranged from 10 to 35mm. Endoscopic clearance was achieved in all cases. Histology showed a wide range of diagnoses, mostly benign (table). There was 1 complication; a microperforation which was identified and clipped intraprocedurally, giving a complication rate of 4.7%. On follow up, there was 1 recurrence (recurrence rate 4.7%) which was managed endoscopically. 1 patient had surgery as the ESD specimen showed a synovial sarcoma. Endoscopic cure rate was 95.2%.
Table: Histological diagnosis of submucosal tumours resected by ESD

Diagnosis	number
Granular cell tumour	3
GIST	2
Leiomyoma, lipoma	2+2
Pancreatic acinar tissue	1
Carcinoid	6
Inflammatory fibroid polyp	1
Hyperplastic polyp	1
Synovial sarcoma	1
Gangliocytic paraganglioma	1

CONCLUSION: ESD is a safe and novel, minimal access therapeutic technique which has the potential to transform management of submucosal tumours. Patients go from the uncertainty of having repeated endoscopies for an unknown diagnosis, to having it completely removed and cured in the vast majority, without the need for continuing endoscopies. In the remaining cases, ESD specimens provide an accurate histological diagnosis based on which definite management plans can be made.

P1271 PER-ORAL ENDOSCOPIC MYOTOMY (POEM) FOR ACHALASIA CARDIA, CASE SERIES FROM SINGLE TERTIARY CARE CENTRE

S. Davavala[1,*], A. Bapaye[1], N. Dubale[1], S. Date[1], V. Thorat[1]
[1] *Department of digestive diseases and Endoscopy, Deenanath Mangeshkar Hospital and Research Centre, Pune, Pune, India*
Contact E-mail Address: *amolbapaye@gmail.com*

INTRODUCTION: Treatment for achalasia cardia includes endoscopic (balloon dilatation/botulinum injection) or surgical Heller's myotomy. Per-oral endoscopic myotomy (POEM) is an upcoming modality. This study reports preliminary results of POEM in patients suffering from achalasia cardia.
AIMS & METHODS: Patients with achalasia cardia confirmed on endoscopy (EGD), high-resolution manometry (HRM) and barium swallow and undergoing POEM were included. Associated co-morbidities & previous treatments for achalasia were recorded. Eckhardt dysphagia score was recorded before the procedure. Procedure time, technical success and complications were noted. Follow up was by EGD, with or without HRM and post procedure Eckhardt score at 4 weeks.
RESULTS: 20 patients were enrolled, Male: Female (1:1). Achalasia Type: I – 4, II – 12, III – nil, Not Done - 4. Significant comorbidities: 6 / 20(30%). Categories: naïve patients (n-10), previous therapies – Heller's myotomy (n-2), botulinum injection – (n-1) and Balloon dilatation – (n-6). Mean symptom duration: 24-420 weeks. Mean pre- procedure Eckhardt score – 6.5; mean LES pressure 43.3mmHg (Range – 17 -74 mmHg). Mean procedure duration (minutes) was 187.5 (60 – 330), clinical success in all (100%) and no complications encountered. Technical difficulties occurred in 4 / 20 (20%) patients. Follow up (mean 6 months) mean Eckhardt score was 1.5 ($p = 0.001$) and mean LES pressure 12.8 ($p = 0.018$). Relief in dysphagia was in all patients (100%) and occasional heartburn in – 8 / 20 (40%).
CONCLUSION: POEM is safe and effective treatment for achalasia cardia. It is effective in treating naïve, previously treated patients and also in those with comorbid illness that may preclude surgical treatment.

INTRODUCTION: Intramucosal undifferentiated-type (UD-type) early gastric cancer (EGC) ≤ 2cm without ulceration has been treated by endoscopic submucosal dissection (ESD) as an investigational treatment. However, it is difficult to estimate the depth of invasion in UD-type EGC compared with differentiated-type. In addition, tumor margin is indistinct in some UD-type EGCs extending along the proliferative zone in the middle layer of the mucosa, leaving normal ducts covering the superficial epithelium.
AIMS & METHODS: This study aimed to evaluate factors related to non-curative ESD of UD-type EGC. 137 consecutive UD-type EGCs in 127 patients who underwent ESD met the inclusion criteria: i) they had a poorly differentiated adenocarcinoma or signet ring cell carcinoma histologically proven by preoperative biopsy, ii) the cancer was intramucosal and appeared on endoscopy to be ≤ 2 cm and without ulceration, iii) they had had no prior endoscopic treatment or surgery of the upper gastrointestinal tract. This study assessed short-term outcomes of ESD, factors related to non-curative ESD and width of tumor extension along the mucosal proliferative zone in 0-IIc lesions. Curative resection of ESD for UD-type EGC was defined as the presence of an intramucosal cancer ≤ 2 cm without ulceration or lymphovascular invasion and with clear lateral and vertical margins on histological assessment.
RESULTS: Of 137 lesions, en bloc resection was achieved in 99.3% and R0 resection 94.2%. The median procedure time was 65 (10-300) minutes. Delayed bleeding, perforation and delayed perforation rates were 2.9%, 2.9% and 0.7%, respectively. Macroscopic types (0-IIc/0-IIa or 0-IIa+IIc/0-IIb) were 133/3/1. Median tumor size was 11mm (1-45). Pure sig morphology was identified in 58.4% and por including with other component in 41.6%. Curative resection was 70.1% and was significantly higher with pure sig than por (81.3%/52.6%, $p < 0.0001$). Main causes of non-curative ESD in all patients were submucosal invasion (16.8%) (minute submucosa $< 500\mu m$/deeper submucosa $\geq 500\mu m = 8.0\%/8.8\%$), tumor size > 20mm (12.4%) and ulceration (7.3%) (with overlapping, shown in table). Submucosal invasion and resected tumor size >20mm were significantly more common in por than in pure sig (29.8%/7.5%, $p < 0.001$ and 19.3%/10.0%, $p = 0.009$). 43 lesions (31.4%) were preoperatively underestimated by more than 5mm in size. 75% (6/8) of the lesion which were preoperatively diagnosed as 20mm in size were over 20mm. Extension along the proliferative zone was found in 74 of 133 0-IIc lesions (55.6%) and median width of extension was 980μm (0-11650μm). Increasing lesion size was associated with more extension along the proliferative zone (preoperative tumor size and median width of extension: 1-5mm/6-10mm/11-15mm/16-20mm = 490μm / 960μm /1040μm /1960μm).

Submucosal invasion (SM1/SM2)	**23(11/12)**	**16.8% (8.0%/8.8%)**
>2cm in size	**17**	**12.4%**
Ulceration	**10**	**7.3%**
Lympho-vascular invasion	**4**	**2.9%**
Positive lateral/vertical margin	**5/4**	**3.6%/2.9%**
Piecemeal resection	**1**	**0.7%**

CONCLUSION: Careful preoperative assessment is needed for UD-type EGC, especially if tumor size is near 20mm.

Contact E-mail Address: *shkim@eulji.ac.kr*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is a major treatment option for gastric neoplasms. However, ESD causes Post-ESD delayed bleeding (PEDB), one of the significant complication. Few studies showed that risk factor of PEDB is large artificial ulcer. Known as ESD induced ulcer is different from Peptic ulcer disease healing mechanism. Major healing mechanism is muscle contraction. For preventing the PEDB, prophylactic coagulation during the ESD was performed. So, we want to probe the effect of prophylactic coagulation induced thermal injury to the delayed ESD bleeding. The primary end point of this study is the relations between the post dissection coagulation time (PDCT) and delayed post ESD bleeding.
AIMS & METHODS: A total of 288 lesions diagnosed with early gastric neoplasms and treated by ESD from March 2005 to February 2013 in Eulji Hospital, retrospectively. PEDB was defined as the time of the bleeding after 24hrs: early PEDB, and late PEDB. Also the lesion was categorized non bleeding visible vessel, oozing bleeding and spurting bleeding. We analyzed associations between bleeding and the following factors of the characteristics of the patients and the lesions: age, sex, pathology, macroscopic findings (elevated, flat and depressed lesion), location, size of the resected lesion, duration time of the procedure, the type of the resection methods; enbloc or piecemeal resection, and fibrosis or not. Also, we measured the PDCT.
RESULTS: PEDB which is in 3.0% lesions (16/288). Delayed bleeding which oozing and spurting bleeding is only 1.5% (9/288). The male sex ($P<0.001$), piecemeal resection was risk factor of delayed bleeding ($p=0.025$). Compared with non bleeding group, larger resected size (4.26/3.50(cm), $p=0.02$), and delayed procedure time (96.62/58.24(min), $P< 0.001$) to be risk factors for delayed bleeding. And the PDCT was longer delayed bleeding group, but there are not significant (9.86/7.33(min) $p=0.19$). The location and macroscopic finding, pathology and fibrosis were not significant also.
CONCLUSION: This study demonstrated risk factors for PEDB. The male sex, piecemeal resection, large resected size and delayed procedure time are increase PEDB risk. However, we don't clarify the relationship between PDCT as thermal injury variable and PEDB because of small volume size of study.

P1274 LIMITED VALUE FOR FOLLOW UP ENDOSCOPY IN SEVERE OESOPHAGITIS: FINDINGS FROM A LARGE LONDON DISTRICT GENERAL HOSPITAL

S. Subramaniam[1,*], G. Goodchild[1], K. Besherdas[1]
[1]*Department of Gastroenterology, Barnet & Chase Farm Hospitals NHS Trust, London, United Kingdom*
Contact E-mail Address: *sharmila.subramaniam@nhs.net*

INTRODUCTION: The American Society of Gastrointestinal Endoscopy recommends the practice of endoscopic follow-up for patients with gastro-oesophageal reflux disease (GORD) with oesophagitis after adequate medical therapy has achieved mucosal healing, specifically to exclude masquerading Barrett's oesophagus (BE) or underlying cancer. Historically, follow-up oesophagogastro-duodenoscopy (OGD) for patients with GORD with oesophagitis was reserved for patients whose symptoms failed to respond to medical therapy, those who had severe oesophagitis or an oesophageal ulcer, or for those who needed additional biopsies to clarify a diagnosis. It could be argued that repeat OGD is not necessary as it gives a low yield in cancer and BE detection especially if initial appearance is benign and not indicative of BE.
AIMS & METHODS: The aim of this study was to assess the findings in patients who underwent a follow-up OGD for severe oesophagitis.
A single centre (large district general hospital), retrospective analysis of patients diagnosed with severe oesophagitis (Los Angeles classification Grade C or D) who subsequently underwent follow-up OGD over 8 years from 2005 was performed. Data was obtained using the GI Audit tool from the Unisoft endoscopy reporting system. Patients were assessed for the presence of cancer or BE at repeat OGD.
RESULTS: 76 patients with severe oesophagitis (31 grade D oesophagitis, 45 grade C oesophagitis) were included in the study. At follow up OGD, findings were: normal in 43, grade A oesophagitis in 18, grade B oesophagitis in 12, BE in 3. Of the 3 patients with BE on review, all had Grade D oesophagitis at initial OGD, one had appearance of BE macroscopically at initial OGD and the other 2 were both of non circumferential short segment (<3cm) BE without intestinal metaplasia. No patients had oesophageal cancer at follow up OGD.
CONCLUSION: In this study, the pick-up rate of cancer or BE at follow-up OGD assessment in patients with Grade C or D oesophagitis is very low (0.3%). Those in whom BE is diagnosed at follow up endoscopy, had preceding grade D oesophagitis and BE is short segment and without intestinal metaplasia. This pick up rate of BE is much lower than that reported if all patients with symptoms of GORD were endoscoped suggesting that the presence of severe oesophagitis is not a marker for detection of BE. From this study, we concluded the practice of endoscopic follow-up in patients with severe oesophagitis adds to higher healthcare costs without improving patient outcomes. OGD is a valuable diagnostic tool and for endoscopy services to be effective it is essential that it is not overloaded with inappropriate referrals. If our findings are replicated at other centres then guidelines on follow up OGD in oesophagitis should be re-visited.

P1275 ODYNOPHAGIA AND ITS YIELD ON UPPER GI ENDOSCOPY - A SYMPTOM WORTH ASKING ABOUT

S. Subramaniam[1,1,*], G. Goodchild[1], K. Besherdas[1]
[1]*Department of Gastroenterology, Barnet & Chase Farm Hospitals NHS Trust, London, United Kingdom*
Contact E-mail Address: *sharmila.subramaniam@nhs.net*

INTRODUCTION: Odynophagia can be defined as a painful sensation in the oesophageal region that occurs in relation to swallowing. Unlike dysphagia, which has historically been an alarm symptom or warning sign of oesophageal cancer, odynophagia is not classified as an alarm symptom and does not form part of the suspected upper gastrointestinal (GI) cancer referral form in the UK. Endoscopy is the gold standard imaging modality for the diagnosis of mucosal lesions in the oesophagus. However, there is no clear data regarding the findings at endoscopy in patients scoped for odynophagia. Mucosal abnormalities even in the presence of typical symptoms of gastro-oesophageal reflux disease, namely heartburn and regurgitation are absent in up to 70%.
AIMS & METHODS: We hypothesise that the presence of odynophagia has a high predictive value of mucosal abnormality at endoscopy and aimed to assess the findings at endoscopy for patients scoped for odynophagia.
A retrospective analysis of all patients who underwent upper GI endoscopy for odynophagia as a primary symptom over an 8-year period (2005-2013) within an NHS Trust in north London was performed. Data was obtained from the Unisoft Endoscopy reporting software. The findings at endoscopy in patients with odynophagia were scrutinized.
RESULTS: 50 patients were endoscoped for odynophagia during the study period. 34 of 50 patients (68%) had oesophageal mucosal lesions (4 Barrett's mucosa, 2 candida oesophagitis, 14 reflux oesophagitis, 6 malignant tumour, 5 oesophageal stricture, 3 oesophageal ulcers). 12% (6 of 50) had oesophageal cancer. A further 10 had hiatus hernia, 1 had a motility disorder and 1 had oesophageal diverticulum.
CONCLUSION: From this study, 68% of patients endoscoped for odynophagia have a positive endoscopic mucosal abnormality. Odynophagia as a symptom has a high sensitivity for abnormal endoscopy. 12% of patients endoscoped for odynophagia had oesophageal cancer. This prevalence is similar to the diagnosis of cancer in patients referred on the 'two week wait upper GI cancer referral form'. We recommend the symptom of odynophagia be classified as an alarm symptom and those presenting with odynophagia all undergo upper GI endoscopy to define the exact mucosal abnormality and exclude oesophageal cancer.

INTRODUCTION: Guidelines for gastroenterological endoscopy in patients undergoing antithrombotic treatment published by Japan Gastroenterological Endoscopy Society has been revised recently. In the revised guidelines, endoscopic biopsy is allowed without interruption of antithrombotic agents but hemorrhagic risk of endoscopic biopsy for gastric lesions in the patients with continuous use of antithrombotic agents has not been evaluated. We investigated whether bleeding caused by biopsy is more likely to occur in patients with continuous use of antithrombotic agents.
AIMS & METHODS: The aim of this study is to evaluate a risk of bleeding caused by endoscopic biopsy for gastric lesions with continuous use of antithrombotic agents (ATA) in accordance with the revised Japanese guidelines. Subjects were 4197 gastric biopsies in 2059 patients between January 2012 and December 2013. Subjects were classified into three groups according to the status of administration of ATA. Multivariate analysis was performed to identify independent risk factors associated with biopsy-caused bleeding which needed endoscopic hemostasis.
RESULTS: Patients were classified into three groups; those who had not taken antithrombotic agents (no ATA group: 3253 biopsies), those who had stopped these agents completely (stop ATA group: 266 biopsies), and those who had received and continued antithrombotic agents (ATA group: 678 biopsies). Endoscopic hemostasis was performed in 5 biopsies in the no ATA group (0.15%), 9 biopsies in the stop ATA group (3.38%, $P<0.001$, compared with

no ATA group) and 3 biopsies in the ATA group (0.44%, p = 0.15, compared with no ATA group). In multivariate analysis using logistic regression analysis, ATA use ($P < 0.001$, RR 3.61), and biopsy from upper third region of the stomach ($P = 0.001$, RR 5.53) were risk factors for biopsy-caused bleeding but continuous use of ATA did not increase additional hemorrhagic risk even in continuous use of multiple ATA.

CONCLUSION: Use of antithrombotic agents increased risk of bleeding caused by biopsy for gastric lesions but continuous use of antithrombotic agents did not increase additional hemorrhagic risk. Interruption of antithrombotic agents is not necessary even in the use of multiple antithrombotic agents in the endoscopic biopsy for gastric lesion. This study was performed in a single center, and further studies in multiple centers are necessary.

INTRODUCTION: Mixed type early gastric adenocarcinomas, which have both differentiated and undifferentiated histopathological component, have been reported to have higher incidence of lymph node metastasis than pure differentiated or undifferentiated types. The endoscopic features to distinguish mixed type early gastric cancer from other subtypes have not been previously described.

AIMS & METHODS: We reviewed endoscopic findings of 1230 early gastric adenocarcinomas that were resected in the National Cancer Center Tokyo between January 2011 and December 2012. The following cases were excluded: lesions located at the esophago-gastric junction, specimens from patients who had received chemotherapy within 1 year before resection, cancers located in the remnant stomach after previous gastrectomy and specimens suspected to be recurrent cancers after previous endoscopic resection. After excluding, total of 1047 lesions were evaluated finally. Endoscopic findings that were evaluated include location in the stomach, relationship with atrophic mucosa, color, clarity of demarcation with surrounding mucosa and endoscopic morphology of the lesions. Histopathological findings were evaluated size, depth, presence/absence of an ulcer and evidence of venous/lymphatic invasion. Histopathologically, these lesions were divided into 3 subtype; pure differentiated type, pure undifferentiated type and mixed type.

RESULTS: One thousand and forty seven lesions were consisted of 156 mixed type, 738 differentiated type and 153 undifferentiated type. When compared to differentiated type early gastric cancer, mixed type is more commonly located in the middle third of the stomach (odds ratio = 1.636, 95% C. I. = 1.077-2.487), located in the atrophic border area or the unatrophic area (odds ratio = 4.237, 95% C. I. = 2.330-7.705), 0-IIc type in Paris classification (odds ratio = 4.282, 95% C. I. = 2.515-7.289), larger than 20mm (odds ratio = 4.226, 95% C. I. = 2.703-6.608), have ulcerative findings (odds ratio = 1.868, 95% C. I. = 1.146-3.043) and have submucosal invasion (odds ratio = 3.237, 95% C. I. = 2.042-5.131) in multivariate analysis. In comparison to undifferentiated type early cancer, mixed type is more commonly located in the atrophic area (odds ratio = 1.839, 95% C. I. = 1.062-3.183), reddish colored (odds ratio = 4.966, 95% C. I. = 2.595-9.504), and have submucosal invasion (odds ratio = 1.935, 95% C. I. = 1.121-3.341). Histopathologically, mixed type cancers have a higher incidence of lymphatic invasion than the other subtypes in univariate analysis (p-value < 0.001).

CONCLUSION: Mixed type early gastric cancers have distinct endoscopic findings.

P1278 USEFULNESS OF LAPAROSCOPIC AND ENDOSCOPIC COOPERATIVE SURGERY FOR GASTRIC SUBMUCOSAL TUMORS, INCLUDING ESOPHAGOGASTRIC JUNCTION TUMORS

S. Hoteya[1,*], S. Haruta[1], H. Shinohra[1], M. Kaise[1], Y. Kuribayashi[1], H. Udagawa[1]
[1]*Gastroenterology, Toranomon Hospital, Tokyo, Japan*

INTRODUCTION: A preoperative histopathological diagnosis of gastric submucosal tumor (gSMT) is not only difficult with a regular biopsy, but it often cannot be obtained even by endoscopic ultrasound/fine-needle aspiration (EUS-FNA). In most gSMT cases, treatment indications are determined on the basis of macroscopic signs visible on diagnostic imaging such as EUS or computed tomography, including growth in size over time or surface ulceration, and a definitive diagnosis is only reached after surgical resection. Recently, however, the use of endoscopic submucosal dissection (ESD) for gSMT and the development of laparoscopic and endoscopic cooperative surgery (LECS) have enabled either preservation of the stomach or minimization of the extent of partial resection, and an increasing number of hospitals are introducing it as less invasive, more reliable treatment. In this study, the outcomes following the recent introduction of LECS for gSMT are presented. We evaluated the feasibility and safety of the LECS for SMTs located at the esophagogastric junction (EGJ), compared with non-EGJ SMTs.

AIMS & METHODS: Treatment for gSMT at our hospital broadly follows the algorithm given in the clinical practice guidelines for gastrointestinal stromal tumor (GIST), in which lesions are classified as those for which surgery is absolutely indicated, those for which it is relatively indicated (including endoscopic surgery), and those that should be monitored. Among those lesions for which surgery is relatively indicated, LECS is indicated for lesions that have an intragastric growth pattern, or for which fundusectomy can be avoided despite an extragastric growth pattern. We retrospectively evaluated the outcome of LECS performed in 29 gSMTs, including 6 EGJ SMTs.

RESULTS: Partial gastric resection was performed for 29 patients in our hospital using LECS between its introduction in February 2011 and February 2014. The mean tumor diameter was 31.2 mm (12-72 mm), with a R0 resection rate of 100%, with no postoperative complications of suture rupture, obstruction, or stasis occurring in any patient. On pathology, the tumors were GIST in 20 cases (low 19, high 1), myoma in 5, aberrant pancreas in 2, schwannoma in 1, and cavernous hemangioma in 1. Endoscopic confirmation of the EGJ enabled the extent of resection to be minimized and the stomach to be preserved, And fundusectomy was successfully avoided in all 6 patients in whom tumors were within 2 cm of the cardia. Although there were significantly differences in tumor size and resected specimen size between EGJ SMTs and non-EGJ SMTs, there were no significant differences in outcomes of LECS procedure.

CONCLUSION: LECS for gSMT is easily performed through cooperation between experts in endoscopy and laparoscopy, with good results. LECS is a low-invasive treatment that is both organ-preserving and curative, especially for EGJ SMTs.

P1279 THE EFFICACY OF CARBON DIOXIDE INSUFFLATION IN UPPER GASTROINTESTINAL TRACT ENDOSCOPIC SUBMUCOSAL DISSECTION: A RANDOMIZED, DOUBLE-BLIND, CONTROLLED PROSPECTIVE STUDY

S.Y. Kim[1,*], J.W. Chung[1], D.K. Park[1], K.A. Kwon[1], **K.O. Kim**[1], **Y.J. Kim**[1]

INTRODUCTION: Recently, endoscopic submucosal dissection (ESD) is one of important treatment modality for gastrointestinal tract neoplasm. ESD is performed with using air insufflations, and is associated with abdominal discomfort. It is well recognized that carbon dioxide (CO2) is absorbed quickly in the body than air. CO2 insufflation is expected to be reduces abdominal discomfort and pain after ESD.

AIMS & METHODS: This prospective study was designed to assess the efficacy of CO2 insufflation instead of air insufflation during upper gastrointestinal tract (esophagus: 1, stomach: 53) ESD. From May 2012 to April 2014, a total of 54 consecutive patients were randomly assigned to CO2 insufflation (CO2 group, n = 26) or air insufflation (Air group, n = 28). Abdominal pain after ESD was chronologically recorded on visual analogue system (VAS) score. Also, we recorded of both group that change of abdominal circumference, the amounts of sedatives, and complication rates.

RESULTS: Baseline patient characteristics (age, gender, tumor size, tumor location, tumor histology) were not different in both groups. The mean procedure time was 54.6 minutes in the CO2 group and 57.5 minutes in the Air group, with no statistically significant difference between both groups. Abdominal pain on VAS in the CO2 group vs. Air group was 0.0 vs. 0.3 before the ESD ($p = 0.210$), 3.4 vs. 4.6 one hour after the ESD ($p = 0.131$), 2.7 vs. 3.8 three hours after the ESD ($p = 0.141$), 1.7 vs. 3.3 six hours after the ESD ($p = 0.015$), and 0.8 vs. 2.3 one day after the ESD ($p = 0.002$). In the CO2 group, the abdominal pain on VAS (six hours after the ESD & one day after the ESD) was significantly lower than that of the Air group. The abdominal circumference change in CO2 group shows less variation than in Air group. However, there was no statistical difference between them (0.89 cm vs. 1.42 cm, $p = 0.422$). The amounts of sedative drugs did not differ between the groups ($p = 0.17$). Complication rates were not statistically different between both groups (CO2 group: 19.2%, 5/26; Air group: 28.6%, 8/28) ($p = 0.53$).

CONCLUSION: The amounts of sedatives or complication rates, there were no differences in the two groups. However, CO2 insufflation during upper gastrointestinal tract ESD is less painful for patients than air insufflation.

P1280 LIMITATIONS OF ESD FOR EARLY GASTRIC CANCER: RETROSPECTIVE ANALYSIS OF FACTORS RELATED TO POSITIVE VERTICAL MARGINS

T. Maehata[1,*], O. Goto[2], R. Morita[1], M. Suzuki[1], Y. Sato[1], S. Ishigooka[1], S.-I. Ozawa[1], K. Hosoya[1], Y. Matsuo[1], M. Yamashita[1], H. Yamamoto[1], H. Yasuda[1], F. Itoh[1]

INTRODUCTION: Endoscopic submucosal dissection (ESD) for early gastric cancer is widely used and contributes greatly to the preservation of gastric function. In clinical practice, however, for cases not indicated for ESD, we occasionally encounter treatments such as diagnostic ESD that are considered overindications. Some cases have incomplete resection because of positive vertical margins and deviate from the rule that ''tumors should be completely resected en bloc.'' In this study, we examined the limitations of ESD (conditions of lesions worthy of full-thickness resection) by identifying the clinicopathological factors involved in positive vertical margins (pVM1) among cases of early gastric cancer resected using ESD.
AIMS & METHODS: A total of 653 lesions of early gastric cancer resected en bloc with ESD at two institutions prior to 2013 were categorized into the pVM1 and pVM0 groups. Factors that influenced pVM1 were extracted by univariate analysis of factors such as patient background (age, sex) and pathological background (site, tumor diameter, macroscopic type, ulcerative findings, pathological invasion depth, degree of differentiation, and vascular invasion) followed by multivariate analysis of those factors.
RESULTS: The pVM1 group included 24 lesions (3.5%). On univariate analysis, tumor diameter ($p < 0.0001$), pathological invasion depth (pT1b; $p < 0.0001$), and degree of differentiation ($p = 0.007$) had a significant effect on pVM1. On multivariate analysis of those factors, pT1b was the only factor that had a significant effect on pVM1. The pVM1 rates in pT1a and pT1b lesions were 0.055% and 19.6% ($p < 0.0001$), respectively, and the diagnostic rate of invasion depth was 92.5% overall and 97% and 84.6% in M-SM1 and SM2, respectively.
CONCLUSION: Submucosal (SM) invasion depth had a significant effect on pVM1. When SM invasive cancer is suspected prior to surgery, full-thickness resection, which is more reliable, is desirable for cT1b gastric cancer not only because of possible lymph node metastasis but also because of the high possibility of incomplete resection when ESD is performed for the primary tumor. The future development of function-preserving or reductive surgeries that bridge the gap between ESD and standard surgery in such cases of potentially invasive gastric cancer is desired.

P1281 CONVENTIONAL ENDOSCOPY USING "NON-EXTENSION SIGN" AS A DIAGNOSTIC MARKER IS SUPERIOR TO ENDOSCOPIC ULTRASONOGRAPHY (EUS) FOR DIAGNOSING DEPTH OF INVASION IN EARLY GASTRIC CANCER

T. Nagahama[1,*], K. Otsu[1], K. Yao[2], K. Imamura[1], T. Matsui[1], A. Iwashita[3]
[1]*Department of Gastroenterology,* [2]*Department of Endoscopy,* [3]*Department of Pathology, Fukuoka University Chikushi Hospital, Chikushino, Japan*

INTRODUCTION: Precise diagnosis of depth of invasion is important for deciding upon the proper treatment for early gastric cancer. The authors previously investigated the possibility of diagnosing depth of invasion with conventional endoscopy using ''non-extension sign'' as a diagnostic marker, and reported that the diagnostic sensitivity, specificity and accuracy for submucosal massive invasion (SM2, 500 micrometers and over) by cancer were 89.7%, 97.7%, 96.6%, respectively [1]. However, it is not clear whether conventional endoscopy is superior to endoscopic ultrasonography (EUS) with regard to discriminating submucosal massively invasive cancer (SM2, 500 micrometers and over) from mucosal cancer (M)/submucosal micro-invasive cancer (SM1, less than 500 micrometers). The present study aimed to compare the diagnostic performance of conventional endoscopy and EUS for SM2 early gastric cancer.
AIMS & METHODS: Consecutive early gastric cancer lesions, in which both preoperative conventional endoscopy and EUS were conducted, were included in the study among 863 lesions (704 patients) treated with endoscopic or surgical resection in our hospital between 2005 and 2012. Lesions were excluded if a definitive diagnosis could not be made through histopathological examination of resected specimens. During conventional endoscopy and EUS, the depth of invasion was diagnosed as M/SM1 or SM2 and immediately recorded into a database. ''Non-extension sign'' was determined as ''positive'' when one of the following two findings is detected according to the conventional endoscopic findings: (i) massive surround elevation; or (ii) mucosal convergence with elevation [1]. The ''non-extension sign'' relate to the increased thickness and rigidity caused by massive submucosal invasion by the cancer. In order to obtain reproducible findings, the stomach was insufflated with a large volume of air to detect non-extensibility. Diagnostic criteria for SM2 were positivity for ''non-extension sign'' on conventional endoscopy and a rupture in the 2nd layer 2 with a tumor echo in the 3rd layer on EUS. Lesions negative for these findings were diagnosed as M/SM1. Histopathological examination was used as the gold standard for diagnosing depth of invasion.
RESULTS: A total of 341 early gastric cancer lesions (M/SM1:SM2 = 284:57) were included in this study. The following results were obtained for the diagnosis of SM2 with conventional endoscopy vs. EUS: sensitivity, 89.5% (95% confidence interval [CI]: 81.5–97.4%) vs. 68.4% (95%CI: 56.3–80.5%) [$p < 0.05$, chi-square test]; specificity, 99.3% (98.3–100%) vs. 83.5% (79.1–87.8%) [$p < 0.0001$]; and diagnostic accuracy, 98.4% (96–99.3%) vs. 80.9% (76.8–85.1%) [$p < 0.0001$].
CONCLUSION: Conventional endoscopy using ''non-extension sign'' showed superior diagnostic performance compared to EUS for the diagnosis of SM2 early gastric cancer. The diagnosis of depth of invasion in early gastric cancer by this conventional endoscopy method has the potential to omit EUS.

INTRODUCTION: We reported a regenerative medical approach to prevent oesophageal stricture after endoscopic submucosal dissection (ESD) using **tissue-engineered oral mucosal epithelial cell sheets** in a short term. In this study, long-term outcome has not yet been determined.
AIMS & METHODS: The aim of our study is to reveal the long-term outcome of cell sheet transplantation. Epithelial cells, isolated from the patient's own oral mucosal tissue, were cultured for 16 days using temperature-responsive culture dishes. Then, the autologous cell sheets were endoscopically transplanted onto the bed of the oesophageal ulcer after endoscopic mucosal resection (EMR) and ESD. Results of 10 patients who underwent endoscopic transplantation of oral mucosal epithelial cell sheets from April 2008 through September 2010 were recoded. We analyzed the outcome, the cause, and the endoscopic findings.
RESULTS: All patients were being followed-up. No stricture was detected in any of the patients. The average period of observation was 1.600 days. One patient was deceased because of pancreatic cancer. One patient underwent chemo-radio therapy for farther treatment. One patient underwent surgery due to metastasis of lymph nodes. Only the lymph nodes were dissected, the oesophagus remained intact. From the endoscopic findings: Melanosis was found at the transplanted site in a patient. Strong iodine staining was shown at the transplanted site in a patient.
CONCLUSION: Transplantation of cell sheets has been proven to be a safe method. No patients showed any controlled oesophageal stricture. This study was only an exploratory research, further studies which involve prospective randomized control studies will be needed.

INTRODUCTION: Endoscopic submucosal dissection (ESD) is currently becoming the major treatment for early gastric cancer (EGC) without risk of lymph node (LN) metastasis. ESD showed better results to remove EGC with relatively high resection rate and low local recurrence rate. On the other hand, when the endoscopic resection (ER) is non-curative, surgical treatment is required. Some patients, however, do not undergo surgery after non-curative

ER, because of their comorbidity, refusal of surgery, and so on. Long-term follow-up data and prognosis factors are needed for the case of non-curative ER.
AIMS & METHODS: The aim of this study is to investigate long-term outcome and evaluate the factors related to prognosis of non-curative ER. This is a retrospective study in consecutive patients with EGC underwent ESD from March 2003 to November 2010 in 10 institutes in the Osaka Gut Forum. We defined curative resection as the lesions meeting expanded criteria with R0 resection. Expanded criteria is following; 1) specified mucosal cancer without ulcer findings irrespective of tumor size, 2) mucosal cancer without ulcers 3 cm diameter or smaller, and 3) minute submucosal invasive cancer 3 cm diameter or smaller. We studied the overall and relapse-free survival rate using Kaplan–Meier methods, and the prognosis factors using Cox's regression model.
RESULTS: We treated 1468 patients with EGC by gastric ESD. Of them, 174 patients (174 lesions) resulted in non-curative resection. One hundred seven patients were underwent surgical treatment and 67 patients were observed. These patients had median age of 72 years (mean, 71.2 years; range, 39-90 years), and a male/female ratio of 132:42. Seventy-two lesions were mucosal cancer and 102 lesions were submucosal cancer. Median follow-up period was 58.5 months. There was one gastric cancer-related death in the case of surgical treatment. The 5-year overall survival rate and relapse-free survival rate were 91% and 86%, respectively, and were not significantly different between surgical and non-surgical groups. The most important factor related to relapse-free survival was age (hazard-ratio: 3.37), followed by lymphatic-vascular invasion (2.90), and depth of tumor (2.45).
CONCLUSION: The patients with non-curative endoscopic resection for EGC generally require additional surgery to avoid recurrence. This study, however, showed no significant advantage of surgery within at least 5 years after ER, even though selection bias can exist. There may be no merit of an additional operation in the patients without lymphatic-vascular invasion.

INTRODUCTION: Among superficial esophageal squamous cell carcinoma (SESCC), cancer invading within the epithelium and the lamina propria mucosa (T1a-EP/LPM) is considered as the indication of endoscopic resection, while surgical resection or chemoradiotherapy is recommended for cancer invading beyond the muscularis mucosa (≥T1a-MM). Many retrospective studies have reported that magnifying endoscopy with narrow band imaging (ME-NBI) can predict invasion depth of SESCC well. However, the true additional effect of ME-NBI on white light imaging (WLI) for diagnosis of invasion depth is unclear because of a lack of prospective data. Thus, a prospective study of ME-NBI was conducted in the present study.
AIMS & METHODS: Patients with SESCC were prospectively enrolled from 7 Japanese institutions. Enrolled patients received primary WLI followed by ME-NBI and the report of primary WLI was completed before the start of ME-NBI by an assistant. Diagnoses of invasion depth by each tool were divided into T1a-EP/LPM and ≥T1a-MM and then collated with the final pathological diagnosis by an independent pathologist blinded to the clinical data. All endoscopists attended the consensus meeting and were trained before the trial to standardize diagnosis among examiners, and this trial was started after achievement of a mean k value ≥0.6 among all participating examiners. The primary end point was diagnostic accuracy for invasion depth.
RESULTS: In total, 55 patients with SESCC were enrolled from June 2011 to October 2013, and the results of WLI and ME-NBI were finally analyzed for a total of 49 lesions. Forty one patients underwent endoscopic submucosal dissection and 8 patients did esophagectomy as the initial treatment. Final pathological diagnosis of invasion depth was T1a-EP/LPM in 31 lesions and ≥T1a-MM in 18 lesions. The accuracy of invasion depth in WLI and ME-NBI was 71.4% and 67.3% ($P=0.661$), respectively. Sensitivity for ≥T1a-MM was 61.1% in both WLI and ME-NBI ($P=1.000$), and specificity for ≥T1a-MM was 77.4% in WLI and 67.7% in ME-NBI ($P=0.393$). Moreover, we will present other data of subset analyses in this meeting.
CONCLUSION: ME-NBI did not demonstrate the additional effect on WLI for diagnosis of invasion depth of SESCC. Further development of diagnostic tool is hopeful in the future.

P1285 A NOVEL SELF-ASSEMBLED PEPTIDE SOLUTION FOR PREVENTION OF POST PROCEDURE BLEEDING AND PROMOTING ULCER HEALING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC LESIONS

T. Uraoka[1,2,*], O. Goto[2], J. Horii[2], Y. Ochiai[2], A. Fujimoto[2], K. Takabayashi[1], Y. Kawahara[3], K. Hori[4], S. Matsuda[5], Y. Kitagawa[5], N. Yahagi[2]
[1]Department of Gastroenterology, Tokyo Medical Center, [2]Division of Research and Development for Minimally Invasive Treatment, Cancer Center, School of Medicine, Keio University, Tokyo, [3]Department of Endoscopy, Okayama University Hospital, [4]Department of Gastroenterology and Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, [5]Department of Surgery, School of Medicine, Keio University, Tokyo, Japan

INTRODUCTION: Endoscopic submucosal dissection (ESD) can remove early stage gastric epithelial neoplasms *en bloc* those that are large, with scarring, however, post-ESD bleeding has been reported in 4-7% of patients. Gastric ESD-induced ulcer is generally treated with proton pump inhibitor (PPI) for at least 8 weeks after ESD. Recently, a self-assembled peptide solution, which has a function as an extracellular matrix scaffold material to replace collagen has been developed.
AIMS & METHODS: The aim of this clinical trial was to assess the safety and efficacy of a novel self-assembled peptide solution for ESD-induced ulcers. Consecutive patients who underwent gastric ESDs enrolled in this study. Patients receiving antithrombotic therapy were included, but such medications were no longer being administered prior to the procedures. Cases with perforation and coagulopathy (INR > 3) despite anticoagulation management after heparin bridge therapy (HBT) were excluded. For every 1 cm of tumor, 1 mm^3 of fully-synthetic peptide solution that self-assembles at physiological pH and forms a gel comprising a network of nanofibers (PuraMatrix™; 3-D Matrix, Ltd) was applied to the ESD-induced ulcer using a catheter immediately after the procedure. Single dose PPI was administered for 8 weeks beginning the morning of the procedure. Ulcer stages were evaluated by endoscopy as active, healing or scarring at 1, 4 and 8 weeks after ESDs. The primary endpoint was the rate of post-ESD bleeding. The secondary endpoints include the transitional rate to healing and scarring stages of gastric ESD-induced ulcers according to the Sakita-Miwa classification.
RESULTS: Of 47 patients recruited, 45 patients with 51 lesions were enrolled for outcome analysis and 2 patients were excluded due to 1 perforations and 1 with coagulopathy. Fourteen patients (31%) were previously on antithrombotic therapy including 5 (11%) requiring HBTs. The mean size of resected specimen was 40±16mm. The rate of post-ESD bleeding was 2.0% (1/51, 95%CI, 0.03 to 10.3). A post-ESD bleeding was successfully managed endoscopically without needed blood transfusion. Transitional rate to healing stage at 1 week was 96%. Follow up endoscopies demonstrated scaring stage in 17% and 98% at 4 and 8 weeks respectively. There were no adverse effects related with PuraMatrix use.
CONCLUSION: The use of this novel self-assembled peptide solution may help reduce post-ESD bleeding rate and promote ulcer healing. Further studies are needed to fully evaluate its efficacy. (UMIN Clinical Trials Registry: 000011548)

INTRODUCTION: The endocytoscopy system (ECS) enables observation of cell nuclei and real-time microscopic diagnosis. High-quality in vivo imaging and accurate diagnosis of ECS images are essential for the practical application of this modality.
AIMS & METHODS: This study sought to determine the diagnostic visualization capabilities of in vivo ECS in superficial esophageal squamous cell carcinoma (SCC) and to reveal the diagnostic accuracy of pathologists. Patients with superficial esophageal SCC or high-grade intraepithelial neoplasia (HGIN) larger than 10 mm were targeted. Endoscopists selected 3 ECS images each of cancerous and non-cancerous lesions in each patient, and central pathologists verified both sets of images and the corresponding parts in the specimens. The ECS images were randomly assigned in each case and subsequently evaluated by 5

pathologists blinded to individual cases. Diagnostic criteria were cellular or structural atypia, specifically nuclear enlargement, anisokaryosis, high nuclear density, and intercellular boundary. The primary endpoint was the diagnostic rate of cancerous lesions on ECS images determined by the pathologists (sensitivity). The secondary endpoints were the inter-observer agreement among the 5 pathologists (multi-rater κ coefficient), the percentage of ECS images useful for diagnosis, and the diagnostic rate of non-cancerous lesions (specificity). Using a prototype integrated endocytoscope, ECS diagnosis was made based on that previously reported by Inoue et al. that defined ECA1–3 as a non-cancerous lesion and ECA4–5 as a cancerous lesion.
RESULTS: Between May 2011 and January 2012, 72 patients were registered at 9 medical facilities. After excluding patients who declined to participate or patients without an available specimen, 68 patients were enrolled. Mean tumor diameter was 22.5 mm (range, 10–60 mm). Fifty-five lesions were squamous cell carcinomas and 13 were HGIN. The diagnostic sensitivity and specificity were 88% (95% CI, 77.2–94.5) and 100% (95% CI, 94.5–100), respectively. The multi-rater κ coefficient was 0.88 (95% CI, 0.80–0.96). In addition, 96% (95% CI, 87.6–99.1) of the ECS images were suitable for diagnosis.
CONCLUSION: In vivo ECS images provided high visualization, with high sensitivity and high specificity in the diagnosis of esophageal squamous cell carcinoma by pathologists. Given the high inter- observer agreement, ECS appears to be useful for the real-time endoscopic histological diagnosis of esophageal squamous cell carcinoma.

INTRODUCTION: For recent advance in image enhanced endoscopy, such as Narrow Band Imaging (NBI), we have more frequent opportunities for early detection of superficial pharyngeal cancer (SPC). Endoscopic resection has been proposed as a safe and effective treatment for SPC. We previously reported endoscopic submucosal dissection (ESD) yielded higher rate of complete resection, and lower rate of local recurrence compared with endoscopic mucosal resection (EMR). But ESD was more time consuming and more frequently complicated by laryngeal edema.
AIMS & METHODS: This study includes consecutive 113 patients treated by endoscopic resection for SPC from October 2006 to December 2013 in one referral cancer center. We treated SPC in first period by EMR, in second period by conventional ESD (cESD) and in recent period by double scope ESD (dsESD), in which we use second thin endoscopy for good counter traction. We compared outcome of these three methods for short term outcome, and we also showed long term outcome after endoscopic resection for SPC.
RESULTS: A total of 166 SPCs in 113 patients (Male: 100, Female: 13) were treated by endoscopic resection (EMR: 55, cESD: 32, dsESD: 79). The size of tumor was 18mm in average, which invaded to CIS/SEP/MP 108/57/1 respectively. All lesions were diagnosed squamous cell carcinoma. In dsESD, the procedure time was shortened compared to cESD (82 min vs 111 min, $p<0.05$) although the rate of laryngeal edema was not decreased (16% vs 9%). It may be because we treat more complicated cases recently. En bloc resection rate and complete resection rate for EMR, cESD and dsESD were 38%, 91%, 97% ($p<0.01$) and 29%, 63%, 84% ($p<0.01$), respectively. Local recurrence was detected in 3 cases after EMR and in 1 case after cESD. We treated by re-EMR in 2 cases, by RT in 1 case and by surgery in 1 case. LN metastasis was detected in 2 patients who were treated by surgical neck dissection. All the salvage treatment was successfully performed. For long time outcome with median follow–up period of 30 months (range 2-86 months), the overall survival rate at 5 years was 88% (95%CI, 82-94), no patient died of SPC. The cumulative development rate of multiple cancers in pharyngeal mucosal sites at 5 years was 27% (95%CI, 18-35). The pharynx was preserved in almost all the patients except for one case who had surgery for local recurrence.
CONCLUSION: Here we showed dsESD was a superior method in treating SPC, for achieving both en bloc and complete resection and reducing the procedure time. Endoscopic resection for SPC is organ preserving with no loss of function and effective treatment with curative intent.

P1288 THE USEFULNESS AND COST-EFFECTIVENESS OF NON-TARGETED GASTRIC BIOPSIES: ARE WE TOO FORWARD WITH THE FORCEPS?

V. Gibson[1,*], S. Needham[1], M. Nayar[1], N. Thompson[1]
[1]*Newcastle Hospitals NHS Trust, Newcastle upon Tyne, United Kingdom*
Contact E-mail Address: *gibsonvm@doctors.org.uk*

INTRODUCTION: There are no agreed guidelines on indications for endoscopic gastric biopsies. Taking and reporting gastric biopsies is costly, and there is a shortage of trained pathologists in the UK. We investigated whether non-targeted gastric biopsies contributed to cost-effective and best patient management.
AIMS & METHODS: We retrospectively analyzed all endoscopic gastric biopsies taken across two teaching hospital sites in a 3-month period, 2/1/13-31/3/13; details were obtained from our histopathology database. For each set of biopsies taken we accessed our endoscopy database for patient demographics, reason for endoscopy, appearance of gastric mucosa, Urease-based Helicobacter test (UBHT) result if obtained, and the grade of endoscopist (Consultant, Registrar or Nurse Specialist). The electronic patient medical record was reviewed to assess whether the biopsy changed the patient's diagnosis or management.
A targeted biopsy was defined as the presence at OGD of a polyp, ulcer or other lesion documented in the report. Non-targeted biopsy was any other appearance, including gastritis. The cost of biopsy included histopathology manpower and processing costs. We looked separately at the cost of UBHT testing plus forceps use.
RESULTS: During the 3-month period 2.265 OGDs were performed. 408 patients had gastric biopsies taken, resulting in 419 biopsy sets (some had multiple endoscopies), an overall biopsy rate of 18.5%. The age range was 18-97 years (median 63 years). 22% of endoscopists were consultants, 33% registrars and 45% nurse specialists. Of the 419 biopsies, 43% were targeted (n = 181) and 57% were non-targeted (n = 238).
Of the non-targeted biopsies, 0.8% (n = 2) revealed an adenocarcinoma, both these biopsies being from the same man who was under surveillance for a strong family history of gastric carcinoma. 70% (n = 168) showed a form of gastritis, 16% (n = 37) showed *H.pylori*, and 13% (n = 31) had normal histology. Of the non-targeted biopsies, 94% (n = 223) had no change to their diagnosis or management based on histology. 1% (n = 2) had a gastrectomy, which was the one man under surveillance, 3% (n = 8) had eradication therapy based on histology as UBHT was not performed, and 2% (n = 6) had recommendation to GP to give eradication therapy if not already given, as result of the UBHT test was unclear. The cost of processing each biopsy set was £103.51. The annual cost of non-targeted biopsies where result did not change the management (n = 223) was £92.330. This compared to £6.90 for each UBHT which would amount to only £6.154 per annum, creating an annual potential saving of £86.177.
CONCLUSION: The majority of non-targeted gastric biopsies did not contribute to patient management. Limiting non-targeted gastric biopsies could save significant resources, as well as contributing to patient safety by limiting unnecessary biopsies.

INTRODUCTION: Barrett's esophagus (BE)-associated neoplasia can be treated by endoscopy, but accurate assessment of neoplastic lesions in BE is challenging.
AIMS & METHODS: This study aimed to investigate the role of confocal laser endomicroscopy (CLE) as an adjunct in the endoscopic treatment of BE-associated neoplasia by assessing lateral and sub-squamous tumor extension (SSTE). In the context of a prospective single arm clinical pilot trial patients referred for endoscopic resection of BE-associated neoplasia (high grade dysplasia and esophageal adenocarcinoma) underwent high-definition white light endoscopy with narrow band imaging (NBI), followed by CLE-mapping of suspected neoplastic lesions prior to endoscopic mucosal resection (EMR) or endoscopic submucosal resection (ESD) depending on lesion size and anticipated histology.
RESULTS: In 7/38 (18%) patients CLE revealed additional neoplastic tissue as compared to prior white light and NBI – two concomitant lesions, two cases of lateral tumor extension within the Barrett's epithelium and three cases of previously undetected SSTE. Overall, en-bloc resection (tumor-free lateral margin) was achieved in 28/34 neoplastic lesions (82%) and complete resection (tumor-free lateral and basal margins) in 21/34 neoplastic lesions (62%).
CONCLUSION: CLE-assisted endoscopic resection of BE-associated neoplasia was safe and effective in this study, proved by a high additional diagnostic yield of CLE (including visualization of occult SSTE) and a favorable en-bloc resection rate. The clinical value of CLE for assisting endoscopic therapy of BE-associated neoplasia deserves further evaluation in randomized controlled trials.

P1290 DIFFERENCE IN ENDOSCOPIC VACUUM-ASSISTED CLOSURE (E-VAC) AND ESOPHAGEAL STENTING IN POSTSURGICAL GASTROESOPHAGEAL LEAKAGE

Y.S. Jeong[1,*], Y.S. Park[1], J.Y. Lee[1], Y.J. Choi[1], Y.H. Kwon[1], J.J. Hwang[1], K.C. Yoon[1], A. Lee[1], H.J. Lee[1], H. Yoon[1], C.M. Shin[1], N. Kim[1], D.H. Lee[1]
[1]*Internal medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*
Contact E-mail Address: *nadapk@naver.com*

INTRODUCTION: After esophagectomy or proximal gastrectomy, the reported incidence of esophageal leakage ranges from 5% to almost 30%. Gastroesophageal leakage increases morbidity and mortality rates, and several treatments are used to control leakage such as approximation with endoclipping, injection with tissue adhesive agents of histoacryl or fibrin glue, and endoscopic implantation with self-expendable metal stents (SEMS). But these treatments included endoluminal esophageal stent always could not be successful. E-VAC therapy has recently been reported as an effective treatment modality for postsurgical anastomotic leakage.
AIMS & METHODS: The aims of this study are to show the relative differences therapy of between esophageal stenting and E-VAC in treating postsurgical gastroesophageal leakage.

From 2006 to 2014, 13 patients treated with postsurgical gastroesophageal leakage in one medical center were evaluated (Male: Female = 11: 2). Mean age were 71.4 ± 5 years in E-VAC group and 63.1 ± 6 years in stenting group. Among the patients, 7 patients were treated by E-VAC. It has been proceeded endoscopically placing drainage tube armed with size-adjusted sponge in the necrotic cavities, and then applied continuous suction of mean pressure 125 mmHg. We changed sponges and drain twice a week. On the other hand, 6 patients were treated by covered SEMS. In stenting group, we removed the stent after 6 to 8 weeks because of difficulty to remove stent due to tissue hyperplasia. The followings were compared: clinical success rate, recurrence, mean closure time and mean hospital stay.

RESULTS: The 7 patients treated with E-VAC were all treated successfully. Of the 6 patients treated with stenting, 5 patients of them were treated successfully. However, one patient in stenting group died of cancer progression without control of leakage by stenting. One patient in the stenting group after 69 days and one patient in the E-VAC group after 63 days recurred. They were treated with same method. Mean closure time was 17.8 ± 17 days in E-VAC group and 16.8 ± 14 days in stenting group. Mean hospital stay were 33 ± 30 days in E-VAC group and 50.5 ± 29 days in stenting group.

Table 1. Postsurgical gastroesophageal leakage treated by endoscopic vacuum closure (E-VAC) and esophageal stenting: characteristics and treatment in 13 patients.

	E-VAC Group	Stenting Group
Age (year), mean ± SD	71.4 ± 5	63.1 ± 6
Male / Female	5 / 2	6 / 0
Clinical Success Rate	100 %	83 %
Closure Time, mean ± SD	17.8 ± 17	16.8 ± 14
Hospital Stay, mean ± SD	33 ± 30	50.5 ± 29

CONCLUSION: E-VAC therapy might be effective treatment option for postsurgical gastroesophageal leakage.

P1291 PROPER MUSCLE LAYER DAMAGE AFFECTS ULCER HEALING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

Y. Horikawa[1,*], H. Mizutamari[1], N. Mimori[1], Y. Kato[1], K. Shimazu[1], S. Ohkubo[1]
[1]*Gastroenterology, HIRAKA GENERAL HOSPITAL, Yokote city, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is the established therapy for superficial gastrointestinal neoplasms. As the larger ulcers associated with ESD, management of artificial ulcers has become more important. However, the relationship between ulcer healing factors and treatment is still unclear.

AIMS & METHODS: We aimed to evaluate the ESD-related artificial ulcer reduction ratio at 4 weeks to assess the factor associating with ulcer healing after ESD that may lead to optimal treatments.

Between January 2009 and December 2013, a total of 375 lesions fulfilled the expanded criteria for ESD. After exclusion, 328 lesions were divided into two groups based on the ulcer reduction rate and analyzed: Group A, rate <90% and Group B, rate ≥90%. These two groups were compared based on clinicopathological / endoscopic features, concomitant drugs, and treatments.

RESULTS: The ulcer reduction rate was significantly correlated with factors related to the ESD procedure, i.e., procedure time, submucosal fibrosis, and exposure of the proper muscle layer, in univariate analysis. Multivariate logistic regression analysis showed that submucosal fibrosis (F2) ($p = 0.03$; OR, 16.46; 95% CI, 1.31–206.73) and exposure of the proper muscle layer ($p = 0.01$; OR, 4.27; 95% CI, 2.04–8.92) were statistically significant predictors of delayed healing.

CONCLUSION: This single-center retrospective study indicated that ESD-induced artificial ulcer healing was affected by submucosal fibrosis and exposure of the proper muscle layer, which induced damage to the contraction of the muscle layer.

P1292 LENS COATING WITH LIQUID CERAMICS IS USEFUL TO MAINTAIN GOOD VISIBILITY FOR TRANSNASAL SMALL-CALIBER ESOPHAGOGASTRODUODENOSCOPY

Y. Komazawa[1,*], M. Yuki[1], M. Kusunoki[1], Y. Kobayashi[1], S. Nakashima[1], T. Shizuku[1]
[1]*Izumo-city General Medical Center, Izumo, Japan*

INTRODUCTION: Unsedated transnasal small-caliber esophagogastroduodenoscopy (TN-EGD) is used to examine the upper gastrointestinal tract and its feasibility as compared to conventional transoral EGD has been shown. However, a well-known limitation encountered with TN-EGD is poor image quality as compared to conventional endoscopy due to the small size of the CCD, while insufficient lens cleansing is related its small caliber water jet nozzle. Poor visibility may affect endoscopic diagnostic accuracy, thus maintenance of good visibility is very important. Liquid ceramics coating is known to be an effective means to keep glasses or lenses clean because of its hydrophilic characteristic. Using a randomized prospective double-blind trial, we evaluated the efficacy of lens coating with liquid ceramics for TN-EGD.

AIMS & METHODS: Basic *in vitro* (Study I) and randomized prospective clinical (Study II) studies were performed. Two groups of small-caliber endoscopes, with and without ceramics coating (C- and N-group, respectively), were prepared. For lens coating, we applied a very small quantity of liquid ceramics onto the lens, then completely wiped it off with gauze.

Study I: Endoscopic lenses in the C- and N-groups were soiled with lard oil and washed using a lens cleansing procedure that consisted of air and subsequent washing solution from the endoscopic jet nozzle, then photographs of a test chart were obtained with them. Image quality was judged by 3 experts who had no knowledge of grouping.

Study II: We randomly assigned 115 patients who underwent TN-EGD to the C- and N-groups. TN-EGD procedures were performed by 3 expert endoscopists, who judged the level of endoscopic visibility using a 5-grade visual analogue scale after TN-EGD. This study was approved by the ethics committee of Izomo City General Medical Center. Written informed consent was obtained from all participants.

RESULTS: In Study I, photographic image quality was significantly better in the C-group as compared to the N-group ($P < 0.05$). In Study II, the level of endoscopic visibility in the C-group was also significantly superior ($P < 0.05$).

CONCLUSION: For EGD with transnasal small-caliber endoscopy, lens coating with liquid ceramics may be useful to maintain a good visual condition and improve diagnostic accuracy.

P1293 THE EFFIECTIVENESS OF CHROMOENDOSCOPIC METHOD USING AN ACETIC ACID–INDIGOCARMINE MIXTURE FOR SUPERFICIAL FLAT-TYPE (0-IIB) EARLY GASTRIC CANCERS

Y. Kawahara[1,*], H. Okada[1], S. Kawano[1], K. Hori[1], T. Tsuzuki[2], M. Kita[2], H. Kanzaki[2], Y. Kohno[2], K. Miura[2], K. Yamamoto[2]
[1]*Department of Endoscopy,* [2]*Department of gastroenterology and hepatology, Okayama University, Okayama, Japan*
Contact E-mail Address: *yoshirok@md.okayama-u.ac.jp*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been established as a standard treatment for early gastric cancer (EGC) in Japan. The advantage of ESD is that it enables the *en-block* resection of large lesions, thereby allowing the accurate pathological evaluation of the resected lesions and avoidance of recurrence after piecemeal resection. Therefore, it is important to accurately determine the extent of gastric cancer invasion and resect the cancer. However, in superficial flat-type gastric cancer (0-IIb type), it is often difficult to determine the extent of tumor invasion.

AIMS & METHODS: We previously reported the effectiveness of chromoendoscopic method using an acetic acid–indigo carmine mixture (AIM) in one hundred gastric cancer cases. The aim of the present study was to estimate the accuracy of this chromoendoscopic method using an acetic acid–indigo carmine mixture (AIM) in superficial flat-type cases.

Studied were 112 flat-type EGC lesions. EGC were initially observed by white light (WL) after which indigo carmine (IC) solution was sprinkled onto the gastric mucosa. Images by WL and IC observation were recorded by a digital filing system. After washing away IC solution with water, AIM solution was sprinkled onto the gastric mucosa and images were recorded. Margin lines of EGC determined by each observation were drawn on recorded images by graphic software for comparison with resected specimens. First, diagnostic accuracy of the endoscopic images with each modality was independently evaluated with regard to the recognition of the entire contact border around the lesions by two endoscopists who have extensive experience in the diagnosis and management of EGC. Second, the agreements between the endoscopic views with efficient modality were evaluated and, finally, the evaluations of the two endoscopists were compared and, in case of any conflicts in the findings, an agreement was reached through discussion, and margin lines of EGC determined by each observation were drawn on the recorded images by graphic software.

After lines were similarly drawn on images of resected specimens, the extent of the lesions was compared with that determined by endoscopic images.

RESULTS: We found that AIM chromoendoscopy enabled us to achieve a very clear enhanced visualization of flat-type EGC lesions. Diagnostic accuracy of WL, IC, and AIM observations were 23.0%(n = 26), 54%(n = 60) and 82%(n = 92), respectively. No adverse events occurred with the AIM method. Diagnostic accuracy of AIM observation was significantly higher than that by WL observation ($P < 0.0001$) and IC observation ($P < 0.0001$).

CONCLUSION: We can achieve clearer visualization of the tumor extent by the AIM chromoendoscopy than by the IC method.

P1294 THE RESULT OF GLASGOW-BLATCHFORD SCORE COMPARED TO OTHER SYSTEMS IN ACUTE UPPER GASTROINTESTINAL BLEEDING

Y.S. Shin[1,*], D.H. Kang[1], H.W. Kim[1], C.W. Choi[1], S.B. Park[1], B.J. Song[1], S.J. Kim[1], Y.Y. Choi[1], D.K. Kang[1], H.K. Lim[1], S.K. Oh[1], H.S. Nam[1]
[1]*Division of Gastroenterology, Department of Internal Medicine, School of Medicine Pusan National University, Pusan National University Yangsan Hospital, Yangsan-si, Korea, Republic Of*
Contact E-mail Address: *shadam@naver.com*

INTRODUCTION: Upper gastrointestinal bleeding has been a major cause of hospital admission and mortality throughout the world. Therefore prediction of the risk in the patients with acute upper gastrointestinal bleeding (AUGIB) is important subject. Several scoring systems have been used to identify patients with acute upper gastrointestinal bleeding who are at a high risk. Glasgow-Blatchford score (GBS) predicts the need for medical intervention (such as

blood transfusion or endoscopy) by using the results of blood tests and vital sign. Rockall score (RS) is calculated by endoscopic finding, age, comorbidity, vital sign and used to predict outcome. But this scoring system has disadvantage of complicated calculation.
Recently AIMS65 is the simple risk scoring system that identified five factors such as serum albumin, international normalized ratio, altered mental status, systolic blood pressure and age. We studied retrospectively the usefulness of these scoring systems and compared these systems. We hope that our study will help for assessing the need for clinical intervention, re-bleeding and death in cases of AUGIB.
AIMS & METHODS: We found 384 patients who underwent urgent endoscopy due to UGIB from December 2008 to August 2013 at Pusan national university Yangsan Hospital. Of these patients, 223 patients were satisfied with UGIB and included in this study. All 223 patients were assessed by GBS, RS and AIMS65. At the same time the patients who needed the clinical intervention or died in-hospital within 30 days were defined as unfavorable outcome patients. Then the result of each scoring system was compared with clinical outcome.
RESULTS: Overall in-hospital mortality was 2.2% (5/223). In our total 223 patients, 43.9% (98/223) were classfied as unfavorable outcome patients. The re-bleeding rate was shown as 9.4% (21/223). Compared to these scoring system, there was little significant difference in predicting the need of therapeutic intervention and death. But GBS was significantly elevated in unfavorable outcome patients ($p = 0.0119$). Also GBS was superior to the other scores for predicting the need for packed red blood cell transfusions ($p = 0.0134$).
CONCLUSION: In acute upper gastrointestinal bleeding, GBS, RS and AIMS65 scoring system can predict need for intervention and unfavorable clinical outcome in AUGIB. GBS was more advantageous to the prediction of blood transfusion. On the other hand, these systems were similar to predict clinical outcome.

INTRODUCTION: New guidelines for gastroenterological endoscopy considering the associated risk of thrombosis were revised in 2012, by the Japan Gastroenterological Endoscopy Society. The new edition of the guidelines includes discussions of gastroenterological hemorrhage associated with continuation of antithrombotic therapy, as well as thromboembolism associated with withdrawal of antithrombotic therapy. Therefore, we aimed to assess the feasibility of endoscopic submucosal dissection (ESD) without cessation of antithrombotic agents.
AIMS & METHODS: This was a retrospective study from a single institution. This study enrolled 330 neoplasms (47 esophageal neoplasms, 161 gastric neoplasms and 122 colorectal neoplasms) in 310 patient who had ESD from April 2013 to May 2014. 75 patients who were receiving antithrombotic agents because of their high-risk status for a thromboembolic event (after implantation of coronary stent, after valve replacement, or a previous history of thromboembolic event or heart failure due to atrial fibrillation) were involved. We evaluated the rate of post-ESD severe bleeding complications (overt hematemesis/hematochezia, a drop of hemoglobin > 2g/dL from baseline, or requirement of endoscopic hemostasis, and/or transfusion).
RESULTS: Of 310 patients, 58 took antiplatelet agent, among whom 13 continued aspirin, 4 replaced with heparin. 26 took anticoagulant agent, among whom 22 replaced with heparin. Of 310 patients, 9 took antiplatelet agent and anticoagulant agent in combination therapy. This 9 cases was performed ESD with continued aspirin under replacement of heparin. Post-ESD bleeding occurred in 4 subjects (1.2%) including 2 from the continued aspirin group, 1 from the withdrawal antiplatelet agent group who had a renal dysfunction, and 1 from the no-antithrombotic agents group who was big specimen diameter. Univariate analysis revealed antiplatelet therapy (OR = 13.69, 95%CI: 1.24-348.24, $p = 0.0036$) was associated with post-ESD bleeding, but continued aspirin (OR = 8.00, 95%CI: 0.49-247.40, $p = 0.059$) was not statistically significant. All post-ESD bleeding cases were treated successfully by endoscopic hemostasis. Emergency surgery was not required in any of the cases. Blood transfusion was needed in 1 patient (0.3%). Among 75 subject who had antithrombotic therapy, 2 developed acute cerebral infection (2.6%) including 1 from the continued aspirin group, 1 from the withdrawal antiplatelet agent group. No event occur in the anticoagulant group replaced with heparin.
CONCLUSION: ESD without cessation of antithrombotic agents, can be acceptable if performed carefully for patients with antiplatelet therapy.

P1296 DETECTION OF COLONIC POLYPOID LESIONS BY PET OR PET-CT IN PHYSICAL CHECK-UP POPULATIONS

S. Park[1,*]
[1]*Center for Health Promotion, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of*
Contact E-mail Address: *semi2010.park@samsung.com*

INTRODUCTION: A 18-Fluorodeoxyglucose positron emission tomography (FDG-PET) or PET-computed tomography (PET-CT) is used clinically detect malignant lesions. The efficacy of PET or PET-CT comparing colonoscopy to detect colonic polypoid lesions including premalignant adenomas and colon cancers is not well defined in large number of populations.
AIMS & METHODS: The aim of this study is to evaluate the efficacy of PET or PET-CT comparing standard colonoscopy to detect colonic polypoid lesions in physical check-up examinees.
Methods: A total of 4063 persons with synchronous evaluation of PET or PET-CT with colonoscopy were enrolled between 2003 and 2010 for the physical checkup at our single health promotion center.
RESULTS: Colonoscopy with biopsy confirmed the adenomas and cancers in 1212 of 4063 examinees. The focal FDG uptake by PET or PET-CT showed in 19 examinees of positive colonoscopic findings. Sensitivity, specificity, positive predictive value, and negative predictive value to detect colonic polypoid lesions including adenomas and cancers by PET or PET-CT comparing with standard colonoscopy were 1.6%, 99%, 82%, and 70%, respectively. The sensitivity of PET or PET-CT according to the adenoma size was increased (1.7% for 1-10mm, 3.3% for 11-20mm, 40% for $>$20mm). A total of 8 patients had high grade dysplasia ($n = 1$), rectal neuroendocrine tumors ($n = 5$) or colon cancers ($n = 3$). Among them, only 1 patient with 5cm sized advanced colon cancer showed FDG-PET uptake.
CONCLUSION: In physical check-up examinees, a PET or PET-CT comparing with conventional colonoscopy did not detect colonic advanced adenomas, rectal neuroendocrine tumor (rectal carcinoid) or early colon cancers smaller than 1 cm. Therefore, detection of colonic polypoid lesions except advanced colon cancers by PET or PET-CT was insufficient in physical check-up populations.

P1297 WATER EXCHANGE ATTENUATES REAL-TIME INSERTION PAIN AND POTENTIALLY ENHANCES COST SAVINGS BY PROMOTING COMPLETION OF UNSEDATED COLONOSCOPY

S. Cadoni[1,*], S. Sanna[2], P. Gallittu[1], M. Argiolas[2], V. Fanari[2], M.L. Porcedda[2], M. Erriu[3], F.W. Leung[4]

Contact E-mail Address: *cadonisergio@gmail.com*

INTRODUCTION: We tested the hypothesis that water exchange (WE) produces significantly lower insertion pain scores than air insufflation (AI) and water immersion (WI).
AIMS & METHODS: A 2-center RCT stratified enrolment of diagnostic and screening patients given on-demand sedation. Primary outcome: real-time maximum insertion pain recorded by an unblinded observer. Before discharge patients reported recalled pain to a blinded observer and guessed the method used.
RESULTS: 576 patients were randomized to AI ($n = 193$), WI ($n = 197$), WE ($n = 186$). Patients' correct guesses were $<33\%$. Table 1 shows the primary outcome and recalled pain (Visual analogue scale: 0 = none, 10 = worst). Comparison of primary outcome and recalled pain in unsedated patients (Pearson correlation 0.6, $p < .0005$) confirmed its validation. Uniquely, WE has no significant investigator differences in mean pain score during insertion ($p < .48$), and lower standard deviation. Recalled pain did not reveal differences in the three groups. Individual colonoscopist's real-time pain scores, however, were susceptible to type II errors due to small numbers. Since adoption of WE, ~85% of colonoscopies are unsedated. Immediate return to routine activities after successful unsedated colonoscopy was feasible. Estimates of resources saved on-site: patients, € 2.074; nursing time € 3.121; pharmacy expenses, € 194. At home, patients € 89.731. Table 1: Investigators' real-time and recalled pain, mean (95% CI). M, maximum; R, recalled; CI, confidence interval; SD, standard deviation. ≠, ANOVA.

Table to abstract P1297

Investigators	Pain	WE	WI	AI	P ≠
1	M	2.2 (1.6-2.8)	4.8 (4.0-5.6)	5.5 (4.8-6.2)	<0.0005
	R	1.9 (1.4-2.4) n=46	3.3 (2.4-4.1) n=40	3.9 (3.2-4.6) n=47	<0.0005
2	M	3.0 (2.3-3.7)	3.5 (2.7-4.2)	4.3 (3.8-5.2)	0.048
	R	2.2 (1.7-2.8) n=46	2.8 (2.1-3.5) n=43	2.8 (2.0-3.6) n=48	0.386
3	M	2.3 (1.0-3.6)	2.3 (1.0-3.6)	4.0 (2.9-5.1)	0.096
	R	0.5 (0.4-1.4) n=14	0.1 (0.1-0.3) n=19	0.5 (0.1-1.0) n=13	0.486
4	M	2.2 (0.8-3.6)	2.3 (1.6-2.9)	2.8 (2.0-3.5)	0.574
	R	0.2 (0.1-0.6) n=28	0.1 (0.1-0.3) n=12	0.2 (0.1-0.4) n=29	0.766
5	M	2.9 (1.8-4.0)	3.7 (2.3-5.1)	3.5 (2.2-4.8)	0.699
	R	0.7 (0.1-1.5) n=13	0.8 (0.1-1.6) n=16	0.3 (0.1-0.8) n=20	0.509
6	M	2.4 (1.6-3.2)	2.6 (1.5-3.7)	3.4 (2.4-4.5)	0.255
	R	0.2 (0.1-0.4) n=23	0.2 (0.1-0.4) n=20	0.6 (0.1-1.2) n=33	0.066
Within group, *P* value≠ (SD)		M 0.48 (2.1) R <0.0005 (1.7)	M <0.0005 (2.6) R <0.0005 (2.3)	M <0.0005 (2.7) R <0.0005 (2.5)	– –

CONCLUSION: This head-to-head comparison shows WE to have the lowest real-time insertion pain score, high repeatability and reproducibility by endoscopists with otherwise significantly different pain scores during insertion when using AI or WI. WE equalizes differences in method-related real-time pain among investigators. Promotion of the unsedated option lessens the burden of sedation on patients on-site and at home. Direct (nursing staff time) and indirect (patients) cost savings appear to be plausible. (NCT01781650, 01780818)

P1298 SHOULD PATIENTS WITH RECTAL BLEEDING HAVING A FLEXIBLE SIGMOIDOSCOPY COME FULLY PREPARED FOR A COLONOSCOPY?

S. Subramaniam[1,*], K. Besherdas[1]
[1]*Department of Gastroenterology, Barnet & Chase Farm Hospitals NHS Trust, London, United Kingdom*
Contact E-mail Address: *sharmila.subramaniam@nhs.net*

INTRODUCTION: The vast majority of patients referred for investigation of rectal bleeding have benign anal disease or proctitis. Flexible sigmoidoscopy (FS) has been widely used for the investigation of patients with rectal bleeding with same day single phospho-soda enema preparation prior to the examination. However, conversion to full colonoscopy is warranted if adenomatous polyps or colon cancer is detected to exclude synchronous lesions. We hypothesise that as the patients age at presentation of rectal bleeding increases, the prevalence of adenomatous polyps and colon cancer increases and thereby the requirement for evaluation of the entire colon. If this is established then we should recommend that patients undergoing FS for rectal bleeding should be scoped with full bowel preparation and converted to a colonoscopy if polyp or cancer is detected at the time of FS.
AIMS & METHODS: The aim of the study was to assess the diagnostic yield of FS in detecting colon cancer/polyp in patients of different ages presenting with rectal bleeding. A single centre, retrospective analysis of patients with rectal bleeding investigated with FS in a district general hospital from north London was performed. The patients were identified using the Unisoft Endoscopy reporting software over a period from June 2006 to March 2014. Data obtained during the study period was scrutinised for diagnosis and whether further full colonic imaging was indicated as judged by diagnosis of colon cancer or adenomatous polyp.
RESULTS: 1406 FS were performed in the study period. The table below demonstrates the findings at FS in patients with rectal bleeding according to age category. 25% of patients over 45 years of age have a cancer or polyp diagnosed that requires further full colonic imaging.

Age (years)	**<45**	**>45**	**>55**	**>65**	**>75**	**>85**	**>95**
Number of procedures	224	1179	944	666	404	144	12
Normal	90	308	223	126	72	34	3
Normal (%)	*40*	*26*	*23*	*19*	*18*	*24*	*25*
Cancer	0	67	64	56	40	12	0
Cancer (%)	*0*	*5*	*7*	*9*	*10*	*8*	*0*
Polyp	27	220	192	144	85	21	2
Polyp (%)	*12*	*19*	*20*	*22*	*21*	*15*	*17*
Other benign cause eg colitis/haemorrhoids	91	677	554	419	237	89	7
Other benign cause (%)	*40*	*57*	*59*	*63*	*58*	*62*	*58*

CONCLUSION: 25% of patients over 45 years of age undergoing FS for rectal bleeding have a colon cancer or polyp diagnosed that require further colonic imaging. Preparing all patients for a full colonoscopy at the time of attendance for FS and conversion to colonoscopy if a polyp or cancer is detected would save reattendance in 25% of patients over the age of 45 for rectal bleeding. The prevalence of polyps and cancer however is low in patients under 45 years of age and these patients could continue to have FS with enema preparation just prior to the procedure.

P1299 IS THE LOCATION OF THE POLYP IN THE COLON A RISK FACTOR FOR THE OCCURRENCE OF COMPLICATIONS FOLLOWING ENDOSCOPIC MUCOSAL RESECTION?

S. Khater[1,*], M. Barret[1], G. Rahmi[1], G. Malamut[1], E. Samaha[1], L. Abbes[1], J.M. Canard[1], C. Cellier[1]
[1]*Hopital Europeen Georges Pompidou, paris, France*

INTRODUCTION: Endoscopic mucosal resection (EMR) is a commonly used technique to remove colorectal polyps. Complications such as bleeding and perforation can occur, with rates reported reaching 10% in some series. Some risk factors for the occurrence of these complications have been identified in the literature, such as the size of the polyp, its shape (flat or sessile), the presence of comorbid conditions and the use of antiplatelet and anticoagulant drugs. Some studies also found that the location of the polyp can be a risk factor.
AIMS & METHODS: The aim of this study is to determine if the location of the polyp in the colon is a risk factor for the occurrence of complications after EMR of supracentimetric polyps. Clinical and endoscopic data were collected by retrospective methods for all patients who underwent endoscopic resection of polyps of one centimeter or more from January 2001 to march 2013 at the Georges Pompidou European Hospital in Paris. A univariate and a multivariate analysis were used to identify risk factors for the development of complications.
RESULTS: 378 polyps were resected in 263 patients (mean age: 65.2 years [29-92], 57.9% of men). The mean size of the polyps was 17.2 mm. 67.2% were sessile, 20.9% flat and 11.9% pedunculated. Polyps were located in the right colon (proximal to the left colic flexure) in 62.4% of cases and in the left colon and rectum in 37.6% of cases. Endoscopic clip placement after EMR was performed in 53.7% of cases. 7.9% of patients were taking anticoagulant drugs and 19.8% were taking antiplatelet therapy. Complications after EMR occurred in 7.6% (29/378) of cases; there was 4 perforations (1.1%) and 25 hemorrhage (6.6%). The clinical outcome was favorable with conservative or endoscopic treatment in 96.5% of cases; only one patient had a surgery following a perforation. No death occurred. A complication was observed in 8.4% (20/236) and 6.3% (9/142) of cases following polyp resection in the right colon and the left colon, respectively ($p = 0.6$). A perforation occurred in 1.3% (3/236) and 0.7% (1/142) in the right and in the left colon respectively ($p = 1$). The rate of bleeding after EMR was 7.2% (17/236) in the right colon and 5.6% (8/142) in the left colon ($p = 0.6$), respectively. The univariate and the multivariate analysis showed that the only factor that was significantly associated with the occurrence of complications following EMR was the use of anticoagulant drugs ($p < 0.0001$). However, the location of the polyp, its size, its shape, the use of clips, the age of the patient or the use of antiplatelet drugs were not predictive factors for complications.
CONCLUSION: In this study, the location of the polyp in the right or left colon doesn't seem to be a risk factor for the occurrence of complications following EMR of supracentimetric polyps.

P1300 THE UTILITY OF ENDOCYTOSCOPY, WHICH CAN PROVIDE ADDITIONAL DIAGNOSTIC VALUE TO MAGNIFYING CHROMOENDOSCOPY FOR PREDICTING A MASSIVELY INVASIVE COLORECTAL CANCER: A RETROSPECTIVE COMPARATIVE STUDY

S.-E. Kudo[1,*], S. Kataoka[1], Y. Mori[1], K. Wakamura[1], Y. Kouyama[1], Y.-S. Ogawa[1], K. Igarashi[1], M. Kutsukawa[1], K.-I. Takeda[1], K. I. Ichimasa[1], M. Misawa[1], **T. Kudo**[1], T. Hayashi[1], H. Miyachi[1], H. Inoue[1]
[1]*Showa University Northern Yokohama Hospital, Tsuzuki-ku, Yokohama-shi, Japan*
Contact E-mail Address: *shinichikataok@hotmail.com*

INTRODUCTION: Magnifying chromoendoscopy (MC) is a Japanese standard diagnostic method for endoscopically predicting a massively invasive submucosal colorectal cancer (SMm) which has the possibility of metastasis[1]. Recently developed ultra-magnifying (450-fold) endoscopy "endocytoscopy (EC)" was also reported to be useful for predicting SMm.[2]
AIMS & METHODS: The aim was to assess the additional value of EC to MC for diagnosing colorectal lesions. Consecutive lesions which were resected after colonoscopical examination with use of EC were enrolled in this retrospective study between May 2005 and March 2013 in Showa University Northern Yokohama Hospital. Advanced-type lesions were excluded from the analysis. At colonoscopy, the on-site endoscopists diagnosed each lesion on the basis of MC+EC findings after assessing it on the basis of MC findings alone. The diagnostic abilities of MC+EC were compared to those of MC alone with reference to the histopathology of the resected specimens. As main outcome measure, the diagnostic abilities of predicting both neoplastic change and SMm were evaluated according to Kudo's pit pattern classification[1] and the EC classification[2].
RESULTS: Overall, 524 patients with 578 specimens were available for analysis. Of them, there were 71 non-neoplastic lesions,279 dysplasias, 15 slightly invasive submucosal cancers, and 94 SMms. The main results were shown in the table.

Table to abstract P1300

	MC alone	MC+EC	Pvalue (McNemar'stest)
Diagnostic ability of predicting.neoplastic change			
Sensitivity	93.0%	93.0%	1.000
Specificity	97.4%	96.8%	0.343
Accuracy	96.9%	96.4%	0.032
deeper than SMm			
Sensitivity	75.5%	81.0%	0.070
Specificity	97.9%	99.2%	0.041
Accuracy	94.3%	96.4%	0.002

CONCLUSION: Though MC alone has feasible diagnostic ability for predicting both neoplastic change and SMm, observation with EC can provide additional diagnostic value to MC for predicting SMm with substantial reliability.

Contact E-mail Address: *sinichi-katuki@otaru-ekisaikai.jp*

INTRODUCTION: Endoscopic submucosal dissection (ESD) method for the colorectal neoplasm has been spread all over the world in recent years. However there aren't so many medical facilities where the method is carried out completely.
There are 4 reasons - First, there are a lot of various shapes of colons. Second, the colon wall is very thin. Third, the feces in the colon contain much bacteria. Fourth, sometimes there are adhesion or malformation in the patients colon.
Furthermore once perforation arises, there is a possibility of emergency open surgery. Moreover, with the tumor in the proximal colon, ESD method becomes more difficult. In order to solve those difficulties, we basically employ short type DBE.
AIMS & METHODS: Our purpose was to evaluate the efficacy and safety of ESD by using short type DBE for the tumor located in the proximal colon in a prospective, randomized trial.
We treated the tumor located in the proximal colon using two types of scopes, the Conventional Scopes (CS) and Double Balloon Endoscopes (DBE). CS we used were EC450RD5M (Fujifilm Co., Tokyo, Japan), and PCF-Q260JL/I (Olympus Co., Tokyo, Japan) and DBE we used was EC450BI5 or EN530BI (Fujifilm Co., Tokyo, Japan).
The period of the evaluation was from Nov.2012 to Mar.2014.
We divided 70 cases into two groups: Group A (treated by CS), and Group B (treated by DBE). We examined the reaching time, the treatment time, the completing rate, the negative rate of cut end (lateral and vertical), the average hospitalization, the average cost and the perforation rate.
RESULTS: There were 32 cases in Group A and 38 cases in Group B. The number of ESD in the Group A were 32 lesions and Group B were 40 lesions. The reaching time to the cecum were 8.4±3.9 min. in the Group A and 5.3±2.2 min. in the Group B. The treatment time were 41.3±14.4 min. in the Group A and 26.2±9.1 min. in the Group B. The negative rate of cut end (lateral and vertical) were 87.5% (28/32) in the Group A and 100% (40/40) in the Group B. The perforation rate was 3.1% (1/32) in the Group A and no cases in the Group B.
The average cost were 591.7 EUR. in the Group A and 657.7 EUR. in the Group B (converted by EUR.-JPY. as of April 19th)
CONCLUSION: The cost spent on DBE is slightly more expensive than that spent on CS. However, given the low rate of perforation, the shortened time spent on ESD, and the accuracy of en-block resection, ESD by using DBE is beneficial for the patients who have the tumor in his or her proximal colon.

INTRODUCTION: Recently, endoscopic submucosal dissection (ESD) has been applied for superficial colorectal neoplasms and the number of publications about it has been increasing, but little is known about the outcomes of colorectal ESD for the lesions over 50 mm.
AIMS & METHODS: In this study, we evaluated the feasibility and safety of colorectal ESD for the lesions over 50 mm compared to the lesions less than 50 mm. A total of 674 superficial colorectal neoplasms in 629 patients treated by ESD at Kobe University Hospital from July 2008 to July 2013 were included in the analysis. Among these lesions, 28 residual or local recurrent lesions after previous treatment were excluded, as result, 646 lesions were analyzed for this study. Resected lesions were divided into two groups, large lesion group (tumor size ≥50 mm) and small lesion group (tumor size <50 mm).
RESULTS: Of 646 lesions included in this study, 530 lesions were classified into the small lesion group and 116 were into the large lesion group. The median operation time (range) in the large lesion group was 109 (37-596) minutes, and it was 55 (6-248) minutes in the small lesion group. Median procedure speed (range) in the large lesion group was 0.28 (0.06-0.83) cm^2/minutes, and it was 0.19 (0.04-0.83) cm^2/minutes in the small lesion group. The en bloc resection rate and the curative resection rate in the small lesion group was 98.7% and 96.0%, and those were 95.7% and 91.4% in the large lesion group, respectively. In terms of adverse events, perforation, muscle damage and postoperative bleeding occurred at similar frequency in both groups. To investigate further, the outcome of ESD depends on the part of the bowel (rectum, left colon and right colon) was analyzed. The median operation time was significantly longer in the large lesion group and the median procedure speed was significantly faster in the large lesion group in all bowel parts. The en bloc resection rate and the curative resection rate were not significantly different between two groups in either locations. In terms of adverse events, significant differences were not found in either locations.
CONCLUSION: ESD on colorectal lesions over 50 mm takes longer operation time, however, it is resected time effectively without increasing the risk of adverse events compared to smaller lesions by ESD.

P1303 ENDOSCOPIC DIAGNOSIS AND CLINICAL MANAGEMENT OF SESSILE SERRATED ADENOMA/POLYP

S. Ishigooka[1,*], S.-I. Ozawa[1], Y. Matsuo[1], K. Hosoya[1], M. Yamashita[1], Y. Sato[1], T. Maehata[1], H. Yasuda[1], F. Itoh[1]
[1]*Gastroenterology and Hepatology, St. Marianna University School of Medicine, Kawasaki, Japan*
Contact E-mail Address: *s2 ishigouoka@marianna-u.ac.jp*

INTRODUCTION: Sessile serrated adenoma/polyp (SSA/Ps) are known to be precursors of sporadic cancers (CRCs) with microsatellite instability (MSI). Consequently, colonoscopic identification of SSA/Ps has important implications for preventing CRCs. Although we reported evaluation of magnifying colonoscopy in the diagnosis of serrated polyps (*World J gastroenterol* 2012 August 28; 18 (32)), accurate endoscopic diagnosis is often difficult.
AIMS & METHODS: Our aim is the establishment of more accurate diagnostic criteria and examination of the clinical management for the present.
This study examined 191 serrated lesions excised in our hospital as suspected serrated lesions after magnified observation between January 2008 and March 2014. Patient characteristics (sex, age), conventional colonoscopic findings (location, size, morphology, color, mucin) and magnified colonoscopic findings (pit pattern diagnosis) were compared with histopathological diagnosis. Surface microstructures were analyzed using magnifying endoscopy.
RESULTS: Lesions comprised 57 HPs (29.8%) and 134 SSA/Ps (70.2%: complicated with cancer in 8 cases).
Conventional colonoscopy showed that SSA/Ps were characterized by existence in the right side of colon [$P < 0.001$], flat-elevated lesion [$P < 0.001$], normal-colored or pale in color of mucosa [$P < 0.001$], and with large amounts of mucin [$P < 0.001$]. Magnified colonoscopy showed the type II-open shaped (type II-O) pit pattern as characteristic of SSA/Ps [PPV 92.4%, specificity 86%]. All cancer cases were observed only in female. Cancer was also present in 8 lesions, in all of which a type III or IV or V pit pattern was also present within the same lesion.
CONCLUSION: In our study, we have understood to be able diagnose as SSA/P, which indicated both flat shaped and type II-O pit pattern, and SSA/Ps which had malignant potential indicated another pit patterns other than type II-O pit pattern. Consequently, we should consider excise not only large lesions, also lesions that have Type II-O pit pattern including the Type III, IV, V pit pattern.

INTRODUCTION: Many laterally spreading tumors (LST) are detected in the rectum while the frequency of hyperplasia is high and there are few conventional small adenoma lesions. A hardly elevated, flat lesion with wide pits has been often observed at the margin of LST. This lesion has been termed "skirt". We have reported that LST with skirt were located in the rectum, however, the clinicopathological characteristics of LST with skirt have not been clarified.
AIMS & METHODS: The aim of this retrospective study was to clarify the clinicopathological characteristics of LST with skirt. Between February 2006 and December 2013, a total of 986 LST in 806 consecutive patients were resected endoscopically or surgically in our hospital. LST were macroscopically classified into the following three groups: granular-homogeneous type (LST-GH), granular-nodular mixed type (LST-GM) and non-granular type (LST-NG). The location was divided into two regions: rectum (from upper rectum to lower rectum) and colon (from cecum to recto-sigmoid colon). The "skirt" was defined by three findings: 1) spreading at the margin of LST, 2) presenting as a hardly elevated lesion, and 3) presenting with wide-shape pits. We assessed the clinicopathological characteristics such as age, gender, location, size, macroscopic type of LST, histopathological findings. We also assessed the endoscopic findings of skirt regarding the characteristics of pit in tumor surface using chromoendoscopy with indigo carmine dye or crystal violet dye, and the characteristics of microvessels by magnifying narrow band imaging (NBI) endoscopy.
RESULTS: Of the 986 LST, skirt was identified in the peripheral region of 34 LST (3.4%). All LST with skirt were attaching LST-GM. Of the 34 LST with skirt, 25 LST (74%) were located in the rectum and 9 LST (26%) were located in the colon (4 in cecum, 3 in sigmoid colon, and 2 in recto-sigmoid colon). The mean sizes of LST with skirt and LST without skirt were 46.5 ± 19.3 mm and 30.0 ± 16.8 mm. While carcinoma components were found in 27 lesions (80%) of LST with skirt, 437 lesions (46%) of LST without skirt were carcinoma. Significant differences were seen in the location ($p < 0.001$), the size of tumor ($p < 0.001$) and the frequency of carcinoma ($p < 0.001$) between LST with skirt and LST without skirt. In contrast, there were no significant differences in age and gender. Of the 34 LST with skirt, 26 were available for the histopathological analysis of region of skirt and all were diagnosed as low-grade dysplasia. With regard to the endoscopic findings at the surface of skirt, 29 (85%) showed coral reef-like appearance pit (which was often visible in ulcerative colitis) and the others showed type II like or type IIIL like pit pattern. As for the surface microvessels of the skirt surface, all regions could not be detected as meshed capillary vessels showing feature of lo-grade dysplasia, and were identified as capillary pattern type I.
CONCLUSION: Significant characteristics of LST with skirt were more frequent in rectal LST-GM lesions, larger tumor size, and high frequency of cancers compared to LST without skirt. In the portion of skirt, there was dissociation between endoscopic and histological findings.

INTRODUCTION: Bowel cleansing before colonoscopy is currently based upon lavage solutions of polyethylene glycol (PEG) or NaP with large amounts of fluids ingested in a split manner. This prospective randomized study compared a PEG protocol with a new method of bowel cleansing based upon infusion of water into the colon at low pressure (Angel of Water, Lifestream, Austin, TX), named hereafter the Prepsystem.
AIMS & METHODS: The device for water infusion is made of a reservoir of water maintained at 37°C. The patient is installed on an adapted seat allowing easy evacuation of water and faeces. Water is infused by gravity through a cannula, into the rectum. Patients with an indication of colonoscopy and no history of colorectal surgery or IBD were randomly assigned to PEG preparation (2L PEG in the evening before and 2L in the morning of colonoscopy) or the Prepsystem. All patients followed a low residue diet for 5 days. In the Prepsystem group, sennosides (Pursennide 80 mg, Novartis, Rueil Malmaison, France) were administered in the evening before and patients underwent 2 cleansing cycles, by infusion of 35L tap water each, about one hour before the colonoscopy. Quality of bowel cleansing was assessed with the Boston score by an endoscopist blinded to the preparation type. Boston scores in both groups were compared with a non-parametric test, with a signifcance level of 5%.
RESULTS: 100 patients were included (62 males, 59±13 y.). Main indications for colonoscopy were colorectal cancer screening (n = 57) and abdominal pain with recent change in bowel habits (n = 32). 50 patients received the Prepsystem and 50 the PEG protocol. Groups were comparable for age, sex and colonoscopy indication. 6 patients were excluded from the analysis after an incomplete colonoscopy for anatomical reasons, preventing calculation of the Boston score: 4 in the Prepsystem and two in the PEG groups. Consequently, 46 and 48 patients were analysed in the Prepsystem and PEG groups respectively. The median Boston score was 7 in both groups, without statistical difference. In the Prepsystem group, the colonoscopy was not completed up to the caecum in 2 patients because of poor cleansing. Mild mucosal tears induced by the cannula were observed in the rectum in 5 patients of the Prepsystem group. Mean duration of the colonoscopy was not different in the Prepsystem (19±3 min) and the PEG (22±1 min) groups. Blood electrolytes were not significantly modified after bowel cleansing in both groups. Patient satisfaction was good to excellent in all cases in the Prepsystem group.
CONCLUSION: The Prepsystem water infusion protocol appeared as effective as the split PEG protocol for bowel cleansing before colonoscopy. Patient tolerance of the Prepsystem was good. Further studies should evaluate the benefit of this protocol in patients with contraindications or poor tolerance to PEG cleansing or in ambulatory patients.

P1306 COLONOSCOPIC WITHDRAWAL TIME IS BELOW THE RECOMMENDED 6 MINUTES IN UNOBSERVED ENDOSCOPISTS AND SIGNIFICANTLY INCREASES UNDER MONITORING

S. Vavricka[1,*], L. Degen[2], R. Rechner[1], L. Biedermann[1], G. Rogler[1], M. Manz[3], C. Beglinger[2], E. Safroneeva[4], A. Schoepfer[5]

INTRODUCTION: Six minutes are recommended as the minimum withdrawal time for screening colonoscopy. However, there is a lack of data regarding the question how well this recommendation is followed by gastroenterologists unaware of being monitored in daily practice.
AIMS & METHODS: We aimed to assess first the withdrawal times in endoscopists unaware of being monitored, second if they would change the withdrawal time when knowing to be monitored (with subsequent increase in adenoma detection rate), and third, whether they could subjectively guess their withdrawal times. Seven experienced gastroenterologists performed 558 screening colonoscopies in a tertiary referral centre. Colon retraction times were first measured without and then with the gastroenterologist's knowledge of being monitored.
RESULTS: The mean withdrawal time in endoscopists unaware of being monitored was 4.7 ± 1.6 min (range 1-13 min) without colonic intervention and 7.1 ± 3.9 min (range 2-25 min) with colonic intervention. In endoscopists aware of their being monitored the withdrawal time without intervention rose to 8.1 ± 2.8 min and with intervention to 9.3 ± 3.9 min ($p < 0.001$ when compared to the withdrawal times unaware of being monitored). Adenoma detection rate increased significantly ($p = 0.001$) in endoscopists aware of being monitored. The subjective estimate of withdrawal time with and without intervention was comparable to the measured withdrawal time (7.7 ± 2.7 vs. 8.1 ± 2.8 min, $p = 0.180$; 9.3 ± 3.9 vs. 9.2 ± 4.3 min, $p = 0.796$).
CONCLUSION: Colonic withdrawal time in unmonitored gastroenterologists is shorter than recommended and increases when being monitored. Adenoma detection rate increases in monitored endoscopists. Endoscopists are good in guessing the measured withdrawal time. Withdrawal time should be monitored using a watch in the endoscopy room.

P1307 USEFULNESS OF AN ENDOSCOPE WEIGHT-REDUCING AID DURING GASTROSCOPY AND COLONOSCOPY

T. Fujii[1,*]
[1]*Gastroenterology, TF CLINIC, Tokyo, Japan*
Contact E-mail Address: *tfclinic@khaki.plala.or.jp*

INTRODUCTION: In recent years, as the diagnostic/therapeutic endoscopic procedures continue to increase in numbers, the left-arm/-shoulder burden continues to increase for the endoscopists performing these procedures, resulting in their overuse injuries (upper extremity biomechanical overload).
AIMS & METHODS: To help relieve the biomechanical overload associated with endoscopic procedures. Following installment of an infusion rail, an infusion runner system, and an infusion stand from the ceiling, a highly retractable Teflon tube was connected to the infusion stand with its lower end clipped to an endoscope, so that the endoscope could be left hanging from the system. With this device weight-reducing aid, the infusion rail and the Teflon tube gave greater freedom to endoscopist movement during endoscopy. The endoscopes available at the clinic (GIF-XP260, GIF-Q260, PCF-Q240ZI, and CF-H260AZI; Olympus) were compared in a diagnostic setting, with the endoscope connectors attached to each system, for weight as well as for force exerted on each device, with or without the weight-reducing aid.
RESULTS: The weight of each device with/without the weight-reducing aid was 0.66 kg/1.17 kg (0.56) for GIF-XP260, 0.8 kg/1.3 kg (0.62) for GIF-Q260, 0.96 kg/1.49 kg (0.64) for PCF-Q240ZI, and 0.97kg/1.58kg [0.61) for CF-H260AZI, respectively. The force exerted on each device with/without the weight-reducing aid was 6.46 Newton (N)/11.46 N (0.56) for GIF-XP260, 7.84 N/12.74 N (0.62) for GIF-Q260, 9.4 N/14.6 N (0.64) for PCF-Q240ZI, and 9.5 N/15.48 N (0.61) for CF-H260AZI, respectively.
CONCLUSION: An endoscope weight-reducing aid was developed. Endoscope weight reductions with this aid may not only help decrease the physical burden on the endoscopist performing endoscopic procedures but allow him/her to maintain concentration during prolonged diagnostic/therapeutic procedures, thus leading to better diagnostic yield and clinical outcome.

INTRODUCTION: Endoscopic submucosal dissection (ESD) provides a high rate of curative resection for large superficial neoplasms, as it allows en-bloc resection. It allows relatively large tumors to be included as candidates for endoscopic resection in place of surgical resection. Resection of large tumors would leave large ulcers at the site of ESD, and a large size of the defect after ESD can influence the healing progress. Consequently, post-ESD stenosis is a major complication in stomach and esophagus. A circumferential extent of the mucosal defect (CEMD) of ≧3/4 was found as a major risk factor for postoperative stricture. On the other hand, the situation might be different in the colorectum.
AIMS & METHODS: The aim of this study is to investigate the risk factor of post ESD stenosis in the colorectum. From September 2003 to October 2013, 619 consecutive superficial colorectal tumors were treated by ESD. Among them, 34 cases in which CEMD was 3/4 or more, were thoroughly investigated. Only one case was whole circumferential resection. CEMD was classified endoscopically as being 3/4-9/10 or 9/10 < just after the ESD procedure. Post-ESD stenosis was diagnosed when a standard 11.5mm diameter colonoscope could not be negotiated through the colonic segment at the site of ESD. Follow-up endoscopy was performed 4 to 6 months later. If patients had any different clinical symptoms from those prior to the ESD, endoscopy was performed in order to check for post-ESD stenosis.
RESULTS: Post-ESD stenosis didn't occur in 585 cases which CEMD was under 3/4. In 34 cases in which CEMD was 3/4 or more, postoperative stricture developed in 3 of them. Two cases were controlled only by a few sessions of endoscopic balloon dilatation. The other which was whole circumferential resection case from lower rectum to dentate line required steroidal suppository and Finger bougienage as daily regimen for 90 days and three sessions of endoscopic balloon dilatation. There was significant difference in CEMD but no significant difference in circumferential and longitudinal diameter of the resected specimen and procedure time between presence and absence of postoperative stricture groups.
CONCLUSION: Post-ESD stenosis didn't occur among cases with a CEMD of less than 9/10. Even in cases that developed postoperative stricture, the symptoms could be controlled by a few sessions of endoscopic balloon dilatation and conservative treatment. Thus, we concluded that near and whole circumferential resection is acceptable for lesions of the colorectum.

P1309 ENDOSCOPIC EXAMINATION OF GASTROINTESTINAL LESIONS ASSOCIATED WITH MICROANGIOPATHY CAUSED BY IMMUNOSUPPRESSANTS

T. Yamaguchi[1,*], M. Ito[2], J.-I. Haruta[1], M. Doisaki[1], T. Ishikawa[1], **T. Yama**[1]

INTRODUCTION: There is a concern within the scientific community that many iatrogenic diseases will increase and diversify as a result of the diversification and increasingly widespread use of immunosuppressants (calcineurin inhibitors). Patients often experience lower gastrointestinal tract symptoms such as diarrhoea, melena and lower abdominal pain after allogeneic hematopoietic stem cell transplantation (allo-HSCT). The cause is often attributed to transplantation associated microangiopathy (TAM); however, the differentiation of this from gastrointestinal graft-versus-host disease (GVHD) is difficult, which may lead to patients being mistakenly treated for severe gastrointestinal GVHD.
AIMS & METHODS: We performed lower gastrointestinal endoscopies in patients experiencing post-transplantation abdominal pain to investigate the effectiveness of this procedure. The subjects were 101 patients selected from a group of 824 patients who underwent allo-HSCT at this medical facility during the 16-year period from 1998 to 2013 because of leukemia, myelodysplastic syndrome, malignant lymphoma, or aplastic anemia. The selected patients had all experienced abdominal symptoms such as diarrhoea, abdominal discomfort and abdominal pain within 6 months of the procedure, had undergone lower gastrointestinal endoscopy and histopathological examination and had been diagnosed with TAM based on the presence of microangiopathy with ischemic (non-inflammatory) crypt loss in mucosa of the biopsy specimens.
RESULTS: (1) The major findings obtained from the endoscopic examination of TAM were edema, rubefaction, coarse mucosa, inflammation, ulcers and mucosal loss. (2) Endoscopic examination enabled the identification of findings in 100% of the cases, with the highest percentage of findings concentrated in the ascending colon, sigmoid colon and rectum. (3) Pathological diagnosis revealed that the number of severe cases had been decreasing in recent years and that a small percentage of cases were complicated with GVHD or cytomegalovirus (CMV) infection. (4) A correlation was observed between the endoscopic severity and the histologic severity of TAM. (5) Magnification endoscopy allowed for the accurate diagnosis of TAM, including its severity and stage.
CONCLUSION: The results of the present study showed that active use of endoscopy for gastrointestinal symptoms following allo-HSCT allows the clinical picture of TAM to be elucidated and is useful in determining subsequent treatment strategies.

Contact E-mail Address: *i_gralnek@rambam.health.gov.il*

INTRODUCTION: Adenoma miss rates during colonoscopy have become widely acknowledged. This is primarily due to inadequate visualization of the proximal aspects of colonic folds and flexures. EndoRings™ (EndoAid Ltd., Caesarea, Israel) is a silicone rubber device, that is fitted onto the distal end of the colonoscope. Its flexible circular wings engage and mechanically stretch colonic folds during withdrawal.
AIMS & METHODS: In this multicenter tandem colonoscopy study, we compared adenoma miss rates (per lesion analysis) between standard colonoscopy (SC) and colonoscopy using EndoRings™ (EC). Secondary aims were to compare polyp miss rates, cecal intubation time, withdrawal time and total procedure time. Subjects referred for screening, surveillance or diagnostic colonoscopy were randomly assigned to undergo EC followed by SC or SC followed by EC.
Both colonoscopies were performed on the same day by the same endoscopist. Polyps detected during the first procedure were immediately removed. Diminutive (1-2 mm), rectal polyps with hyperplastic appearance were not removed. The study sample size was calculated with a two-group chi-square test with 80% power and 0.05 two-sided significance level. Based on an expected adenoma miss rate of 35% with SC and 10% with EC, an expected mean number of adenomas per subject of 0.75 and a 10% drop-out rate, a total sample size of 126 subjects will be required.
RESULTS: To date, 96 subjects have been enrolled After excluding 8 subjects due inability to reach the cecum or other protocol violations, 88 subjects (59% male, mean age 58 ± 9 years) remained for analysis. Indications for colonoscopy were screening n = 25 (28%), surveillance n = 26 (30%) and diagnostic evaluation n = 37 (42%). Forty three subjects were randomly assigned to undergo EC first followed by SC and 43 subjects to undergo SC first followed by EC. In the study group, 43 adenomas were detected during first pass with EC and 7 additional adenomas during the second procedure with SC. In the control group, 14 adenomas were detected during the first pass colonoscopy with SC and 14 additional adenomas during the second procedure with EC. The adenoma miss rate (14%) in subjects undergoing EC first was statistically significantly ($p = 0.001$) lower compared to subjects who underwent SC first (50%). Similar results were found for polyp miss rates, i.e. 11% for EC and 59% for SC ($p < 0.001$). The adenoma detection rate was statistically significantly ($p = 0.01$) higher with EC (51%) when compared to SC (24%). Mean cecal intubation times (9.4 min. vs. 8.3 min., $p = 0.15$) and withdrawal times (7.3 min. vs. 6.9 min., $p = 0.12$) were not significantly different between EC and SC. Mean total procedure time was longer ($p < 0.001$) with EC (21.9 min.) compared to SC (17.8 min.) due to removal of more polyps.
CONCLUSION: The interim results of this study (inclusion of all patients expected in June 2014) demonstrate that colonoscopy with EndoRings™ results in significantly lower adenoma and polyp miss rates than standard colonoscopy.

INTRODUCTION: Cecum intubation rate (CIR) and adenoma detection rate (ADR) are used as quality indicators for colonoscopy. Both parameters are easy to measure and have been found to be negatively associated with the occurrence of post-colonoscopy colorectal cancer (CRC). Comparing CIR and ADR between hospitals could provide useful incentives for quality improvement if possible inter-hospital differences depend at least to some extent on modifiable institutional and procedural factors.
AIMS & METHODS: The aim of this study was to compare the quality of routine colonoscopy between seven hospitals in the Netherlands to determine to what extent possible differences in CIR and ADR could be attributed to

procedural- and hospital-related factors. We prospectively registered all colonoscopies performed between November 2012 and January 2013 in two academic and five general hospitals in the Netherlands. Colonoscopies in patients with inflammatory bowel disease (IBD) or hereditary CRC syndromes were excluded. To correct for casemix variation, we performed adjusted multivariate analyses for age, gender, ASA score and indication.
RESULTS: A total of 3,129 patients were included (54% female; mean age 59±15 years). The majority of procedures (90%) were performed in adequately prepared colons, defined as a Boston Bowel Preparation Scale (BBPS) score ≥6. Mean CIR was 95% and ranged from 89% to 99% between hospitals ($p<0.01$). In multivariate analysis, independent predictors for CIR were BBPS ≥6 (odds ratio (OR) 23.3, 95%CI 13.5-40.1), and hospital ($p<0.01$), with ORs ranging from 1.1 to 9.7 (largest hospital as reference). Mean ADR was 32% and varied between hospitals, ranging from 23% to 43% ($p<0.01$). Nurse endoscopists and fellows detected adenomas more frequently than gastroenterologists (36% and 34% vs. 30%, $p<0.01$), but this difference was not significant in multivariate analysis ($p=0.21$). Independent predictors for ADR were a BBPS ≥6 (OR 1.8, 95%CI 1.3-2.5), use of conscious sedation (1.7, 95%CI 1.1-2.6), cecum intubation (OR 2.0, 95%CI 1.3-3.0) and hospital ($p<0.01$) with ORs ranging from 0.5 to 1.4 (largest hospital as reference). We combined the CIR and ADR per hospital in a scatter plot, providing an overview that can be used by hospitals to drive quality improvements.
CONCLUSION: Differences in quality of colonoscopy between hospitals can be depicted using CIR and ADR. As both CIR and ADR are affected by modifiable institutional and procedural factors that are independent of casemix, a comparison between hospitals can help improving quality of colonoscopy.

P1312 THE 'GOLDEN RETRIEVER' STUDY: IMPROVING POLYP RETRIEVAL RATES BY PROVIDING COMPETITIVE FEEDBACK

T.D. Belderbos[1,*], M.G. van Oijen[1], L.M. Moons[1], P.D. Siersema[1]
[1]*Gastroenterology and Hepatology, University Medical Center Utrecht, Utrecht, Netherlands*

INTRODUCTION: Colonoscopy surveillance is an essential part of screening programs aiming to prevent colorectal cancer. Recommendations on the adequate surveillance interval for patients with one or more colorectal polyps are predominantly based on the presence and grade of neoplasia found after histopathological evaluation. Therefore, it is important that resected colorectal polyps, especially right-sided lesions, are retrieved for histology. The internationally accepted standard for polyp retrieval rate is 90%.
AIMS & METHODS: The primary aim of this study was to evaluate the effect of education and competitive feedback on the overall polyp retrieval rate. The secondary aim was to investigate the association between polyp size or location and non-retrieval. We included consecutive colonoscopies in a single center between April 1, 2013 and April 1, 2014. Patients with inflammatory bowel disease or familial colorectal cancer syndromes were excluded for analysis. All gastroenterologists and trainees performing colonoscopy were educated on the importance of polyp retrieval and techniques to improve retrieval 6 months after the start of the study (end of September 2013). Then, the polyp retrieval competition was started by publicly providing feedback on the retrieval rate of all endoscopists and the monthly best performers (or 'golden retrievers'). We compared overall retrieval rates during six months prior to and after October 1, 2013.
RESULTS: Overall polyp retrieval rate improved from 88.6% (466/526) to 93.2% (923/990) when comparing consecutive colonoscopies performed in 6 months before and during the polyp retrieval competition ($p=0.002$). Non-retrieval occurred significantly more often in polyps ≤5 mm compared to polyps >5 mm (11.1% vs. 1.7%, $p=0.005$). The retrieval rate of left-sided polyps was higher compared to right-sided polyps during the 6 months previous to the competition (92.6% vs. 84.1%, $p=0.003$), but this difference was not significant anymore when the 6 months of competition were also taken into account (92.5% vs 91.1%, $p=0.334$).
CONCLUSION: A simple intervention to improve awareness and dedication is able to increase both overall and right-sided polyp retrieval rates in order to meet the international standard of 90%.

P1313 EFFICACY AND TOLERABILITY OF SODIUM PHOSPHATE TABLETS AND POLYETHYLENE GLYCOL SOLUTION IN BOWEL PREPARATION FOR COLONOSCOPY: A PROSPECTIVE STUDY

T. Tashima[1,*], K. Ohata[1], M. Takita[1], Y. Matsuyama[1], Y. Minato[1], K. Nonaka[1], N. Matsuhashi[1]
[1]*Gastroenterology, NTT Medical Center Tokyo, Tokyo, Japan*

INTRODUCTION: As the result of the increment of colorectal cancer, the importance of high quality screening colonoscopy has been rapidly increasing. Polyethylene glycol (PEG) solution and sodium phosphate (NaP) solution are effective for colon cleansing before colonoscopy. However, large volume and unpleasant taste reduce tolerability and acceptability. Recently, NaP tablet has been developed to improve patient compliance and tolerability.
AIMS & METHODS: The aim of this study was comparing the efficacy and tolerability of the two different preparations. We have performed prospective cohort study to compare the efficacy of bowel preparation and patient's acceptance between NaP tablets and PEG during May 2011 and February 2013. We assigned patient randomly to two groups. Group A (n=250) received NaP before colonoscopy. Group B (n=250) received PEG before procedure. We analyzed the effectiveness of bowel preparation by endoscopist's scoring based on the grading system and patient acceptance by patient's questionnaire. In the grading system, we classified the cleansing grade into 5 categories, and defined the favorable and effective cleansing group as grade 1 and 2.
RESULTS: 440 patients (217 NaP; 223 PEG) completed the study preparation and patient's questionnaire prior to colonoscopy. There were statistically no significant differences in (gender ($p=0.87$), age ($p=0.37$), height ($p=0.64$) and weight ($p=0.12$)) between the two groups. Effectiveness of bowel preparation was significantly higher in Group A (88.0% vs 80.7%, $p=0.035$). There were no significant differences in acceptance between the two groups (A; 81.9%, B; 78.6%, $p<0.05$). Among 133 patients who have experienced both NaP tablets and PEG, (57.1%), (25.6%), and patients (17.3%) preferred NaP tablets, PEG, and either of the two in future colonoscopy. There was no severe adverse event through this study in both groups.
CONCLUSION: In conclusion, NaP tablets preparation is easy to take, well tolerated, and more preferred by patients than PEG.
Disclosure of Interest: None declared

P1314 PATHOLOGICAL FEATURES OF LATERALLY SPREADING TUMOR OF THE COLORECTUM; REFERENCES AMONG SUBTYPES AND SUBMUCOSAL INVASION

T. Ishigaki[1,*], S.-E. Kudo[1], H. Miyachi[1], T. Hayashi[1], Y. Kouyama[1], Y. Maeda[1], K. Ichimasa[1], H. Nakamura[1], Y. Yagawa[1], N. Toyoshima[1], Y. Mori[1], M. Masashi[1], T. Kudo[1], T. Hisayuki[1], K. Wakamura[1], A. Katagiri[1], E. Hidaka[1], F. Ishida[1], S. Hamatani[1]
[1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama City, Japan*

INTRODUCTION: Laterally spreading tumors (LSTs) are usually good indication for endoscopic treatment because they are rather benign in spite of their large diameter. There are four subtypes in LSTs; granular type [homogeneous type (H) / nodular mixed type (M)], and non-granular type [flat-elevated type (F) / pseudo-depressed type (PD)]. Their pathological features are different among subtypes.
AIMS & METHODS: The aim of this study is to evaluate the pathologial features of LSTs focusing on their subtypes and submucosal (SM) invasion. In a retrospective review of the colonoscopy database (Apr 2001 to Dec 2013) at our institution, we selected cases of colorectal neoplasms based on the following criteria; endoscopically diagnosed cases of LSTs that underwent subsequent endoscopic or surgical resection. We evaluated pathological features (size, rate of SM invasion) according to LSTs subtypes. Furthermore, we examined the LSTs with SM invasion which treated from Apr 2010 to Dec 2013 focusing on their locus of SM invasion. For analysis, we used chi-square test and one way ANOVA post hoc test for statistical analysis.
RESULTS: A total of 2226 LSTs were eligible for inclusion. The main results are shown in the table. As the three types of LST(G(M)/NG(F)/NG(PD)) became larger, the ratio of submucosal invasion became higher. But LST-G(H) showed low rate of that even when they were large in diameter. LST-NG(PD) had higher ratio of submucosal invasion (45.1%; 102/226) than the other types ($P<0.01$). LSTs with SM invasion which treated from Apr 2010 to Dec 2013 were 104 lesions. The locus of SM invasion at LST-G(M) was almost (78.8%; 21/27) under nodule. In LST-NG(PD), SM invasion was tend to occur multifocally (45.2%; 14/31) compared with the other type (12.3%; 9/73) ($P<0.01$).

	Total	LST-G(H)	LST-G(M)	LST-NG(F)	LST-NG(PD)	P-value
N	2226	573	450	977	226	
Size (mm)	25.1±15.9	26.3±16.8	37.4±20.4	19.7±9.8	21.3±8.8	P<0.01
Rate of SM invasion (%)	12.7 (282/2226)	0.7 (4/573)	17.6 (79/450)	9.9 (97/977)	45.1 (102/226)	P<0.01

CONCLUSION: Pathological features of LSTs are different among subtypes. To understand the way of SM invasion in LSTs is useful to choise the appropriate treatment method.

INTRODUCTION: Colorectal flat-elevated neoplasms can be classified into small-flat adenoma and laterally spreading tumor (LST). LSTs are subcategorized into granular-type LST (LST-G) and nongranular-type LST (LST-NG). LSTs tend to extend laterally and circumferentially rather than vertically along the colonic wall and seem be found at an early stage tumor such as adenoma. However, LSTs with large nodules or depressions tend to invade the submucosa. These observations suggest that there may be biological differences between LST-Gs and LST-NGs.
AIMS & METHODS: We examined the clinicopathological and molecular features of 24 granular-type laterally spreading tumors (LST-Gs) and 57 nongranular-type LSTs (LST-NGs) that were resected endoscopically at Showa University Hospital from July 2007 through December 2011. We investigated the frequency of *KRAS* and *BRAF* mutations, and DNA methylation of seven genes or sequences (MINT1, MINT2, MINT31, *p16*, *MLH1*, *SFRP1* and *ESR1*) by pyrosequencing. We also examined the methylation level of *SFRP1* and *ESR1* in

normal adjacent mucosa. A tumor was considered to be CpG island methylator phenotype (CIMP) -positive if 2 or more CIMP markers (MINT1, MINT2, MINT31, *p16* and *MLH1*) were methylated.
RESULTS: We observed significant differences in the tumor size (30 mm vs. 15 mm), the frequency of *KRAS* mutation (75%, 18/24 vs. 5%, 3/57) and CIMP (35%, 8/23 vs. 5%, 3/57,) between LST-Gs and LST-NGs ($P < 0.001$). The frequency of *TP53* mutation tended to be higher in LST-NGs than LST-Gs (14%, 8/57 vs. 0%, 0/24, $P = 0.05$). However, we found no significant differences in the frequency of *BRAF* mutation between two groups. For LST-NGs, the histological grade was increased with an increase in the tumor size. The frequency of Dukes' A cancer was significantly higher in tumors larger than 20 mm or equal than tumors less than 20 mm in size ($P < 0.05$). In contrast, LST-G showed no correlation of a size-dependent increase in the histological grade. No significant differences in the frequency of KRAS mutation and CIMP in LST-Gs and LST-NGs were observed by tumor size. Although the methylation levels were relatively low, we observed *SFRP1* and *ESR1* methylation in normal adjacent mucosa as well as tumor tissues of LST-G and LST-NGs (median methylation density: *SFRP1* methylation, 18% and 22%; *ESR1* methylation, 19% and 20%, respectively).
CONCLUSION: Our results suggest that different molecular mechanisms may exist in these subtypes of colorectal flat-type neoplasms. Furthermore, *SFRP1* and *ESR1* methylation in normal adjacent mucosa might be associated with field effects defined by epigenetic changes as early events predisposing to laterally spreading manner of LSTs.

P1316 IMPROVING THE QUALITY OF COLONOSCOPY BOWEL PREPARATION USING A SMART PHONE APPLICATION

V. Lorenzo-Zúñiga[1,2,*], V. Moreno-de-Vega[1], J. Boix[1]
[1]*Gastroenterology, Hospital Universitari Germans Trias i Pujol/CIBERehd,* [2]*CIBERehd, Badalona, Spain*

INTRODUCTION: Bowel preparation for colonoscopy is a complex undertaking, involving diet modifications and laxative choice according to patient needs. An adequate level of cleansing is critical for the efficacy and the quality of colonoscopy. Bowel preparation is inadequate in an up to 30% of patients undergoing colonoscopy, and has been associated with patient characteristics, previous failure to adequately prepare colon and noncompliance with cleansing instructions. Education of patients before colonoscopy is very important to ensure compliance. Early data have shown a significant improvement in bowel preparation quality in patients who used the smart phone application (SPA). Therefore, we created a novel SPA aimed to increased bowel preparation quality and patient satisfaction, using different educational tools.
AIMS & METHODS: To determine whether SPA could improve proper bowel preparation in patients undergoing colonoscopy, and to evaluate the effect of SPA on patient satisfaction.
We performed a randomized, double-blind, pilot study with two parallel arms from January to April 2014. Outpatients submitted for colonoscopy, owners of a smart phone and able to manage a SPA, were included. We enrolled 194 consecutive patients (104 female, 90 male, age range 26-75 yrs) that were randomnly allocated by nurse assistant to one of the following bowel preparation protocols: a) SPA Group (n = 95): patients downloaded this free SPA onto their smart phone. The app provides to patients timed alerts and explains the procedure providing tips, examples of low fiber diet, and educational video to explain how to prepare the purgative solution; and b) Control Group (n = 99): written instructions for bowel preparation, with visual aids explaining the procedure and how to prepare the solution, was given to each patient. All procedures were performed in afternoon time, and patients received the same purgative regimen (2-L PEG solution plus ascorbic acid), in a full-dose same-day regimen. The study was powered to detect an improvement in quality of bowel preparation using the Herefield Cleansing Scale (HCS) scale. To evaluate the effect of SPA on patient satisfaction were assessed with a specific questionnaire at time of the colonoscopy. Patients were asked if they used the application and their satisfaction with the app. Endoscopists were blinded to the actual treatment given to each patient and to the answers. Results are expressed as median (CI 95%)
RESULTS: There was no significant difference in the HCS scores in both regimens (17.00 ± 3.11 in the SPA group vs 16.21 ± 3.60 in the control group; $p = 0.188$); however, the use of SPA was superior to written instructions in overall successful cleansing (100% vs 90.9%; $p = 0.003$.) (HCS scores A or B), with specifically better cleansing in the right colon ($p = 0.016$) and in the transverse colon ($p = 0.040$), respectively. Patient-reported tolerability and the overall experience with the prescribed bowel preparation was significantly higher for the SPA group than for the control group ($p < 0.001$).
CONCLUSION: Successful cleansing and patient acceptability with the use of SPA were superior to written instructions in outpatients submitted for colonoscopy prepared 2-L PEG solution plus ascorbic acid.

INTRODUCTION: Endoscopic mucosal resection (EMR) is an endoscopic technique developed for removal of sessile or flat neoplasms confined to the superficial layers of colorectal mucosa. EMR can provide effective cure for Paris type Is and type II colorectal neoplasia and node-negative early cancer, avoiding the need of surgical resection.
AIMS & METHODS: 186 colorectal neoplasm in 142 patients were removed by EMR between January 2012 and November 2013. All patients previously underwent total colonoscopy by EC590ZW/L («Fujinon», Japan) or CF-160L («Olympus», Japan) endoscopes. Resection included following stages: (1) guided local or total chromoscopy by 0.5% indigo carmine solution, (2) mucosal examination of pit-pattern, (3) submucosal injection of fluid, (4) snare mucosectomy, (5) estimation of results, (6) clip closure of defect when feasible.
RESULTS: EMR were performed in total of 186 colorectal neoplasia: 152 Paris type II and 34 Paris type Is. Neoplasia lesions size ranged from 3-39 mm (mean size 17.8 mm). Mean resection time was 11.8 min (range 1-38 min). Mucosectomies were performed in total of 152 non-polypoid lesions with 91 (59.9%) right colonic, 39 (25.6%) left colonic and 22 (14.5%) identified rectal lesions. Histology confirmed adenoma (tubular, tubulo-villous, villous) in 94, adenoma with LGD in 29, adenoma with HGD in 20, and intramucosal Ca in 9 lesions respectively. The majority of lesions - 90 (59.2%) were lesions of type 0-IIa, 8 (5.3%) type 0-IIb, 2 (1.3%) type 0-IIc, 30 (19.7%) type 0-IIa+c or 0-IIc+a, and 22 (14.5%) - Lateraly Spreading Tumor.
Mucosectomies were performed in 34 polypoid lesions (Is) with 12 (35.3%) right colonic, 14 (41.2%) left colonic and 8 (23.5%) identified rectal lesions. Histology confirmed adenoma (tubular, tubulo-villous, villous) in 25, adenoma with LGD in 5, adenoma with HGD in 2, and intramucosal Ca in 2 lesions respectively. The majority of lesions - 30 (88.3%) were lesions of type 0-Is, 4 (11.7%) type 0-Is+IIc. En-block resection was performed in 172 (92.5%) cases, resection by several fragments – in 14 cases (7.5 %). All removed in parts lesions were over 20 mm in size. Three patients experienced an episode of delayed bleeding. No perforation were seen. In two patients we found relapses of neoplasia (after 1y). 21 cases of dysplasia and 8 cases of adenocarcinoma were revealed in 36 neoplasms with 0-IIc component. With the absence of 0-IIc component (150 neoplasms) dysplasia was observed in 35 cases and adenocarcinoma – in 3 cases.
CONCLUSION: Endoscopic management – EMR is a safe and effective treatment for Paris type Is and type II of colorectal neoplasia and may be an alternative to surgery in selected patients. Presence of 0-IIc focus significantly correlates to the presence of dysplasia or adenocarcinoma.

INTRODUCTION: It is now available to estimate histological feature of colorectal lesions using magnifying chromo-endoscopy (pit pattern classification). In regard to diminutive (≦5mm) adenomatous polyps (DAP), it has been reported that the prevalence of advanced histological features was low[1)]. However diminutive invasive cancer has been found. We basically permit to left untreat and follow up DAP with type IIIL pit pattern and resect ones with type IIIs, IV or V in routine colonoscopy.
AIMS & METHODS: The aim of this retrospective study was to assess our management DAP using pit pattern classification. Objective was the patients who were performed total colonoscopy between April 2000 and December 2012 in Showa University Northern Yokohama Hospital. Inclusion criteria was defined as follows; 1: all polyps were performed magnifying chromo-endoscopy. 2: all adenomatous polyps of >5mm were removed or no adenomatous polyp was detected at initial colonoscopy. 3: followed up colonoscopy was examined>3 years after initial colonoscopy. Patients who had a history of familial adenomatous polyposis, hereditary non-polyposis, advanced colorectal cancer or inflammatory bowel disease were excluded. They were divided into three groups according to the finding and treatment at initial colonoscopy as follows; Group A: No neoplastic polyp was detected. Group B: All neoplastic polyps including DAP were resected. Group C: DAP with type IIIL pit pattern were left untreated. The groups were compared in cumulative incidence of index lesion (≧10mm, or high grade dysplasia) or invasive cancer at follow-up colonoscopy.
RESULTS: A total of 4550 patients were enrolled in our study. 1565 patients classified into Group A, 2021 in Group B, 964 in Group C. Index lesion was detected in 18 patients (1.2%) in Group A, 145 (7.2%) in Group B, and 64 (6.7%) in Group C, respectively. Invasive cancer was detected in 10 patients (6.3%) in Group A, 10 (4.9%) in Group B, and 4 (4.1%) in Group C, respectively. There were not significant differences in incidence of invasive cancer among three groups. In regard to incidence of index lesion, Group A was significant lower than Group B and Group C. There was no significant difference between Group B and Group C.
CONCLUSION: Removing DAP with type IIIL pit pattern did not decrease an incidence of index lesion and invasive cancer, significantly. DAP with type IIIL pit pattern could be allow to left untreat and follow up.

INTRODUCTION: Autofluorescence is the natural emission of light by biological structures such as nicotinamide adenine dinucleotide (NADH) and flavins. NADH is increased in tumour cells because of anaerobic glycolysis. Recent report that the dual-wavelength excitation method is useful technique for the detection of early colonic tumours, reveals that the precise measurement of NADH fluorescence intensity as a method for visualizing colonic tumours with cooling EM-CCD[1)].
AIMS & METHODS: The aim of this study is to evaluate colorectal tumour hypoxia by autofluorescence imaging with a high-performance CMOS imager that needs no cooling.
Study samples were 91 colorectal tumour specimens obtained by endoscopic resection in our department between October 2012 and February 2014 (12 sessile serrated adenoma/polyp (SSA/P), 40 adenoma and 39 mucosal adenocarcinoma (M-ca) specimens). The resected specimens were irradiated with excitation lights of 365 nm and 405 nm, and autofluorescence images were obtained with a high-performance CMOS imager with band pass (475±25nm) and long pass filters (≥450 nm). Ratio images (F365ex/F405ex, band pass filter images (bp images) and long pass filter images (lp images)) were created for evaluation of lesion brightness (High, Iso or Low) compared with the brightness of normal mucosa.
RESULTS: In bp images, to evaluate the brightness of the lesion in all case is that High group is 84.6% (77/91), Iso group is 8.8% (8/91) and Low group is 6.6% (6/91). Histologic SSA/P was depicted on a total of 12 bp images, with 66.7% (n = 8) falling into the High group, 8.33% (n = 1) falling into the Iso group and 25.0% (n = 3) falling into the Low group; adenoma/M-ca was depicted on a total of 79 bp images, with 87.3% (n = 69) falling into the High group, 8.86% (n = 7) falling into the Iso group and 3.80% (n = 3) falling into the Low group.
In lp images, to evaluate the brightness of the lesion in all case is that High group is 70.3% (64/91), Iso group is 19.8% (18/91) and Low group is 9.9% (9/91). Histologic SSA/P was depicted on a total of 12 lp images, with 33.3% (n = 4) falling into the High group, 33.3% (n = 4) falling into the Iso group and 33.3% (n = 4) falling into the Low group; adenoma/M-ca was depicted on a total of 79 lp images, with 75.9% (n = 60) falling into the High group, 17.7% (n = 14) falling into the Iso group and 6.33% (n = 5) falling into the Low group.
CONCLUSION: Our results show that autofluorescence images obtained with a high-performance CMOS imager may be useful for clinical detection and functional diagnosis of colon tumours.

P1320 CLINICAL COURSE AFTER CIRCUMFERENTIAL AND SUB-CIRCUMFERENTIAL RECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION FOR LARGE RECTAL NEOPLASMS

Y. Ohara[1,*], T. Toyonaga[2], S. Tanaka[2], T. Yoshizaki[2], F. Kawara[2], T. Ishida[1], N. Hoshi[1], Y. Morita[1], E. Umegaki[1], T. Azuma[1]

Contact E-mail Address: *yosy29april@gmail.com*

INTRODUCTION: Recently, the techniques of endoscopic submucosal dissection (ESD) have been improved, and rectal circumferential and sub-circumferential ESD has been often performed. In esophageal ESD, several clinical studies reported that resection of more than three-quarter circumference is closely related to esophageal stricture after ESD. However, little is known about clinical course after ESD for wide spreading rectal neoplasms.
AIMS & METHODS: The aim of this study is to clarify clinical course of patients who underwent circumferential and sub-circumferential rectal ESD. Fifty nine rectal neoplasms in 59 patients which required more than three-quarter circumferential resection at our hospital and an affiliated hospital from April 2005 to December 2013 were included in the analysis.
RESULTS: Of 59 lesions in this study, 48 lesions were morphologically classified as lateral spreading tumor (LST) granular type, 2 were LST non-granular type, 2 were 0-IIa, and 7 were 0-I. The median specimen and tumor size were 85 (ranging 43-254) cm and 72 (12-245) cm, respectively. The median procedure time was 139 (33-596) minutes. In terms of the range of submucosal defects that resulted from ESD treatments, 6 lesions required circumferential dissection, 5 lesions required more than 11/12 (eleven-twelfth), and 48 lesions required three-quarter to 11/12 circumferential dissection. Perforation and postoperative bleeding occurred in one case each, however, both could be treated conservatively. To prevent post-operative rectal strictures, steroids were injected into ulcer floor after ESD in 5 cases, steroid suppositories were administered in 3 cases, and oral steroids were administered in one case. There were 9 cases of non-curative resection due to deep invasion or lymphatic/venous invasion, and, 7 cases underwent additional surgery. Fifty two cases, excluding 7 surgical cases, were followed up by colonoscopy to evaluate the rectal strictures after ESD. Four surgical treatment cases were also evaluated for strictures by follow-up colonoscopy and/or by surgical specimens. Of these total 56 cases, strictures occurred in 7 cases (13%). All cases were the lesions which required resection of more than 11/12 circumference, and some cases did not receive steroid treatment. Endoscopic balloon dilation (EBD) was performed to treat the stricture, and it was successfully improved in all cases.
